Editors

John C Watkinson MSc (Nuclear Medicine; London) MS (London) FRCS (General Surgery) FRCS (ENT) DLO

One-Time Honorary Senior Lecturer and Consultant ENT/Head and Neck and Thyroid Surgeon, Queen Elizabeth Hospital University of Birmingham NHS Trust and latterly the Royal Marsden and Brompton Hospitals, London, UK
Currently Consultant Head and Neck and Thyroid Surgeon, University Hospital, Coventry and Warwick NHS Trust; and Honorary Consultant ENT/Head and Neck and Thyroid Surgeon, Great Ormond Street Hospital (GOSH)
Honorary Senior Anatomy Demonstrator, University College London (UCL)
Business Director, Endocrine MDT, The BUPA Cromwell Hospital, London, UK.

Raymond W Clarke BA BSc DCH FRCS FRCS(ORL)

Consultant Paediatric Otolaryngologist, Royal Liverpool Children's Hospital, Liverpool, UK
Senior Lecturer and Associate Dean, University of Liverpool, UK.

Section Editors

Louise Jayne Clark MBChB MD(DIST) FRCS (ORL) FRCS (ENT)

Queen Elizabeth University Hospital, Glasgow, UK.

Adam J Donne PhD FRCS (ORL-HNS)

Consultant Paediatric ENT Surgeon, Alder Hey Children's NHS Foundation Trust, Liverpool,
Honorary Senior Lecturer, Liverpool University, UK.

R James A England FRCS (ORL-HNS)

Consultant Otolaryngologist Head and Neck and Thyroid Surgeon, Honorary Senior Lecturer,
Hull and East Yorkshire NHS Hospitals Trust and Hull University, UK.

Hisham M Mehanna PhD BMedSc (HONS) MBChB (hons) FRCS FRCS (ORL-HNS)

Chair of Head and Neck Surgery and Director of the Institute of Head and Neck Studies and Education,
School of Cancer Sciences, University of Birmingham, UK.

Gerald William McGarry MD MBChB FRCS (ORL-HNS) FFSTed

Consultant Surgeon, Head and Neck and Anterior Skull Base Surgery, Glasgow Royal Infirmary
Greater Glasgow and Clyde NHS, Glasgow, UK
Honorary Clinical Senior Lecturer, University of Glasgow, UK.

Sean Carrie FRCS

Consultant Otolaryngologist, Skull Base Surgeon, Newcastle-upon-Tyne Hospitals NHS Foundation, UK
Honorary Senior Clinical Lecturer, Newcastle University, UK.

This book contains information obtained from authentic and highly regarded sources. While all reasonable efforts have been made to publish reliable data and information, neither the author[s] nor the publisher can accept any legal responsibility or liability for any errors or omissions that may be made. The publishers wish to make clear that any views or opinions expressed in this book by individual editors, authors or contributors are personal to them and do not necessarily reflect the views/opinions of the publishers. The information or guidance contained in this book is intended for use by medical, scientific or healthcare professionals and is provided strictly as a supplement to the medical or other professional's own judgement, their knowledge of the patient's medical history, relevant manufacturer's instructions and the appropriate best practice guidelines. Because of the rapid advances in medical science, any information or advice on dosages, procedures or diagnoses should be independently verified. The reader is strongly urged to consult the relevant national drug formulary and the drug companies' and device or material manufacturers' printed instructions, and their websites, before administering or utilizing any of the drugs, devices or materials mentioned in this book. This book does not indicate whether a particular treatment is appropriate or suitable for a particular individual. Ultimately it is the sole responsibility of the medical professional to make his or her own professional judgements, so as to advise and treat patients appropriately. The authors and publishers have also attempted to trace the copyright holders of all material reproduced in this publication and apologize to copyright holders if permission to publish in this form has not been obtained. If any copyright material has not been acknowledged please write and let us know so we may rectify in any future reprint.

Except as permitted under U.S. Copyright Law, no part of this book may be reprinted, reproduced, transmitted, or utilized in any form by any electronic, mechanical, or other means, now known or hereafter invented, including photocopying, microfilming, and recording, or in any information storage or retrieval system, without written permission from the publishers.

For permission to photocopy or use material electronically from this work, please access www.copyright.com (<http://www.copyright.com/>) or contact the Copyright Clearance Center, Inc. (CCC), 222 Rosewood Drive, Danvers, MA 01923, 978-750-8400. CCC is a not-for-profit organization that provides licenses and registration for a variety of users. For organizations that have been granted a photocopy license by the CCC, a separate system of payment has been arranged.

Volume 2 – Table of Contents	xxv
Volume 3 – Table of Contents	xxix
Abbreviations	xxxiii

Section 1 Basic Sciences

Cell biology

1: Molecular biology	3
<i>Michael Kuo, Richard M. Irving and Eric K. Parkinson</i>	
2: Genetics in otology and neurotology	15
<i>Mohammed-Iqbal Syed</i>	
3: Gene therapy	29
<i>Seiji B. Shibata and Scott M. Graham</i>	
4: Mechanisms of anticancer drugs	39
<i>Sarah Payne and David Miles</i>	
5: Radiotherapy and radiosensitizers	51
<i>Christopher D. Scrase, Stewart G. Martin and David A.L. Morgan</i>	
6: Apoptosis and cell death	59
<i>Angela Hague</i>	
7: Stem cells	69
<i>Navin Vig and Ian C. Mackenzie</i>	
8: Aetiology and pathogenesis of goitre	75
<i>Neil Sharma and Kristien Boelaert</i>	
9: Genetics of endocrine tumours	83
<i>Waseem Ahmed, Prata Upasna and Dae Kim</i>	

Wound healing

10: Soft and hard tissue repair	93
<i>Sarah Al-Himdani and Ardesbir Bayat</i>	
11: Skin flap physiology	107
<i>Colin MacIver and Stergios Doumas</i>	
12: Biomaterials, tissue engineering and their application in the oral and maxillofacial region	119
<i>Kurt Busuttill Naudi and Ashraf Ayoub</i>	

Immunology

13: Defence mechanisms	125
<i>Ian Todd and Richard J. Powell</i>	

14: Allergy: Basic mechanisms and tests	137
<i>Sai H.K. Murng</i>	

15: Evaluation of the immune system	149
<i>Moira Thomas, Elizabeth Drewe and Richard J. Powell</i>	

16: Cancer immunology	157
<i>Osama Al Hamarneh and John Greenman</i>	

17: Human papillomavirus	167
<i>Mustaffa Junaid and Hisham M. Mehanna</i>	

18: Connective tissue diseases: ENT complications	173
<i>Eileen Baildam</i>	

Microbiology

19: Microorganisms	181
<i>Ursula Altmeyer, Penelope Redding and Nitish Khanna</i>	

20: Viruses and antiviral agents	195
<i>Richard B. Townsley, Camille A. Huser and Chris Hansell</i>	

21: Fungal infections	205
<i>Emily Young, Yujay Ramakrishnan, Laura Jackson and Shahzada K. Ahmed</i>	

22: Antimicrobial therapy	221
<i>Ursula Altmeyer, Penelope Redding and Nitish Khanna</i>	

23: Human immunodeficiency virus	229
<i>Neil Ritchie and Alasdair Robertson</i>	

Haematology

24: Blood groups, blood components and alternatives to transfusion	239
<i>Samah Alimam, Kate Pendry and Michael F. Murphy</i>	

25: Haemato-oncology	249
<i>Robert F. Wynn and Mark Williams</i>	

26: Haemostasis: Normal physiology, disorders of haemostasis and thrombosis	259
<i>Elizabeth Jones and Russell David Keenan</i>	

Pharmacotherapeutics

27: Drug therapy in otology	275
<i>Wendy Smith</i>	

28: Drug therapy in rhinology	283
<i>Wendy Smith</i>	

29: Drug therapy in laryngology and head and neck surgery	293
<i>Wendy Smith and Rogan Corbridge</i>	

Perioperative management

- 30:** Preparation of the patient for surgery 301
Michael Murray and Urmila Ratnasabapathy
- 31:** Recognition and management of the difficult airway..... 309
Valerie Cunningham and Alistair McNarry
- 32:** Adult anaesthesia 333
Daphne A. Varveris and Neil G. Smart
- 33:** Adult critical care 351
Robert I. Docking and Andrew Mackay
- 34:** Paediatric intensive care..... 361
Louise Selby and Robert Ross Russell

Safe and effective practice

- 35:** Training, accreditation and the maintenance of skills 369
B. Nirmal Kumar, Andrew Robson, Omar Mirza and Baskaran Ranganathan
- 36:** Communication and the medical consultation 379
Uttam Shiralkar
- 37:** Clinical governance and its role in patient safety and quality improvement 389
Samit Majumdar and S. Musheer Hussain
- 38:** Medical ethics..... 395
Paul Baines
- 39a:** Medical jurisprudence in otorhinolaryngology 409
Maurice Hawthorne
- 39b:** Medical negligence in otorhinolaryngology 427
Maurice Hawthorne
- 40:** Non-technical skills for ENT surgeons..... 453
Simon Paterson-Brown and Stephen R. Ell

Interpretation and management of data

- 41:** Epidemiology 465
Jan H.P. van der Meulen, David A. Lowe and Jonathan M. Fishman
- 42:** Outcomes research..... 483
Iain R.C. Swan and William Whitmer
- 43:** Evidence-based medicine in medical education and clinical practice..... 495
Phillip Evans
- 44:** Critical appraisal skills 503
Paul Nankivell and Christopher Coulson

Advances in technology

- 45:** Electrophysiology and monitoring 525
Patrick R. Axon and Bruno M.R. Kenway

- 46:** Optical coherence tomography 533
Jameel Muzaffar and Jonathan M. Fishman
- 47:** Recent advances in technology..... 541
Wai Lup Wong and Bal Sanghera
- 48:** Image-guided surgery, 3D planning and reconstruction..... 559
Ghassan Alusi and Michael Gleeson
- 49:** Interventional techniques 569
James V. Byrne
- 50:** Laser principles in otolaryngology, head and neck surgery 581
Brian J.G. Bingham
- 51:** Contact endoscopy of the upper aerodigestive tract 587
Mario Andrea and Oscar Dias

Section 2 Head and Neck Endocrine Surgery**Overview**

- 52:** History of thyroid and parathyroid surgery 597
Waraporn Imruetaicharoenchoke, Ashok R. Shaha and Neil Sharma
- 53:** Developmental anatomy of the thyroid and parathyroid glands..... 603
Julian A. McGlashan
- 54:** Developmental anatomy of the pituitary fossa 611
John Hill and Sean Carrie
- 55:** Physiology of the thyroid and parathyroid glands 619
Martin O. Weickert
- 56:** Physiology of the pituitary gland 629
Mária Hérincs, Karen Young and Márta Korbonits
- 57:** Imaging in head and neck endocrine disease 643
Steve Colley and Sabena Fareedi
- 58:** Thyroid and parathyroid gland pathology..... 651
Ram Moorthy, Sonia Kumar and Adrian T. Warfield

Thyroid disease

- 59:** Clinical evaluation of the thyroid patient..... 705
Andrew Coatesworth and Sebastian Wallis
- 60:** Investigation of thyroid disease 709
Anthony P. Weetman
- 61:** Benign thyroid disease 717
Christopher M. Jones and Kristien Boelaert
- 62:** Management of differentiated thyroid cancer..... 751
Hisham M. Mehanna, Kristien Boelaert and Neil Sharma

63: Management of medullary thyroid cancer 757 <i>Barney Harrison</i>	80: Thyroid and parathyroid surgery: Audit and outcomes 893 <i>David Chadwick</i>
64: Management of anaplastic thyroid cancer/lymphoma 765 <i>James D. Brierley and Richard W. Tsang</i>	81: Medicolegal aspects of head and neck endocrine surgery 899 <i>Barney Harrison</i>
65: Management of locoregionally recurrent differentiated thyroid cancer 773 <i>Iain J. Nixon and Ashok R. Shaha</i>	
66: Non-surgical management of thyroid cancer 779 <i>Laura Moss</i>	
Thyroid surgery	
67: Thyroidectomy 793 <i>Ricard Simo, Iain J. Nixon and Ralph P. Tufano</i>	82: Clinical evaluation of the pituitary patient 905 <i>Sean Carrie, John Hill and Andrew James</i>
68: Surgery for locally advanced and nodal disease 805 <i>Joel Anthony Smith and John C. Watkinson</i>	83: Investigation of pituitary disease 915 <i>Thozbukat Sathyapalan and Stephen L. Atkin</i>
69: Minimally invasive and robotic thyroid surgery 811 <i>Neil S. Tolley</i>	84: Primary pituitary disease 923 <i>Christopher M. Jones and John Ayuk</i>
70: Surgery for the enlarged thyroid 819 <i>Neeraj Sethi, Josh Lodhia and R. James A. England</i>	85: Surgical management of recurrent pituitary tumours 941 <i>Mihir R. Patel, Leo F.S. Ditzel Filho, Daniel M. Prevedello, Bradley A. Otto and Ricardo L. Carrau</i>
Parathyroid disease	
71: Clinical evaluation of hypercalcaemia 827 <i>Mo Aye and Thozbukat Sathyapalan</i>	86: Adjuvant treatment of pituitary disease 951 <i>Andy Levy</i>
72: Investigation of hyperparathyroidism 833 <i>M. Shabed Quraishi</i>	
73: Management of hyperparathyroidism 843 <i>Neil J.L. Gittoes and John Ayuk</i>	
74: Management of persistent and recurrent hyperparathyroidism 851 <i>David M. Scott-Coombes</i>	
75: Management of parathyroid cancer 857 <i>Pamela Howson and Mark Sywak</i>	
Parathyroid surgery	
76: Bilateral parathyroid exploration 865 <i>R. James A. England and Nick McIvor</i>	
77: Minimally invasive parathyroidectomy 873 <i>Parameswaran Rajeev and Gregory P. Sadler</i>	
78: Surgical failure and reoperative surgery 879 <i>Schelto Kruijff and Leigh Delbridge</i>	
Thyroid and parathyroid outcomes	
79: Complications of thyroid and parathyroid surgery and how to avoid them 887 <i>Erin A. Felger, Dipti Kamani and Gregory W. Randolph</i>	
Pituitary disease	
Section 3 Rhinology	
	87: Anatomy of the nose and paranasal sinuses 961 <i>Dustin M. Dalgorf and Richard J. Harvey</i>
	88: Outpatient assessment 977 <i>Martyn L. Barnes and Paul S. White</i>
	89: Physiology of the nose and paranasal sinuses 983 <i>Tira Galm and Shabzada K. Ahmed</i>
	90: Measurement of the nasal airway 991 <i>Ron Eccles</i>
	91: Allergic rhinitis 999 <i>Quentin Gardiner</i>
	92: Non-allergic perennial rhinitis 1011 <i>Jameel Muzaffar and Shabzada K. Ahmed</i>
	93: Occupational rhinitis 1017 <i>Hesham Saleh</i>
	94: Rhinosinusitis: Definitions, classification and diagnosis 1025 <i>Carl Philpott</i>
	95: Nasal polyposis 1037 <i>Louise Melia</i>
	96: Fungal rhinosinusitis 1047 <i>Eng Cern Gan and Amin R. Javer</i>
	97: Medical management for rhinosinusitis 1059 <i>Claire Hopkins</i>

98: Surgical management of rhinosinusitis 1071 <i>A. Simon Carney and Raymond Sacks</i>	109: Granulomatous conditions of the nose 1211 <i>Joanne Rimmer and Valerie J. Lund</i>
99: The frontal sinus 1081 <i>Salil Nair</i>	110: Abnormalities of smell 1227 <i>Richard L. Doty and Steven M. Bromley</i>
100: Mucoceles of the paranasal sinuses 1107 <i>Darlene E. Lubbe</i>	111: Disorders of the orbit..... 1243 <i>Nithin D. Adappa and James N. Palmer</i>
101: Complications of rhinosinusitis 1113 <i>Stephen Ball and Sean Carrie</i>	112: Diagnosis and management of facial pain 1253 <i>Rajiv K. Bhalla and Timothy J. Woolford</i>
102: The relationship between the upper and lower respiratory tract 1125 <i>Nigel K.F. Koo Ng and Gerald W. McGarry</i>	113: Juvenile angiofibroma 1265 <i>Bernhard Schick</i>
103: Nasal septum and nasal valve..... 1135 <i>Shahram Anari and Ravinder Singh Natt</i>	114: Endoscopic management of sinonasal tumours 1269 <i>Alkis J. Psaltis and David K. Morrissey</i>
104: Nasal septal perforations 1149 <i>Charles East and Kevin Kulendra</i>	115: Surgical management of pituitary and parasellar diseases 1281 <i>Philip G. Chen and Peter-John Wormald</i>
105: Management of enlarged turbinates 1157 <i>Andrew C. Swift and Samuel C. Leong</i>	116: Extended anterior skull base approaches 1289 <i>Carl H. Snyderman, Paul A. Gardner, Juan C. Fernandez-Miranda and Eric W. Wang</i>
106: Epistaxis 1169 <i>Gerald W. McGarry</i>	117: Imaging in rhinology 1305 <i>Gregory O'Neill</i>
107: Nasal and facial fractures 1183 <i>Dae Kim and Simon Holmes</i>	Index 1319
108: CSF leaks 1203 <i>Scott M. Graham</i>	

Contributors

Nithin D Adappa MD

Assistant Professor
Department of Otorhinolaryngology, Head and Neck
Surgery
University of Pennsylvania
Philadelphia, USA.

Shahzada K Ahmed BSC(HONS) DLO FRCS (ORL-HNS) PHD

Consultant Rhinologist and Skull Base Surgeon
Queen Elizabeth Hospital
Birmingham, UK.

Waseem Ahmed MBBS BSC FRCS (ORL-HNS)

Clinical Fellow in Otology
Gloucestershire NHS Hospitals Foundation Trust
Gloucester, UK.

Osama Al Hamarneh MBBS MD FRCS (ORL-HNS)

Interface Fellow in Head and Neck Surgical Oncology
Department of Otolaryngology Head and Neck Surgery
Royal Hallamshire Hospital
Sheffield, UK.

Sarah Al-Himdani MBChB MRCS (ENG)

Plastic Surgery Speciality Registrar
Plastic and Reconstructive Surgery Research
Manchester Institute of Biotechnology
University Hospital of South Manchester NHS
Foundation Trust
Institute of Inflammation and Repair, Faculty of Medical
and Human Sciences
University of Manchester, Manchester Academic Health
Science Centre, Manchester, UK.

Samah Alimam MBChB MRCP

Haematology Specialty Registrar
Central Manchester Foundation Trust
Manchester, UK.

Ursula Altmeyer MRCP FRCPath

Consultant Microbiologist
University Hospital Crosshouse
NHS Ayrshire & Arran
Scotland, UK.

Ghassan Alusi PHD FRCS (ORL-HNS)

Consultant Otolaryngologist
ENT Department
Barts and the London NHS Trust
London, UK.

Shahram Anari MD MSc FRCS (ORL-HNS)

Consultant Otorhinolaryngologist/Head &
Neck Surgeon
Department of Otolaryngology
Heartlands Hospital
Birmingham, UK.

Mario Andrea MD PHD

Professor of Otolaryngology
Faculty of Medicine
University of Lisbon
Lisbon, Portugal.

Steve L Atkin MBBS PHD

Professor of Medicine
Weill Cornell Medical College Qatar
Qatar Foundation
Education City
Doha, Qatar.

Patrick R Axon MD FRCS (ORL-HNS)

Consultant Otolaryngologist and Skull Base Surgeon
Department of Otolaryngology
Cambridge University Hospitals
Cambridge, UK.

Mo Aye MB BS FRCP FRCPE

Consultant Endocrinologist
Centre for Metabolic Bone Disease
Hull Royal Infirmary
Hull, UK.

Ashraf Ayoub PHD BDS MDS FDSRCS FDSRCP

Professor of Oral and Maxillofacial Surgery
Dental School, School of Medicine
College of Medical, Veterinary and Life Sciences
University of Glasgow
Glasgow, UK.

John Ayuk MD MRCP

Consultant Endocrinologist
Department of Endocrinology
Queen Elizabeth Hospital, Birmingham; and
Honorary Senior Lecturer
University of Birmingham
Birmingham, UK.

Eileen Baidam MBChB MRCP DCH FRCP FRCPC

Consultant Paediatric Rheumatologist
Alder Hey Children's Foundation NHS Trust
Alder Hey, Liverpool; and
Honorary Senior Lecturer
Liverpool University
Liverpool, UK.

Paul Baines MD PHD MRCP FRCA FFICM

Consultant in Paediatric Intensive Care
Alder Hey Children's NHS Foundation Trust
Liverpool, UK.

Stephen Ball MRCS PHD

NIHR Academic Clinical Lecturer & Speciality Registrar
in ENT Surgery
Newcastle University & Newcastle Hospitals
Newcastle, UK.

Martyn L Barnes MBBS MD MSC(OXON) FRCS-ORL(EDIN)
Rhinology and Anterior Skullbase Fellow to Dr Richard Douglas, North Shore Hospital, Auckland; and Honorary Senior Clinical Teacher University of Dundee; and Director to SurgTech Ltd Dundee, UK.

Ardeshir Bayat BSC(HONS) MBBS MRCS(ENG, EDIN) PHD
Clinical Scientist and Associate Professor Plastic and Reconstructive Surgery Research Manchester Institute of Biotechnology University Hospital of South Manchester NHS Foundation Trust Institute of Inflammation and Repair, Faculty of Medical and Human Sciences University of Manchester, Manchester Academic Health Science Centre, Manchester, UK.

Rajiv K Bhalla BSC (HONS) FRCS (ORL-HNS) MD PGCERT MED ED
Consultant ENT Surgeon and Rhinologist Department of Otolaryngology, Head and Neck Surgery Manchester Royal Infirmary Manchester, UK.

Brian JG Bingham MBCHB FRCS ED GLAS
Consultant ENT Surgeon Department of Otolaryngology, New Victoria Hospital & Southern General Hospital; and Honorary Senior Lecturer in Otorhinolaryngology University of Glasgow Glasgow, UK.

Kristien Boelaert MD PHD FRCP
Reader in Endocrinology Centre for Endocrinology, Diabetes and Metabolism Institute of Metabolism and Systems Research College of Medical and Dental Sciences University of Birmingham; and Honorary Consultant Endocrinologist Department of Endocrinology University Hospital Birmingham NHS Foundation Trust Birmingham, UK.

James D Brierley MBBS FRCP FRCR FRCSP(C)
Professor Department of Radiation Oncology University of Toronto Princess Margaret Cancer Centre Toronto, Canada.

Steven M Bromley MD FANN
Director South Jersey MS Center and Bromley Neurology PC Audubon New Jersey, USA.

James V Byrne MD FRCS FRCR
Professor of Neuroradiology University of Oxford; and Consultant Neuroradiologist John Radcliffe Hospital Oxford, UK.

A Simon Carney BSC (HONS) MBCHB FRCS FRACS MD
Associate Professor and Head of ENT Unit Flinders University and Flinders Medical Centre Adelaide, South Australia.

Sean Carrie MB CHB FRCS FRCS (ORL)
Consultant Rhinologist and Hon Senior Lecturer Newcastle upon Tyne Hospitals NHS Foundation Trust Newcastle University Newcastle, UK.

Ricardo L Carrau MD
Professor, Director of the Comprehensive Skull Base Surgery Program Department of Otolaryngology, Head & Neck Surgery The Ohio State University Wexner Medical Center Columbus, Ohio, USA.

David Chadwick BM BCH FRCS(ED) MD
Consultant Endocrine Surgeon Chesterfield Royal Hospital Chesterfield, UK.

Philip G Chen MD
Assistant Professor & Program Director Rhinology & Otolaryngology Department of Otolaryngology, Head and Neck Surgery University of Texas Health, San Antonio Texas, USA.

Andrew Coatesworth FRCS (ORL-HNS)
Consultant ENT Surgeon York Teaching Hospital NHS Foundation Trust York Hospital York, UK.

Steve Colley
Consultant Radiologist Queen Elizabeth Hospital Birmingham, UK.

Rogan Corbridge MBBS BSC FRCS FRCS (ORL)
Consultant ENT Surgeon Oxford Centre for Head and Neck Oncology John Radcliffe Hospital Oxford, UK.

Christopher Coulson PHD FRCS (ORL-HNS)
Consultant Otolaryngologist NIHR Clinical Lecturer, Otolaryngology Head and Neck Surgery School of Cancer Sciences, University of Birmingham Queen Elizabeth Hospital Birmingham, UK.

Valerie Cunningham MBCHB FRCA FFICM
Consultant Anaesthetist Institute of Neurosciences Queen Elizabeth University Hospital Glasgow, UK.

Dustin M Dalgorf MD FRCS

Clinical Lecturer
Rhinology and Skull Base Surgery
Mount Sinai Hospital and St Joseph's Health Centre
University of Toronto
Toronto, Canada.

Leigh Delbridge MD FRACS

Emeritus Professor of Surgery
University of Sydney
Sydney, Australia.

Oscar Dias MD PHD

Professor of Otolaryngology
Faculty of Medicine
University of Lisbon
Lisbon, Portugal.

Leo FS Ditzel Filho MD

Neurosurgeon
Department of Neurosurgery
Wexner Medical Center at The Ohio State University
Columbus, Ohio, USA.

Robert I Docking MBCHB FRCA

Specialty Registrar, Anaesthesia and
Intensive Care Medicine
Glasgow Royal Infirmary
Glasgow, UK.

Richard L Doty PHD

Professor and Director
Smell & Taste Center
University of Pennsylvania Medical Center
Philadelphia, USA.

Stergios Doumas MD DDS

Maxillofacial/Head & Neck Fellow
Leeds Teaching Hospitals NHS Trust
Leeds, UK.

Elizabeth Drewe MBBS PHD MRCP MRCPATH

Consultant Clinical Immunologist
Nottingham University Hospitals NHS Trust
Nottingham, UK.

Charles East FRCS

Consultant Surgeon
University College London Hospitals NHS Trust; and
Honorary Senior Lecturer, University College London
London, UK.

Ron Eccles BSC PHD DSC

Professor Emeritus
Common Cold Centre
School of Biosciences
Cardiff University
Cardiff, UK.

**Stephen R Eil BSC (HONS) MBBS CERTAVMED MD
FRCS (EDIN) FRCS (ORL-HNS)**

Consultant ENT Surgeon
Hull and East Yorkshire Hospitals NHS Trust; and
Honorary Professor, University of Hull
Hull, UK.

R James A England FRCS (ORL-HNS)

Consultant Otolaryngologist Head and Neck and
Thyroid Surgeon; and
Honorary Senior Lecturer
Department of Otolaryngology, Head and Neck Surgery
Hull and East Yorkshire Hospitals NHS Trust
Hull, UK.

Phillip Evans BSC(HONS) MSC MED FHEA

Senior University Teacher
College of Medical, Veterinary and Life Science
University of Glasgow
Glasgow, UK.

Sabena Fareedi MBBS BSC MRCP FRCP

Consultant Neuroradiologist
Queen Elizabeth Hospital
Birmingham, UK.

Erin A Felger MD FACS

Associate Program Director of General Surgery
Assistant Professor of Clinical Surgery Georgetown
University
Endocrine Surgeon
Medstar Washington Hospital Center
Washington DC, USA.

Juan C Fernandez-Miranda MD

Associate Professor of Neurological Surgery
Director of the Complex Brain Surgery Program
Associate Director of the Center for Cranial Base Surgery
Department of Neurological Surgery
University of Pittsburgh School of Medicine
Pittsburgh, USA.

**Jonathan M Fishman MA (CANTAB) PHD DOHNS FRCS
(ORL-HNS)**

Clinical Lecturer, Academy of Medical Sciences
University College London
London, UK.

Tira Galm FRCS (ORL-HNS) MBA

Rhinology Fellow
Queen Elizabeth Hospital
Birmingham, UK.

Eng Cern Gan MBBS MRCS (EDIN) MMED (ORL) FAMS

Consultant, Department of Otorhinolaryngology, Head
& Neck Surgery
Changi General Hospital; and
Senior Clinical Lecturer
Yong Loo Lin School of Medicine
National University of Singapore, Singapore.

Paul A Gardner MD

Neurosurgeon
Department of Neurological Surgery
University of Pittsburgh School of Medicine
Pittsburgh, USA.

Quentin Gardiner MB CHB FRCS (ENG & ED) FRCS (ORL)

Consultant Rhinologist
Ninewells Hospital and Medical School
Dundee, UK.

Neil JL Gittoes PHD FRCP

Consultant Endocrinologist
Department of Endocrinology
Queen Elizabeth Hospital Birmingham; and
Honorary Senior Lecturer
University of Birmingham
Birmingham, UK.

Michael Gleeson MD FRCS

Professor of Otolaryngology and Skull Base Surgery
Institute of Neurology, University College London; and
Consultant
Guy's, Kings and St Thomas' and the National Hospital
for Neurology and Neurosurgery; and
Honorary Consultant Skull Base Surgeon
Great Ormond Street Hospital for Sick Children
London, UK.

Scott M Graham MD

Professor of Otolaryngology, Head and Neck Surgery; and
Professor, Department of Neurosurgery
The University of Iowa; and
Director of the Division of Rhinology
University of Iowa Hospital and Clinics
Iowa City, Iowa, USA.

John Greenman PHD

Professor of Tumour Immunology & Scientific Director,
Daisy Building
Head, School of Biological, Biomedical and
Environmental Sciences
University of Hull
Hull, UK.

Angela Hague BSC PHD

Senior Teaching Fellow
School of Oral and Dental Sciences
University of Bristol
Bristol, UK.

Chris Hansell BSC PHD

Post-Doctoral Research Associate
Institute of Infection, Inflammation and Immunity
University of Glasgow
Glasgow, UK.

Barney Harrison MB BS MS FRCS

Consultant Endocrine Surgeon
Royal Hallamshire Hospital
Sheffield, UK.

Richard J Harvey MD

Program Head and Professor
Rhinology and Skull Base
Applied Medical Research Centre
University of New South Wales
Faculty of Medicine and Health Sciences
Macquarie University
Sydney, Australia.

Maurice Hawthorne FRCS

Consultant Otolaryngologist, Head and Neck Surgeon
James Cook University Hospital
Middlesbrough, UK.

Mária Hérincs MD MBBS

Clinical Fellow
Department of Endocrinology
William Harvey Research Institute
Barts and the London School of Medicine
Queen Mary University of London
London, UK.

John Hill MBBS FRCS FRCS(ENT) FRCSEd FRCSEd FRCSEd FRCSEd

Consultant Otolaryngologist
Freeman Hospital
Newcastle, UK.

Claire Hopkins FRCS (ORL-HNS) DM

Professor of Rhinology, King's College, London
Consultant ENT Surgeon
Guy's and St Thomas' NHS Trust
London, UK

Simon Holmes BDS MD BS FDS RCS FRCS

Consultant Oral and Maxillofacial Surgeon
Barts and the London NHS Trust
London, UK.

Pamela Howson BMEDSCI MBBS FRACS

Breast, Endocrine and General Surgeon
Concord and Auburn Hospitals
Sydney, Australia.

Camille A Huser BSC MSC PHD

Post-Doctoral Research Associate
MRC University of Glasgow Centre for Virus Research
Glasgow, UK.

S Musheer Hussain MB BS MSC (MANC) FRCS (EDIN) FRCS (ENT) FFST FRCS (ORL)

Consultant Otolaryngologist Head and Neck Surgeon
Honorary Professor of Otolaryngology and Consultant
ENT Surgeon
Licenced Teacher of Anatomy
Ninewells Hospital & University of Dundee Medical School
Dundee, UK.

Waraporn Imruetaicharoenchoke MD

Consultant Surgeon
Division of Head Neck and Breast Surgery
Department of Surgery
Faculty of Medicine Siriraj Hospital
Mahidol University
Bangkok, Thailand.

Richard M Irving MD FRCS (ORL-HNS)

Consultant in Neurotology
University Hospital Birmingham NHS Trust and Diana
Princess of Wales (Birmingham Children's) Hospital; and
Honorary Senior Lecturer
University of Birmingham
Birmingham, UK.

Laura Jackson BSC PHD MBCHC FRCS(ORL-HNS)

Specialty Registrar ENT
New Cross Hospital
London, UK.

Andrew James BSC MB MCH MD FRCP

Consultant Endocrinologist
Newcastle upon Tyne Hospitals NHS Foundation Trust
Newcastle University
Newcastle, UK.

Amin R Javer BSC MD FRCSC FARS

Clinical Professor of Surgery
University of British Columbia; and
Director, St Paul's Sinus Centre
Vancouver, Canada.

Christopher M Jones BMEDSC(HONS) MB CHB(HONS) MRCP

Wellcome Trust Clinical Research Fellow
Faculties of Biological Sciences, Medicine & Health
University of Leeds
Leeds, UK.

Barts and the London School of Medicine
Queen Mary University of London
London, UK.

Foreword

The eighth edition of *Scott-Brown* signals the beginning of a new and exciting era for ear, nose and throat surgeons, and also the end of 10 years of very hard work undertaken by John Watkinson and Ray Clarke, the Editors-in-Chief, their team of subeditors and, not least, the publishers. Whatever subspeciality the current generation of trainees decides to follow, they will all have to read and refer to *Scott-Brown* in order to complete their education and gain accreditation. It will be a constant companion and guide throughout their professional lives.

When asked to write the foreword for this edition, I was immediately reminded that I had read John Ballantyne and John Groves's third edition as a trainee, bought the fourth edition as a senior registrar, written chapters for Alan Kerr and Philip Stell in the fifth edition, edited the *Basic science* volume of the fifth edition and was ultimately Editor-in-Chief of the seventh edition. As each edition takes about 10 years to produce, that makes me very old indeed. John and Ray have one final task as Editors-in-Chief: to recommend their successors to the publishers. That was made easy for me as both of them had proved themselves more than capable with the previous edition, and the eighth edition is now their masterpiece. They can enjoy the next 10 years as thousands of surgeons worldwide recognize and thank them for their industry.

This edition reflects the continued expansion of our speciality into fields that *Scott-Brown* himself could

never have imagined. It lays the groundwork for the current generation to make their contribution that will, no doubt, be prompted by technological developments, an evidence base of what is wise and what is not, together with the experience gained by teamwork with other clinicians in today's multidisciplinary approach to patient care.

Simply looking at the table of contents it is clear to see that our role in endocrine surgery has increased dramatically over the last 10 years. The thyroid and parathyroids now account for 30 chapters. How would *Scott-Brown* have viewed that when the tonsils and adenoids justify just one chapter each, and the sore throat has a mere passing reference? Times have certainly changed and ENT surgery has grown up. We have reflected on our past practices, and the evidence base for our management protocols that was emphasized in the previous edition of *Scott-Brown* has been taken to heart.

I hope that this edition will find its way into every medical library in the world and onto every ENT surgeon's bookshelf. It will serve and guide surgeons throughout the English-speaking world, whether they live in high- or low-income countries. It is said that the tragedy of getting old is that we feel young. Reading these volumes makes me wish that I had my time all over again.

Michael Gleeson

Preface

When we were asked to head up the editorial team for this, the eighth edition of *Scott-Brown*, we were mindful of Michael Gleeson's towering achievement in bringing the seventh edition to fruition. Michael delivered a much-loved text – conceived in the early post-war years when antimicrobials, the operating microscope and the National Health Service were all in their infancy – in an entirely new format that befitted modern surgical scholarship. Authors, editors and readers alike had become acutely conscious of the need to quote high-quality evidence to guide clinical decisions; the concept of grading clinical recommendations – and, by implication, acknowledging gaps in the evidence base of our practice – was born. Recognizing the enormity of Michael's contribution led us into the trap that has befallen every editor who has come before us; we grossly underestimated the task ahead. We had misjudged the pace of change. What began as an 'update' of some outdated chapters became a complete rewrite to reflect the advances that marked the decade between editions, but we were determined to keep the text to a manageable size! In the end, we have 330 chapters, but with a slightly smaller page count than the seventh edition.

The basic science knowledge that underpins our clinical practice is no longer focused just on anatomy and physiology; genetics, molecular biology, new techniques for auditory implantation, information technology, new medical therapies for many old disorders together with seismic changes in endoscopic technology and in medical imaging have transformed our specialty. Today's head and neck surgery would have been unrecognizable to the early authors and editors. Surgical oncologists have recourse to completely different treatment strategies than did their predecessors and now work as part of multidisciplinary teams. They deal with different disease patterns and vastly changed patient expectations. Thyroid and parathyroid surgery has become almost exclusively the domain of the otolaryngologist. Surgery of the pituitary fossa has come within our ambit, as has plastic and reconstructive surgery of the head and neck as well as aesthetic facial surgery. Neurotology, audio-vestibular medicine, rhinology and paediatric otolaryngology are accepted subspecialties, each with its own corpus of knowledge and skills and each warranting a sizeable section of this text. Contemporary otolaryngology is now a collection of subspecialty interests linked by common 'stem' training and a shared passion for looking after patients with disorders of the upper respiratory tract and the head and neck.

There is a view that a single text – even a multivolume tome of this size – cannot cover the entire knowledge base of modern clinical practice. The subspecialist will, of course, need recourse to supplementary reading. The pace of change shows no sign of slowing down, but there is still a need for a comprehensive working text embracing the whole spectrum of our workload. That was the task we set our authors and section editors; we think they have done our specialty proud.

In the new 'digital' editorial world authors create manuscripts on personal computers. They transmit chapters, figures, amendments and revisions across continents and

time zones with a few keystrokes. The bulky packages containing grainy photographic prints and the reams of paper with closely-typed and heavily scored text that accumulated on authors' and editors' desks are a distant memory. References, guidelines and systematic reviews are all available online; the editorial 'red pen' has been replaced by a cursor on the screen. This 'new age' has enabled us to look ever further for expertise. We are proud to have enlisted the support of authors from more than 20 countries for this edition. *Scott-Brown* always enjoyed particular affection and respect in Asia, Australia, Africa and the Middle East. It has been a joy to welcome authors in increasing numbers from many of these parts of the world. We are now a truly global specialty and the eighth edition fully reflects this.

What has not changed is the huge time commitment authors and editors need to make. That time now has to be fitted into an increasingly pressurized work environment. Revalidation, mandatory training, more intense regulatory scrutiny, expanding administrative burdens and ever-expanding clinical commitments leave little time for scholarship. Our section editors are all busy clinicians. They have generously given their time, first instructing authors, cajoling them and then editing their chapters, virtually all of which have been completely rewritten since the last edition. Each author was chosen because of his or her specific clinical and scientific expertise and none has disappointed. Authors and section editors receive no reward other than the satisfaction of knowing that they have made a contribution to teaching and learning in a specialty that has given us all so much professional satisfaction. We are profoundly grateful to them and hope that their endeavours spur the next generation of otolaryngologists to carry on this noble tradition. *Scott-Brown* simply wouldn't happen without this generous and dedicated commitment, unstintingly and graciously given.

It is impossible to produce a book like *Scott-Brown* without the contribution of many individuals working behind the scenes. We would like to express our gratitude to our Publishers, Taylor and Francis, and to the staff who have worked on this project from its early days in 2011 to publication in 2018. In particular we would like to mention Cheryl Brandt who with good humour and patience helped to reel in many of the 330 chapters. Miranda Bromage joined the team in 2016 and her publishing experience and enthusiasm for medical education have helped guide this new edition through its final phases to publication. Finally, we are indebted to Nora Naughton who has dedicated so much more than just her extensive publishing skills to this project. Nora's meticulous attention to detail, combined with her warmth and wisdom have encouraged us all at the end of this endeavour.

We are truly 'passing on the torch' of a huge amount of accumulated knowledge and wisdom; it is this that gives us, the Editors-in-Chief, the greatest pleasure.

Read on and enjoy, our thoughts are yours.

RWC
JCW

I wish to acknowledge the love, happiness and inspiration that have been passed on to me by both my parents and grandparents. I recognize and value the friendship of my dear friend Ray Clarke who has been with me all the way on this rewarding and worthwhile endeavour. I would specifically like to thank Esme, Helen and William, without whom none of this would have been achievable. Their love and support has helped guide me through the years leading up to the publication of this tome, and my final thanks go to Angela Roberts and Sally Holden for their typing and editing skills.

JCW 2018

Thanks to my wife Mary for her patience and support. My parents, Emmet and Doreen Clarke, both sadly died during the preparation of this book. They would have been proud to have played a part in such a scholarly enterprise.

RWC 2018

Black Hut on the River Test – Pastel by W G Scott-Brown – circa 1970. Reproduced by kind permission of Mr Neil Weir, who was presented with the original by the artist.

A Tribute to Bill Scott-Brown

Walter Graham ('Bill') Scott-Brown. 1897–1987

Walter Graham ('Bill') Scott-Brown was twenty-three when he arrived at Corpus Christi College Cambridge in 1919. One of the generation of young men whose entry to university and the professions was delayed by their participation in the First World War, he had joined the Gunners in 1915 as an 18-year-old. He considered himself blessed to have survived – although wounded – when so many of his contemporaries never returned from the Front. In those early post-WW1 years the medical school at St Bartholomew's ('Barts') in London was keen to attract 'gentlemen'. To this end a series of scholarships – 'Shuter's scholarships' – was established to lure those with humanities degrees from Oxford and Cambridge into medicine. It was via this scheme that the young Scott-Brown qualified MB, BCh in 1925. By now married to Margaret Bannerman, one of the very few women medical graduates of her generation, the two established a general practice in Sevenoaks, Kent. His work here involved looking after children with poliomyelitis, which was then commonplace, and his MD thesis was on polio-related bulbar palsy. It earned him the Copeman Medal for research from the University of Cambridge. While working in general practice, Bill pursued his interest in the then fledgling specialty of otolaryngology, securing fellowships from London and Edinburgh. Postgraduate training was haphazard; there were no structured programmes or even junior posts, so the young Scott-Brown was fortunate to be awarded a Dorothy Temple Cross Travelling Fellowship. Mrs Florence Temple Cross had set up these awards (now administered by the Medical Research Council) in memory of her daughter, who died in 1927 aged thirty-two.

They were made available to young physicians to help them travel to overseas centres specifically to study tuberculosis, then rampant and one of the commonest causes of death in young adults. The young Scott-Brown visited the leading pioneers of the day in Berlin, Vienna, Budapest, Stockholm, Copenhagen, Madrid and Venice. Here he developed his considerable endoscopy skills. He reported that his first bronchoscopies were done on a Venetian street entertainer who, for a few coins, would inhale sundry objects that the doctors would then dexterously retrieve from his main stem and segmental bronchi – without of course any anaesthesia!

Times were lean on Scott-Brown's return. Margaret ('Peggy') was now a popular and well-established GP who supported him as his private practice developed. Eventually he secured appointments at East Grinstead, the Royal National and Royal Free Hospitals. He had a thriving Harley Street practice and was the favoured otolaryngologist of the aristocracy. His reputation was such that he became laryngologist to the Royal family, was appointed Commander of the Victorian Order and was a particular favourite of the then Princess Royal, HRH Mary the Countess of Harewood.

By 1938 he was wealthy enough to purchase a farm in Buckinghamshire where he bred prize-winning short-horn cattle. Ironmongery and blacksmith work were hard to come by during the war years, so Scott-Brown prided himself on his ability to make his own agricultural implements, cartwheels and farm wagons in a makeshift forge he himself established on the farm. He would while away endless hours here at weekends following a busy week in London. An accomplished fly fisherman, he was part of the exclusive Houghton Club whose members fished the River Test in Hampshire, where he numbered aristocrats including the Prince of Wales among his circle.

Scott-Brown's celebrated textbook came about in the early 1950s, when he became ill with jaundice and heart trouble. He was advised to rest, and took 6 months off work. Not satisfied with editing what has become the standard UK textbook, he took up painting as well. He became a celebrated artist whose work is still prized in many private collections. One of his pastels is reproduced on the preceding page.

Bill Scott-Brown lived to be 90. He died in July 1987, six weeks after his beloved Peggy and just as the fifth edition of the celebrated textbook that still bears his name was going to press. His legacy lives on in the pages of this book, and we are proud to continue the tradition of scholarship and learning which he established all those years ago.

We would like to thank Martin Scott-Brown for his help in compiling the biography above.

John C. Watkinson and Raymond W. Clarke
London, 2018

Acknowledgements

We acknowledge our debt of gratitude to the many authors who have contributed to previous editions of Scott-Brown's Otorhinolaryngology, and in particular to authors from the seventh edition, published in 2008.

Chapter 1, Molecular biology, contains some material from 'Molecular biology' by Michael Kuo and Richard M Irving. The material has been revised and updated by the current author.

Chapter 3, Gene therapy, contains some material from 'Gene therapy' by Scott M Graham and John H Lee. The material has been revised and updated by the current author.

Chapter 5, Radiotherapy and radiosensitizers, contains some material from 'Radiotherapy and radiosensitizers' by Stewart G Martin and David AL Morgan. The material has been revised and updated by the current author.

Chapter 11, Skin flap physiology, contains some material from 'Skin flap physiology' by A Graeme B Perks. The material has been revised and updated by the current author.

Chapter 15, Evaluation of the immune system, contains some material from 'Evaluation of the immune system' by Elizabeth Drewe and Richard J Powell. The material has been revised and updated by the current author.

Chapter 31, Recognition and management of the difficult airway, contains some material from 'Recognition and management of the difficult airway' by Adrian Pearce. The material has been revised and updated by the current author.

Chapter 34, Paediatric intensive care, contains some material from 'Paediatric intensive care' by Helen Allen and Rob Ross Russell. The material has been revised and updated by the current author.

Chapter 41, Epidemiology, contains some material from 'Epidemiology' by Jan HP van der Meulen and David A Lowe. The material has been revised and updated by the current author.

Chapter 44, Critical appraisal skills, contains some material from 'Critical appraisal skills' by Martin Dawes. The material has been revised and updated by the current author.

Chapter 45, Electrophysiology and monitoring, contains some material from 'Electrophysiology and monitoring' by Patrick R Axon and David M Baguley. The material has been revised and updated by the current author.

Chapter 46, Optical coherence tomography, contains some material from 'Optical coherence tomography' by Mariah Hahn and Brett E Bouma. The material has been revised and updated by the current author.

Chapter 92, Non-allergic rhinitis, contains some material from 'Nonallergic perennial rhinitis' by Claus Bachert. The material has been revised and updated by the current author.

Chapter 107, Nasal and facial fractures, contains some material from 'Nasal fractures' by Brent A McMonagle and Michael Gleeson and 'Fractures of the facial skeleton' by Simon Holmes and Michael Gleeson. The material has been revised and updated by the current author.

Chapter 109, Granulomatous conditions of the nose, contains some material from 'Granulomatous conditions of the nose' by David J Howard and Valerie J Lund. The material has been revised and updated by the current author.

Volume 2 – Table of Contents

Section 1 Paediatrics

- 1:** Introduction to paediatric otorhinolaryngology
Raymond W. Clarke
- 2:** The paediatric consultation
Raymond W. Clarke
- 3:** Recognition and management of the sick child
Julian Gaskin, Raymond W. Clarke and Claire Westrope
- 4:** Anaesthesia for paediatric otorhinolaryngology procedures
Crispin Best
- 5:** The child with special needs
Kate Blackmore and Derek Bosman
- 6:** The child with a syndrome
Thushitha Kunanandam and Haytham Kubba
- 7:** Management of the immunodeficient child
Fiona Shackley
- 8:** Hearing screening and surveillance
Sally A. Wood
- 9:** Hearing tests in children
Glynis Parker
- 10:** Management of the hearing impaired child
Chris H. Raine, Sue Archbold, Tony Sirimanna and Soumit Dasgoupta
- 11:** Paediatric implantation otology
James Ramsden and Payal Mukherjee
- 12:** Congenital middle ear abnormalities
Jonathan P. Harcourt
- 13:** Otitis media with effusion
Peter J. Robb and Ian Williamson
- 14:** Acute otitis media
Peter A. Rea and Natalie Ronan
- 15:** Chronic otitis media
William P.L. Hellier
- 16:** Microtia and external ear abnormalities
Iain Bruce and Jaya Nichani
- 17:** Disorders of speech and language
Suzanne Harrigan and Andrew Marshall
- 18:** Cleft lip and palate
David M. Wynne and Louisa Ferguson
- 19:** Craniofacial anomalies
Benjamin Robertson, Sujata De, Astrid Webber and Ajay Sinha
- 20:** Balance disorders in children
Louisa Murdin and Gavin A.J. Morrison
- 21:** Facial paralysis in children
S. Musher Hussain
- 22:** Epistaxis
Mary-Louise Montague and Nicola E. Starritt
- 23:** Neonatal nasal obstruction
Michelle Wyatt
- 24:** Rhinosinusitis and its complications
Daniel J. Tweedie
- 25:** Lacrimal disorders in children
Caroline J. MacEwen and Paul S. White
- 26:** The adenoid and adenoidectomy
Peter J. Robb
- 27:** Paediatric obstructive sleep apnoea
Steven Powell
- 28:** Stridor
Kate Stephenson and David Albert
- 29:** Acute laryngeal infections
Lesley Cochrane
- 30:** Congenital disorders of the larynx, trachea and bronchi
Chris Jephson
- 31:** Acquired laryngotracheal stenosis
Michael J. Rutter, Alessandro de Alarcón and Catherine K. Hart
- 32:** Juvenile-onset recurrent respiratory papillomatosis
Rania Mehanna and Michael Kuo
- 33:** Paediatric voice disorders
Ben Hartley and David M. Wynne
- 34:** Foreign bodies in the ear, nose and throat
Adam J. Donne and Katharine Davies
- 35:** Paediatric tracheostomy
Mike Saunders

36: Perinatal airway management
*Pensée Wu, May M.C. Yaneza, Haytham Kubba,
W. Andrew Clement and Alan D. Cameron*

37: Cervicofacial infections
Nico Jonas and Ben Hartley

38: Diseases of tonsils, tonsillectomy and tonsillotomy
Yogesh Bajaj and Ian Hore

39: Salivary glands
Neil Bateman and Rachael Lawrence

40: Tumours of the head and neck
Fiona McGregor and James Hayden

41: Cysts and sinuses of the head and neck
Keith G. Trimble and Luke McCadden

42: Haemangiomas and vascular malformations
Daniel J. Tweedie and Benjamin E.J. Hartley

43: Drooling and aspiration
Haytham Kubba and Katherine Ong

44: Reflux and eosinophilic oesophagitis
Ravi Thevasagayam

45: Oesophageal disorders
Graham Haddock

Section 2 The ear

Audio-vestibular medicine

46: Anatomy and embryology of the external and middle ear
Peter Valentine and Tony Wright

47: Anatomy of the cochlear and vestibular system: Relating ultrastructure to function
Jonathan Gale and Andrew Forge

48: Physiology of hearing
Soumit Dasgupta and Michael Maslin

49: Physiology of equilibrium
Floris L. Wuyts, Leen K. Maes and An Boudewyns

50: Perception of sounds at the auditory cortex
Frank E. Musiek and Jane A. Baran

51: Psychoacoustic audiometry
Josephine E. Marriage and Marina Salorio-Corbetto

52: Evoked measurement of auditory sensitivity
Jeffrey Weibing and Nicholas Leahy

53: Prevention of hearing loss
Shankar Rangan and Veronica Kennedy

54: Hearing aids
Harvey Dillon

55: Beyond hearing aids: An overview of audiological rehabilitation
Lucy Handscombe

56: Age-related sensorineural hearing impairment
Linnea Cheung, David M. Baguley and Andrew McCombe

57: Noise-induced hearing loss and related conditions
Andrew McCombe and David M Baguley

58: Autosomal dominant non-syndromic SNHL
Polona Le Quesne Stabej and Maria Bitner-Glindzicz

59: Ototoxicity
Andy Forge

60: Idiopathic sudden sensorineural hearing loss
Tony Narula and Catherine Rennie

61: Tinnitus and hyperacusis
Don McFerran and John Phillips

62: Evaluation of balance
Adolfo M. Bronstein

63: Ménière's disease
Vincent W.F.M. van Rompaey

64: Benign paroxysmal positional vertigo
Yougan Saman and Doris-Eva Bamiou

65: Superior semicircular canal dehiscence
Harry R.F. Powell and Shakeel R. Saeed

66: Vestibular neuritis
Charlotte Agrup

67: Vestibular migraine
Louisa Murdin and Lina Luxon

68: Vestibular rehabilitation
Marousa Pavlou

69: Auditory neuropathy spectrum disorder and retrocochlear disorders in adults and children
Rosalyn A. Davies and Raj Nandi

70: Understanding tinnitus: A psychological perspective
Laurence McKenna, Elizabeth Marks and David Scott

71: Auditory processing disorders across the age span
Doris-Eva Bamiou and Cristina Ferraz B. Murphy

72: Neuropsychiatric aspects of vestibular disorders
Julius Bourke, Georgia Jackson and Gerald Libby

Otology

- 73:** Clinical examination of the ears and hearing
George G. Browning and Peter-John Wormald
- 74:** Furunculosis
Malcolm P. Hilton
- 75:** Myringitis
Samuel A.C. MacKeith
- 76:** Keratosis obturans, primary auditory canal cholesteatoma and benign necrotizing otitis externa
Tristram H.J. Lesser
- 77:** Acquired atresia of the external ear
Jonathan P. Harcourt
- 78:** Otitis externa and otomycosis
Simon Carney
- 79:** Periochondritis of the external ear
James W. Loock
- 80:** Exostosis of the external auditory canal
Phillip J. Robinson and Sophie J. Hollis
- 81:** Osteoradionecrosis of the temporal bone
James W. Loock
- 82:** Acute otitis media and otitis media with effusion in adults
Anil Banerjee
- 83:** Chronic otitis media
George G. Browning, Justin Weir, Gerard Kelly and Iain R.C. Swan
- 84:** Myringoplasty
Charlie Huins and Jeremy Lavy
- 85:** Ossiculoplasty
Daniel Moualed, Alison Hunt and Christopher P. Aldren
- 86:** Eustachian tube dysfunction
Holger H. Sudhoff
- 87:** Otoendoscopy
David A. Bowdler, Annabelle C.K. Leong and David D. Pothier
- 88:** Tuberculosis of the temporal bone
Ameet Kishore
- 89:** Otosclerosis
Christopher P. Aldren, Thanos Bibas, Arnold J.N. Bittermann, George G. Browning, Wilko Grolman, Peter A. Rea, Rinze A. Tange and Inge Wegner
- 90:** Otological effects of Paget's disease
Ian D. Bottrill

91: Ear trauma
Stephen C. Toynton

92: Otaglia
Philip D. Yates

Implantation otology

- 93:** Bone-conduction hearing aids
James Ramsden and Chris H. Raine
- 94:** Cochlear implants
Andrew Marshall and Stephen Broomfield
- 95:** Middle ear implants
Maarten J.F. de Wolf and Richard M. Irving
- 96:** Auditory brainstem implants
Shakeel R. Saeed and Harry R.F. Powell

Section 3 Skull base

- 97:** Imaging of the temporal bone
Steve Colley
- 98:** Anatomy of the skull base and infratemporal fossa
Charlie Huins
- 99:** Evaluation of the skull base patient
Jeyanthi Kulasegarah and Richard M. Irving
- 100:** Vascular assessment and management
Joe J. Leyon, Kurdow Nader and Swarupsingh Chavda
- 101:** Natural history of vestibular schwannomas
Mirko Tos, Sven-Eric Stangerup and Per Caye-Thomasen
- 102:** Surgical management of vestibular schwannomas
Shakeel R. Saeed and Christopher J. Skilbeck
- 103:** Stereotactic radiosurgery
Paul Sanghera, Geoffrey Heyes, Helen Howard, Rosemary Simmons and Helen Benghiat
- 104:** Neurofibromatosis 2
Gareth Evans
- 105:** Non-vestibular schwannoma tumours of the cerebellopontine angle
Simon K.W. Lloyd and Scott A. Rutherford
- 106:** Middle fossa surgery
Raghu N.S. Kumar, Sunil N. Dutt and Richard M. Irving
- 107:** Jugular foramen lesions and their management
Rupert Obholzer
- 108:** Petrous apex lesions
Michael Gleeson

109: Approaches to the nasopharynx and Eustachian tube
Gunesh P. Rajan

110: Tumours of the temporal bone
Marcus Atlas, Noweed Ahmad and Peter O’Sullivan

111: Clinical neuroanatomy
John J.P. Patten

112: The facial nerve and its non-neoplastic disorders
Michael Gleeson

113: Tumours of the facial nerve
Patrick R. Axon and Samuel A.C. MacKeith

114: Osteitis of the temporal bone
Cheka R. Spencer and Peter Monksfield

115: Squamous carcinoma of the temporal bone
Liam Masterton and Neil Donnelly

116: Complications of skull base surgery
Abdul Karim Nassimizadeh and Chris Coulson

Volume 3 – Table of Contents

Section 1 Head and Neck

1: History

Patrick J. Bradley

2: Aetiology of head and neck cancer

Pablo H. Montero, Snehal G. Patel and Ian Ganly

3: Epidemiology of head and neck cancer

Kristen B. Pytynia, Kristina R. Dahlstrom and Erich M. Sturgis

4: Staging of head and neck cancer

Nicholas J. Roland

5: The changing face of cancer information

Richard Wight

6: Introducing molecular biology of head and neck cancer

Nikolina Vlatković and Mark T. Boyd

7: Nasal cavity and paranasal sinus malignancy

Cyrus Kerawala, Peter Clarke and Kate Newbold

8: Nasopharyngeal carcinoma

Raymond King-Yin Tsang and Dora Lai-Wan Kwong

9: Benign salivary gland tumours

Jarrold Homer and Andy Robson

10: Malignant tumours of the salivary glands

Vincent Vander Poorten and Patrick J. Bradley

11: Tumours of the parapharyngeal space

Suren Krishnan

12: Oral cavity tumours including lip reconstruction

Tim Martin and Omar A. Ahmed

13: Oropharyngeal tumours

Terry M. Jones with Mererid Evans

14: Tumours of the larynx

Vinidh Paleri, Stuart Winter, Hannah Fox and Nachi Palaniappan

15: Rehabilitation after total laryngectomy

Yvonne Edels and Peter Clarke

16: Management of hypopharyngeal cancer

Prathamesh Pai, Deepa Nair, Sarbani Ghosh Laskar and Kumar Prabbash

17: Neck metastases from an unknown primary

Ricard Simo, Jean-Pierre Jeannon and Maria Teresa Guerrero Urbano

18: Metastatic neck disease

Vinidh Paleri and James O'Hara

19: Principles and practice of radiotherapy in head and neck cancer

Sara Meade and Andrew Hartley

20: Quality of life and survivorship in head and neck cancer

Simon Rogers and Steve Thomas

21: Palliative care for head and neck cancer

Catriona R. Mayland and John E. Ellershaw

22: Transoral laser microsurgery

Mark Sayles, Stephanie L. Koonce, Michael L. Hinni and David G. Grant

23: Anatomy as applied to transoral surgery

Mark Puvanendran and Andrew Harris

24: Chemotherapy

Charles G. Kelly

25: Cysts and tumours of the bony facial skeleton

Julia A. Woolgar and Gillian L. Hall

26: Head and neck pathology

Ram Moorthy, Adrian T. Warfield and Max Robinson

27: Open conservation surgery for laryngeal cancer

Volkert Wreesman, Jatin Shah and Ian Ganly

28: Measures of treatment outcomes

Helen Cocks, Raghav C. Dwivedi and Aoife M. I. Waters

29: Applications of robotics in head and neck practice

Chris Holsinger, Chafeek Tomeh and Eric M. Genden

30: Biologically targeted agents in head and neck cancers

Kevin J. Harrington and Magnus T. Dillon

31: Prosthetic rehabilitation of head and neck defects

Chris Butterworth

32: Multidisciplinary team working

Andrew Davies, Nigel Beasley and David Hamilton

33: Nutritional considerations

Rachael Donnelly, Susannah Penney, Sian Lewis, Lesley Freeman and Pippa Lowe

- 34:** Speech voice and swallow rehabilitation after chemoradiation
Justin W.G. Roe and Katherine A. Hutcheson
- 35:** Surgical anatomy of the neck
Laura Warner, Christopher Jennings and John C. Watkinson
- 36:** Clinical examination of the neck
James O'Hara
- 37:** Imaging of the neck
Ivan Zammit-Maempel
- 38:** Neck trauma
Andrew J. Nicol and Johannes J. Fagan
- 39:** Benign neck disease
Ricard Simo, Jean-Pierre Jeannon and Enyinnaya Ofo
- 40:** Neck space infections
James W. Moor
- 41:** Anatomy and embryology of the mouth and dentition
Barry K.B. Berkovitz
- 42:** Benign oral and dental disease
Konrad S. Staines and Alexander Crighton
- 43:** Salivary gland anatomy
Stuart Winter and Brian Fish
- 44:** Physiology of the salivary glands
Mrganke De and T. Singh
- 45:** Imaging of the salivary glands
Daren Gibson and Steve Colley
- 46:** Non-neoplastic salivary gland diseases
Stephen R. Porter, Stefano Fedele and Valeria Mercadante
- 47:** Anatomy of the pharynx and oesophagus
Joanna Matthan and Vinidh Paleri
- 48:** Physiology of swallowing
Joanne Patterson and Stephen McHanwell
- 49:** Causes and assessment of dysphagia and aspiration
Helen Cocks and Jemy Jose
- 50:** Functional investigations of the upper gastrointestinal tract
Joanne Patterson and Jason Powell
- 51:** Pharyngitis
Sharan Jayaram and Conor Marnane
- 52:** Cricopharyngeal dysphagia
Nimesh N. Patel and T. Singh
- 53:** Oesophageal diseases
Shajahan Wahed and S. Michael Griffin
- 54:** Neurological disease of the pharynx
Kim Ab-See and Miles Bannister
- 55:** Rehabilitation of swallowing disorders
Maggie-Lee Huckabee and Sebastian Doeltgen
- 56:** Chronic aspiration
Guri S. Sandhu and Khalid Ghufoor
- 57:** Temporomandibular joint disorders
Andrew Sidebottom
- 58:** Anatomy of the larynx and tracheobronchial tree
Nimesh N. Patel and Shane Lester
- 59:** Physiology of the larynx
Lesley Mathieson and Paul Carding
- 60:** Voice and speech production
Paul Carding and Lesley Mathieson
- 61:** Assessment and examination of the larynx
Jean-Pierre Jeannon and Enyinnaya Ofo
- 62:** Evaluation of the voice
Julian A. McGlashan
- 63:** Structural disorders of the vocal cords
Yakubu Gadzama Karagama and Julian A. McGlashan
- 64:** Functional disorders of the voice
Paul Carding
- 65:** The professional voice
Declan Costello and Meredydd Harries
- 66:** Speech and language therapy for voice disorders
Marianne E. Bos-Clark and Paul Carding
- 67:** Phonosurgery
Abie Mendelsohn and Marc Remacle
- 68:** Movement disorders of the larynx
Declan Costello and John S. Rubin
- 69:** Acute infections of the larynx
Sanjai Sood, Karan Kapoor and Richard Oakley
- 70:** Chronic laryngitis
Kenneth MacKenzie
- 71:** Contemporary management of laryngotracheal trauma
Carsten E. Palme, Malcolm A. Buchanan, Shruti Jyothi, Faruque Riffat, Ralph W. Gilbert and Patrick Gullane

72: Upper airway obstruction and tracheostomy
Paul Pracy and Peter Conboy

73: Physiology of sleep and sleep disorders
John O'Reilly

74: Obstructive sleep apnoea: Medical management
Dev Banerjee

75: The surgical management of snoring and obstructive sleep apnoea
Bhik Kotecha and Mohammed Reda Elbadawey

76: Laryngotracheal stenosis in adults
Guri S. Sandhu and S.A. Reza Nouraei

77: Reflux disease
Mark G. Watson and Kim Ah-See

78: Paralysis of the larynx
Lucian Sulica and Babak Sadoughi

79: Outpatient laryngeal procedures
Matthew Stephen Broadhurst

Section 2 Plastic Surgery

80: Rhinoplasty following nasal trauma
Charles East

81: Pre-operative assessment for rhinoplasty
Hesham Saleh and Catherine Rennie

82: External rhinoplasty
Santdeep Paun

83: Revision rhinoplasty
Claudia Rudack and Gerhard Rettinger

84: Aesthetic dorsal reduction rhinoplasty
Julian M. Rowe-Jones

85: Nasal reconstruction
Ullas Raghavan

86: Pinnaplasty
Victoria Harries and Simon Watts

87: Blepharoplasty
Brian Leatherbarrow

88: Surgical rejuvenation of the ageing face
Gregory S. Dibelius, John M. Hilinski and Dean M. Toriumi

89: Non-surgical rejuvenation of the ageing face
Lydia Badia, Peter Andrews and Sajjad Rajpar

90: History of reconstructive surgery
Ralph W. Gilbert and John C. Watkinson

91: Grafts and local flaps in head and neck cancer
Kenneth Kok and Nicholas White

92: Pedicled flaps in head and neck reconstruction
Ralph W. Gilbert and John C. Watkinson

93: Reconstructive microsurgery in head and neck surgery
John C. Watkinson and Ralph W. Gilbert

94: Benign and malignant conditions of the skin
Murtaza Khan and Agustin Martin-Clavijo

95: Facial reanimation surgery
Demetrius Evriviades and Nicholas White

96: Partial and total ear construction
Cher Bing Chuo

97: A combined prosthetic and surgical approach
Hitesh Koria, M. Stephen Dover and Steve Worrollo

Abbreviations

1,25-DHCC	1,25 dihydroxycholecalciferol	AEF	auditory-evoked cortical magnetic field
2D	two-dimensional	AERD	aspirin-exacerbated respiratory disease
3D	three-dimensional	AES	assigned educational supervisors
4D CT	four-dimensional computed tomography	AF	atrial fibrillation; <i>or</i> anterior fontanelle
5-FdUMP	5-fluoro-2 deoxyuridine monophosphate	AFAP	attenuated familial adenomatous polyposis
5-FU	5-fluorouracil	AFIP	Armed Forces Institute of Pathology
5-FUMP	5-fluorouridine monophosphate	AFOI	awake fibre-optic intubation
6MP	6-mercaptopurine	AFRS	allergic fungal rhinosinusitis
18-FDG	2-18-fluoro-2-deoxy-D-glucose	AFU	angiofollicular unit
A	adenine; <i>or</i> anterior	AGHDA	Assessment of Growth Hormone Deficiency in Adults
AACE	American Association of Clinical Endocrinologists	AH	adenohypophysis
AAES	American Association of Endocrine Surgeons	AICA	anterior inferior cerebellar artery
AAGBI	Association of Anaesthetists of Great Britain and Ireland	AIDS	acquired immunodeficiency syndrome
AAOHNS	American Academy of Otolaryngologists/Head and Neck Surgeons	AIFR	acute invasive fungal rhinosinusitis
AAV	adeno-associated virus	AIFS	acute invasive fungal sinusitis
ABBA	axillo-bilateral-breast approach	AIH	amiodarone-induced hypothyroidism
ABG	arterial blood gas	AIP	aryl hydrocarbon receptor-interacting protein
ABPA	allergic bronchopulmonary aspergillosis	AIT	amiodarone-induced thyrotoxicosis
ABR	auditory brainstem response	AJCC	American Joint Committee on Cancer
ABRS	acute bacterial rhinosinusitis	AKT	serine/threonine kinase
AC	air conduction; <i>or</i> alternating coupled; <i>or</i> adenylate cyclase	ALLO	alloimmunization
ACE	angiotensin-converting enzyme	ALTB	acute laryngotracheobronchitis
ACGME	Accreditation Council for General Medical Education	ALS	advanced life support; <i>or</i> amyotrophic lateral sclerosis; <i>or</i> acid labile subunit
ACh	acetylcholine	ALSPAC	Avon Longitudinal Study of Parents and Children
AchR	acetyl choline receptor	ALTB	acute laryngotracheobronchitis
ACR	American College of Rheumatology	AML	acute myeloid leukaemia
ACT	Aid for Children with Tracheostomies	AMR	antimicrobial resistance
ACTH	adrenocorticotrophic hormone	AN	acoustic neuroma; <i>or</i> auditory neuropathy; <i>or</i> audiovestibular nerve
AD	Alzheimer's disease	ANA	anti-nuclear antibody
ADAM-33	A disintegrin and metalloprotease 33k	AN/AD	auditory neuropathy/auditory dyssynchrony
ADC	apparent diffusion coefficient	ANCA	antineutrophil cytoplasmic antibody
ADCC	antibody-dependent cellular cytotoxicity	ANSD	auditory neuropathy spectrum disorder
ADH	antidiuretic hormone	ANTS	anaesthetists' non-technical skills
ADP	adenosine diphosphate	AOM	acute otitis media
ADR	adverse drug reaction	AON	anterior olfactory nucleus
ADU	avoidable, delayed or undertransfusion	AP	anterior-posterior; <i>or</i> action potential
Ad-VEGF	adenovirus-encoding vascular endothelial growth factor	APACHE	acute physiology and chronic health evaluation
AEA	anterior ethmoidal artery	APC	antigen presenting cell; <i>or</i> activated protein C; <i>or</i> argon plasma coagulation; <i>or</i> adenomatous polyposis coli
AED	aerodynamic equivalent diameter		

APIT	activated partial thromboplastic time	BMD	bone mineral density
APOF	aggressive psammomatoid ossifying fibroma	BMI	body mass index
APTT	activated partial thromboplastin time	BMP	bone morphogenetic protein; <i>or</i> bone morphogenic protein
AQP2	aquaporin 2	BOR	brachio-oto-renal; <i>or</i> branchioterrenal syndrome
ARIA	allergic rhinitis and its impact on asthma	BP	blood pressure
ARR	absolute risk reduction	BPE	bilateral parathyroid exploration
ARS	acute rhinosinusitis	BSAC	British Society for Antimicrobial Chemotherapy
ARSAC	Administration of Radioactive Substances Advisory Committee	BTA	British Thyroid Association
ART	advanced rotating tomograph; <i>or</i> antiretroviral therapy	C	cytosine
ARIA	allergic rhinitis and its impact on asthma	CAD	caspase-activated DNase
ARS	acute rhinosinusitis	CAF	carcinoma-associated fibroblasts
ASA	aspirin-induced asthma; <i>or</i> aspirin-sensitive asthma; <i>or</i> American Society of Anesthesiologists	CAG	curriculum advisory group
a-SCC	anterior semicircular canal	cAMP	3',5'-monophosphate
AT	ataxia telangiectasia; <i>or</i> auditory therapy or training; <i>or</i> autotransplantation	CAP	compound action potential; <i>or</i> category of auditory performance; <i>or</i> College of American Pathologists
ATA	American Thyroid Association	CAPS	cryopyrin-associated periodic syndromes
ATC	anaplastic thyroid carcinoma; <i>or</i> air traffic control	CARD	caspase recruitment domain
ATD	ascending tract of Deiters; <i>or</i> adult therapeutic dose	CaSR	calcium-sensing receptor
ATIII	antithrombin III	CASTLE	carcinoma with thymus-like elements
ATP	adenosine triphosphate	CBD	case-based discussion
ATR	acute transfusion reaction	CBF	ciliary beat frequency
AVP	arginine vasopressin	CCD	charge-coupled device
AW	anterior wall	CCH	C-cell hyperplasia
BABA	bilateral axillo-breast approach	CCP	cyclic citrullinated peptide
BAC	bacterial artificial chromosome	CCR	chemokine receptor
BADS	British Association of Day Surgery	CCT	Certificate of Completion of Training
BAES	British Association of Endocrine Surgeons	CD	cluster of differentiation; <i>or</i> colloid droplets; <i>or</i> compact disk; <i>or</i> Cowden's disease
BAETS	British Association of Endocrine and Thyroid Surgeons	CDA	cold dry air
BAT	basophil activation test	CDAD	<i>C. difficile</i> associated diarrhoea
BCHD	bone conduction hearing device	CDC	Centers for Disease Control and Prevention
BCP	biphasic calcium phosphate	CDI	<i>C. difficile</i> infection
BCSH	British Committee for Standards in Haematology	CDK	cyclin-dependent kinase
BD	Behcet's disease	CEA	carcinoembryonic antigen
BDP	beclomethasone dipropionate	CEFTE	carcinoma of the thyroid with Ewing family tumour elements
BFU-E	burst-forming unit erythroid	CEPOD	Confidential Enquiry into Perioperative Deaths
BiPAP	bilevel positive airway pressure	CER	control event rate
BIPP	bismuth and iodoform paraffin paste	CESR	Certificate of Eligibility for Specialist Registration
BIS	bispectral index	CEX	clinical evaluation exercises
BL	Burkitt's lymphoma	CF	cystic fibrosis; <i>or</i> characteristic frequency
BMA	British Medical Association; <i>or</i> bone marrow aspirate	CFD	colour-flow duplex Doppler; <i>or</i> computational fluid dynamics
		c-FOS	fos proto-oncogene

CFTR	cystic fibrosis transmembrane conductance regulator	CREST	calcinosis, Raynaud's, oesophageal involvement, sclerodactyly, telangiectasis
CG	clinical governance	CRF	corticotrophin-releasing factor
CGD	chronic granulomatous disease	CRH	corticotrophin-releasing hormone
CGH	comparative genomic hybridization	CRH-R	corticotrophin releasing hormone receptor
CGIFS	chronic granulomatous invasive fungal sinusitis	CRP	C-reactive protein; <i>or</i> canalith repositioning procedure
CGRP	calcitonin gene-related peptide	CRS	chronic rhinosinusitis; <i>or</i> congenital rubella syndrome
CHI	Commission for Healthcare Improvement (UK)	CRSwNP	chronic rhinosinusitis with nasal polyps
CHOP-R	cyclophosphamide, doxorubicin, vincristine, prednisone and rituximab	CRSsNP	chronic rhinosinusitis without nasal polyps
CI	cochlear implant; <i>or</i> cardiac index; <i>or</i> confidence interval; <i>or</i> concha inferior	CRS	chronic rhinosinusitis; <i>or</i> congenital rubella syndrome
CICV	can't intubate can't ventilate	CS	corticosteroid; <i>or</i> cell salvage and autologous transfusions
CIFR	chronic invasive fungal rhinosinusitis	CSC	cancer stem cells
CIFS	chronic invasive fungal sinusitis	CSF	cerebrospinal fluid
CINCA	chronic infantile neurologic cutaneous articular syndrome	CSS	Churg-Strauss syndrome
CJD	Creutzfeldt–Jakob disease	CST	core surgical training
CK	cytokeratin	CT	computed tomography; <i>or</i> conventional thyroidectomy
CKD-MBD	chronic kidney disease mineral bone disorder	CTA	composite tissue allograft; <i>or</i> computed tomography angiography
CLL	chronic lymphatic leukaemia; <i>or</i> chronic lymphocytic leukaemia	CTLA	cytotoxic T-lymphocyte-associated antigen
CM	concha media; <i>or</i> cochlear microphonic; <i>or</i> cricothyroid muscle	CTM	cricothyroid membrane
CMAP	compound muscle action potential	Cu-ATSM	Cu(II)-diacetyl-bis-N4-methylthiosemicarbozone
CML	chronic myeloid leukaemia	DA	double adenoma
CMSO	complementary metal oxide detectors	DACH	diaminocyclohexane
CMT	Charcot—Marie—Tooth; <i>or</i> combined modality therapy	DAHANCA	Danish Head and Neck Cancer Study
CMV	cytomegalovirus	DAMPs	damage-associated molecular pattern molecules
CN	cranial nerve; <i>or</i> cochlear nuclei; <i>or</i> cochlear nerve	DAS	Difficult Airway Society
CNS	central nervous system	DAT	direct antiglobulin test
CO ₂	carbon dioxide	DAVF	dural arteriovenous fistulas
CoAA	coactivator AA	dB	decibel
COF	cemento-ossifying fibroma	DBM	demineralized bone matrix
COMET	Core Outcomes Measures in Effectiveness Trials	DCE MRI	dynamic contrast-enhanced MRI
CONSORT	Consolidated Standards of Reporting Trials	DCR	dacryocystorhinostomy
COPD	chronic obstructive pulmonary disease	DD	death domain
COSI	Client Oriented Scale of Improvement	DDAVP	desmopressin
COX-2	cyclo-oxygenase 2	DDE	Doctrine of Double Effect
CPA	cerebellopontine angle	DED	death effector domain
CPAP	continuous positive airway pressure	DFN3	deafness type 3
CPD	citrate phosphate dextrose; <i>or</i> continuing professional development	DFO-H	deferoxamine-hesperan
CPG	central pattern generator	DHI	dizziness handicap inventory
CRC	colorectal cancer	DHTR	delayed haemolytic transfusion reaction
CRD	component resolved diagnostics	DI	diabetes insipidus
CREB	cAMO binding element	DIC	disseminated intravascular coagulation
		DIO	deiodinases

DISC	death inducing signal complex	ECP	eosinophil cationic protein; <i>or</i> extra corporeal perfusion
DIT	diiodotyrosine; <i>or</i> di-iodothyronine	ECS	extracapsular spread
DLBCL	diffuse large B-cell lymphoma	EDTA	ethylenediaminetetraacetic acid
DM	diabetes mellitus; <i>or</i> decision making	EEA	endoscopic endonasal approach
DMARDS	disease-modifying anti-rheumatic drugs	EEG	electroencephalography; <i>or</i> electroencephalogram
DMSA	dimercapto succinic acid	EER	experimental event rate
DMSO	dimethylsulfoxide	EFRS	eosinophilic fungal rhinosinusitis
DNA	deoxyribonucleic acid	EFVPTC	encapsulated follicular variant of PTC
DNAR	do not attempt resuscitation	EGF	epidermal growth factor
dNTP	deoxynucleoside triphosphate	eGFR	estimated glomerular filtration rate
DOAC	direct oral anticoagulant	EGFR	epidermal growth factor receptor
DOHNS	Diploma in Otolaryngology – Head and Neck Surgery	ELISA	enzyme-linked immunosorbent assay
DOPS	direct observation of procedural skills	EMG	electromyography
DPA	Data Protection Act (UK)	EMT	epithelial-mesenchymal transition
DPOAE	distortion product otoacoustic emission	EMRS	eosinophilic mucin rhinosinusitis
DR	death receptor; <i>or</i> drug resistance	ENA	extractable nuclear antigen
DSA	digital subtraction angiography	ENoG	electroneurography
dsRNA	double-stranded RNA	ENS	empty nose syndrome
DTC	differentiated thyroid cancer	ENT	ear, nose and throat
DTD	DT-diaphorase	EORTC	European Organisation for Research and Treatment of Cancer
dTMP	deoxythymidine monophosphate	EPO	erythropoietin
dUMP	deoxyuridine monophosphate	EPOS	European position paper on rhinosinusitis and nasal polyps
DVT	deep vein thrombosis	EQ-5D	EuroQol
DWI	diffusion weighted image	ER	enhancement ratio; <i>or</i> endoplasmic reticulum
EAACI	European Academy of Allergology and Clinical Immunology	ER α	oestrogen receptor alpha
EAC	external auditory canal; <i>or</i> external acoustic canal	ERAS	enhanced recovery after surgery
EAL	ethmoidal artery ligation	ERK	extracellular signal-regulated kinase
EAT	endoscopic-assisted thyroidectomy	ERS	European Rhinological Society
EBM	evidence-based medicine	ES	embryonic stem; <i>or</i> endolymphatic sac
EBNA	Epstein–Barr virus-associated nuclear antigen	ESBL	extended spectrum β -lactamase
EBP	evidence-based practice	ESPAL	endonasal ligation of the sphenopalatine artery
EBRT	external beam radiotherapy	ESR	erythrocyte sedimentation rate
EBSLN	external branch of the superior laryngeal nerve	ESS	endoscopic sinus surgery; <i>or</i> Epworth Sleepiness Scale; <i>or</i> empty sella syndrome
EBUS	endobronchial ultrasound	ET-1	endothelin-1
EBV	Epstein–Barr virus	ETE	extrathyroidal extension
ECA	external carotid artery	ETT	endotracheal tube
ECAL	external carotid artery ligation	EUA	examination under anaesthesia
ECG	electrocardiogram	EUCAST	European Committee on Antimicrobial Susceptibility Testing
ECM	extracellular matrix	EVAL	ethylene-vinyl alcohol copolymer
ECMO	extracorporeal membrane oxygenation	EWTD	European Working Time Directive
ECochG	electrocochleography	Fab	fragment antigen binding
ECog	electrocochleogram	FACT	functional assessment of cancer therapy
ECOG	Eastern Cooperative Oncology Group (USA)	FADD	Fas-associated death domain

Fas-L	Fas ligand	G	guanine
FBC	full blood count	GABA	gamma-aminobutyric acid
Fc	fragment crystallizable	GABHS	group A beta-haemolytic streptococcus
FcεRI	high affinity IgE receptors	GAG	glycosaminoglycan
FD	fibrous dysplasia	GBI	Glasgow Benefit Inventory
FDA	Food and Drug Administration (USA)	GBM	anti-glomerular basement membrane
FDG	fluorodeoxyglucose; <i>or</i> 2-[18F] fluoro-2-deoxy-D-glucose; <i>or</i> F18-fluoro-2-deoxy-D-glucose	GC	glucocorticoid
FD-OCT	fourier domain optical coherence tomography	G-CSF	granulocyte-colony stimulating factor
FDG-PET	2-[18F] fluoro-2-deoxy-D-glucose positron emission tomography; <i>or</i> fluorine-18-labelled deoxyglucose positron emission tomography	GD	Graves' disease
FE	frontal ethmoidal cell	GERD	gastroesophageal reflux disease
FEA	finite element analysis	GH	growth hormone
FESS	functional endoscopic sinus surgery	GHABP	Glasgow Hearing Aid Benefit Profile
FEIBA	factor VIII inhibitor bypassing agent	GHRH	growth hormone-releasing hormone
F-ETNIM	fluorine-18 fluoroerythronitroimidazole	GHRP	growth hormone-releasing peptide
FFP	fresh frozen plasma	GI	gastrointestinal
FGF	fibroblast growth factor	GMC	ganglion mother cell; <i>or</i> General Medical Council (UK)
FHH	familial hypocalciuric hypercalcaemia	GM-CSF	granulocyte-macrophage colony stimulating factor
FIHP	familial isolated hyperparathyroidism	GMS	Gomori's methamine silver stain
FiO ₂	fraction of inspired oxygen	GnIH	gonadotrophin inhibitory hormone
FIPA	familial isolated pituitary adenomas	GnRH	gonadotrophin-releasing hormone
FISH	fluorescence <i>in situ</i> hybridization	GORD	gastro-oesophageal reflux disease
FITS	functional inferior turbinosurgery	gp	glycoprotein
FIV	feline immunodeficiency virus	GP	general practitioner
FLAIR	fluid attenuated inversion recovery	GPA	granuloma; <i>or</i> granulomatosis with polyangitis
FMF	familial Mediterranean fever	G protein	guanine nucleotide-binding regulatory protein
FMISO	fluorine-18 fluoromisonidazole	GRADE	Grading of Recommendation, Assessment, Development and Evaluation
fMRI	functional magnetic resonance imaging	GRB2	growth factor receptor binding protein 2
FMTC	familial medullary thyroid cancer	Gs	G-protein adenylate cyclase stimulator
FN	facial nerve	GSH	glutathione
FNA	fine-needle aspiration/aspirate	GSP	stimulatory G protein
FNAB	fine-needle aspiration biopsy	GTN	nitroglycerin
FNAC	fine-needle aspiration cytology	GTR	guided tissue regeneration
FNHTR	febrile non-haemolytic transfusion reactions	GTV	grow tumour volume
FOI	fibreoptic orotracheal intubation	GvHD	graft-versus-host disease
FRS	fungal rhinosinusitis	HA	hydroxyapatite
FS	folliculostellate; <i>or</i> frontal sinus	H&E	haematoxylin and eosin
FSH	follicle-stimulating hormone	H&N	head and neck
fT ₃	free T ₃	H ₂	histamine receptor type 2
fT ₄	free T ₄	HA	hydroxyapatite
FTC	frequency threshold curve; <i>or</i> follicular thyroid carcinoma	HAART	highly active antiretroviral therapy
FT-UMP	follicular tumour of uncertain malignant potential	HAI	hospital-acquired infection
FVPTC	follicular variant of papillary thyroid carcinoma	HBME-1	mesothelium-associated antibody
		Hb	haemoglobin
		HbA	adult haemoglobin

HBO	hyperbaric oxygen	HSC	haematopoietic stem cell
HBOT	hyperbaric oxygen therapy	HSCT	haemopoietic stem cell transplant
HCG	human chorionic gonadotrophin	HSD	hydroxysteroid dehydrogenase enzyme
HD	haemodialysis	HSE	handling and storage errors
HDL	high-density lipoprotein	HSV	herpes simplex virus
HDM	house dust mite	HSV-1	herpes simplex virus type 1
HDU	high dependency unit	HSV-2	herpes simplex virus type 2
He-Ne	helium-neon	HSV-TK	herpes simplex thymidine kinase
HEPA	high-efficiency particulate air	HTA	hyalinizing trabecular adenoma; <i>or</i> Health Technology Assessment
HES	hospital episode statistics	hTERT	human telomerase reverse transcriptase
HFJV	high-frequency jet ventilation	HTR	haemolytic transfusion reaction
HFT	hereditary familial telangiectasia	HTT	hyalinizing trabecular tumours
HGF	hepatocyte growth factor	HU	Hounsfield unit
HH	hypogonadotrophic hypogonadism	HUI	Health Utilities Index
HHI	Hearing Handicap Inventory; <i>or</i> hereditary hearing impairment	HVDT	health visitor distraction test
HHIE	Hearing Handicap Inventory for the Elderly	Hz	hertz
HHT	hereditary haemorrhagic telangiectasia	HZV	herpes zoster virus
HHV-6	human herpesvirus 6	IAC	internal auditory canal
HHV-8	human herpesvirus 8	IAR	intermittent allergic rhinitis
HI	hearing impaired	IBCT	incorrect blood component transfused
Hib	<i>Haemophilus influenzae</i> b	ICA	internal carotid artery
HIDS	hyper-IgD syndrome	ICAD	inhibitor caspase-activated DNase
HIT	heparin-induced thrombocytopenia	ICAM	intercellular adhesion molecule
HIV	human immunodeficiency virus	ICAM-1	intercellular adhesion molecule 1
HL	hearing loss; <i>or</i> hearing level; <i>or</i> hairy leukoplakia	ICD	International Classification of Disease
HLA	human leukocyte antigen	ICF	International Classification of Functioning
HLH	haemophagocytic lymphohistiocytosis	ICS	intra-operative cell salvage
HM	history of migraine; <i>or</i> hemifacial microsomia	ICU	intensive care unit
HMW	high molecular weight	IDD	intracellular death domain
HMWC	high molecular weight compound	IDT	infant distraction test; <i>or</i> intra-dermal test
HMWCK	high molecular weight cytokeratin	IFN	interferon
HNSCC	head and neck squamous cell carcinoma	IFN- α	interferon-alpha
Ho-YAG	holmium yttrium aluminium garnet	IFN- β	interferon-beta
HPA	hypothalamic-pituitary-adrenal axis	IFN- γ	interferon-gamma
HPC	haemangiopericytoma	IFVPTC	invasive follicular variant of PTC
HPT	hyperparathyroidism	Ig	immunoglobulin
HPT-JT	hyperparathyroidism-jaw tumour	IGD	isolated GnRH-deficiency
HPV	human papillomavirus; <i>or</i> human herpes virus 8	IgE	immunoglobulin E
HPZ	herpes zoster	IGF	insulin-like growth factor
HR	hazard ratio	IGF-I	insulin-like growth factor 1
HRA	Human Rights Act	IGF-II	insulin-like growth factor II
HRQOL	health-related quality of life	IGFBP	insulin-like growth factor binding protein
HR	heart rate	IgG	immunoglobulin G
HRT	hormone replacement therapy	IgG κ C	immunoglobulin G kappa chain
HRV	rhinoviruses	IGS	image-guided surgery
		IHC	immunohistochemistry; <i>or</i> inner hair cell
		IIT	iodide-induced thyrotoxicosis

IJV	internal jugular vein	K	Kirschner
IL	interleukin	KCCT	kaolin cephalin clotting time
IL-1	interleukin-1	KDOQI	Kidney Disease Quality Outcomes Initiative
IL-2	interleukin-2	keV	kilo electron volt
IL-3	interleukin-3	KOH	potassium hydroxide solution prep test
IL-5	high interleukin	KISS-R	kisspeptin receptor (also known as GR54)
IL-6	interleukin-6	KS	Kaposi's sarcoma
ILMA	intubating laryngeal mask airway	KTP	potassium titanyl phosphate
i.m.	intramuscular		
IMA	internal maxillary artery	LA	lymphangioma
IMAL	internal maxillary artery ligation	LAR	local allergic rhinitis
IMF	intermaxillary fixation	LAT	lateral aberrant thyroid
IMP	importin	LC1	liver cystolic 1
IMRT	intensity-modulated radiation therapy	LCM	laser capture microdissection
iNOS	inducible nitric oxide synthase	LDH	lactate dehydrogenase
INR	international normalized ratio; <i>or</i> interventional neuroradiology	LDL	low-density lipoprotein; <i>or</i> loudness discomfort level
IOM	institute of Medicine	LED	light-emitting diode
IONM	intra-operative neural/nerve monitoring	LFA	lymphocyte-function associated antigen
IOPTH	intra-operative PTH	LFJV	low-frequency jet ventilation
IOQPTH	intra-operative quick assay of intact parathyroid hormone	LH	luteinizing hormone
IOUS	intra-operative ultrasound scanning	LHB	lateral-head-back
IP	Inverted papilloma	LH-R	luteinizing hormone receptor
IPD	invasive pneumococcal disease	LINAC	linear accelerator
iPSCs	induced pluripotency stem cells	LKM	liver kidney microsomal
IPSS	inferior petrosal sinus sampling	LM	laryngeal mask
IRI	ischaemia-reperfusion injury	LMA	laryngeal mask airway
IRS	insulin receptor substrate; <i>or</i> Intergroup Rhabdomyosarcoma Study	LMW	low molecular weight
ISAAC	International Study of Asthma and Allergies in Childhood	LMWC	low molecular weight compound
ISCP	International Surgical Curriculum Programme	LMWH	low molecular weight heparin
ISL	<i>in situ</i> ligation	LOCR	lateral opticocarotid recess
IT	inferior turbinate	LOD	logarithm to the base 10 of the odds that the markers are linked at a recombination distance of N centimorgans
ITA	inferior thyroid artery	LOH	loss of heterozygosity
ITAM	immunoreceptor tyrosine-based activation motif	LP	lamina papyracea; <i>or</i> lichen planus; <i>or</i> lymphocyte predominant
ITP	idiopathic thrombocytopenic purpura	LPR	laryngopharyngeal reflux; <i>or</i> late phase reactions
ITU	intensive therapy unit	LR	likelihood ratio
i.v.	intravenous	LR-OCT	long-range optical coherence tomography
IVIg	intravenous immunoglobulin	LTRA	leukotriene receptor antagonists
		LW	lateral wall
JAK2	Janus kinase 2	M	metastases
JCST	Joint Committee on Surgical Training	M2	Matrix 2 ion channels
JIA	juvenile idiopathic arthritis	MAb	monoclonal antibodies
JLNS1	Jervell and Lange-Nielsen syndrome	MABP	mean arterial blood pressure
JNA	juvenile nasopharyngeal angiofibroma	MAC	membrane attack complex; <i>or</i> <i>Mycobacterium avium</i> complex
JNK	c-Jun N-terminal kinase		

MAD	mucosal atomization device	MMR	measles, mumps and rubella
MAGE-3	melanoma-associated antigen-3	MNG	multinodular goitre
MALT	mucosa-associated lymphoid tissue	MOCR	medial opticocarotid recess
MAOI	monoamine oxidase inhibitor	MODS	multiple organ dysfunction syndrome
MAP	minimum audible pressure	MOE	malignant otitis externa
MAPK	mitogen-activated protein kinase	MOFT	multiple oxyphil follicular tumour
MAS	mandibular advancement splint; <i>or</i> macrophage activation syndromes	MOS	Medical Outcomes Study
MBL	mannose-binding lectin	MPA	microscopic polyangiitis
MC2R	melanocortin 2 receptor	MPTS	Medical Practitioner's Tribunal Service
MCP	monocyte chemotactic protein	MPO	myeloperoxidase
MCS	mental component summary	MPTP	1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine
MCT	medullary thyroid carcinoma	MR	magnetic resonance
MCV	mean corpuscular volume	MRA	magnetic resonance angiography
MDCT	multi-detector row CT	MRC	Medical Research Council (UK)
MDS	myelodysplastic syndrome	MRCs	Member of the Royal College of Surgeons
MDT	multidisciplinary team	MRI	magnetic resonance imaging
ME	middle ear	mRNA	messenger ribonucleic acid
MEG	magnetoencephalography	MRSA	methicillin-resistant <i>Staphylococcus aureus</i>
MEK	MAPK/extracellular signal related kinase	MS	multiple sclerosis
MEN	multiple endocrine neoplasia	MSBOS	maximum surgical blood ordering schedule
MeSH	medical subject heading	MSCs	mesenchymal stem cells
MET	middle ear transducer	MSF	multi-source feedback
M-FISH	multifluor FISH	MSSA	methicillin-susceptible strains
MGHD	multiple gland hyperplasia disease	MT	maxilloturbinal; <i>or</i> middle turbinate
MGO	methylglyoxal	MTC	medullary thyroid carcinoma
MGUS	monoclonal gammopathy of uncertain significance	mtDNA	mitochondrial DNA
MHC	major histocompatibility complex	mTORC1	mammalian target of rapamycin 1
MHP	massive haemorrhage pack	mTORC2	mammalian target of rapamycin 2
MI	myocardial infarction	MW	medial wall
mIBG	metaiodobenzylguanidine; <i>or</i> iodine-123-metaiodobenzylguanidine	N	nodal
MIBI	sestamibi; <i>or</i> technetium-99m	NADP	nicotinamide adenine dinucleotide phosphate
MIC	minimum inhibitory concentration	NADPH	reduced form of nicotinamide adenine dinucleotide phosphate
μOCT	micro-optical coherence tomography	NANIPER	non-allergic non-infectious perennial rhinitis
MIFC	minimally invasive follicular carcinoma	NAP4	Fourth National Airway Project
MIP	minimally invasive parathyroidectomy; <i>or</i> maximum intensity projection; <i>or</i> macrophage inflammatory protein;	NARES	non-allergic rhinitis with eosinophilia syndrome
miRNA	micro ribonucleic acid	NBCA	n-butyl-2-cyanoacrylate; <i>or</i> N-butylcyanoacrylate
MIST	minimal invasive sinus techniques	NBT	nitro blue tetrazolium
MIT	monoiodotyrosine; <i>or</i> mono-iodothyronine; <i>or</i> minimally invasive thyroidectomy	NCAS	National Clinical Assessment Service (UK)
MIVAT	minimally invasive video-assisted thyroidectomy	NCEPOD	National Confidential Enquiry into Patient Outcome Death (UK)
MLKL	mixed lineage kinase domain-like protein	NCIC	National Cancer Institute of Canada
MLTB	microlaryngotracheobronchoscopy	ncRNA	non-coding ribonucleic acid
MMC	mitomycin C; <i>or</i> Modernising Medical Careers	Nd-YAG	neodymium-yttrium aluminium garnet
MMP	mucous membrane pemphigoid; <i>or</i> matrixmetalloprotease	NET	nerve excitability test; <i>or</i> neuroendocrine tumour

NF1	neurofibromatosis type 1	OPCS	Office for Population Censuses and Surveys (UK)
NF2	neurofibromatosis type 2	OPF	osteoplastic flap procedure
NH	normal hearing; <i>or</i> neurohypophysis	OR	occupational rhinitis
NHANES	National Health and Nutrition Examination Survey	OREP	olfactory event-related potential
NHL	non-Hodgkin's lymphoma	ORL	otorhinolaryngology
NHS	National Health Service (UK)	OSA	obstructive sleep apnoea
NHSLA	National Health Service Litigation Authority	OSATS	obstructive structured assessment of technical skill
NIBP	automatic non-invasive blood pressure	OTOF	otoferlin
NICE	National Institute for Health and Care Excellence (UK)	OXTR	oxytocin receptor
NIFTP	non-invasive follicular tumour with papillary-like nuclei	P	phosphate; <i>or</i> posterior
NIH	National Institutes of Health (USA)	PA	pernicious anaemia
NIM	nerve integrity monitor	PAC	P1 artificial chromosome; <i>or</i> pulmonary artery catheter; <i>or</i> parathyroid carcinoma
NIPF	nasal inspiratory peak flow	PACS	picture archiving and communication systems
NIS	Na ⁺ /I ⁻ symporter	PACU	post-anaesthesia care unit
NK	natural killer	PAF	platelet-activating factor
nLTP	non-specific lipid transfer protein	PBA	procedure-based assessment
NNT	number needed to treat	PBP	progressive bulbar palsy
NO	nitric oxide	PCA	patient-controlled analgesia
NO ₂	nitric dioxide	PCC	prothrombin complex concentrate; <i>or</i> Professional Conduct Committee (UK); <i>or</i> pheochromocytoma
NOAC	novel oral anticoagulant	PCD	primary ciliary dyskinesia
NOE	naso-orbito-ethmoid	PCOS	polycystic ovary syndrome
NOTSS	non-technical skills for surgeons	PCR	polymerase chain reaction
NOS	not otherwise specified	PCS	physical component summary
NP	nasopharynx; <i>or</i> nasopharyngeal	PD	Parkinson's disease
NPC	nasopharyngeal cancer; <i>or</i> nasopharyngeal carcinoma	PDCAT	poorly differentiated carcinoma of the thyroid
NPSA	National Patient Safety Agency (UK)	PDE	phosphodiesterase
NPT	near patient testing	PD1	programmed cell death protein 1
NPV	negative predictive value	PDGF	platelet-derived growth factor
NRTIs	nucleoside/nucleotide reverse transcriptase inhibitors	PDL	pulsed dye laser
NSAID	non-steroidal anti-inflammatory drug	PDR	Physicians' Desk Reference
NSF	national service framework; <i>or</i> nasoseptal flap	PDS	polydimethylsiloxane
NSHI	non-syndromic hearing impairment	PDT	photodynamic therapy
NTT	near-total thyroidectomy	PE	polyethylene; <i>or</i> pulmonary embolism; <i>or</i> pharyngo-oesophageal
O ₃	ozone	PEG	percutaneous endoscopic gastrostomy
OAE	otoacoustic emission	PER	persistent allergic rhinitis
OB	olfactory bulb	PET	polyethylene terephthalate; <i>or</i> positron emission tomography
OCT	optical coherence tomography	PET-CT	positron emission tomography/computed tomography
ODP	operating department practitioner	PET-MRI	positron emission tomography-MRI
OF	ossifying fibroma	PF	posterior fontanelle; <i>or</i> cisplatin/5-fluorouracil
OFDI	optical frequency domain imaging		
OIDA	observe; interpret; decide; act		
OMC	ostiomeatal complex		
OPC	oropharyngeal cancer; <i>or</i> oropharyngeal candidiasis		

PF4	platelet factor 4	PTP	post-transfusion purpura
PFAPA	periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis	PTU	propylthiouracil
PFS	progression-free survival	PUOF1	pituitary-specific positive transcription factor 1
PG	paraganglioma	PVA	polyvinyl alcohol
PGA	polyglycolic acid	PVC	polyvinyl chloride
PGD2	prostaglandin D2	PW	posterior wall
PGE1	prostaglandin-E1	QALY	quality adjusted life year
PGI2	prostacycline; <i>or</i> prostaglandin I2	QOL	quality of life
PGL	persistent generalized lymphadenopathy	RA	retinoic acid
PHPT	primary hyperparathyroidism	RAE	Ring, Adair, Elwyn
PI	pulsatility index; <i>or</i> protease inhibitors	RAF	rapidly accelerated fibrosarcoma signal-regulated kinase
PI3K	phosphatidylinositol 3	RAI	radioactive iodine
PICU	paediatric intensive care unit	RANKL	regulation of nuclear factor κ B ligand
PIII	parathyroid III	RANTES	regulated on activation, normal T-cell expressed and secreted
PIP	peak inspiratory pressure	RAS	recurrent aphthous stomatitis; <i>or</i> rat sarcoma protein family
PIV	parainfluenza virus; <i>or</i> parathyroid IV	RAST	radioallergosorbent test
PKA	protein kinase A	RAT	rapid antigen testing; <i>or</i> robotic-assisted thyroidectomy
PLAT	paraganglioma-like adenoma of the thyroid	RB	retinoblastoma
PLD	potentially lethal damage	RBC	red blood cell
PM	particulate matter	RCC	Rathke cleft cyst; <i>or</i> red cell count
PNH	paroxysmal nocturnal haemoglobinuria	RCoA	Royal College of Anaesthetists
PNIF	peak nasal inspiratory flow	RCT	randomized controlled trial
p.o.	by mouth	RET	rearranged during transfection
POGO	prescription of gain and output	RF	rheumatoid factor; <i>or</i> radio frequency
POMC	propiomelanocorticotrophin	RFLP	restriction fragment length polymorphism
PONV	postoperative nausea/vomiting	RFRP	RFamide-related peptide
PP	pyrophosphate	RFTVR	radiofrequency tissue volume reduction
PPD	purified protein derivative; <i>or</i> parathyroid proliferative disease	rFVIIa	recombinant factor VIIa
PPV	positive predictive value	rhBMP-7	recombinant human bone morphogenetic protein 7
PR3	proteinase 3	rhPTH	recombinant human parathyroid hormone
PRISMA	Preferred Reporting Items for Systematic Reviews and Meta-Analyses	rhTSH	recombinant human TSH
PRL	polypeptide hormone prolactin	RHD	Reported Hearing Disability
PRP	platelet-rich plasma	RIG	radiologically inserted gastrostomy
PRPP	5-phospho-alpha-D-ribose 1-diphosphate	RLN	recurrent laryngeal nerve
PSA	prostate-specific antigen; <i>or</i> pleomorphic salivary adenoma; <i>or</i> persistent stapedial artery	RLNP	recurrent laryngeal nerve palsy
PS-OCT	polarization-sensitive OCT	RNA	ribonucleic acid
PT	prothrombin time	RNP	ribonucleoprotein
PTAH	phosphotungstic acid haematoxylin	ROS	reactive oxygen species
PTC	papillary thyroid cancer; <i>or</i> psychophysical tuning curve	ROSE	rapid on-site evaluation
PTG	parathyroid gland	ROTEM	thromboelastography
PTH	parathyroid hormone	RP	rapid prototyping; <i>or</i> relapsing polychondritis
PTHrP	parathyroid hormone-related protein; <i>or</i> parathyroid hormone-related peptide	RR	relative risk
PTMC	papillary thyroid microcarcinoma		
pTNM	pathological tumour, nodes, metastases		

RRA	radioiodine remnant ablation	SLE	systemic lupus erythematosus
RRR	relative risk reduction	SLICC	Systemic Lupus International Collaborating Clinics
RSDI	Rhinosinusitis Disability Index	SLIT	sublingual immunotherapy; <i>or</i> sublingually in drops or tablets
RSOM	rhinosinusitis outcome measure	SLN	superior laryngeal nerve
RSTL	relaxed skin tension line	SMAS	superficial or subcutaneous musculoaponeurotic system
RSV	respiratory syncytial virus	SAMD	submucosal diathermy
RT	radiotherapy	SMR	submucosal resection
RTOG	Radiation Therapy Oncology Group	SMS	short message service; <i>or</i> indium-111 pentetretotide
rT3	reverse triiodothyronine	SNHL	sensorineural hearing loss
RTK	receptor tyrosine kinase	SNOT	sino-nasal outcome test
RUDS	reactive upper airways dysfunction syndrome	SNUC	sinonasal undifferentiated carcinoma
SA	solitary adenoma; <i>or</i> situational awareness	SO ₂	sulphur dioxide
SAD	supraglottic airway device	SOCS2	suppressors of cytokine signalling 2
SAGM	saline-adenine-glucose-mannitol	SOE	supraorbital ethmoid cells
SAPS	simplified acute physiology score	SOFA	sequential organ failure assessment
SBS	sick building syndrome	SOFT	solitary oxyphil follicular tumour
s.c.	subcutaneous	SOS	guanine nucleotide exchange factor (son of sevenless)
SCC	squamous cell carcinoma or cancer; <i>or</i> semicircular canal	SPA	sphenopalatine artery
SCCA	squamous cell carcinoma antigen	SPECT	single photon emission computed tomography
SCCHN	squamous cell carcinoma of the head and neck	SPET	single photon emission tomography
SCID	severe combined immunodeficiency	SPF	sphenopalatine foramen
SCIT	subcutaneous immunotherapy	SPLINTS	scrub practitioners list of intra-operative non-technical skills
SCL-90	Symptom Checklist-90	SPT	skin prick test; <i>or</i> station pull through
SCM	sternocleidomastoid muscle	SPTX	subtotal parathyroidectomy
SCN	severe congenital neutropenia; <i>or</i> solid cell nests	SRS	subacute rhinosinusitis
SEER	Surveillance, Epidemiology, and End Results (program)	SS	somatostatin
SERM	selective-oestrogen receptor modifier	ssDNA	single-stranded DNA
SETTLE	spindle cell tumour with thymus-like differentiation	SSC	superior semicircular canal; <i>or</i> Surviving Sepsis Campaign
SF-36	Medical Outcome Study Short-Form 36-Item Health Survey	SSEP	steady-state potential
SFF	speaking fundamental frequency; <i>or</i> solid free form fabrication	SSLP	simple sequence length polymorphism
SHC	SH2-containing protein	SSQ	speech, spatial and qualities
Shh	sonic hedgehog	SSTR1-5	somatostatin receptors 1-5
SHI	syndromic hearing impairment	SSRI	selective serotonin reuptake inhibitor
SHOT	serious hazards of transfusion	ST	superior turbinate; <i>or</i> subtotal thyroidectomy
SHPT	secondary hyperparathyroidism	STAT	signal transducer and activator of transcription
SIADH	syndrome of inappropriate antidiuretic hormone	STD	standard deviation
sIgE	specific immunoglobulin E	STRP	short tandem repeat polymorphism
SIGN	Scottish Intercollegiate Guidelines Network	SUV	standardized uptake value
SIP	sickness impact profile	SV	stroke volume
siRNA	small interfering ribonucleic acid	SVCO	superior vena caval obstruction
SLD	sublethal damage	SVS	selective venous sampling

SVCO	superior vena cava obstruction	TNM	tumour, node, metastasis
SVR	systemic vascular resistance	TNO	transnasal oesophagoscopy
Syk	signal-propagating kinase	TOE	transoesophageal echocardiography; <i>or Trichophyton, Oidiomyces and Epidermophyton</i>
T	thymine; <i>or</i> tumour	TOF	tracheo-oesophageal fistula
T1WI	T1-weighted images	TPO	thyroid peroxidase; <i>or</i> thyroperoxidase
T2WI	T2-weighted images	TPP	thyrotoxic periodic paralysis
T3	triiodothyronine	TPTX	total parathyroidectomy
T4	thyroxine	TPZ	tirapazamine
TAA	tumour associated antigens	TRALI	transfusion-related acute lung injury
TACO	transfusion-associated circulatory overload	TRAM	transverse rectus abdominis myocutaneous
TAD	transfusion-associated dyspnea	TRH	thyrotrophin-releasing hormone
TAGVHD	transfusion-associated graft-versus-host disease	tRNA	transfer ribonucleic acid
TAM	tumour associated macrophages	TSA	tumour specific antigens
TB	tuberculosis; <i>or Mycobacterium tuberculosis</i>	TSH	thyroid-stimulating hormone; <i>or</i> thyrotrophin
TBG	thyroxine-binding globulin	TSHoma	TSH-secreting adenoma
TcT	cytotoxic	TSH-R	TSH receptor
^{99m} Tc	technetium-99m	TT	thrombin time; <i>or</i> total thyroidectomy
Tc-99m (v) DMSA	pentavalent dimercaptosuccinic acid	TTF-1	thyroid transcription factor-1
TC	thyroid cartilage	TTP	thrombotic thrombocytopeniac purpura
TCI	target-controlled infusion	TUNEL	TdT-mediated nick end labelling
TCP	tricalcium phosphate	U	uracil
TCR	T-cell receptor	UCT	unclassifiable complications of transfusion
t.d.s.	3 times a day	UICC	International Union Against Cancer
TEG	thromboelastography	UIC	urinary iodine concentration
TFT	thyroid function test	UKRETS	UK Registry of Endocrine and Thyroid Surgery
TG	thyroglobulin	UMP	uridine monophosphate
TgAb	thyroglobulin antibodies	UNICEF	United Nations Children's Fund
TGF	transforming growth factor	UP	uncinate process
TGF- α	transforming growth factor alpha	UPSIT	University of Pennsylvania Smell Identification Test
TGF- β	transforming growth factor beta	URTI	upper respiratory tract infection
TGF- β 1	transforming growth factor beta 1	US	ultrasound; <i>or</i> ultrasonography
Th	T-helper	USH	Usher syndrome
Th1	T-helper 1 cell	USH1B	Usher syndrome type 1B
Th2	T-helper 2 cell	USS	ultrasound scan
THST	thyroid hormone suppression therapy	UV	ultraviolet
THW	thyroid hormone withdrawal	V2R	vasopressin type 2 receptor
TI	thyroid isthmusectomy	VA	Veterans' Affairs; <i>or</i> vestibular aqueduct
TIL	tumour infiltrating lymphocytes	VAC	vacuum-assisted closure
TIVA	total intravenous anaesthesia	VAS	visual analogue scale; <i>or</i> visual analogue score
TKI	tyrosine kinase inhibitor	VATS	video-assisted thoracoscopic surgery
TL	total lobectomy	VC	vocal cord
TME	tumour microenvironment		
TMC1	transmembrane channel-like gene 1		
TMJ	temporomandibular joint		
TNF	tumour necrosis factor		
TNF- α	tumour necrosis factor alpha		

VCAM-1	vascular cell adhesion molecule-1	WDTC	well-differentiated thyroid cancer
vCJD	variant Creutzfeldt—Jakob disease	WDT-UMP	well-differentiated tumour of uncertain malignant potential
VCP	vocal cord paralysis	WHAFFT	worrisome histologic alteration following fine-needle aspiration of the thyroid gland
VDA	vascular disrupting agent	WHO	World Health Organization
VEGF	vascular endothelial growth factor	WIFC	widely invasive follicular carcinoma
VEGFR	vascular endothelial growth factor receptor	WMD	weighted mean difference
VF	vocal fold	WP	Woodruff's plexus
VHI	Voice Handicap Index	WPBA	workplace based assessments
VHI-10	Voice Handicap Index-10	WS	Waardenburg syndrome
VHQ	Vertigo Handicap Questionnaire	XLA	X-linked agammaglobulinaemia
VILI	ventilator induced lung injury	XM	crossmatch
VN	vestibular nuclei; <i>or</i> vagus nerve	YAC	yeast artificial chromosome
VNO	vomero nasal organ	YAG	yttrium aluminium garnate
VOC	volatile organic compound		
VTE	venous thromboembolism		
VTFF	vertex-to-floor		
vWD	von Willebrand disease		
vWF	von Willebrand factor		
VZV	varicella zoster virus		
WBS	whole-body scan		
WDC-NOS	well-differentiated carcinoma, not otherwise specified

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: molecular biology, genetics and cell biology.

INTRODUCTION

Molecular biology describes the study of the biochemical processes that govern the behaviour of cells. These processes form the fundamental mechanisms by which cell function, cell–cell interactions and cell turnover are regulated. Disruption of this regulation may lead to disease, whilst an understanding of these mechanisms allows the physician to attempt to predict disease behaviour and to explore methods of restoring this regulation at a molecular level. This chapter reviews the principles of molecular genetics and outlines aspects of the molecular biology of the cell in the context of otolaryngological disease processes and describes some of the techniques that form the backbone of current molecular biology. It should give the reader sufficient background knowledge of molecular biology to understand subsequent chapters discussing the molecular biology of specific otolaryngological conditions.

MOLECULAR GENETICS: DNA STRUCTURE AND FUNCTION

Hereditary information in eukaryotes is stored in the form of double-stranded deoxyribonucleic acid (DNA) and is referred to as the genome. DNA forms a double-helix structure as a result of hydrogen bonds between complementary pairs of nucleotides, adenine (A) with thymine (T) and cytosine (C) with guanine (G). The nucleotides on each strand are organized linearly in triplets, known as codons. Each specific sequence determines

a single specific amino acid, for example ACU specifies threonine. However, as there are more triplet combinations (64) than commonly encountered amino acids (20), some proteins may be represented by different codons (e.g. lysine by AAA as well as AAG) and some codons (UAA, UGA and UAG) are ‘stop’ codons, constituting a signal for arrest of translation. The overwhelming majority of this DNA (99.9%) exists in the cell nucleus as the nuclear genome, which, in the human, is estimated to be 3000 megabase pairs in physical size and encodes 30 000–35 000 genes. The remaining DNA (16.6 kilobase pairs) forms the mitochondrial genome, encoding 37 genes. The mitochondrial genome and its potential role in cancer diagnostics will be discussed later.

Each DNA molecule is packaged into a chromosome by complex folding of the DNA around proteins. Diploid human cells contain 22 pairs of autosomes (1 to 22) and a pair of sex chromosomes (XX or XY) that determines the sex of the organism. One of each pair of chromosomes is maternally inherited and the other is paternally inherited. Each chromosome has a distinctive shape, size and banding pattern, but have the common appearance of two arms apparently separated by a constriction. The centromere is microscopically recognizable as the central constriction separating the chromosome into a long arm (q for queue) and a short arm (p for petit), but its biological role lies in anchoring the chromosome to the mitotic spindle for segregation during cell division. The ends of the chromosomes are capped by telomeres, which are specialized structures containing unique simple repetitive sequences. They maintain the structural integrity of the

chromosome and provide a solution for complete replication of the extreme ends of the chromosome. The conventional nomenclature for chromosomal locus assignment is given by the chromosome number, followed by the arm and finally the position on the arm, for example, 3p21 indicates position 21(two-one) on the short arm of chromosome three.

During normal cell division, DNA replication is achieved by the separation of the two strands by DNA helicase. Each separated single strand then acts as a template for polymerization, catalyzed by DNA polymerase, of nucleotides forming a new complementary strand and thus double-stranded DNA identical to the original dsDNA. As each daughter DNA consists of one original and one newly synthesized DNA strand, the process is known as semi-conservative replication. The specificity of the complementary relationship between the nucleotides on each strand forms the basis for many techniques of modern molecular biology and molecular cytogenetics.¹ The accuracy with which DNA replication takes place is remarkable with an estimated error rate of less than one in 10^9 nucleotide additions. Such accuracy is of vital importance to the individual as a permanent change in DNA, or mutation may cause inactivation of a gene essential to cell survival or cell cycle control. The high fidelity of DNA sequence replication is achieved by unidirectional 5'-to-3' direction of DNA replication, a rigorous DNA proofreading mechanism that detects mismatched DNA and efficient DNA repair pathways that excise and repair DNA damage. Failure of these mechanisms, such as is encountered in xeroderma pigmentosum, Fanconi's anaemia and ataxia telangiectasia, leads to accumulation of DNA replication errors and a high incidence of malignancies.

Although the human nuclear genome is 3×10^9 base pairs in size, about 90% of it is non-coding, with all the genes being coded by the remaining 10% of the DNA. Within the non-coding DNA are dispersed short arrays of repeat units of pairs or triplets of nucleotides (di-/trinucleotides). The exact function of these microsatellite repeats is not entirely clear, but their existence and frequency of dispersion throughout the genome have greatly facilitated study of the genetics of tumours and many inherited disorders, which will be discussed later.

A gene is a region of the chromosomal DNA that produces a functional ribonucleic acid molecule (RNA). It comprises regulatory DNA sequences that determine when and in which cell types that gene is expressed, exons that are coding sequences and interspersed introns that are non-coding DNA sequences. These regulatory sequences often consist of CpG islands, short stretches of DNA rich in dinucleotides of cytosine and guanine. The methylation status of these CpG islands determines whether that gene is expressed in a particular cell or tissue, being unmethylated in tissues where the genes are expressed. As will be discussed later, aberration of this control is one of the mechanisms of tumour suppressor gene inactivation. However, these same genes can also be regulated by proteins that recognize methylated sequences called histones² and these in turn can be regulated by polycomb genes

such as *BM11*.³ Transcription is the intra-nuclear process driven by RNA polymerase whereby one of the two DNA strands acts as a template for the synthesis of a single RNA strand which is complementary to the DNA, except that uracil replaces thymine in RNA. This primary RNA transcript then undergoes post-transcriptional processing, or splicing.⁴ Traditional dogma held that one gene produces one protein and therefore splicing was considered to occur simply in order to remove the non-coding intronic sequences, producing messenger RNA (mRNA). It is now known that by 'alternative splicing', one gene can result in the production of several different but often related proteins in different tissues.⁵

The mature mRNA then migrates into the cytoplasm where it acts as a template for the synthesis of a polypeptide during translation, a process regulated and catalyzed by cytoplasmic ribosomes. Successive amino acids are added to the polypeptide chain according to the triplet code on the mRNA, which is recognized by the transfer RNA (tRNA), to which each corresponding amino acid is covalently bound. Translation is commenced upon recognition of an initiation codon (usually but not exclusively AUG/methionine) and terminated upon recognition of a stop codon. The polypeptide subsequently undergoes a variable degree of post-translational modification and/or cleavage to produce the mature protein product, which may have an intra-cellular role or may be exported to the endoplasmic reticulum and hence to the extracellular space to execute its function.

The mitochondrial genome is considerably smaller than the nuclear genome, but it deserves mention here because of the increasing recognition of the role of mitochondrial DNA (mtDNA) mutations in human disease. The mitochondrial genome is only 16.6kb in size, comprising 37 genes, which encode polypeptides that are principally involved in the respiratory chain. mtDNA is double-stranded but does not form a double-helix or chromosomes, but instead takes the form of a circular double-stranded DNA structure with a heavy and a light strand. Unlike the nuclear genome, which is inherited from mother and father, the mitochondrial genome of an individual is entirely maternally inherited.

OTHER REGULATORS OF GENE EXPRESSION

In the last few years it has become apparent that gene expression is 'fine-tuned' by several classes of molecule. Small interfering RNAs (siRNAs) were first discovered in plants and are now widely used as research tools to suppress gene expression. However, natural versions of siRNAs exist (microRNAs- miRNAs) and are thought to be biologically significant regulators of gene expression.⁶ miRNAs are small non-coding RNA molecules that function through base-pairing with mRNA, thus preventing their translation into proteins. There may be more than 1000 miRNAs in the human genome⁷ and some of them are associated with oral cancer; they are also secreted into

body fluids making them candidates for the non-invasive detection of the disease.⁸ In addition, long non-coding RNAs (ncRNAs) have been identified that are thought to regulate various aspects of gene expression, including transcription, splicing, translation, siRNA-directed gene regulation and epigenetic regulation.⁹ Whilst the study of ncRNAs is still new they have been implicated in a number of diseases, including ageing and cancer.

KEY POINTS

- The double-stranded alpha helical structure of DNA, mainly located in the nucleus, consists of nucleotide triplets called codons which code for specific amino acids and stop signals, and forms the substrate for hereditary information in eukaryotes.
- The 22 pairs of autosomes and one pair of sex chromosomes, each with their distinctive shape, size and banding pattern, represent a complex folding of DNA around proteins to give the characteristic shape of a central constriction (centromere) separating the chromosome into a long arm (q) and a short arm (p) with a telomere cap at each end to maintain structural integrity.
- Chromosome locus nomenclature: chromosome number – 3p21 – position on chromosome arm.
- Semiconservative replication of DNA during normal cell division results in the separation of two strands of DNA by DNA helicase, each strand then acting as a template for polymerization by DNA polymerase. High fidelity is vital to prevent permanent change or mutations.
- A gene is a region of chromosomal DNA which produces functional RNA consisting of:
 - regulatory DNA sequences
 - exons, which are coding sequences
 - introns, which are non-coding sequences.
- Transcription is the intra-nuclear process driven by RNA polymerase whereby one of the two DNA strands acts as a template for single-stranded RNA synthesis complementary to the DNA, except that in RNA T is replaced by U. Splicing refers to post-transcriptional processing of RNA.
- Translation is the cytoplasmic process in which mRNA acts as a template for the synthesis of polypeptide by adding successive amino acids to the polypeptide chain, according to the triplet codon of the mRNA that is recognized by the tRNA to which the corresponding amino acid is covalently bonded. This process is regulated and catalyzed by cytoplasmic ribosomes. Post-translational modification produces mature proteins.
- Gene expression can be modulated by naturally-occurring miRNAs and ncRNAs.

METHODS IN MOLECULAR BIOLOGY

Basic techniques of DNA fragmentation and identification

Unlike RNA, DNA is extremely stable, which is understandable from the function that each has in the cell. For purposes of studying the DNA and in order to clone specific DNA, the DNA molecule needs to be divided into manageable fragments. Although the ability to cut (and also to join up) DNA molecules now appears to be a

Figure 1.1 DNA cleavage by restriction endonucleases. Derived from Ref. 10, with permission.

very straightforward process, it was only 1970 when the first restriction endonuclease was identified in a strain of *Haemophilus influenzae*, hence its name *HindII* (pronounced Hin-dee-two). It is believed that this restriction endonuclease acts *in vivo* in bacteria as an immune or host-defence system, recognizing non-self DNA in bacteriophages and cleaving them. By surveying many different bacteria, a wide range of restriction endonucleases is now available, each of which recognizes specific target sites based on sequences of four to eight nucleotides. As a specific, a seven nucleotide sequence (heptanucleotide) will occur less frequently than a four nucleotide sequence (tetranucleotide), statistically, endonucleases recognizing heptanucleotide targets will cut less frequently thereby yielding larger fragments than those recognizing tetranucleotides. As the DNA is double-stranded, the resultant fragments may have blunt ends or cohesive ('sticky') ends (Figure 1.1). The nature of the ends of DNA fragments thus generated impact upon the way in which they can be ligated (joined) into recombinant molecules. Ligation of DNA fragments with cohesive ends is more efficient than joining of blunt-ended fragments.

Electrophoresis

Negatively charged phosphate groups on the DNA backbone confer a net negative charge on linear DNA. This allows fragments of different sizes to be resolved within a suitable gel matrix by the application of an electric current across the matrix. The DNA will migrate towards the positive electrode with the smaller fragments travelling faster than the larger fragments.¹⁰ The size of the fragment can be estimated by the use of a graduated DNA ladder containing fragments of known molecular weight. The choice of the particular matrix depends on the fragment sizes that one is trying to resolve. Polyacrylamide gels can resolve differences of just one base pair between fragments of several hundred base pairs in size by virtue of a small pore size in the gel matrix. These gels can be used for DNA sequencing and resolution of alleles varying in only one dinucleotide repeat. Agarose gels can resolve fragment sizes from around 100 bp to 20 kb. Beyond that size, electrophoretic mobility is no longer proportional to fragment size. Resolution of fragments sizes in excess of 50 kb, such as larger bacterial artificial chromosomes (BAC) or yeast artificial chromosomes (YAC) require the use of pulsed field electrophoresis.

Hybridization

Hybridization is the specific annealing of single DNA (or RNA) strands, the probe, to a DNA sample, the target. It serves to detect the presence of a specific sequence of DNA either in the cell or on a hybridization membrane and recognition that hybridization has occurred is achieved either by radioactively labelling the probe and localizing the radioactivity by autoradiography or by labelling the probe with fluorochromes that fluoresce when excited by light of specific wavelengths (Figure 1.2). Hybridization on a membrane requires the initial transfer of DNA on to a nitrocellulose membrane from an agarose gel. This elegantly simple process is eponymously known as Southern blotting after the scientist who described the process in 1975. Two other commonly used transfer techniques have their names derived from Southern blotting as jargon terms. Northern blotting is essentially the same process used for transfer of RNA to a membrane. Western blotting is one of the mainstays of protein analysis and involves the transfer of electrophoresed protein bands from a polyacrylamide gel on to a nitrocellulose or nylon membrane to which they bind strongly. Detection of the protein is usually achieved by the use of antibodies to specific antigens presented by the protein with the antibody being labelled radioactively, enzymatically or fluorescently.

Cytogenetics and molecular cytogenetics

Although microscopy had already reached high levels of resolution in the early 1930s, the correct number of human chromosomes was not determined until 1958. The era of classical cytogenetics had thus begun. Cytogenetics is the study of chromosomal abnormalities and rearrangements. It currently has a major role to play in pre-natal diagnosis of Down syndrome and other congenital syndromes characterized by numerical chromosomal abnormalities. In the early part of this century, Theodore Boveri proposed that cancer arose from chromosomal alterations. This hypothesis was not proven until the consistent chromosomal translocation, t(9;22), was demonstrated in chronic myeloid leukaemia. Since that time, cytogenetic analysis has been the mainstay of genetic analysis in reticuloendothelial malignancies, being responsible for the identification of

consistent translocations in different leukaemias. Its use in solid tumours has been hampered by the difficulties of establishing short-term primary cultures from head and neck cancers for chromosomal analysis and the erratically acquired chromosomal changes in long-term cell lines, which may have occurred *in vitro*, influenced by culture conditions. Nevertheless, some studies have identified chromosomal areas consistently showing frequent breakpoints suggesting the location of putative tumour suppressor genes (including 3p21, 5p14, 8p11, 17p21, 18q21) and gain or amplification implying the presence of putative protooncogenes at other sites (including 3q, 5p, 8q, 11q13). Although the refinement of karyotyping has been radically enhanced by the introduction of 24-colour combinatorial multicolor FISH (M-FISH), the resolution and therefore utility of solid tumour karyotyping remains limited.¹¹

Hybridization to target DNA in cells, using fluorescence detection, is known as fluorescence *in situ* hybridization (FISH). Fluorescence *in situ* hybridization allows the analysis of copy number of a known specific DNA sequence within intact nuclei. In reticuloendothelial malignancies and solid tumour-derived cell lines, the use of both single-copy probes and centromere alpha-satellite repeat probes on metaphase preparations has enhanced and refined classical karyotyping. Interphase FISH has been applied to solid tumour sections to assess the copy number of a known sequence in breast, prostate, bladder, brain, lung and head and neck tumours.

Fluorescence-labelled hybridization has also been combined with cytogenetics to produce the powerful technique of comparative genomic hybridization (CGH).¹² Comparative genomic hybridization permits the rapid medium resolution screening of the entire genome by comparatively hybridizing matched tumour and normal DNA from a patient, which are labelled with different fluorochromes, on to normal metaphase chromosome preparations. Under red-green dual filter fluorescence microscopy and computer-aided image analysis, areas of genetic 'neutrality' appear yellow, under-representation appears green, and over-representation appears red. Areas of genetic under-representation suggest the possibility of a tumour suppressor gene lying within that region while areas of over-representation may indicate the location of a putative oncogene. This technique has been applied to the rapid genetic analysis of many tumour types including squamous cell carcinomas of the head and neck. The advent of molecular cytogenetics has obviated the need for primary short-term cultures and refined the location of chromosomal aberrations in solid tumours.

Figure 1.2 *In situ* hybridization.

Polymerase chain reaction

Perhaps the single molecular technique that has had the most dramatic impact on molecular biology has been the polymerase chain reaction (PCR). The original problem lay in obtaining sufficient quantities of a particular DNA sequence such that DNA profiling (e.g. sequencing) and DNA manipulation (e.g. cloning) could be achieved. The only 'requirement' is that the sequences flanking the stretch of DNA of interest is known. With that proviso,

PCR achieves faithful and exponential amplification of a specific sequence of DNA by repeated cycles each consisting of dsDNA denaturation, hybridization of specific oligonucleotides (primers) and extension of the polynucleotide by rapidly altering the reaction temperature between segments of each cycle. dsDNA denaturation is achieved by raising the temperature of the reaction to 94°C for 30 seconds, thus disrupting the hydrogen bonds between the strands and exposing the hydrogen bond donor and acceptor groups to allow base pairing. The oligonucleotide primers are then allowed to hybridize to the denatured DNA (annealing) at around 55–65°C for 90 seconds before the reaction temperature is raised to 72°C to permit extension of the DNA strand by DNA polymerase in the presence of deoxynucleoside triphosphates (dNTPs). With each cycle resulting in the doubling of the copies of the DNA sequence, a 30-cycle PCR taking approximately two hours would amplify a single copy of a DNA sequence 268 million-fold (Figure 1.3). Although the PCR was originally described by Mullis and Faloona in 1987, one practical problem prevented its instant exploitation.¹³ The DNA polymerase used in the original reaction was denatured during the DNA denaturation segment and therefore had to be added after each and every cycle. The solution came in 1989 when Lawyer isolated and characterized the DNA polymerase, Taq polymerase, from the thermophilic bacterium *Thermus aquaticus* which normally resided in temperatures above 95°C.¹⁴ This polymerase was therefore ‘heat resistant’ and did not need to be replenished between cycles.

The PCR holds a central position in many molecular biological techniques as well as clinical diagnostic methods. The fundamental principle of DNA amplification has been adapted to amplify messenger RNA and to amplify areas where the initial flanking oligonucleotide sequences are not known. It is often described as a sensitive and powerful technique, but with great power comes the potential for corruption! In theory, a single copy of DNA can be amplified. Therefore, careless experimental technique may lead to contamination of the DNA sample with other DNA (e.g. from the skin of the investigator)

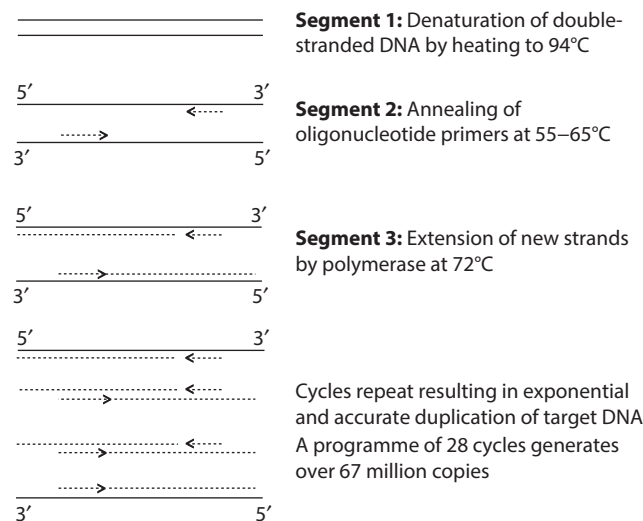

Figure 1.3 The polymerase chain reaction.

and consequently to an artefactual result. The Taq polymerase originally described in the technique does not have proofreading properties, but newer cloned enzymes such as Pfu polymerase incorporates a proofreading function to increase amplification fidelity for sequencing reactions.

The sensitivity of PCR also presented a problem for the analysis of genetic alterations in certain solid tumours. Squamous cell carcinomas of the head and neck are histologically often characterized by a large stromal element within the tumour. The genetic alterations in the tumour may not be present in the stromal tissue and thus total DNA extracted from the tumour will contain DNA from both benign and malignant tissue. This *in situ* contamination can now be eliminated by the use of laser capture microdissection (LCM) of tumours. LCM involves the placement of a laser-activated film over a tissue specimen. When areas of ‘pure’ tumour cells are identified, a focal laser pulse lifts the tissue on to the film in specimens down to 30 µm in diameter.¹⁵

KEY POINTS

- Restriction endonucleases are enzymes that were initially identified in bacteria that can cut and join up DNA. They recognize specific target sites based on sequences of four and eight nucleotides.
- Electrophoresis is a technique for resolving the size of DNA fragments, which carry a negative charge from the phosphate groups on their backbone. Using a gel matrix with an electric current applied across it, the DNA will migrate to the positive electrode at a rate inversely proportional to its size.
- Hybridization is the specific annealing of single DNA or RNA strands (probe) to a DNA sample (target) to detect the presence of a specific sequence of DNA in the cell or hybridization membrane. Variants include the eponomously named Southern, Northern and Western blotting techniques.
- Cytogenetics is the study of chromosomal abnormalities and rearrangements important in the diagnosis of congenital syndromes characterized by numerical chromosomal abnormalities (e.g. Down syndrome and leukaemia types).
- FISH refers to fluorescence *in situ* hybridization which involves hybridization to target DNA cells using fluorescence detection and allows the analysis of copy number of a known specific DNA sequence within intact nuclei.
- PCR achieves faithful and exponential amplification of a specific sequence of DNA by repeated cycles each consisting of:
 - DNA denaturation by heating to 94°C to denature hydrogen bonds between strands
 - annealing (hybridization) of oligonucleotide primers to denatured DNA at 55–65°C
 - extension of DNA strand by DNA polymerase.

MOLECULAR ABERRATIONS OF CELLULAR BIOLOGY

Loss of heterozygosity and the expression of recessive mutant alleles

Retinoblastoma is a childhood cancer, which exhibits both hereditary and sporadic occurrence, with the inherited form transmitted as a highly penetrant autosomal

dominant trait. The proposition by Alfred Knudson in 1971, based upon a statistical analysis of the occurrence of retinoblastoma in children, that two genetic events were required to inactivate the gene mitigating against development of the cancer, was a major landmark in the understanding of tumour suppressor genetics.¹⁶ In hereditary retinoblastomas, a single additional somatic event in a cell that carried the inherited mutation was sufficient to give rise to the disease while two somatic events were required to produce a sporadic retinoblastoma. This became known as Knudson's 'two-hit' hypothesis. The subsequent study on matched tumour and blood DNA from patients with sporadic retinoblastoma by Webster Cavenee not only proved Knudson's hypothesis but also established the paradigm for all subsequent investigations of tumour suppressor genes.¹⁷ For the first time, the now widely accepted mechanisms of tumorigenesis were reconciled, viz. that neoplasms can arise in a multistep manner, that chromosomal events can lead to tumour formation and that chromosome loss with or without reduplication can lead to expression of recessive mutations. Perhaps even more strikingly, the authors presciently suggested that development of homozygosity for recessive mutant alleles at the *Rb-1* locus may give rise to the development of other tumours and that other additional dominant mutations may be involved in the development of retinoblastoma. Cavenee proposed the various chromosomal mechanisms that could

reveal recessive mutations and these are summarized for a putative tumour suppressor gene in **Figure 1.4**, adapted from the figure in his original paper. To these can now be added hypermethylation of the 5' CpG island resulting in transcriptional inactivation of the gene, discussed below.¹⁸ The simplest way of revealing a recessive mutant allele is by deletion of the wild-type allele, resulting in hemizyosity at the particular locus on the remaining chromosome. It is inferred from this that areas of frequent allelic loss in tumours may represent the location of putative tumour suppressor genes and this hypothesis underpins the commonly employed method of molecular detection of allelic losses, loss of heterozygosity (LOH).

The practical exploitation of the concepts outlined above hinges on the presence of the previously described microsatellites, highly polymorphic non-coding DNA sequences, also referred to as simple sequence length polymorphisms (SSLP) or short tandem repeat polymorphisms (STRP), which are distributed approximately every 100 000 bp throughout the human genome. These microsatellites contain small dinucleotide or trinucleotide repeat units, the number of which may differ between the two alleles in a particular person. Microsatellite markers are now available which map thousands of these sequences to chromosomal loci. When DNA sequences containing these microsatellite markers are amplified by PCR in a person heterozygous for that

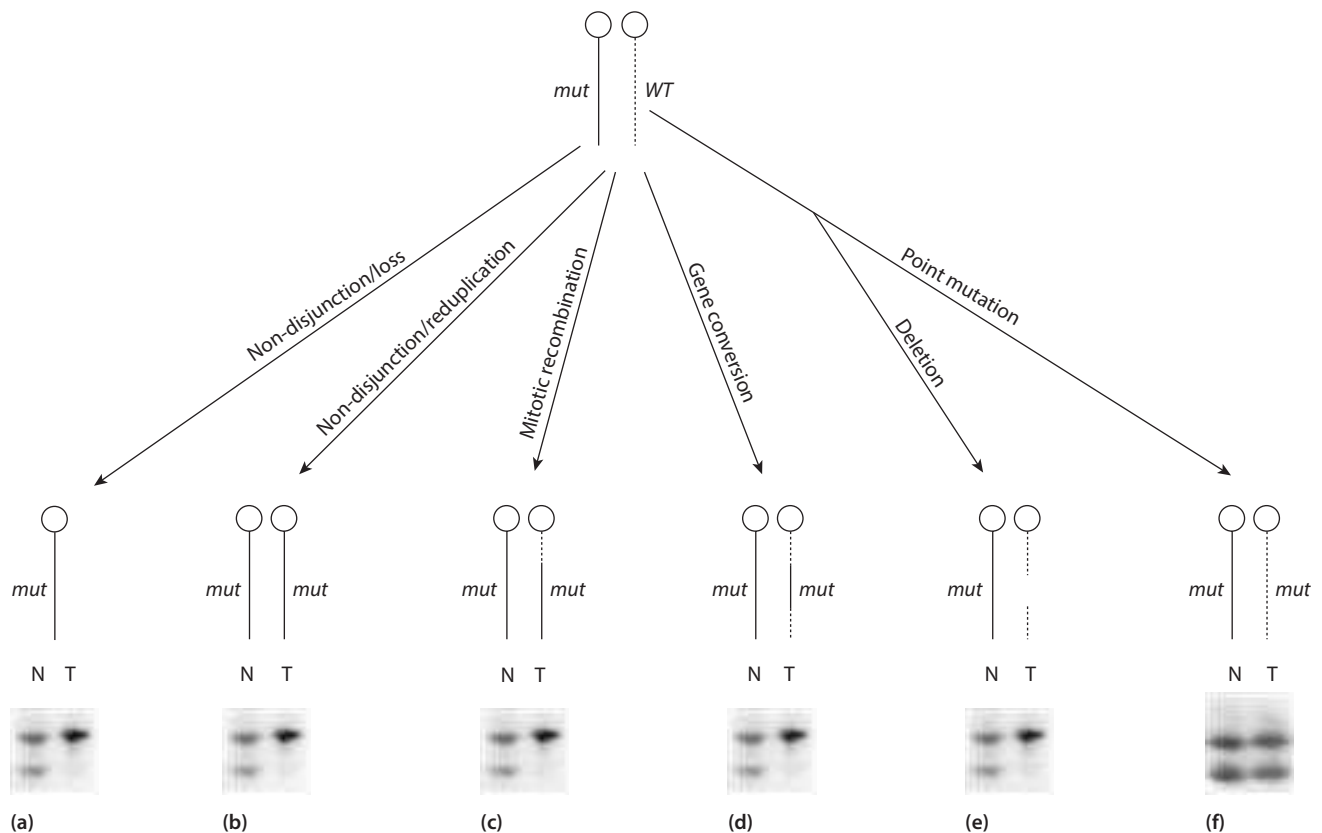

Figure 1.4 Chromosomal mechanisms that could reveal recessive mutations. In this example, before cell division, the tissue concerned carries a mutation in one copy of the hypothetical tumour suppressor gene. In each of the scenarios (a–f), the recessive mutation is revealed. If the individual is heterozygous for a microsatellite marker within or very close to the mutated gene, the hypothetical PCR results are given below each ideotype. The only mechanism that escapes observed loss of heterozygosity is F. *mut*, mutated; N, normal; T, tumour; WT, wildtype. After Ref. 17, with permission.

particular microsatellite, the PCR will yield two products of different lengths, which can be resolved on an electrophoretic gel. Where amplification of tumour DNA from such a subject yields only one product, the tumour is said to show LOH, implying allelic loss. Persons who are homozygous for a particular marker are said to be non-informative for that marker. The concept of examining the variation and extent of allelic deletion in tumours was introduced by Vogelstein in an analysis of colorectal carcinomas and termed allelotyping.¹⁹ Allelotypes generated in this fashion have identified several areas of frequent allelic deletion from which some of the responsible tumour suppressor genes have been cloned or identified. The most common areas of loss in HNSCC are at chromosome 9p21, 17p13, 13q14, 4p, 5q21 and several discrete regions on 3p and 8p.^{20, 21}

Inactivation of genes and oncogenic transformation

Allelic deletion is only one mechanism by which a copy of a gene can be inactivated. As there are two copies of each gene, inactivation of the gene requires inactivation of both copies of the gene, 'the second hit'. This may occur as a result of a genetic mutation or transcriptional silencing. Conversely, a protooncogene may be converted into an oncogene by a simple increase in the copy number of the gene (gene amplification) resulting in an overproduction of protein or by point mutations that affect the control of protein activity.

Not all mutations result in alteration in function of a gene. DNA mutation may occur as a result of base substitutions, as well as nucleotide insertions and deletions. Insertions and deletions of nucleotides are very rare in coding DNA, but if they occur they may produce a shift in the 'reading frame' that dramatically alters the coding downstream from the mutation. Base substitution is a more common form of mutation in coding DNA, which may have a range of consequences on the function of the gene; a loss of function (e.g. *p53*, *Rb*), a gain in function, often due to stabilization of the active protein (e.g. *c-erbB2*, *K-ras*) or no net functional effect. Since an amino acid may be encoded by different codons with a 'third base wobble' (e.g. GUA, GAC, GUG and GUU all encode valine), a substitution of the third base would result in no change to the amino acid. This is known as a silent substitution. At the other extreme is the nonsense mutation, whereby base substitution results in a stop codon which leads to truncation of the polypeptide and a dramatic reduction in function.

Loss of function in the presence of a normal (wildtype) allele may occur as a result of transcription silencing. The methylation status of CpG islands surrounding the promoter regions of genes determines whether a particular gene is expressed within a cell such that methylation of a CpG island 'switches off' the gene that it is regulating. CpG islands regulating housekeeping genes (i.e. genes encoding proteins essential for cell survival) are unmethylated in all cell types whereas those regulating cell-specific

genes (e.g. muscle-specific actin gene in muscle cells), are only unmethylated in the relevant cell. Many tumour suppressor genes (e.g. *CDKN2A* (p16^{INK4A}), *APC*, *RASSF1A*) are now recognized to be inactivated by hypermethylation of the promoter region in malignant tumours.

Gene sequencing

Recently a variety of next generation sequencing methods have been applied to the field. One method is to construct a library of DNA fragments and to use biotinylated RNA baits to capture the exomic sequences using streptavidin coated magnetic beads prior to loading them onto the sequencing machine following digestion of the RNA bait and a few cycles of PCR. This strategy was able to obtain 10 or more sequencing reads for over 90% of the targeted bases and this approach and similar strategies have revealed the mutational landscape of head and neck squamous cell carcinoma, including the frequent mutation of the *NOTCH1* gene, which had not been identified previously.²²⁻²⁴

Proteomics and metabolomics

As the Human Genome Mapping Project powers its way towards a high-resolution sequence of the entire genome, the natural progression of research has been towards the elucidation of the repertoire of proteins that control cell signalling and cell growth. Proteomics is the profiling of proteins in cells and serum by two-dimensional gel analysis separating proteins by charge and mass, by X-ray crystallography and by mass spectrometry.²⁵ Proteomics has the ability to identify post-translational modifications, some of which are cancer cell-specific, which would not be detected by genetic or expression profiling. The power of this approach is particularly evident in cancer studies as it has the ability to compare the entire protein pattern of tumour tissue and normal tissue in a manner analogous to comparative genomic hybridization.

However, the functional consequences of changes to the proteome, especially some enzymes, can only be inferred and a more direct approach is to measure the levels of small molecules, or metabolites. Metabolomics is the global analysis of metabolites but is a relatively new discipline and no single technique is suitable for the analysis of all different types of molecule. Therefore, a mixture of techniques such as gas chromatography, high-pressure liquid chromatography and capillary electrophoresis are used to separate metabolites and the molecules are then identified using methods such as mass spectrometry. Metabolomics has already been applied to the detection of oral cancer in saliva²⁶ and serum.²⁷

Telomerase

Aberration of telomere biology has a now well-recognized role to play in cancer development. The length of the telomere is maintained in germline cells by the enzyme telomerase that is absent in normal somatic cells.²⁸ This observation led to the theory that progressive shortening

of telomeres with each cell division leads to cell senescence and ageing of the organism. Several mechanisms for this have been proposed. A critical shortening of the telomere may leave a non-telomere-free DNA end that signals cell cycle arrest. Telomere loss could also extend to the deletion or inactivation of genes located subtelomericly, again leading to cell cycle arrest. Two important consequences of critical telomere shortening in cells that survive the cell crisis are genomic rearrangements and chromosomal loss, which may in turn lead to malignant transformation. This is particularly relevant to rapidly dividing and regenerating tissues, such as skin and mucosa. Paradoxically, while some of these survivors will subsequently go into cell cycle arrest due to critical telomere length shortening, a proportion will then express telomerase activity. Such activity is capable of cell immortalization by maintaining telomere length indefinitely and its role in cancer is now unquestionable. Telomerase activity has been demonstrated in 80% of oral cancers and around 50% of oral leukoplakia lesions.²⁹ Even among premalignant lesions, telomerase activity was associated with degree of dysplasia, suggesting that telomerase activation occurs during the late stage of oral premalignancy. The potential for anti-telomerase drugs as a novel treatment remains promising, especially as they are now thought to target cancer stem cells.³⁰

KEY POINTS

- Practical techniques based on loss of heterozygosity of tumour DNA are based on Knudson's two-hit hypothesis, which states that two genetic events are required to inactivate the gene that prevents the development of a condition.
- The number of microsatellite repeats (i.e. non-coding base pairs dispersed throughout the genome) may differ between two alleles in the same person making that person heterozygous for that particular allele. If tumour DNA from such a subject when amplified by PCR yields only one product, the tumour is said to show loss of heterozygosity implying allelic loss.
- Inactivation of genes can occur by:
 - allelic deletion
 - genetic mutation
 - transcriptional silencing
 - conversion of protooncogene to oncogene due to gene amplification.
- Some mutations do not result in change of function. They can be silent or nonsense mutations.
- Next generation sequencing has produced a mutational landscape of head and neck cancer.
- Proteomics refers to the profiling of proteins in cells and serum by 2D gel analysis, X-ray crystallography and by examination of protein interactions. This can be used to identify post-translational modifications, some of which are cancer cell specific and are not detected by genetic profiling.
- Metabolomics can be used to detect small molecules accumulating in the tissues and body fluids of oral cancer patients.
- Critical telomere shortening or inefficient telomere DNA repair can lead to both cell cycle arrest and cell immortalization due to expression of telomerase, which, for example, has been demonstrated in 80% of oral cancers.

MAPPING AND IDENTIFICATION OF GENES ASSOCIATED WITH DISEASE

The traditional approach to understanding the molecular biology of disease was to look for and characterize the abnormal protein. Diabetes mellitus and sickle cell anaemia are two conditions that were elucidated at the molecular level in this way. Finding the protein when present in minute quantities, in an inaccessible site such as the inner ear, or when nothing is known of its mode of action, is, however, virtually impossible. This is the case with most of the genes involved in cellular growth control and also in inner ear function. Our approach to understanding such conditions relies on determining the chromosomal location, isolating and sequencing the gene so that the structure of the protein can be determined. This is known as the reverse genetic or positional cloning technique.

Strategies employed in determining the sites of these disease genes include cytogenetic analysis, molecular genetic analysis (typically LOH studies) and linkage analysis. Where a clearcut inheritance of a disease can be demonstrated, then linkage analysis can be useful in determining the location of the responsible gene. The key advance that has made this approach increasingly successful has been the construction of a high-resolution linkage map of the entire human genome. This map consists of genetic markers spaced less than 1 centimorgan apart and the process of linkage involves determining which of these the disease gene is close to. Analysis of the coinheritance of the genetic marker and the disease trait in families allows one to determine the probability of their physical proximity or linkage to each other. The statistical probability of linkage is expressed in terms of LOD scores. LOD is short for logarithm to the base 10 of the odds that the markers are linked at a recombination distance of N centimorgans. An LOD score of 3.0 favours linkage while a score of -2.0 effectively rules out linkage.

Successful linkage analysis typically requires large pedigrees with many individuals known to have the disease trait and likewise many confirmed to be free of the disease. The process involves initial family analysis with clinical evaluation and accurate diagnosis. DNA samples are then obtained from each individual and genotyping and linkage analysis can then be carried out. Linkage and molecular deletion analysis generate genetic markers either side of the disease gene location. These genetic markers can be used to identify 'chunks of genomic DNA' cloned into yeast (yeast artificial chromosomes (YAC)) or bacteria (bacterial artificial chromosomes/P1 artificial chromosomes (BAC/PAC)) and organized into libraries. By a number of methods, these 'chunks' of genomic DNA can be directionally organized to produce a physical map of the region of interest from which candidate disease genes can be identified. The Human Genome Mapping Project has, to a great extent, physically mapped the human genome such that in some cases, when the region of interest is sufficiently small, all genes known to be between the markers can be considered positional candidates. The candidates are then analysed in disease

families until one is found that demonstrates mutations in affected individuals.

To facilitate the identification of the disease gene from a number of candidates within a particular region, several strategies are available. One such approach exploits our knowledge of animal models of the diseases that parallel

human inherited disorders. Another potential source of candidate genes is to identify and characterize genes that are expressed within a particular tissue. Genes expressed within the cochlea, for example, represent the genes critical for cochlear function and thus are excellent candidate genes for hereditary hearing loss.

FUTURE RESEARCH

Although giant strides have already been made in the delineation of molecular events underlying disease processes, the knowledge of these events is far from comprehensive. A clearly identifiable adenoma–carcinoma sequence facilitated the correlation between genetic and histopathological progression models in colorectal cancer.¹⁹ Several similar progression models have been proposed in head and neck squamous cell carcinoma evolution from epithelial dysplasia through to frank carcinoma, but the heterogeneity of carcinomas in different subsites precludes a molecular genetic progression model of equal rigour to that in colorectal cancer. Nevertheless, *p16* and *p53* inactivation have been identified as the two most frequent and critical events in head and neck carcinogenesis. An understanding of the sequence of genetic aberrations that occur in pathogenesis of tumours can assist in the prediction of progression from premalignant conditions to frank malignancy. An example of this is seen in the accumulation of genetic abnormalities in oral epithelium leading to the progression of oral dysplasia to oral squamous cell carcinoma. By analysing for loss of heterozygosity at 19 microsatellite loci in a series of oral dysplastic lesions and oral malignancies, Rosin et al.³¹ showed that LOH at 3p and/or 9p occurred in virtually all cases of oral dysplasia which progressed to frank malignancy implying a ‘gatekeeper’ role of genes at those loci in the development of oral cancer, in themselves imparting a 3.8-fold increased relative risk of progression to squamous carcinoma. Furthermore, additional LOH at 4q, 8p, 11q or 17p imparted a 33-fold increased relative risk for developing cancer.³¹ In certain cases, molecular genetic profiling has added a new dimension to age-old debates. For example, discordant genetic anomalies in inverted sinonasal papillomas and sinonasal carcinomas lend weight to the opinion that the former does not undergo malignant degeneration into the latter.³²

Traditional methods of allelotyping and mutational analysis remain extremely time-consuming and labour-intensive. Recent years have seen the development of gene arrays (or ‘gene chips’) that allow the rapid assessment of the genetic profile of tumours or cell lines.³³ cDNA of up to 30 000 genes can be placed in arrays on glass slides on to which DNA and RNA samples can be allowed to hybridize using an automated two-colour fluorescence method for detection.³⁴ Hybridization with DNA can yield extensive genomic information, while hybridization with RNA takes genetic profiling a step further by semiquantitatively analysing the expression of genes rather than simply the presence or absence of the DNA. As the genetic aberrations and pathways associated with specific tumour development become better dissected, ‘designer’ chips can be produced that allow for screening for known mutations of those involved genes.³⁵ Array technology has also been married with molecular cytogenetics to produce array-based comparative genomic hybridization, which obviates the need for metaphase chromosome spreads for CGH.

The clinician might be forgiven for an expression of cynicism regarding the ‘molecular revolution’, feeling that little has changed despite ambitious predictions. The translation of molecular biology research into clinical practice – ‘from

laboratory to bedside’ – is without doubt the greatest challenge facing the clinician scientist. Progress so far has been largely at the level of disease classification, premorbid diagnosis and patient counselling. However, several discrete arms to translational research have hinted at the future role of genetic analysis determining the likely effectiveness of existing anti-cancer treatments. There are also isolated examples of effective novel therapeutic interventions.

Molecular analysis played a vital role in differentiating neurofibromatosis type I from neurofibromatosis type II, and it now seems difficult to understand how we ever confused the two in the first place. Such clarity of diagnosis is also anticipated for many syndromic and non-syndromic causes of sensorineural hearing loss as the genes are characterized and the clinical features analysed in more detail. This may enable clinicians to determine in which cases hearing loss will be progressive and target monitoring more appropriately. Diagnostic genetic testing will also become increasingly available to families with hereditary hearing loss and clinicians will need to be conversant with the ethical issues of testing and the implications of the results. By characterizing hearing loss at the molecular level we are also developing a greater understanding of inner ear physiology as the critical proteins involved in hearing become elucidated. This may lead to the development of agents able to repair and regenerate the diseased inner ear. The administration of these agents is already being evaluated using miniature infusion pumps.

It is hoped that in the future molecular characterization of tumour tissue will provide for a more accurate diagnosis and prognosis than conventional histopathological analysis. This may lead to a more rational treatment plan based on molecular features. Some genotype–phenotype correlations have already been made, particularly with respect to radio- and chemoresistance in tumours, but confirmation is needed with larger sample sizes as to their applicability into clinical practice. Refinement of the staging of tumours by probing of resection margins and the detection of histological subclinical metastatic disease in regional lymph nodes have been elegantly demonstrated by Brennan et al.³⁶ at Johns Hopkins. However, the technical complexity of the methodology has precluded its widespread application in the clinical arena. The development of technically simpler but equally sensitive techniques will inevitably render molecular staging routine in oncological practice. Although surveillance for tumour recurrence is less of a problem in the upper aerodigestive tract when compared with intra-abdominal malignancies, the emergence of molecular markers in saliva and serum will have a role in follow-up protocols for head and neck cancers.³⁷

A comprehensive understanding of the molecular mechanisms underlying disease processes gives the potential of therapeutic restoration of DNA or protein function, as well as exploitation of the genetic abnormality for targeting of therapy. An example of the latter is the use of ONYX-015. ONYX-015 is an E1B 55-kDa gene-deleted adenovirus engineered to selectively replicate in and lyse *p53*-deficient cells while sparing normal cells. This tumour-targeting property has led

to a successful phase II trial of concomitant ONYX-015 and cisplatin/5-FU in the treatment of recurrent HNSCC, which indicated substantial objective responses as well as a high proportion of complete responses.³⁸ Post-treatment biopsies of tumour masses confirmed the replication selectivity of the virus *in vivo*.

A consideration of some of the landmarks in molecular biology (e.g. enzymatic DNA cleavage (1970) and PCR (1987)) readily indicates that molecular biology is a relatively young science. However, the rapid development of molecular techniques of such power and diversity as comparative genomic hybridization and gene array technology has permitted the dissection of molecular pathways and the identification of their disruption in disease processes. Some of these processes in specific diseases will be discussed in subsequent chapters. The future in the laboratory lies in the extension of our understanding of these molecular processes and the future in the clinic lies in the exploitation of

these molecular techniques in better informing disease classification, staging and treatment:

- ▶ Development of a molecular genetic progression model for head and neck squamous cell carcinoma of similar rigour to that for colorectal carcinoma.
- ▶ Development of gene arrays or gene chips that allow the rapid assessment of the genetic profile of tumours and can allow semiquantitative analysis of gene expression.
- ▶ Designer chips may be produced that allow for screening for unknown mutations of involved genes.
- ▶ Potential role for genetic analysis in determining the likely effectiveness of existing anti-cancer treatments.
- ▶ Providing more accurate diagnosis and prognosis than conventional histopathological techniques.
- ▶ Potential therapeutic restoration of DNA or protein function, as well as exploitation of a genetic abnormality for targeting therapy (e.g. use of ONYX-015).

KEY POINTS

- Strategies employed in determining the sites of disease genes that code for the abnormal proteins include cytogenetic, molecular genetic and linkage analysis.
- Whilst genomics and other omics has generated a large body of data, cancers are complicated tissues. Future research may shift towards understanding the cancer environment and how perhaps to target this in future therapeutic strategies.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using a variety of relevant generic keywords, including: DNA, genetics, hereditary hearing loss, connexin 26, neurofibromatosis 2 and familial paragangliomas.

INTRODUCTION

Advances in molecular genetics have helped to identify causative genes and proteins responsible for pathologies; this knowledge is pertinent to molecular target therapy and promises novel therapeutic interventions.

This chapter aims to review the mechanisms and principles of molecular genetics of hearing impairment, vestibular schwannoma, and glomus tumours, and will keep the reader abreast of new developments that may be relevant to identifying and treating these diseases in clinical practice.

MOLECULAR GENETICS OF HEARING LOSS

Hearing loss is the most frequent sensory impairment in humans, with significant social and psychological implications. Permanent childhood hearing impairment of a moderate or greater degree (i.e. detection thresholds 40 decibels hearing level averaged across 0.5, 1, 2 and 4 kHz) is present at birth in about 1.6 per 1000 live births, of which approximately 1.0 in 1000 are bilateral impairments and 0.6 in 1000 are unilateral impairments.^{1,2} However, studies have shown that the prevalence of permanent childhood hearing impairment continues to increase through infancy, and by the school entry hearing screen (4–5 years of age) possibly affects 3.5 per 1000 children.² It is estimated that at least

two thirds of cases of childhood-onset hearing loss have a genetic cause, with the remaining third caused by environmental factors (e.g. cytomegalovirus infection, meningitis, acquired conductive loss, and the impact of extracorporeal membrane oxygenation (ECMO)).³ Improved clinical knowledge, awareness, and advances in antibiotics and vaccines has led to a decline in hearing loss resulting from environmental factors. Likewise, significant progress in the genetics of hereditary hearing impairment (HHI) has improved our understanding of the causes and early detection of HHI.

Classification

The most useful distinction in hereditary hearing impairment (HHI) is syndromic versus non-syndromic. When SNHL occurs in isolation it is termed non-syndromic and when it is accompanied by other systemic disturbances it is termed syndromic. The majority of hearing impairments are non-syndromic (~70%), whereas a minority are syndromic (~30%).

Non-syndromic HHI is further classified by mode of inheritance:

- Autosomal recessive ~80%
- Autosomal dominant ~18%.⁴

Rare modes of transmission include X-linked and mitochondrial transmission, which account for the remaining 2% of hearing impairment.

MOLECULAR GENETICS OF NON-SYNDROMIC HEARING IMPAIRMENT (NSHI)

Thus far, more than 100 forms of non-syndromic hearing impairment (NSHI) have been discovered (see the Hereditary Hearing Loss website at <http://hereditary-hearingloss.org>). Most of these are still identified as loci: only the chromosomal location of the defective gene is known.

The different gene loci for non-syndromic deafness are designated DFN (for DeaFNess). Loci are named based on mode of inheritance:

- DFNA: Autosomal dominant
- DFNB: Autosomal recessive
- DFNX: X-linked.

The number following the above designations reflects the order of gene mapping and/or discovery and this information is regularly updated on the Hereditary Hearing Loss website.

Genes for NSHI have been categorized by the function of the proteins each gene encodes. Several superfamilies are represented, including gap junctions, myosins, adhesion proteins and ion channels.

Unlike in some conditions where a common mutation in just one gene is responsible for the majority of cases (e.g. the deltaF508 deletion of three nucleotides in the *CFTR* gene in cystic fibrosis), hearing loss is genetically very heterogeneous involving mutations in many genes.⁵ It is therefore not possible to predict the risk of developing hearing loss from assessing a single or even a selection of the genes that have currently been identified.⁶

The most frequent causative genes are discussed below.

Gap junction proteins

Thus far, three connexin genes have been implicated in NSHI: *CX26*, *CX30*, and *CX31*, corresponding to the proteins connexin 26, connexin 30, and connexin 31, which are designated by their molecular mass.

GJB2 (*connexin 26*) is by far the foremost prominent hearing impairment gene. The discovery that *GJB2*, located at the DFNB1 locus, is a causative gene for hearing impairment⁷ led to the unexpected revelation that more than half of the recessive NSHL and approximately 30% to 50% of innate hearing loss are due to *GJB2* mutations.^{7,8} Among the 300 mutations documented worldwide up to now (see The Human Gene Mutation Database at www.hgmd.org), one particular mutation, 35delG, is responsible for 70% of all the *GJB2* mutations.⁹ This finding made an enormous impact in the hearing loss field, as it facilitated diagnostic and genetic screening of NSHL patients. Another mutation imperative to note is 167delT, which is most frequent among Ashkenazi Jews and is also present in Palestinians.¹⁰

The connexion-deafness homepage (<http://davinci.org.es/deafness/>) provides a database of all published mutations as well as common polymorphisms in *GJB2* and other connexin genes. More than 100 unique non-syndromic *GJB2* gene variants have already been described. The reported mutations mostly include mutation types that can be detected by sequencing analysis, such as nonsense, missense, splicing and frameshift mutations.

Myosins

Numerous types of unconventional myosins have been identified as NSHI causing genes: *MYO1A*, *MYO3A*, *MYO6*, *MYO7A* and *MYO15A* (encoding myosin I, myosin IIIA, myosin VI, myosin VIIA and myosin XVA proteins, respectively). The term ‘unconventional’ myosins refers to all non-muscle myosin subclasses (in contrast with the ‘conventional’ myosins that include only the myosin II subclass). Expression of these unconventional myosins is not limited to the cells and tissues of the inner ear, yet the expression of their dysfunction is largely restricted to hearing impairment.

The myosin VI protein was first implicated in the hearing mechanism when it was found to be mutated in the spontaneously deaf mouse Snell’s *waltzer* (*sv*).¹¹ The role of myosin VI in human deafness remains to be determined.

Myosin VII has been linked to both rodent and human deafness. Mutations in the *MYO7A* human homologue were identified as the genetic cause for Usher syndrome type 1B¹² and Usher syndrome type 2A.¹³ Contiguous to this discovery, human *MYO7A* was also linked to NSHL in two distinctive loci: DFNB2¹⁴ and DFNA11.¹⁵

Myosin XV is the largest of all the myosin heavy chains and mutations in myosin XV have been pathogenically linked to DFNB3 in humans and shaker 2 phenotype in mice. Myosin XV is a critical factor in the evolvment of the hair bundle and in the staircase formation of the bundle¹⁶ and it binds another deafness molecule, whirling at the tip link zone, suggesting that the two molecules might control stereocilia elongation patterning during development and may be implicated in stabilizing connections between stereocilia.¹⁷

Pendrin

Mutations in the pendrin gene *SLC26A4* are the second most frequent cause of autosomal recessive NSHI, accounting for up to 3.5% of cases.¹⁸ *SLC26A4*, which codes for an anion transport protein, also underlies Pendred syndrome, which is one of the most common forms of syndromic hearing impairment.

Adhesion proteins

Adhesion proteins include a diverse group of distinct protein families including integrins, selectins, members of the immunoglobulin superclass family and cadherins.

Cadherin 23 is a vital member of a specific unit designated for maintaining stereocilia inter-cohesion.¹⁸

More than 20 mutations in the *CDH23* gene have been identified in people with non-syndromic hearing impairment and more than 30 mutations have been shown to cause the Usher syndrome type 1D. The *USH1D* locus was found to coincide with the recessive NSHI locus *DFNB12*, which is associated with prelingual moderate to profound hearing loss. These data suggested that *DFNB12* and *USH1D* in fact are mutually derived from *CDH23* allelic mutations, both resulting in syndromic and non-syndromic forms of hearing loss.^{19, 20}

Autosomal dominant non-syndromic hearing impairment

Unlike autosomal recessive non-syndromic hearing loss, in autosomal dominant non-syndromic hearing loss there is not a single identifiable gene responsible for the majority of cases. The clinical manifestations and molecular genetics of known genes causing autosomal

dominant non-syndromic hearing impairment are outlined in [Table 2.1](#).

Autosomal recessive non-syndromic hearing impairment

Fifty per cent of people with autosomal recessive non-syndromic hearing impairment have mutations in *GJB2*.⁸ The other 50% of cases are attributed to mutations in numerous other genes. The clinical manifestations and molecular genetics of known genes causing autosomal recessive non-syndromic hearing impairment are outlined in [Table 2.2](#).

X-linked non-syndromic hearing impairment

DFNX3 is characterized by a mixed conductive-sensorineural hearing loss, the conductive component of

which is caused by stapedial fixation. In contrast to other types of conductive hearing loss, surgical correction is precluded because an abnormal communication between the cerebrospinal fluid and perilymph results in leakage ('perilymphatic gusher') and complete loss of hearing when the oval window is fenestrated or removed.

Clinical manifestations and molecular genetics of known genes causing X-linked non-syndromic hearing impairment are summarized in [Table 2.3](#).

Mitochondrial non-syndromic hearing impairment

The genes and mutations associated with mitochondrial non-syndromic hearing impairment are outlined in [Table 2.4](#).

Molecular genetics of syndromic hearing impairment (SHI)

Hearing impairment is denoted as an integral clinical phenotype in more than 400 genetic syndromes.²¹ Syndromic forms of hearing impairment are estimated to be responsible for up to 30% of prelingual deafness, but its contribution to deafness is relatively small reflecting the occurrence and diagnosis of postlingual deafness.

Syndromic hearing loss is discussed further by modes of inheritance.

Autosomal dominant syndromic hearing impairment

WAARDENBURG SYNDROME (WS)

WS is mostly a genetic autosomal dominant disorder, considered to be the most frequent autosomal dominant form of syndromic hearing loss, constituting approximately 2% of all congenital hearing impairment.²²

The primary phenotypes observed in this syndrome may include variable degrees of sensorineural hearing loss, pigmentation abnormalities (skin, hair, eyes), dystopia canthorum (wide distance between the inner corners of the eyes). Gastrointestinal symptoms like constipation and Hirschsprung disease, neural tube and limb defects may also be observed. Four different types of WS (I to IV) have been described, grouped by distinct physical characteristics. WS I characteristically has the presence and WS II the absence of dystopia canthorum. In WS III there are

typically limb abnormalities and in WS IV Hirschsprung disease is present.

All of WS1 and some of WS3 cases are associated with mutations in the *PAX3* gene. WS2 is caused by mutations in the transcription factors *MITF* and *SNAI2*. WS4 is due to alterations in *EDNRB*, *EDN3* or *SOX10* genes.²³

BRANCHIOOTORENAL SYNDROME

Branchiootorenal (BOR) syndrome is the second most prevalent autosomal dominant syndromic type of hearing loss.²⁴ The major features of this syndrome are hearing loss (conductive, mixed or sensorineural) in association with branchial cleft cysts or fistulae, deformities of the external, middle or internal ear, and renal malformations.

In approximately 40% of families segregating a BOR phenotype, mutations in *EYA1* can be identified; in a few other families mutations have been found in *SIX1*²⁵ and *SIX5*.²⁶

STICKLER SYNDROME

Stickler syndrome comprises of progressive sensorineural hearing loss, cleft palate, abnormal development of the epiphysis, vertebral abnormalities and osteoarthritis. Three types are recognized, based on the molecular genetic defect: STL1 (*COL2A1*), STL2 (*COL11A1*) and STL3 (*COL11A2*). STL1 and STL2 are characterized by severe myopia, which predisposes to retinal detachment; this aspect of the phenotype is absent in STL3 because *COL11A2* is not expressed in the eye.

NEUROFIBROMATOSIS 2

The hallmark of neurofibromatosis 2 (NF2) is hearing loss caused by bilateral vestibular schwannomas. Approximately 50% of affected patients have no family history of NF2; therefore these patients represent new germ line mutations in the NF2 gene. This is discussed further in the section on NF2 in this chapter.

Autosomal recessive syndromic hearing impairment

USHER SYNDROME

Usher syndrome (USH) is the most frequent autosomal recessive syndromic form of hearing loss. More than 50% of the deaf-blind community in the USA have USH. According to the genotype and phenotype differences, USH has several subtypes:

- Type I: congenital severe-to-profound sensorineural hearing loss, vestibular dysfunction and onset of retinitis pigmentosa in the first decade of life
- Type II: mild-to-severe sensorineural hearing loss, normal vestibular function and onset of retinitis pigmentosa in the first or second decade of life
- Type III: progressive hearing loss, progressive vestibular dysfunction and onset of retinitis pigmentosa is variable.

To date 15 different loci and 12 genes have been reported (<http://hereditaryhearingloss.org>). One of these identified genes, *MYO7A*, encoding myosin 7A, is a unique molecular motor for hair cells.²⁷ Cadherin 23, an adhesion molecule, coded by *CDH23* gene may have an important role in cross linking of stereocilia.²⁸

PENDRED SYNDROME

This is the second most common type of autosomal recessive syndromic hearing loss. It is usually characterized by severe congenital sensorineural hearing loss and euthyroid goitre that develops in puberty or adulthood. The deafness is also commonly associated with an abnormality of the labyrinth which may be anatomical (Mondini dysplasia or dilated vestibular aqueduct) and/or functional. Almost 50% of the families have *SLC26A4* (PDS) gene mutation on chromosome 7q21-q34. The gene is responsible for sulfate transport. Its protein product, pendrin, is involved in the transport of iodine and chloride ions. *SLC26A4* gene mutation should be investigated in the patients who have progressive hearing loss, Mondini dysplasia or large vestibular aqueduct syndrome. The same mutation can also cause DFNB4.²⁹

JERVELL AND LANGE-NIELSEN SYNDROME

This is characterized by a congenital hearing loss and an elongation of the QT interval on electrocardiography. Affected individuals have episodic syncope and may have sudden death. The JLNS1 locus in the *KVLQT1*

gene located on chromosome 11p15.5, or the JLNS2 locus in the *KCNE1* (IsK) gene located on chromosome 21q22.1-q22.2 are responsible for the syndrome. These are potassium channel genes.³⁰

BIOTINIDASE DEFICIENCY

This condition results from a deficiency of an enzyme required for the normal cycling of the water-soluble vitamin biotin. Clinically it is characterized by a variable sensorineural hearing loss (in 75% of children), with associated neurological, ophthalmological and dermatological abnormalities. Biotinidase deficiency can be prevented with supplementation of biotin.

REFSUM DISEASE

Refsum disease is characterized by severe progressive sensorineural hearing loss and retinitis pigmentosa caused by faulty phytanic acid metabolism.

X-LINKED SYNDROMIC HEARING IMPAIRMENT: ALPORT SYNDROME

Progressive sensorineural hearing loss, renal disorder (glomerulonephritis, haematuria, renal failure) and eye problems (lenticular and macular abnormalities) are observed. Almost 50% develop progressive bilateral hearing loss, which usually begins in the second decade.³⁰ This syndrome is X-linked in 85%, autosomal recessive in 15% and autosomal dominant in the remainders. In the X-linked form, males are more severely affected than females. The *COL4A5* gene on Xq22 and the *COL4A3* and *COL4A4* genes on chromosome 2q36-q37 are responsible for the syndrome.³⁰

Implication of discovery of genes associated with hearing loss

Why has the genetics of hearing loss become such a focus for researchers?

First, from a biological perspective, the amount of information gained about the auditory and vestibular systems has been dramatic. Second, from a diagnostic aspect, clinicians are now able to discern the aetiology of hearing loss of a large number of patients by relatively simple genetic testing. Third, from a genetic counselling aspect, genetic counsellors are able to predict with much greater certainty what the chances are of another child being born with deafness in the family. Fourth, from a therapeutic aspect, the discovery of genes may provide solutions for treatment and therapy for alleviating hearing loss.²²

Genetics of aminoglycoside toxicity

Aminoglycoside-induced ototoxicity is a potentially preventable form of acquired hearing loss. The mitochondrial 12S rRNA is a hot spot for mutations associated with both aminoglycoside-induced and non-syndromic hearing loss. Of those, the homoplasmic 1555A>G and 1494C>T

mutations at the highly conserved decoding region of the 12S rRNA have been associated with hearing loss worldwide.³¹ In particular, these two mutations account for a significant number of cases of aminoglycoside ototoxicity. The 1555A>G or 1494C>T mutation is expected to form a novel 1494C–G1555 or 1494U–A1555 base-pair at the highly conserved A-site of 12S rRNA. These transitions make the human mitochondrial ribosomes more bacteria-like and alter binding sites for aminoglycosides. As a result, the exposure to aminoglycosides can induce or worsen hearing loss in individuals carrying one of these mutations.³¹

One of these mutations, 1555A>G, has also been reported in hearing-impaired patients with no history of exposure to aminoglycoside antibiotics, suggesting that in some carriers of this mutation aminoglycoside exposure is sufficient, but not necessary, for hearing loss to occur, and additional environmental and/or genetic risk factors likely exist.^{32–34} One way to assess individual risk is by careful evaluation of family history. The other is DNA-based mutation detection technologies, which offer a far more precise method for identification of at-risk individuals, but the appropriateness of screening for these two mutations and the circumstances under which screening should be conducted are not yet clear and perhaps screening only high-risk populations would be a better approach. At-risk populations might be defined as those individuals with increased risk of exposure to aminoglycoside antibiotics because of some other, unrelated condition such as cystic fibrosis or an immunological dysfunction, or individuals in whom the use of aminoglycoside antibiotics is under consideration for treatment of infectious disease.

Data on the prevalence of aminoglycoside use in the population are also needed. Data from such studies will provide information about the clinical utility of testing for genetic susceptibility to aminoglycoside ototoxicity and will support discussions of screening for genetic susceptibility to aminoglycoside ototoxicity by identifying high-risk populations. Data from these types of studies will also help establish guidelines for pretest genetic counseling and informed consent of subjects.

GENETICS OF NEUROFIBROMATOSIS TYPE 2

Neurofibromatosis type 2 (NF 2) is much rarer than NF1, with an incidence estimated to be 1:25 000.³⁵ Disease prevalence has now risen to 1:60 000 on account of better survival and improved treatment.³⁶

Neurofibromatosis type 2 is an autosomal dominant condition with the hallmark of bilateral vestibular schwannomas, but is also associated with meningiomas, ependymomas, and pre-senile cataracts. The mean age of onset of symptoms from vestibular schwannoma is estimated to be 20 years.³⁷ The majority of vestibular schwannomas are sporadic in occurrence and unilateral, presenting in the fifth decade. The bilateral vestibular schwannomas that occur in patients with NF2 represent 2–4% of all

vestibular schwannomas^{38, 39} and present in the second and third decades of life.

NF1 and NF2 are recognized as separate genetic and clinical diseases with the localization of the respective genes to chromosomes 17 and 22. The NF2 gene was localized to chromosome 22 through a genetic linkage analysis.⁴⁰ Subsequently the NF2 locus was further mapped close to the centre of the long arm of chromosome 22 (22q12).⁴¹ In 1993 the NF2 gene was identified by Rouleau et al.⁴² and Trofatter et al.⁴³ and since then mutations in the NF2 gene have been identified not only in NF2 related vestibular schwannomas, but also in sporadic vestibular schwannomas and meningiomas.

The NF2 gene is spread over approximately 100 000 bases (100kb) on chromosome 22q12.2 and contains 17 exons (or encoding segments). The transcribed mRNA is 1785 base pairs long and produces a protein of 595 amino acids designated as merlin or schwannoma.^{42, 43}

The gene product is similar in sequence to a family of proteins including moesin, ezrin, radixin, talin and members of the protein 4.1 superfamily. These proteins are involved in linking cytoskeletal components with the plasma membrane and are located in actin rich surface projections such as microvilli, membrane ruffles, and cell contact regions. The N-terminal region of the merlin protein is thought to interact with components of the plasma membrane and the C-terminal with the cytoskeleton. While the exact function of the NF2 protein is as yet unknown, the evidence available suggests that it is involved in cell–cell or cell–matrix interactions, and that it is important for cell movement, cell shape and communication. There is considerable evidence, in both NF2 knockout mice and *in vitro* schwannoma preparations, that loss of function of the merlin protein results in a loss of contact inhibition and consequently leads to tumourigenesis.^{44–46}

NF2 gene defects have been detected in other malignancies including meningiomas, malignant mesotheliomas, melanoma and breast carcinoma.

NF2 mutations and their clinical correlation

The NF2 gene has been postulated to represent a tumour suppressor gene. In approximately 50% of cases, there is no family history of NF2. Therefore, these patients represent new germline mutations in the NF2 gene. To date, more than 200 mutations of the NF2 gene have been identified, including single base substitutions, insertions and deletions.

Mutations were identified in 66% of sporadic cases of vestibular schwannomas, but only in 33% of the NF2 cases; therefore the rate of detection of a mutation in unilateral vestibular schwannomas was significantly higher than that of familial schwannomas.⁴⁷ Genotype-to-phenotype correlation studies suggest that the mutations in the NF2 gene that result in protein truncation are associated with a more severe clinical presentation of NF2 (Wishart type) – larger, multiple, faster growing tumours – while missense and splice site mutations are associated with a milder

form of the disease (Gardner type) – smaller, few and slow growing tumours. However, this has not been held true in other studies, which showed that some missense mutations associated with a severe phenotype.⁴⁷

Given the heterogeneity of clinical response to various types of mutations, no clear genotype-to-phenotype correlation has been established, and this is further evidenced by the fact that phenotypic variability within the NF2 families with the same mutation has been seen.⁴⁸

Although mutations in the NF2 gene play a dominant role in the biology of vestibular schwannomas, they are not uniformly identified in patients with vestibular schwannomas, which suggests that other genetic loci may contribute to the genesis of vestibular schwannomas and ultimately phenotype of the affected individuals.^{49, 50}

Genetic testing and antenatal diagnosis

As detection of tumours at an early stage is effective in improving the clinical management of NF2, pre-symptomatic genetic testing is now an integral part of the management of NF2 families.

Once a mutation has been identified in an affected individual, a 100% specific test is available for the family; however, mutation screening may not reveal causative mutation. Predictive diagnosis by linkage analysis using intragenic markers or markers flanking the NF2 gene is also possible in the great majority of families with two or more living affected individuals.⁵¹

Tumour analysis plays a vital role in providing genetic testing for the offspring of sporadic patients. Indeed analysis should if possible first be carried out on the tumour so that a targeted approach can be used on the blood sample.⁵¹ If both mutational events are identified in the NF2 gene in a tumour and neither is present in the blood the patient must be mosaic for one of these mutations.^{52, 53} Even if only LOH is identified this still allows exclusion of NF2 in 50% of offspring if they can be shown to have inherited the allele ‘lost’ in the tumour.^{52, 53} At-risk individuals who are shown not to have inherited the mutated NF2 gene do not need further follow-up.

Molecular pathophysiology – a link to drug therapy

Recent work on the mechanisms by which the loss of Merlin in the setting of NF2 influences vestibular schwannoma proliferation, has been translated into clinical trials and we are not far away from approved drug therapy for NF2 associated vestibular schwannomas.

The mammalian target of rapamycin (mTOR) is a tyrosine kinase that serves as a hub in the intracellular communication cascade integrating signals from multiple upstream pathways as well as the local intracellular environment. It belongs to two complexes: mTORC1 and mTORC2. mTORC1 is constitutively activated in Merlin-deficient schwannomas.⁵⁴ mTORC1 activation in turn leads to phosphorylation of ribosomal S6 kinase (S6K) and the eukaryotic initiation factor 4E binding protein-1

(4EBP-1), ultimately increasing translation, protein production, and cell growth.⁵⁵ Subsequent studies have shown decreased phosphorylation of downstream targets with mTOR inhibitors such as rapamycin. This and recent supporting preclinical animal data suggesting mTOR inhibition influences vestibular schwannomas cell proliferation have led to three ongoing clinical trials testing everolimus in patients with radiographic progression of NF2-associated vestibular schwannomas (NCT01345136, NCT01490476, NCT01419639).⁵⁶

The loss of Merlin protein in NF2 has been shown to result in abnormal activation of the epidermal growth factor receptor (EGFR) receptor tyrosine kinases (RTKs) proteins. The proteins implicated include EGFR, ErbB2 and ErbB3. These proteins all span the cell membrane and contribute to feedback loops that regulate both cell death and cell division. When Merlin is inactive, EGFR, ErbB2 and ErbB3 remain constitutively active allowing increased cell proliferation and resistance to cell death.⁵⁷ Lapatinib is an oral dual EGFR/ErbB2 inhibitor approved for use in breast cancer. In preclinical studies lapatinib was shown to have substantial inhibition of both cell proliferation and vestibular schwannomas growth.^{58, 59} Lapatinib is now being investigated in two ongoing clinical studies in patients with NF2.

The contribution of abnormal angiogenesis has recently been recognized in benign tumours and provides a novel therapeutic target for NF2-associated vestibular schwannomas. Vestibular schwannomas and peripheral schwannomas have been shown to express vascular endothelial growth factor (VEGF) in both tumour cells and associated endothelial cells.^{60, 61} Recent studies indicated that Merlin also regulates angiogenesis via semaphorin 3F (SEMA3F), a protein that inhibits angiogenesis.⁶² On these observations, bevacizumab, an angiogenesis inhibitor, is being used in at least two clinical trials.

Ras represents a family of proteins responsible for intracellular communication that are frequently altered in the setting of tumours. Merlin has been shown to regulate the interaction of Ras and various growth factors,⁶³ and multiple targets in the Ras pathway have been implicated as part of the pathogenesis of NF2-associated tumours. Sorafenib is an oral multitarget inhibitor of several targets downstream from Ras including Raf/Mek/Erk as well as platelet-derived growth factor (PDGF), vascular endothelial growth factor (VEGF) and c-kit. Similar to sorafenib, nilotinib is a RTK inhibitor of breakpoint cluster region-abelson that also targets PDGF receptor and c-kit. It has also shown promising NF2 *in vitro* and is entering a phase 0 trial with a similar design as described for sorafenib.⁶⁴

GENETICS OF FAMILIAL PARANGLIOMAS

Parangliomas (PGs) are tumours of paranglionic tissue derived from the migration of neural crest cells during foetal development that occur in both sporadic and

familial forms. In the head and neck these most commonly arise from the carotid body (carotid body tumours), jugulotympanic region (glomus tympanicum), jugular bulb (glomus jugulare) and vagus nerve (glomus vagale). Another well known but rare paraganglioma is the pheochromocytoma (PCC).

The yearly clinical incidences of paragangliomas and pheochromocytomas are estimated as 1:1 000 000 and 2:1 000 000 respectively.⁶⁵

Familial PG is inherited in an autosomal dominant manner with maternal imprinting. Therefore, when an individual inherits the PG gene from the mother (regardless of whether she herself is affected), that child is unaffected and becomes a silent carrier of the mutated gene. On the other hand, when a child inherits the PG gene from the father, the offspring will have paragangliomas regardless of the affected status of the father. Subsequently, the affected/unaffected child harbouring the abnormal PG gene will be able to pass the gene to his/her children; he/she will have affected children only if the transmitting parent is a father. This unusual form of incomplete genetic penetrance is caused by sex-specific gene modification during gametogenesis.⁶⁶

Because of this unusual form of inheritance, many sporadic PG could in fact be hereditary PG, and the incidence of familial PG could be much higher than the historically quoted rate of 10%. During the last decade mutations in the genes encoding different subunits of the succinate dehydrogenase (SDH) complex have been linked to familial PCC-PG syndrome, and subsequent genetic screenings have revealed that about 30% of PCC and PG are caused by hereditary mutations.^{67, 68} Similar to familial PG, sporadic PG also demonstrates loss of heterozygosity at PGL1 and PGL2, and this was demonstrated in 38% sporadic cases of carotid body tumours and glomus tumours by Bikhazi et al.⁶⁹ This indirectly tells us that approximately one-third of all sporadic cases of PG may actually be familial.

Currently, four different types of PG are recognized: PGL1, PGL2, PGL3 and PGL4. These are now briefly discussed.

PGL1

PGL1 is caused by germ line mutations of the SDHD gene, located at 11q21.⁷⁰ It is the most common PGL.^{71, 72}

Multiple head and neck PGs are a key feature of this syndrome and they develop in the majority of patients (60–79%), either synchronous or metachronous.^{72–74} There is also a definite risk of developing pheochromocytomas and extra-adrenal PGs (16–21%).^{72–74}

In 2012 Van Hulsteijn et al.⁷⁵ presented a systematic literature review and meta-analysis on the risk of malignant PG in SDHB and SDHD mutation carriers and found that the prevalence of malignant paraganglial tumours reported in SDHD patients with manifest disease varied widely, ranging from 0% to 23%. The pooled incidence for malignant PG was 8% in SDHD mutation carriers.⁷⁵

Tumour penetrance in SDHD mutation carriers is high. Neumann et al.⁷⁶ first published data on age related

penetrance in SDHD mutation carriers in 2004. SDHD mutations conferred 50% penetrance by age 31 rising to 86% by the age of 50. In a study by Hensen et al.⁷⁷ published in 2010, age related penetrance in SDHD patients was 54% by age 40 and 87% by age 70. The average range of age at diagnosis of SDHD-linked tumours is 25–38 years.^{72, 74, 78} As demonstrated by Heesterman et al.⁷⁹ there is also a high prevalence of occult paraganglial tumours in asymptomatic SDHD mutation carriers; in their study, MRI detected HNPGs in 28 out of 47 (59.6%) asymptomatic SDHD patients.

Already in 1989, it was observed that PGL1 families exhibit a peculiar inheritance pattern with a distinct ‘parent-of-origin-dependent effect’.⁸⁰ Whereas SDHD mutations can be inherited both via the maternal and paternal lines, the PGL almost never develops after maternal transmission of the mutation.^{72, 76, 80} As maternally derived SDHD mutation carriers will still pass the mutation to their offspring in 50% of cases, PGL1 can appear to skip generations, which may in part explain the occurrence of SDHD germ line mutations in apparently non-familial cases.^{72, 74, 76}

This virtually exclusive paternal inheritance of disease is consistent with maternal imprinting of the disease gene.⁸⁰ However, imprinting of SDHD has never been established, and the fact that this inheritance pattern is also found in PGL2 families (linked to the SDHAF2 gene, located on 11q13), but not in PGL3 or PGL4 families, suggests that other factors on chromosome 11 explain this phenomenon. It has been found that in SDHD-linked PGs, the whole maternal copy of chromosome 11 is selectively lost.⁸¹ Interestingly, this implies that a second, paternally imprinted tumour suppressor gene located elsewhere on chromosome 11 plays a decisive role in PG tumourigenesis, at least in PGL1 and PGL2.⁸¹ This hypothesis is supported by genetic analysis of the very few ‘exceptions to the rule’, the reported instances of maternal transmission of disease in PGL1 families. In these rare cases, it was shown that invariably not only the SDHD or SDHAF2 gene but also the 11p15 region was affected.^{82, 83} The identity of this secondary tumour suppressor gene remains to be elucidated.⁸⁴

PGL2

PGL2 has a very interesting history, as it was the first PGL to be described.⁸⁴ In 1982 Van Baars et al.⁸⁵ reported on a large Dutch family (295 living family members) with familial HNPGs. It was not until the year 2009 though, that Hao et al.⁸⁶ identified a mutation of the SDHAF2 gene, situated on 11q13, as the underlying cause of PGL2.^{86, 87} SDHAF2, also known as SDH5, plays an important role in flavination of SDHA.⁸⁶

Bayley et al.⁸⁷ identified a second family with PGL2 in Spain. The authors also looked for SDHAF2 mutations in 443 additional HNPGs and pheochromocytoma patients without finding another case of PGL2, suggesting that SDHAF2 plays a modest role as a causative gene in PGLs. Like PGL1, the PGL2 is strongly associated with the occurrence of multiple HNPGs (70–91%) but so far,

no extra-adrenal PGs, pheochromocytomas, or malignant PGs have been described in SDHAF2 mutation carriers.^{86–88} As in PGL1, in PGL2 families transmission of the PGL occurs exclusively via the paternal line. Tumour penetrance has been described to be very high in both the Dutch and the Spanish family (88–100%), and the average age at diagnosis is 33–34 years.^{86–88}

PGL3

Niemann and Müller⁸⁹ first identified a mutation in SDHC, located on 1q21, as the underlying cause of PGL3 in 2000. Until October 2005, only four patients with SDHC mutations had been described.⁸⁴ Most authors concluded that SDHC mutations must be exceedingly rare and therefore, HNPG patients were not routinely tested for mutations of the SDHC gene. This only changed when Schiavi et al.⁹⁰ reported on a total of 22 SDHC mutation carriers in October 2005.

Nevertheless, SDHC mutations have been detected less frequently than SDHD and SDHB mutations.⁷²

In sharp contrast to patients with PGL1 and PGL4, SDHC mutation carriers mostly present with benign, single HNPGs.⁷² Multiple HNPGs are found in 19–31%, and pheochromocytomas, extra-adrenal PGs, and malignant PGs are seldom reported in SDHC mutation carriers.^{72, 73, 90}

In 2009, Neumann et al.⁷² and Burnichon et al.⁷³ found similar prevalence of 4.3% and 3.6% for SDHC mutations in two large HNPG patient series consisting of 445 and 598 PG patients, respectively. The family history is positive in the minority of SDHC patients (12–25%), suggesting a low tumour penetrance.^{72, 73} The average age at diagnosis is higher than for the other PGL (38–46 years).^{73, 90}

PGL4

The PGL4 locus is situated on the 1p36 chromosomal band. The first description of the SDHB mutation as the cause of PGL4 dates back to 2001.⁹¹

In contrast to SDHD mutation carriers, patients with SDHB mutation carriers frequently develop extra-adrenal PGs (in 52–84%) and pheochromocytomas (in 18–28%), and less frequently HNPGs (in 27–31%), while multifocal

HNPGs are significantly less frequently found when compared to SDHD patients.^{72, 78}

The average age at diagnosis is reported to be between 30 and 37 years.^{73, 78}

The most striking clinical feature of PGL4 is the high percentage of malignant pheochromocytomas and malignant HNPGs.^{72, 78}

Neumann et al.⁷² described malignant paraganglial tumours in 13 out of 63 SDHB mutation carriers (20.6%). Ricketts et al.⁷⁸ reported on 40 SDHB patients with malignant PGs and pheochromocytomas in a group of 163 SDHB mutation carriers (25.2%). In a literature review by Pasini and Stratakis,⁹² 50 malignant paraganglial tumours were diagnosed in 105 out of 256 SDHB mutation carriers (41%).

As reviewed by Van Hulsteijn et al.⁷⁵ prevalence of malignant paraganglial tumours in SDHB patients with manifest disease range from 0% to 54% in the literature. In their systematic literature review and meta-analysis on the risk of malignant PG in SDHB and SDHD mutation carriers, the authors found a pooled incidence of 17% in the SDHB group. The pooled risk in prevalence studies, depending on presence of manifest disease, ranged from 13% to 23% in the SDHB group. The authors concluded that incidence and prevalence of malignant HNPGs and pheochromocytomas are higher in SDHB than in SDHD mutation carriers but lower in the SDHB group than hitherto appreciated.⁷⁵

Identification of an *SDHB* gene mutation is also a factor of poor prognosis.⁹² Multivariate analysis of a series of 54 subjects followed in France for PG or malignant pheochromocytoma demonstrated that identification of an *SDHB* mutation was the only risk factor for mortality. The 5-year survival probability was 36% for subjects with an *SDHB* mutation versus 67% for subjects without an *SDHB* mutation with a calculated median survival of 42 months for *SDHB*-mutant patients versus 244 months for wild-type *SDHB* patients.⁹³

SDHB mutations follow an autosomal dominant trait of inheritance.⁹¹ Tumour penetrance is somewhat lower than that seen in SDHD mutation carriers. Benn et al.⁹⁴ estimated the age related tumour penetrance in SDHB mutation carriers to be at 29% at age 30 rising to 45% at age 40.

KEY POINTS

- Advances in molecular genetics have helped to identify causative genes and proteins responsible for pathologies; this knowledge is pertinent to molecular target therapy and promises novel therapeutic interventions.
- The most useful distinction in hereditary hearing impairment (HHI) is syndromic (majority) and non-syndromic (minority). In autosomal dominant non-syndromic hearing loss there is not a single identifiable gene responsible for the majority of cases whereas in autosomal recessive non-syndromic hearing impairment 50% of people have mutations in the GJB2.
- Waardenburg syndrome, Bronchiotorenal syndrome, Stickler syndrome and NF2 represent the most common causes of syndromic autosomal dominant hearing loss, whereas Pendred syndrome and Jervell and Lange-Nielsen syndrome are the commonest causes of syndromic autosomal recessive hearing loss.
- The mitochondrial 12S rRNA is a hot spot for mutations associated with both aminoglycoside-induced and non-syndromic hearing loss. Of those, 1555A>G and 1494C>T mutations at the 12S rRNA have been associated with hearing loss worldwide and account for a significant number of cases of aminoglycoside ototoxicity.

- The NF2 gene is spread over approximately 100 000 bases on chromosome 22q12.2 and contains 17 exons (or encoding segments). More than 200 mutations of the NF2 gene have been identified, that result in protein truncation are associated with a more severe clinical presentation of NF2 (Wishart type) – larger, multiple, faster growing tumours. While missense and splice site mutations are associated with a milder form of the disease (Gardner type) – smaller, few and slow growing tumours.
- Currently, four different types of PG (tumours of paraganglionic tissue derived from the migration of neural crest cells during fetal development that occur in both sporadic and familial form) are recognized:
 - PGL1- the commonest type caused by germ line mutations of the SDHD gene, located at 11q21
 - PGL2- caused by a mutation of the SDHAF2 gene, situated on 11q13
 - PGL3- caused by a mutation of the SDHC gene located on 1q21
 - PGL4- the locus of which is situated on the 1p36 chromosomal band.

GENE THERAPY

Seiji B. Shibata and Scott M. Graham

Introduction	29	Head and neck cancer	34
Cystic fibrosis	31	References	36

SEARCH STRATEGY

Data in this chapter may be updated by a Medline and PubMed Central search using the keywords: gene therapy, cystic fibrosis, head and neck cancer, gene transfer, adenoviral vectors, adeno-associated vectors, ballistic gene delivery, chemosensitization and retroviral vectors.

INTRODUCTION

Gene therapy is the means of delivering exogenous genetic material for therapeutic purposes into the host cell target using vectors. This strategy in principle can be utilized in patients who have genetic defects leading to phenotypic impairment. Gene therapy can be restorative, regenerative or protective in nature by replacing/suppressing/enhancing gene expression. Few new treatment protocols reflect the allure of modern science quite as elegantly as gene therapy. The promise of gene therapy in treating a variety of diseases is, simply put, incredible. This promise has captured the hopes and enthusiasm of the scientific and lay communities alike. Notable initial success in treating severe combined immune deficiency (SCID) seemed to herald imminent success in treating a whole variety of other conditions. In reality, however, progress in bringing the allure of the science to a useful clinical application has been quite limited. Even in the group of SCID subjects¹ – an apparent ‘cure’ – a patient has died from an unusual lymphoproliferative disease.² This has led to a reassessment of the risks of retroviral therapy trials. While great strides have been made in understanding the microbiological complexities of disease states and vectors, the barriers to clinical utility continue to be formidable. However in recent years gene therapy has met major milestones in multiple clinical trials for a number of diseases including Leber’s congenital amaurosis,^{3, 4} X-linked adrenoleukodystrophy⁵ and β -thalassemia.⁶ In the 10-year follow-up study of aforementioned SCID subjects, 18 out of 20 patients are still alive, including four who had leukemia and 17 who

have their immunodeficiency corrected.⁷ Additionally the European commission has recently approved alipogene tiparvovec (Glybera®), an AAV viral vector harbouring human lipoprotein lipase, which will be used for the treatment of familial lipoprotein lipase deficiency disease, making it the first commercial available drug using gene therapy technology in Europe.⁸ Thus, after experiencing several major setbacks gene therapy is making small but steady steps towards clinical reality.

As of 2012, some 1800 human clinical gene therapy trials (including phase I to IV) exist worldwide.⁹ The disease processes involved can be broadly divided into four groups as listed in descending order of number of clinical trials: cancer, monogenetic diseases such as cystic fibrosis (CF) and haemophilia B, cardiovascular disease, and infectious disease trials, which entirely comprise human immunodeficiency virus (HIV). These studies deliver genetic material to target cells via vectors, which act as delivery vehicles to bypass host defences. In the very select circumstances of the skin or eye, a ‘gene gun’ can be used. The treatment aims to replace or repair the defective gene causing a given disease or to provide a new or altered function in a cell. The most common vectors are a variety of replication-deficient viruses although non-viral vectors, such as liposomes, are also used. The characteristics of commonly used vectors are summarized in [Table 3.1](#). We will first review some commonly used gene therapy vectors.

Delivery

The common goal of all gene therapy is to achieve expression of the gene of interest in the targeted cell. To accomplish

TABLE 3.1 The characteristics of commonly used vectors

	Adenovirus	Adeno-associated virus	Retrovirus/lentivirus	Non-viral vectors
Family	<i>Adenoviridae</i>	<i>Parvoviridae</i>	<i>Retroviridae</i>	n/a
Genome	Double-stranded DNA	Single-stranded DNA	Single-stranded DNA	Unlimited size
Infection/tropism	Dividing and non-dividing cells	Dividing and non-dividing cells	Dividing cells	Dividing and non-dividing cells
Host genome interaction	Non-integrating	Non-integrating	Integrating	Non-integrating
Transgene expression	Transient	Potential long lasting	Long lasting	Transient
Packaging capacity	7.5 kb	4.5 kb	8 kb	Unlimited capacity

Source: Adapted and modified from Gene Therapy Net (<http://www.genetherapynet.com>).

this goal several barriers must be overcome: (i) targeting – ideally only cells which require the gene would be affected; (ii) binding and internalization (transfection) – once a gene reaches the cells it must bind and become internalized; (iii) cellular trafficking to the nucleus (transduction) – most methods of internalization require the gene to escape from endosomal degradation and traffic through the cell to the nucleus; and (iv) nuclear expression – once in the nucleus the quantity of gene expression and stability of expression for a given strategy also need to be determined. Each method of delivering a gene to a cell varies in its ability to overcome these barriers.

Adenovirus

Adenovirus is a human pathogenic, non-encapsulated, DNA virus. It has been extensively studied as a means to deliver transgenes both *in vitro* and in human trials. Adenovirus has several characteristics that make it suitable as a therapeutic vector in gene therapy. Relatively simple amplification methods have been developed to propagate high-titer replication defective vectors.¹⁰ Adenovirus efficiently infects both dividing and non-dividing cells by binding to the cox-adenovirus receptor.¹¹ Once a cell binds the viral vector, adenovirus is internalized, escapes from the endosome and is trafficked to the nucleus very efficiently. Even if a specific cell is lacking viral receptors, the virus can be combined with complexes to be internalized via non-receptor-mediated mechanisms. In this alternative pathway of entry, the other components of viral gene delivery remain intact, and therefore efficiency is maintained.^{12, 13} This relative versatility, its ease of construction, efficiency of infection and the efficient expression of transgene make adenovirus an attractive vector for gene therapy.

Adenovirus does have some drawbacks compared to other viral vectors and non-viral systems. It is immunogenic that which limits its ability to re-infect.¹⁴ Multiple studies have shown that both cell- and humoral-mediated immune systems are activated after viral delivery, especially if greater than 10^{10} particles are delivered.¹⁵ This toxicity led to the well-publicized death of a subject in a University of Pennsylvania trial.¹ Besides limiting redelivery, this immune response also results in the clearance of cells expressing the transgene.¹⁶ Several strategies have

shown promise in overcoming this immune-stimulatory problem. ‘Gutted’ vectors, missing almost all of the viral genes, have been shown to be less immunogenic and are expressed for longer periods *in vivo*.^{17, 18} Immune modulation at the time of delivery may decrease the initial inflammatory reaction to the virus.^{17, 18} A further difficulty with adenovirus is that gene expression is transient. The viral genome does not integrate or persist with cell division and gene expression is lost as the cells divide. As demonstrated by more than 50 current open protocols, the adenoviral vector is a very versatile means of gene delivery. As the obstacles of immune stimulation and persistence are addressed, this vector should only become more useful.

Adeno-associated virus

The AAV vector has more recently emerged as a vector with significant therapeutic promise.^{3, 8} AAV is a single-stranded encapsulated virus that belongs to the group of human parvoviruses. Several features of this virus make it attractive as a potential therapeutic tool. First, although it infects human cells this virus has not been associated with a pathologic human disease. It may, therefore, be a safer alternative than other viral vectors. Second, because recombinant AAV vectors do not encode viral proteins, delivery of this vector results in very little immunogenicity.^{19, 20} AAV also persists and infects dividing and non-dividing cells. Although the mechanisms are not fully clear, it appears that in quiescent cells AAV integrates into the host chromosome and in rapidly dividing cells it persists as an extrachromosomal episome.²¹ These factors have made this vector a popular delivery vehicle for many preclinical and human trials. AAV viral vector harbouring human lipoprotein lipase AAV, alipogene tiparvovec (Glybera®) became the first commercially available gene therapy drug in Europe to treat familial lipoprotein lipase deficiency disease in 2012.⁸ Disadvantages such as limited loading capacity (up to 4.2 kb), inefficient expression and delayed onset of expression have made AAV less attractive in the past; however, newer generations of recombinant AAV are now becoming available and are proven to have shorter turnover of transcription and enhanced gene expression potencies.

Retrovirus/lentivirus

Retroviral vectors have the substantial advantage of persistent gene expression. A discussion of retroviral vectors requires a basic understanding of the viral genome and replication. Retroviruses are small, encapsulating vectors with a genome composed of two identical single strands of RNA. The virus binds and is internalized into the cell via interactions between the cell membrane and viral capsule. Once internalized the RNA genome is reverse-transcribed and transported to the nucleus where it integrates as a provirus into the host chromosome. In a normal infectious process, this provirus would then produce viral proteins and RNA genomes for viral packaging. In all retroviral gene therapy vectors, the genome of the virus has been made replication-incompetent by removing the components of the viral gene required for packaging. Thus, these vectors integrated and express the desired gene but will not produce infectious particles.

Several retroviral systems for gene therapy are currently available. Murine oncogenic retroviruses have been the most extensively analyzed and used in preclinical studies.²² Because murine retroviruses only infect dividing cells, the clinical utility of these initial retroviral vectors has been significantly limited.²² To circumvent this obstacle, newer retroviral systems have been developed based on the lentivirus genus of retroviruses. This group of viral vectors that contains the human immunodeficiency virus offers the advantage of infecting dividing and non-dividing cells. They have shown significant promise in pre-clinical *in vivo* studies.^{5, 6, 23} A further biosafety-related issue of retroviruses is that insertion of the provirus is not controlled. It is possible that insertion of the virus next to a proto-oncogene may lead to therapy-induced cancer. Initial evidence from the first successful therapy in patients with severe combined immune deficiency using retroviral gene replacement suggests that a minority of the patients may have developed a non-typable lymphoproliferative disorder as a result of therapy.¹ In addition to controlling insertion, chromosomal silencing of inserted genes has also been reported. In chromosomal silencing, methylation or acetylation of the promoter leads to significant downregulation of transgene expression.^{24, 25} For both of these obstacles, current research has suggested potential solutions. These include controllable chromosomal insertion, chromosomal buffers and methods to controllably excise the provirus.

Non-viral vectors

Naked DNA is one of the most extensively studied methods of gene therapy. This non-viral method of gene therapy has several advantages. These include simplicity, ease of large scale production, minimal immune response and safety.²⁶ The major obstacle for plasmid gene therapy is efficiency. When DNA is placed in an organism, most of the DNA is not internalized. Even if internalization does occur, endosomal degradation destroys nearly all of the remaining plasmid prior to nuclear membrane transit and expression of the desired gene does not occur. In addition,

since plasmid uptake is not receptor-mediated, targeting of the plasmid to a specific cell also remains a major obstacle. In the past 25 years, substantial progress has been made in overcoming these obstacles to non-viral gene transfer. Lastly, plasmid-mediated transfer results in transient expression because the plasmid is lost with cell division. Several methods using site-specific integration or expression of viral proteins have shown promise as a means to overcome this difficulty.^{27, 28} Many of the past therapeutic attempts to utilize plasmid-mediated gene transfer have shown only modest potential. However, as all aspects of plasmid efficiency increase, this should directly correlate with the ability to utilize this technology in therapeutic interventions.

In reviewing progress to date in gene therapy, two diseases of interest to otolaryngologists encapsulate the potential and difficulties of this technique. We will review an apparently attractive candidate for gene therapy, a disease caused by a single mutation inherited in an autosomal recessive fashion – cystic fibrosis.^{29, 30} We will also review progress in a condition with a variety of causalities and a disparate genetic basis, head and neck cancer^{31, 32} – a superficially unattractive candidate for gene therapy. These two diverse diseases serve to illustrate many of the principles, advances and frustrations of gene therapy. In both these examples, human trials remain in nascent stages. Trial sample size is small and results so far do not readily lend themselves to the categorization of levels of evidence, as displayed in other chapters in this text.

CYSTIC FIBROSIS

Cystic fibrosis (CF) represents a seemingly ideal disease for gene therapy. It is the most common lethal genetic disease of one of the wealthiest racial subgroups in the world. There are perhaps 30 000 people with CF in the United States and 70 000 worldwide. It is inherited with an autosomal recessive pattern with carrier rates of 5% in some Caucasian populations.^{33, 34} Remarkably, the median survival for CF patients is less than 40 years³⁵ and unfortunately, the disease remains almost uniformly fatal, invariably from its pulmonary sequelae.^{33, 34} Despite dramatic improvements in the understanding of the molecular basis of CF, the pathogenesis of CF remains unclear and there has as yet been no clinically useful breakthrough in its treatment. Clearly, new treatments and novel animal models faithfully mimicking CF are needed. Conceptually, gene therapy offers the promise of a dramatic and new treatment for CF, thereby a majority of gene therapy trials targeting inherited monogenic disorders in Europe and the USA are currently performed in CF patients.^{9, 30}

Genetic basis

The discovery of the gene for CF in 1989³⁶ set in motion a remarkable series of events, often covered by the lay press with the hyperbole of popular culture, which have culminated in attempts at gene therapy. CF is caused by mutations in a cystic fibrosis transmembrane conductance

regulator (*CFTR*) gene on the long arm of chromosome 7. This gene encodes a CFTR protein, which has been shown to be a cAMP-dependent chloride channel on the apical surface of the epithelium.³⁷ Abnormalities of CFTR impairs the chloride channel and dysregulates salt and water transport across a variety of epithelia. This produces the increase of salt in sweat, obstructive pathology of the lung, pancreatic insufficiency, malabsorption of the GI tract and male infertility due to the lack or stenosis of vas deferens.³⁷ The deletion of three nucleotides results in the deletion of a single phenylalanine residue at position 508 of CFTR, designated $\Delta F508$, is the most common mutation in CF comprising some 70% of cases. Other mutations, now numbering over 1000, are uncommon, occurring in less than 1% of screened populations.

The nasal model for gene transfer in cystic fibrosis

Most interest in CF amongst otolaryngologists has centred on CF sinus disease. Previous reports have claimed benefit from aggressive treatment of CF sinus disease³⁸ and have also suggested that the rhinologic sequelae of CF are important in production of the eventually life-threatening pulmonary complications. Not as widely reported has been the utility of the nose and sinuses in CF as a model for pulmonary disease.³⁹ While the eventual goal of CF gene therapy will clearly be intra-pulmonary administration, there are clearly some difficulties using the lungs for routine experimentation.

Chief amongst these concerns is safety. The prospect of an adverse reaction to vector administration in the lungs of a patient with pre-existing pulmonary compromise is real. In a dose-escalating trial reported by Crystal et al.⁴⁰ in 1994 of intra-pulmonary adenoviral vector administration, the patient who received the largest dose developed a significant adverse reaction with opacities on chest X-ray. The risk of a significant adverse reaction in a localized area of the nose or sinuses is clearly less.⁴¹ The lungs are also more inaccessible than the nose and the nose and sinuses offer ease of access for vector administration and experimental manipulation. For a variety of reasons, CF clinical trials are performed on adults. These patients invariably have severe pre-existing pulmonary compromise and any incremental benefits in pulmonary function afforded by gene therapy would be difficult to measure.

The nasal potential in CF provides a measurable endpoint for gene transfer experimentation. Nasal mucosa maintains and generates a potential difference across its surface and a characteristic voltage trace can be obtained in normal patients. In CF, the nasal mucosa, like the lung mucosa, exhibits the characteristic chloride transport abnormality. CF patients, because of their abnormal ion transport, produce a nasal potential that is different from normal both in its absolute negativity and in its response to certain pharmacologic influences.⁴¹ This trace is so characteristic for CF that it is referred to as its bio-electric phenotype. This potential can be readily and reproducibly measured, in contrast to a number of bronchopulmonary

indices and has been a target of gene therapy strategies in the nose.

In vitro and animal studies

Initially, the feasibility of gene transfer to airway cells was demonstrated *in vitro* and then in a variety of animal experiments. Only one year after the identification of the gene, Rich et al.⁴² showed that expression of cDNA for wildtype CFTR corrected the Cl⁻ channel defect in cultured CF airway epithelia. Zabner et al.⁴³ demonstrated that recombinant adenoviral vectors could deliver CFTR cDNA safely in both cotton rats and rhesus monkeys. Transgenic CF mice provided a means to perform functional testing of CFTR gene expression and have even allowed reversal of the CF phenotype by gene therapy *in utero*.⁴⁴ Unfortunately, however, the CF mice do not produce a disease state comparable to the characteristic manifestations of CF on human lungs or other organ systems.⁴⁵ Recently Zabner et al.^{30, 43, 46} have cloned transgenic CF porcine models that harbour targeted disruption of both CFTR alleles creating an animal model faithfully recapitulating the human phenotype. These transgenic animals also provide the opportunity to study the ion transport defect in the sinuses to further understand the pathogenesis of CF in the nose and sinuses.^{47, 48} Innovative advances in basic science are the basis for the development of novel treatments for CF and for the progression to clinical trials to address questions that could only be answered in humans.

The human CF gene therapy trials: Adenovirus vector

Most of the early human cystic fibrosis gene therapy trials in the United States employed adenoviral vectors. Adenovirus has a degree of tropism for respiratory mucosa and a substantial body of knowledge already existed about adenoviruses as respiratory pathogens. Recombinant viruses are produced by replacing the DNA sequence responsible for replication with CFTR cDNA. The viruses are thus replication-deficient, but still remain sufficiently active to transport genetic material into the target cell. In 1993, Zabner et al.⁴⁹ reported correction of the CF bioelectric potential in a single-dose study where an escalating dose of vector encoding CFTR was applied to the nasal epithelium of three CF patients. Two CF patients underwent a sham procedure using saline and served as controls. No change was noted in the bioelectric phenotype in these two patients. One year later Crystal et al.⁴⁰ published a study in which an adenovirus containing CFTR cDNA was applied to both the upper and lower respiratory tracts of four patients. No statement was made about the nasal potential, but CFTR expression was detected by immunohistochemistry. This report was notable for the widely publicized event of pulmonary toxicity in one of the participants following vector delivery to the lungs. This toxicity was thought to be due to vector-induced inflammation and a reduction of viral vector dose

has largely overcome the problem of acute inflammation in subsequent studies. Hay et al.⁵⁰ produced a further study revealing partial improvement in the nasal potential in a single escalating-dose protocol the following year.

Knowles et al.⁵¹ found molecular evidence of low efficiency gene transfer, but no correction of the nasal potential in a 1995 report. Their experiment involved administration of logarithmically increasing vector doses to four cohorts of three patients. A further study by Zabner et al.⁵² in 1996 addressed the likely need for repeat vector administration. Six patients in two centres in the United States received four or five applications of sequentially escalating concentrations of recombinant adenovirus encoding *CFTR*. In this series, the correction of the nasal potential was more subtle and, importantly, evidence of immunologic response to repeat administration was noted.

Studies involving intra-pulmonary vector administration have scarcely fared better. Zuckerman et al.⁵³ delivered adenovirus encoding *CFTR* to a segmental bronchus in a dose-escalating study. There was evidence of low-level gene expression, as well as evidence of immune and inflammatory responses. In contrast, a single-escalating dose trial from France revealed gene transfer and no detectable immune or inflammatory response after administration of Ad-*CFTR*.⁵⁴

Adenovirus vectors, while efficient delivery vehicles in the laboratory setting, clearly have difficulties in human trials. The human respiratory tract has evolved to efficiently repel a variety of microbial attacks, including of course adenoviruses. Adenovirus does not integrate into the genome and expression is transient thus repeat administration is required. With repeat administration come concerns of inflammation and immunogenicity. All viral vectors aimed at the epithelial surface suffer from the limitation of the viral receptors being located in the basolateral membrane, away from the cell surface. This may be in part overcome by the use of calcium chelators⁵⁵ that briefly disrupt tight epithelial functions, allowing the vector access to the basolateral membrane.

Adeno-associated virus vector

Serotypes 5 and 6 of the adeno-associated virus (AAV) enter airway cells from the apical surface.⁴⁵ Furthermore, AAV are thought to have the least cell toxicity and minimal immunoreaction compared to other viral vector counterparts and offer the potential for integration into the host genome. In practical terms, however, AAV are also associated with limited loading capacity, inefficient expression and delayed onset of expression, thereby may not be an ideal vector in treating CF. Indeed using the maxillary sinus model, 10 CF patients who had undergone prior maxillary antrostomy had AAV vector encoding *CFTR* applied to their maxillary sinus.^{56, 57} Molecular evidence of gene transfer was detected as late as 41 days. A functional endpoint of maxillary sinus voltage measurement was also employed, although some evidence of functional improvement was detected at day 14. There appeared to be no effect on maxillary sinusitis, as assessed endoscopically. In summary, although the AAV vector is safe and

stable the overall level of *CFTR* reconstitution has been too low to provide any functional improvement.^{57, 58}

Lentivirus vector

Lentiviruses are an apparently attractive addition to the list of possible vectors. They have the ability to integrate into and consequently persist in the host genome. They can transduce non-dividing cells – an advantage in airway epithelium where cell turnover is generally low. While a variety of lentiviral options exists, most work has been carried out with the feline immunodeficiency virus (FIV).^{45, 59}

Non-viral vectors

The shortcomings of viral vectors have led to the investigation of non-viral delivery systems. These have included purified or naked DNA in plasmid form or ballistic gene delivery, the so-called gene gun. Only exposed surfaces accessible to a microcarrier coated with DNA are candidates for the gene gun. Although successful in mice lungs this approach is difficult to incorporate in animals with larger lungs due to the lack of equipment design that would match the lung size. Most interest in non-viral gene delivery has centred on liposomes. Liposomes bind to DNA, spontaneously forming complexes that have high affinity for plasma cell membranes. DNA containing liposomes are incorporated into the cell by endocytosis. The advantages of non-viral vectors mainly revolve around safety. They are non-immunogenic and there is no potential for insertion mutagenesis. The main difficulties with non-viral vectors relate to transient expression and less efficient gene transfer as compared to viral vectors.

A 20% correction of nasal potential in nine patients, peaking at three days and disappearing by seven days, was reported by Caplen et al.⁶⁰ employing a cationic liposome vector. The vector was applied by a nasal pump spray, a practical method for likely repeat administration should clinical gene therapy become a reality. In 1997, Gill et al.⁶¹ showed functional *CFTR* gene transfer in six of eight subjects in a further nasal mucosal/liposome study. Alton et al.⁶² reported a placebo-controlled study of liposome-mediated *CFTR* transfer to the lungs and nasal mucosa of CF patients. The treatment group displayed some improvement in airway potential not seen in the liposome-only group. Interestingly, some aspects of toxicity were only seen with pulmonary administration leading the authors to question the value of the nasal model, at least from a safety viewpoint.

KEY POINTS

- Remarkable progress has been made in understanding the molecular basis of cystic fibrosis.
- Equally dramatic progress has been made in examining the basic science of vector production and vector interaction with airway cells.
- The challenge remains to apply this new knowledge and *in vitro* gene therapy success to a clinically relevant and measurable endpoint.

HEAD AND NECK CANCER

In 2000, an estimated 130 000 cases of new head and neck cancer were diagnosed in developed countries.⁶³ Advances in surgical techniques, radiation treatment strategies and chemotherapy medications have improved the survival and quality of life for many of these patients. Unfortunately, despite these innovations, treatment strategies for advanced stage cancer, squamous cancer and certain other head and neck cancer subtypes have not increased survival over the last 40 years.⁶⁴ In order to offer therapy in these advanced cases and to potentially augment current successful therapies, alternative treatment strategies have been examined. Many of these therapies have evolved as a result of our appreciation of the biological basis of oncogenesis. Specifically, this increased understanding has given us gene targets to potentially correct by either replacing or blocking the effect of the mutated gene. The various strategies used in gene therapy fall into four major categories: immune modulation, restorative gene replacement, selective oncolysis and chemosensitization. The following discussion will review both the methods to deliver the genes and the various therapeutic strategies used with these vectors.

Therapy strategies

Gene therapy offers a novel paradigm that leads to the destruction of tumour cells in cancer patients. To date, the approaches to target specific cancer cells fall into four basic categories: (i) chemosensitization; (ii) cytokine gene transfer; (iii) inactivation of protooncogene production; and (iv) selective oncolytic viruses. In the discussion to follow, the rationale and specific results from preliminary gene therapy trials will be presented.

CHEMOSENSITIZATION

Selective sensitization of cancer cells using gene therapy would be an ideal way to kill cancer cells. Using this approach, the expected gene is delivered only to cancer cells and then a second therapy (e.g. radiotherapy or chemotherapy) is used to induce killing in the cells that express the transgene. The best example of this model is delivery of herpes simplex thymidine kinase (HSV-TK).^{31, 65} In this strategy, HSV-TK is delivered to cancer cells. Once expressed, this enzyme changes the prodrug gancyclovir to its toxic nucleoside analogue, which induces cell death. Using this system one would expect that 100% infection of the cancer cell would be required in order to be effective. In reality, a phenomenon termed the bystander effect increases the efficiency of such therapies. In the bystander effect, the infected cell spreads the expressed genes to the cells surrounding it via cell-cell contacts. Using mixing experiments, it has been shown that because of this effect, only half of the cells need to initially express the toxic gene to have the desired effect.^{65, 66} Transfer of *p53* is another example of chemosensitization, as inclusion of this cellular gene sensitizes a cancer cell to apoptosis after treatment

with either radiation therapy or chemotherapy.⁶⁷ Initial laboratory studies showed great promise for these types of therapies. Preclinical animal studies, however, showed only modest *in vivo* results.^{31, 68} Efficiency and targeting have been shown to be difficult *in vivo*. Methods to increase cancer targeting may make these strategies more amenable for human trials in the future. These strategies include redesigning the adenovirus binding site to increase cancer cell selectivity.^{69, 70}

IMMUNE MODULATION

The host immune response has been shown to play a role in cancer eradication. Immune suppression increases the risk of cancer development. In addition to generalized suppression, it has been shown that individuals with head and neck cancer lack an effective local immune response even early in the disease.⁷¹ This immune dysfunction begins at the site of the tumour and progresses systemically with disease progression. This dysfunction occurs as a result of the normal immune system not recognizing the tumour cells. Causes of this include immunological ignorance,⁷² downregulation of major histocompatibility complexes and loss of costimulatory receptor and pathways.⁷³ In some tumours, the cytokine stimulatory pathways (interleukin-2 (IL-2), interferon-gamma and IL-12) that normally upregulate the normal tumour immune response are depressed. One method to break this immune dysregulation is to overexpress the downregulated cytokines. The basis of the first cytokine-based trial for locoregional disease was compelling data from preclinical studies in mice.⁷⁴ A subsequent phase I trial using soluble proteins showed three complete responses and three partial responses in 10 patients.⁷⁵ All these responses were transient. A subsequent phase II trial showed similar transient responses which did not correlate with dose escalation.⁷⁶⁻⁷⁸ However, when IL-2 is administered systemically, significant toxicity develops, including capillary leak syndrome. Gene therapy offers the ability to increase local expression and possibly improve tumour response while limiting systemic toxicity. Phase I trials using non-viral plasmids expressing IL-2 have been completed; demonstrating dose escalation safety, subsequent phase II trials are underway.⁷⁹ Even if such single agent cytokines do not prove useful, it may be possible to deliver combinations, which activate the immune pathway in a synergistic manner. Many such costimulatory questions are currently being examined in preclinical studies.⁸⁰⁻⁸³ As our understanding of tumour immunity increases, better therapies aimed at reactivating the dysfunctional immune response will develop. Gene therapy may likely play a role in the delivery of such therapies.

RESTORATIVE GENE THERAPY

Restoring the function of a key cellular gene whose dysfunction has resulted in cancer progression can be a major goal of gene therapy. Several strategies to replace dysfunctional genes are currently being tested.^{84, 85} The majority

of these involve the disrupted apoptotic pathway found in cancer cells. The most common mutations of these genes in squamous cell cancer of the head and neck are *p53* and *p16*. The most extensively studied of these genes in head and neck cancer is suppressor gene *p53*. This gene plays a role in triggering cell death in many different pathways involving apoptosis. Using an adenoviral vector, placed intra-lesionally, this mutated gene was delivered to 33 patients with locally recurrent squamous cell cancer in a phase I trial.⁸⁶ The study had two arms, surgical and non-surgical. In the surgical arm, patients received treatment pre-operatively, intra-operatively and post-operatively. Of these patients, four patients were alive and disease-free at one year, nine died of their disease and two died of unrelated causes. In the non-surgical arm, two of 17 had a partial response, six had stable disease and nine had progressive disease. The responses seen were most likely not due to effective replacement of mutated genes because *p53* status did not correlate with response.⁸⁶ Gendicine®, a drug with modified adenovirus harbouring *p53* gene was approved by the Chinese State Food and Drug Administration to treat head and neck cancer in China in 2004, becoming the first gene therapy approved for clinical use in humans.⁸⁷ However, the western version of Ad-p53 (Advexin®) for the treatment of head and neck cancer was refused for FDA approval in the USA in 2008.⁸⁷ The overall efficacy of Ad-p53 therapy in head and neck cancer continues to be closely evaluated.

SELECTIVE ONCOLYTIC VIRUS

Infection with wildtype adenovirus results in viral replication and eventual cell lysis. A therapy that harnesses this virus by only allowing replication in cancer cells would offer a self-propagating treatment that continues to produce virus and lyse cancer cells until a tumour is

completely destroyed. Using replication-selective viruses to treat cancer is not entirely new. Initial reports as early as 1912 have used this approach in cancer therapy.⁸⁸ With the advent of increased knowledge of the genetic defects in cancer, we have been able to design vectors aimed at only replicating in cancer cells.^{89, 90} The ONYX-015 is an adenovirus therapy design to accomplish this goal. ONYX-015 is missing the adenovirus *E1B* gene that normally inhibits the cellular *p53* genes. *p53* cellular expression allows only minimal viral expression. Approximately 60% of squamous cell carcinoma (SCCA) do not express functional *p53*. The ONYX-015 virus will selectively replicate only in SCCA cancers with *p53* mutations. Phase I and II clinical trials have shown significant promise with this strategy.⁹¹⁻⁹³ The initial phase I trial showed the virus was safe even when given in high doses.⁶⁴ Fever and injection site pain were the most common adverse effects. Phase II and III clinical trials are currently underway. In addition to developing this therapy as a single agent treatment, its role in combined therapies is also being examined. Phase II studies have shown this combined approach increases response rates from 33% for chemotherapy (5-fluorouracil (5-FU) and cisplatin) to a 65% response rate when intra-tumoural injections of ONYX-015 are added to the regimen.⁹³ Another potential advantage of the ONYX-015 vector is that if it is given intravenously it may circulate and offer potential therapy for distant metastasis. The safety of an intravenous delivery approach has been confirmed in phase I trials revealing safe delivery of high titers of viral vectors. The most common side effects were fever, rigours and elevated liver enzymes.⁹¹ To more fully evaluate the potential of this strategy, more work has to be completed in areas of safety and delivery. Overall, however, this self-propagating tumour selective approach offers significant therapeutic promise.

FUTURE RESEARCH

The death of an 18-year-old man in a 1999 adenoviral gene therapy trial in Philadelphia caused scientists around the world to examine more critically the risks of human gene therapy experimentation. Three years later, a three-year-old boy died in France from a leukaemia-like condition, probably as a result of insertional mutagenesis in a retroviral gene therapy trial for SCID. Both of these tragic events have resulted in increased scrutiny for human gene therapy trials. These events have also brought into sharper focus the balance between the risks and the incredible promise of this treatment. However, following these major setbacks, gene

therapy seems to have entered a new era with several promising clinical trial results together with recent approval of AAV-based Glybera® as a commercial drug in 2012 in Europe to treat familial lipoprotein lipase deficiency disease. Remarkable progress has been made in the last decade in improving the understanding of the basic science and the complexities of host-vector interaction. The challenge for the next decade continues to be the translation of this new expertise into clinical situations in a safe and effective manner.

KEY POINTS

- Our increased understanding of cellular oncogenesis will lead to the development of novel cancer therapies in the years to come.
- Gene therapy is likely to be a part of these therapies.
- A head and neck oncologist will need to understand both the viral vectors and their strategies of implementation to offer a full range of treatment to the cancer patient.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: mechanisms of chemotherapy; principles of tumour biology, chemotherapy and head and neck cancer; EGFR inhibitors, EGFR monoclonal antibodies; VEGF inhibitors, immunotherapy and head and neck cancer.

INTRODUCTION

Anticancer drugs have been developed and used medically since the 1940s, following the observation that nitrogen mustard gas, a chemical warfare agent used in the Second World War, interfered with haematopoiesis. Since then there have been significant therapeutic advances in the development of anticancer drugs although a cure for all cancer types remains an elusive goal. Alongside trials using more traditional types of chemotherapy, there is also now significant interest in developing more target-directed drug therapies and novel therapies, including immunotherapy.

PRINCIPLES OF CHEMOTHERAPY

Cancer is defined as the uncontrolled growth of cells coupled with malignant behaviour: invasion and metastasis. It arises through a complex interaction between genetic and environmental factors, causing genetic mutations in oncogenes and tumour suppressor genes. Chemotherapy aims to exploit the resulting differences in biological and proliferative characteristics between normal and cancer cells where most cytotoxic drugs preferentially affect dividing cells in tumours.

PRINCIPLES OF TUMOUR BIOLOGY

Cellular kinetics

CELL CYCLE

The cell cycle ([Figure 4.1](#)) is divided into a number of phases governed by an elaborate set of molecular switches. Normal non-dividing cells are in **G0**. When actively recruited into the cell cycle they then pass through four phases:

1. **G1**: the growth phase in which the cell increases in size and prepares to copy DNA
2. **S (Synthesis)**: which allows doubling of the chromosomal material
3. **G2**: a further growth phase before cell division
4. **M (Mitosis)**: where the chromosomes separate and the cell divides.

At the end of a cycle the daughter cells can either continue through the cycle, leave and enter the resting phase (**G0**) or become terminally differentiated. Most anticancer agents do not cause cell death during **G0**.

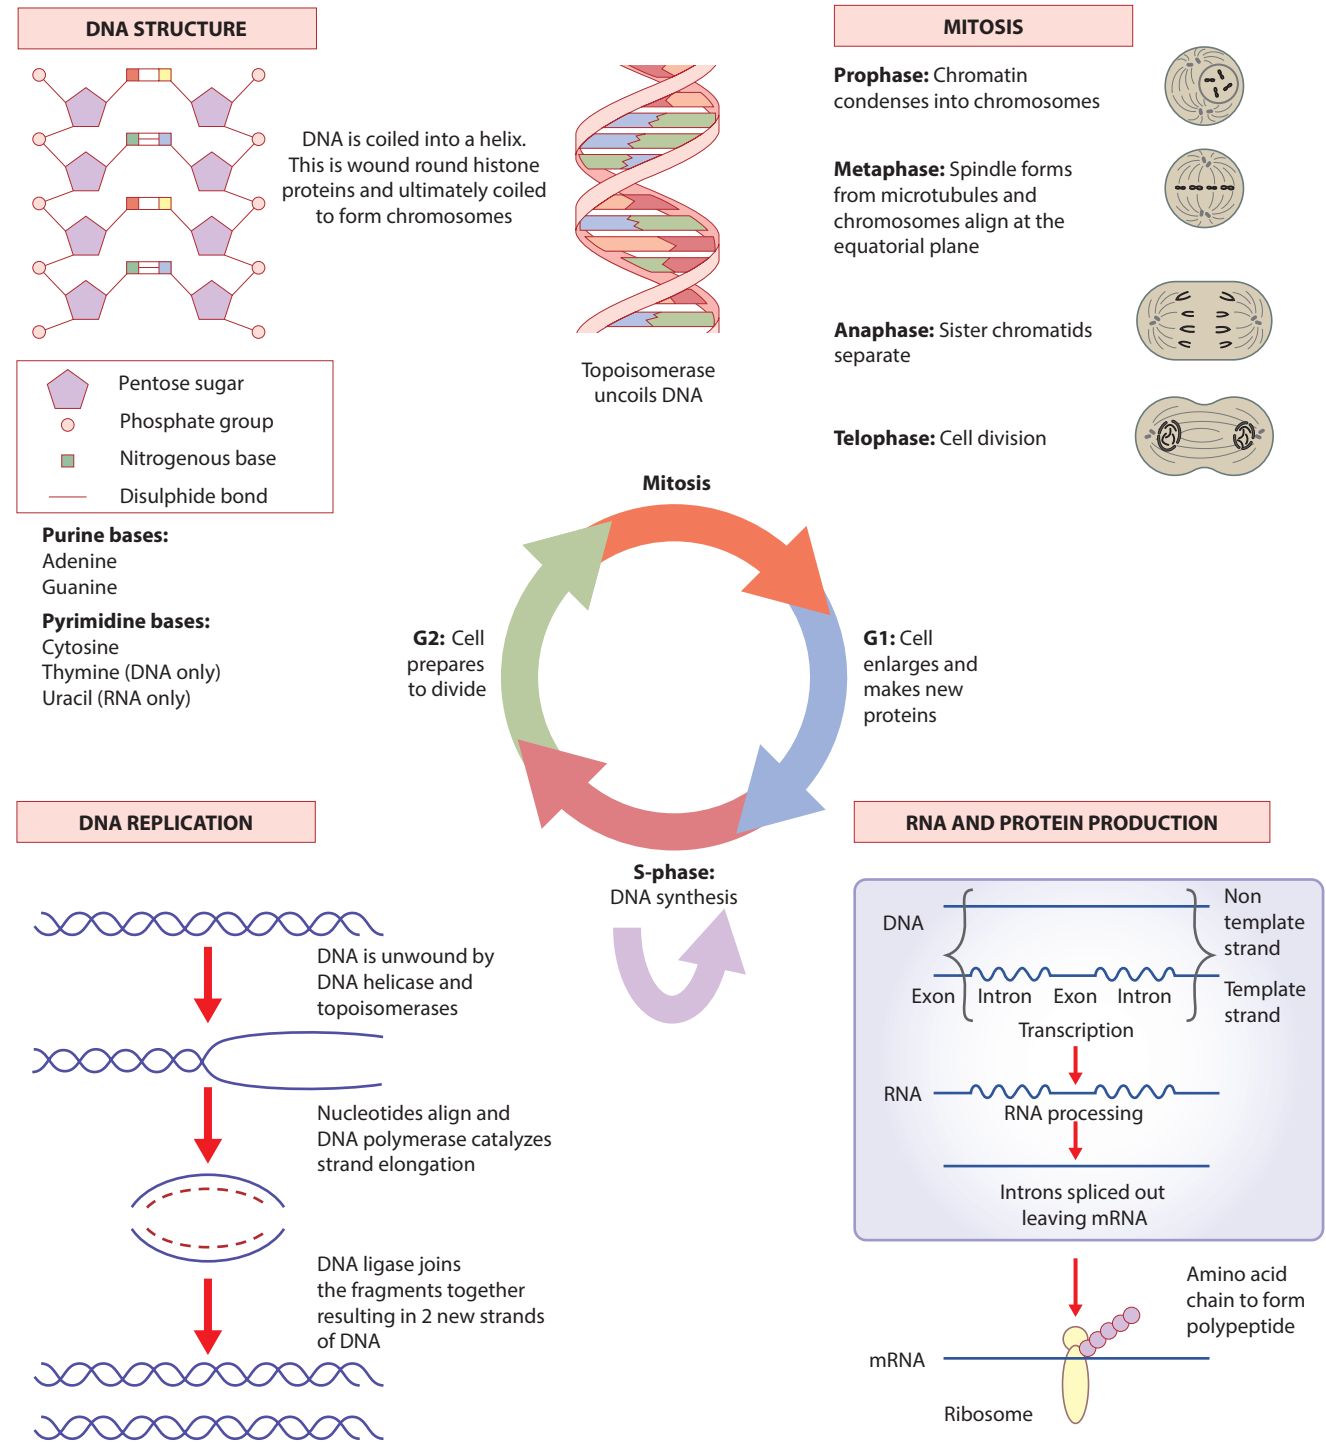

Figure 4.1 Cell cycle: possible targets for chemotherapy.

TUMOUR GROWTH

The kinetics of any population of tumour cells is regulated by the following:

- **Doubling time:** the cell cycle time, which varies considerably between tissue types
- **Growth fraction:** the percentage of cells passing through the cell cycle at a given point in time, which is greatest in the early stages

- **Cell loss:** which can result from unsuccessful division, death, desquamation, metastasis and migration.

Tumours characteristically follow a sigmoid shaped growth curve, in which tumour doubling size varies with tumour size. Tumours grow most rapidly at small volumes (Gompertzian kinetics). Chemotherapy is therefore more likely to be successful in eradicating a small tumour burden. As they become larger, growth is

influenced by the rate of cell death and the availability of blood supply.

Cell signalling

Cells respond to their environment via external signals called growth factors. These interact with cell surface receptors that activate an internal signalling cascade. This ultimately acts at the DNA level through transcription factors that bind to the promoter regions of relevant genes, stimulating the cell cycle and influencing cell division, migration and programmed cell death (apoptosis).

Metastatic spread

A tumour is considered malignant when it has the capacity to spread beyond its original site and invade surrounding tissue. Normally cells are anchored to the extracellular matrix by cell adhesion molecules, including the integrins. Abnormalities of the factors maintaining tissue integrity will allow local invasion and ultimately metastases of the tumour cells.

Mechanism of cell death

There are two main types of cell death: apoptosis and necrosis. Necrotic cell death is caused by gross cell injury, and results in the death of groups of cells within a tissue. Apoptosis is a regulated form of cell death that may be induced or is pre-programmed into the cell (e.g. during development) and is characterized by specific DNA changes and no accompanying inflammatory response. It can be triggered if mistakes in DNA replication are identified. Loss of this protective mechanism would allow mutant cells to continue to divide and grow thereby conserving mutations in subsequent cell divisions. Many cytotoxic anticancer drugs and radiotherapy act by inducing mutations in cancer cells that are not sufficient to cause cell death but that can be recognized by the cell, triggering apoptosis.

FRACTIONAL CELL KILL HYPOTHESIS AND DRUG DOSING

Theoretically the administration of successive doses of chemotherapy will result in a fixed reduction in the number of cancer cells with each cycle.¹ A gap between cycles is necessary to allow normal tissue to recover. Unfortunately these first order dynamics are not observed in clinical practice. Factors such as variation in tumour sensitivity and effective drug delivery with each course result in an unpredictable cell response.

CLASSIFICATION OF CHEMOTHERAPEUTIC AGENTS

Cytotoxic chemotherapy agents have traditionally been classified as phase-specific or non-phase-specific, depending on the effect on the cell cycle. The practical value of

this classification is somewhat limited, and as a consequence drugs are more commonly defined by their particular mechanisms of action.

Phase-specific chemotherapy

These drugs (e.g. methotrexate, vinca alkaloids) kill proliferating cells only during a specific part or parts of the cell cycle. Antimetabolites such as methotrexate are more active against cells in the S phase whereas vinca alkaloids are more M-phase-specific. Attempts have been made to time drug administration in such a way that the cells are synchronized into a phase of the cell cycle that renders them especially sensitive to the cytotoxic agent. For example, vinblastine can arrest cells in mitosis. These synchronized cells enter the S phase together and can be killed by a phase-specific agent such as cytosine arabinoside. Most current drug schedules, however, have not been devised on the basis of cell kinetics.

Cell-cycle-specific chemotherapy

Most chemotherapy agents are cell-cycle-specific, meaning that they act predominantly on cells that are actively dividing. They have a dose-related plateau in their cell killing ability because only a subset of proliferating cells remains fully sensitive to drug-induced cytotoxicity at any one time. The way to increase cell kill is therefore to increase the duration of exposure rather than increasing the drug dose.

Some drugs have an equal effect on tumour and normal cells whether they are in the proliferating or resting phase (e.g. alkylating agents, platinum derivatives). They have a linear dose-response curve; that is, the greater the dose of the drug, the greater the fractional cell kill.

According to mechanism

ALKYLATING AGENTS

These include, for example, nitrogen mustards (melphalan and chlorambucil) and oxazaphosphorines (cyclophosphamide and ifosfamide).

These highly reactive compounds produce their effects by covalently linking an alkyl group (R-CH₂) to a chemical species in nucleic acids or proteins. The site at which the cross-links are formed and the number of cross-links formed is drug-specific. Most alkylating agents are bipolar (i.e. they contain two groups capable of reacting with DNA). They can thus form bridges between a single strand or two separate strands of DNA, interfering with the action of the enzymes involved in DNA replication. The cell then either dies, or is physically unable to divide or triggers apoptosis. The damage is most serious during the S phase as the cell has less time to remove the damaged fragments.

HEAVY METALS

These include, for example, platinum agents (carboplatin, cisplatin and oxaliplatin).

Cisplatin is an organic heavy metal complex. Chloride ions are lost from the molecule after it diffuses into a cell allowing the compound to cross-link with the DNA strands, mostly to guanine groups. This causes intra- and inter-strand DNA cross-links, resulting in inhibition of DNA, RNA and protein synthesis.

Carboplatin has the same platinum moiety as cisplatin but is bonded to an organic carboxylate group.

Oxaliplatin contains a platinum atom complexed with oxalate and a bulky diaminocyclohexane (DACH) group. It forms reactive platinum complexes that are believed to inhibit DNA synthesis by forming interstrand and intra-strand cross-linking of DNA molecules.

ANTIMETABOLITES

Antimetabolites are compounds that bear a structural similarity to naturally occurring substances such as vitamins, nucleosides or amino acids. They compete with the natural substrate for the active site on an essential enzyme or receptor. Some are incorporated directly into DNA or RNA. Most are phase specific, acting during the S phase of the cell cycle. Their efficacy is usually greater over a prolonged period of time, so they are usually given continuously. There are three main classes: folic acid antagonists, pyrimidine analogues and purine analogues.

Folic acid antagonists

Methotrexate competitively inhibits dihydrofolate reductase, which is responsible for the formation of

tetrahydrofolate from dihydrofolate. This is essential for the generation of a variety of coenzymes that are involved in the synthesis of purines, thymidylate, methionine and glycine. A critical influence on cell division also appears to be inhibition of the production of thymidine monophosphate, which is essential for DNA and RNA synthesis. The block in activity of dihydrofolate reductase can be bypassed by supplying an intermediary metabolite, most commonly folinic acid. This is converted to tetrahydrofolate that is required for thymidylate synthetase function (Figure 4.2).

Pyrimidine analogues

These drugs resemble pyrimidine molecules and work by either inhibiting the synthesis of nucleic acids (e.g. fluorouracil (Figure 4.3)), inhibiting enzymes involved in DNA synthesis (e.g. cytarabine, which inhibits DNA polymerase) or by becoming incorporated into DNA (e.g. gemcitabine), interfering with DNA synthesis and resulting in cell death.

Purine analogues

These are analogues of the natural purine bases and nucleotides. 6 mercaptopurine (6MP) and thioguanine are derivatives of adenine and guanine respectively. A sulphur group replaces the keto group on carbon-6 in these compounds. In many cases, the drugs require initial activation. They are then able to inhibit nucleotide biosynthesis by direct incorporation into DNA.

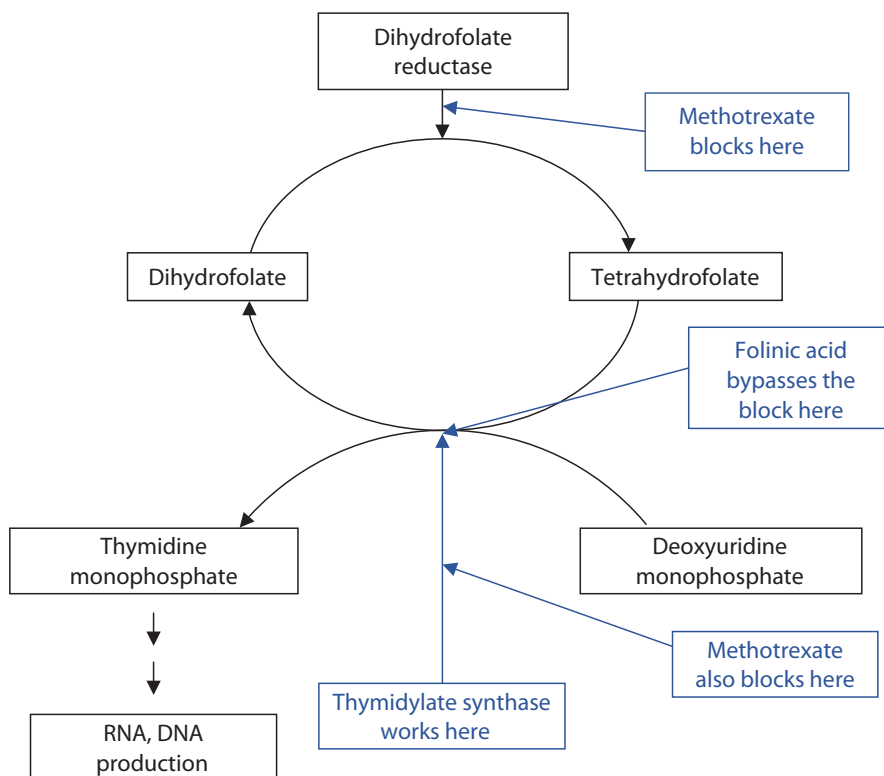

Figure 4.2 Mechanism of action of cytotoxic drugs: methotrexate.

Figure 4.3 Mechanism of action of cytotoxic drugs: fluorouracil. 5-Fluorouracil (5-FU) can participate in many reactions in which uracil would normally be involved. Firstly, it has to be converted to its active form, 5-fluoro-2 deoxyuridine monophosphate (5-FdUMP) (a). This then interferes with DNA synthesis by binding to the enzyme thymidylate synthetase, causing it to be inactivated (b). The binding can be stabilized by the addition of folinic acid. 5-FdUMP, 5-fluorodeoxyuridine monophosphate; 5-FU, 5-fluorouracil; 5-FUMP, binding can be stabilized by the addition of folinic acid. 5-FdUMP, 5-fluorodeoxyuridine monophosphate; 5-FU, 5-fluorouracil; 5-FUMP, 5-fluorouridine monophosphate; dTMP, deoxythymidine monophosphate; dUMP, deoxyuridine monophosphate; NADP, nicotinamide adenine dinucleotide phosphate; NADPH, reduced form of nicotinamide adenine dinucleotide phosphate; PP, pyrophosphate; PRPP, 5-phospho-alpha-D-ribose 1-diphosphate; U, uracil; UMP, uridine monophosphate.

CYTOTOXIC ANTIBIOTICS

Most antitumour antibiotics have been produced from bacterial and fungal cultures (often *Streptomyces* species). They affect the function and synthesis of nucleic acids in different ways:

- **Anthracyclines** (e.g. doxorubicin, daunorubicin, epirubicin) intercalate with DNA and affect the topoisomerase II enzyme. This DNA gyrase splits the DNA helix and reconnects it to overcome the torsional forces that would interfere with replication. The anthracyclines stabilize the DNA topoisomerase II complex and thus prevent reconnection of the strands.
- **Actinomycin D** intercalates between guanine and cytosine base pairs. This interferes with the transcription of DNA at high doses. At low doses DNA-directed RNA synthesis is blocked.
- **Bleomycin** consists of a mixture of glycopeptides that cause DNA fragmentation.
- **Mitomycin C** inhibits DNA synthesis by cross-linking DNA, acting like an alkylating agent.

SPINDLE POISONS

Vinca alkaloids

The two prominent agents are vincristine and vinblastine, which act as mitotic spindle poisons. They bind to tubulin, the building block of the microtubules, which inhibits further assembly of the spindle during metaphase, thus inhibiting mitosis. Other examples include vindesine and vinorelbine.

Taxoids

Paclitaxel (Taxol) and docetaxel (Taxotere) promote assembly of microtubules and inhibits their disassembly. Direct activation of apoptotic pathways has also been suggested to be critical to the cytotoxicity of this drug.²

TOPOISOMERASE INHIBITORS

Topoisomerases are responsible for altering the 3D structure of DNA by a cleaving/unwinding/rejoining reaction. They are involved in DNA replication, chromatid segregation and transcription. It has previously been considered

that the efficacy of topoisomerase inhibitors in the treatment of cancer was based solely on their ability to inhibit DNA replication. It has now been suggested that drug efficacy may also depend on the simultaneous manipulation of other cellular pathways within tumour cells.³ The drugs are phase-specific and prevent cells from entering mitosis from G2. There are two broad classes:

1. **Topoisomerase I inhibitors** (e.g. irinotecan and topotecan). These bind to the enzyme-DNA complex, stabilizing it and preventing DNA replication.
2. **Topoisomerase II inhibitors** (e.g. etoposide). These stabilize the complex between topoisomerase II and DNA that causes strand breaks and ultimately inhibits DNA replication.

CHEMOTHERAPY IN HEAD AND NECK CANCER

Chemotherapy is regularly employed in the management of head and neck cancer. It has not changed the cure rates of locally advanced head and neck cancer. It has, however, allowed improved organ preservation when combined with radiotherapy and has led to a reduction in rates of distant metastases.

CHOICE OF CHEMOTHERAPY IN HEAD AND NECK CANCER

The single agents active in head and neck cancer, with response rates between 15% and 40%, include methotrexate, cisplatin, carboplatin, fluorouracil, ifosfamide, bleomycin, paclitaxel, and docetaxel. Cisplatin is one of the most active drugs against squamous head and neck cancer.⁴ Taxoids and gemcitabine are gaining favour and are being incorporated into many current drug trials.

CHEMOTHERAPY STRATEGIES

Combination chemotherapy

Combinations of cytotoxic agents are widely used for many cancers and may be more effective than single agents. Possible explanations for this include:

- exposure to agents with different mechanisms of action and non-overlapping toxicities
- reduction in the development of drug resistance
- the ability to use combinations of drugs that may be synergistic.

Combination chemotherapy in head and neck cancers usually includes cisplatin.

Adjuvant chemotherapy

This is the administration of chemotherapy after curative surgery or radiotherapy, in patients considered to be at

high risk of relapse. The intention is to eradicate micro-metastatic disease. Randomized trials assessing the use of adjuvant chemotherapy for the patients with head and neck squamous carcinoma do not suggest a significant survival benefit.⁵ [Level 1 evidence]

Neoadjuvant chemotherapy (induction chemotherapy)

Neoadjuvant, or induction chemotherapy, is the use of chemotherapy prior to definitive surgery or radiotherapy in patients with locally advanced disease. The intention is to reduce the tumour bulk before definitive treatment and hence improve local and distant control of the disease. This will also achieve greater organ preservation and overall survival.

Numerous phase III trials have considered the benefit of neoadjuvant chemotherapy. Unfortunately their approaches have been quite heterogeneous, making meta-analysis difficult.⁶ VA Laryngeal Cancer Study Group evaluated induction chemotherapy (cisplatin/5-FU) followed by radiotherapy versus surgery and radiotherapy among patients with stage III/IV disease.⁷ Chemotherapy responders subsequently received radiotherapy; non-responders underwent laryngectomy. An 85% chemotherapy response rate was documented in this study. No survival differences were noted, but there was the benefit of laryngeal preservation among responders. Subsequent studies have continued to examine the topic of organ preservation. The Radiation Therapy Oncology Group (RTOG) 91-11 trial randomized 547 patients with stage III/IV disease to three treatment arms; induction cisplatin/5-FU followed by radiotherapy, cisplatin-based concurrent chemoradiotherapy, and radiotherapy alone.⁸ Concurrent chemoradiation was superior to induction chemotherapy or radiotherapy alone in terms of organ preservation and locoregional control. No differences were observed in relation to overall or disease-free survival comparing induction therapy or concurrent chemoradiation. Taxane-platinum-based combinations have more recently been evaluated and appear superior to cisplatin-5-FU in terms of overall survival, progression free survival, locoregional failure and distant failure for loco-regionally advanced disease.^{9, 10} Toxicity, however, can be quite high.

The role of neoadjuvant/induction chemotherapy continues to remain controversial. It is currently considered on a case-by-case basis and further studies are planned. [Level 1 evidence]

Concurrent chemoradiation (CRT)

This involves the synchronous use of chemotherapy and radiotherapy. In the context of head and neck cancer, this is often used after definitive surgery. The rationale is that chemotherapy can sensitize tumours to radiotherapy by inhibiting tumour repopulation, preferentially killing hypoxic cells, inhibiting the repair of sublethal radiation damage, sterilizing micrometastatic disease outside of the radiation fields and decreasing the tumour mass, which leads to improved blood supply and reoxygenation.

Fractionated radiotherapy, in turn, may sensitize tumours to chemotherapy by inhibiting the repair of drug-induced damage and by decreasing the size of the tumour mass, leading to improved blood supply and enhanced drug delivery. Patients with high-risk features (positive lymph nodes, positive margins, extracapsular spread (ECS), perineural/vascular invasion) have been shown to demonstrate an improved 5-year survival by 13%.¹¹ Two pivotal phase III studies (RTOG 9501 and EORTC 22931) demonstrated improved locoregional control with the addition of chemotherapy in high-risk patients^{12, 13} where a post-hoc analysis of the trials confirmed that ECS of tumour and positive margins were the most important indications for adjuvant chemoradiation.¹⁴ At present there is still debate regarding the optimum chemoradiotherapy programme that should become the standard of care.

Local, regional and metastatic recurrence

Patients with localized squamous cell carcinoma of the head and neck are treated with potentially curative therapy. Unfortunately, many patients develop recurrent disease. The recurrence rate in early-stage squamous cell head and neck cancer is approximately 10–20%,¹⁵ whereas the recurrence rate in locally advanced is approximately 50% with a predominance of locoregional failure.^{15–18} Patients with recurrent or metastatic squamous cell head and neck cancer have a poor prognosis with median overall survival of under 1 year¹⁹ and is mostly made up of patients who have recurrence after initial treatment for localized disease. A small percentage of patients with localized recurrence can be treated with curative intent, but the vast majority receive palliative treatment with systemic therapy.

Chemotherapy in the first line setting is associated with disappointing opportunities for disease control. Objective response rates to commonly used therapies (including methotrexate, docetaxel, paclitaxel) drop off to well under 20% and median survival in phase 3 trials has been reproducibly reported at approximately 5–6 months.^{19–23}

There is clearly a need to explore novel therapies to try to improve disease outcomes. Options being explored include targeted therapies and immunotherapy.

NOVEL THERAPIES FOR THE FUTURE

Despite the introduction of new cytotoxic drugs, the management of advanced head and neck cancer remains challenging. Over the last years interest has focused on the role of novel agents with more targeted mechanisms of action or agents that are able to manipulate the immune system to provide tumour control (immunotherapy).

Targeted therapy

Targeted therapy aims to specifically act on a well-defined target or biologic pathway that, when inactivated, causes regression or destruction of the malignant process.

The main strategies of research have looked at the use of monoclonal antibodies or targeted small molecules.

Monoclonal antibodies

Monoclonal antibodies can be derived from a variety of sources:

- murine – mouse antibodies
- chimeric – part mouse/part human antibodies
- humanized – engineered to be mostly human
- human – fully human antibodies.

Murine monoclonal antibodies may themselves induce an immune response that limits repeated administration. Humanized and, to a lesser extent, chimeric antibodies are less immunogenic and can be given repeatedly.

There are several proposed mechanisms of action of monoclonal antibodies as anticancer agents.²⁴ These include:

- Direct effects may include:
 - induction of apoptosis
 - blocking of the receptors needed for cell proliferation/function
 - anti-idiotypic antibody formation, determinants amplifying an immune response to the tumour cell.
- Indirect effects may include:
 - antibody dependent cellular cytotoxicity (ADCC, conjugating the ‘killer cell’ to the tumour cell)
 - complement-mediated cellular cytotoxicity (fixation of complement leading to cytotoxicity).

A desirable target for MAbs would have the following properties:

- Wide distribution on tumour cells
- High level of expression
- Bound to tumour, allowing cell lysis
- Absent from normal tissues
- Trigger activation of complement on MAb binding
- Remains unchanged following antibody binding to ensure it remains visible to the immune system (i.e. is not internalized or shredded).

Antibodies have also been used as vectors for the delivery of drugs and radiopharmaceuticals to a target of tumour cells.

Interest in the development of antibodies for solid tumours has become increasingly popular, especially with respect to the epidermal growth factor receptor and the vascular endothelial growth factor receptor.

Epidermal growth factor receptor biology

Epidermal growth factor receptor (EGFR) biology is a 170kD transmembrane protein composed of an extracellular ligand-binding domain, a transmembrane lipophilic region and an intracellular protein tyrosine kinase domain (Figure 4.4). When a substrate binds to the receptor, the

Figure 4.4 Simplified epidermal growth factor receptor signal transduction pathways and opportunities for intervention. GRB2, growth factor receptor binding protein 2; MAPK, mitogen-activated protein kinase; MEK, MAPK/extracellular signal related kinase; SOS, guanine nucleotide exchange factor (son of sevenless); c-fos, c-jun and c-myc, nuclear targets involved in gene transcription/cell cycle progression; P, phosphate; TGF α , transformation growth factor α ; PI3-K, phosphatidylinositol 3; AKT, serine/threonine kinase, prosurvival protein; STAT, signal transducing activation of transcription.

ligand-receptor complex dimerizes and is internalized by the host cell. This activates an intracellular protein kinase by autophosphorylation, which in turn activates signal transduction pathways, influencing cell function. This can lead to cell proliferation, as well as invasion and metastasis.

Several investigators have described amplification of the EGFR gene and overexpression of the EGFR surface membrane protein in a large number of human cancers, including squamous cell carcinoma of the head and neck.²⁵ Overexpression is associated with increased proliferative capacity and metastatic potential and is an independent

indicator of poor prognosis.²⁶ Blockade of the EGFR pathway has been shown to inhibit the proliferation of malignant cells and also appears to influence angiogenesis, cell motility and invasion.²⁷ Various strategies have been investigated to manipulate EGFR.

Monoclonal antibodies against EGFR

An example of a monoclonal antibody developed against EGFR is the chimeric IgG antibody cetuximab which has the binding affinity equal to that of the natural ligand and can effectively block the effect of epidermal growth factor and transforming growth factor α .^{6, 8} It also causes internalization of EGFR and targets the cytotoxic immune effector cells towards EGFR expressing tumour cells.²⁷

LOCOREGIONALLY ADVANCED HEAD AND NECK CANCER

The addition of cetuximab to radiotherapy has been shown to improve locoregional control and survival when compared to primary radiotherapy alone for patients with locoregionally advanced head and neck cancer.^{28, 29} Randomized controlled trials however have not demonstrated superiority or non-inferiority of cetuximab-radiotherapy compared to concomitant chemoradiotherapy and so cetuximab-radiotherapy is considered an option for treatment in patients who are not candidates for the chemotherapy used with chemo-radiotherapy.³⁰ [Level 1 evidence]

RECURRENT/METASTATIC HEAD AND NECK CANCER

The addition of cetuximab to platinum-based chemotherapy prolongs median overall survival, progression-free survival, best overall response rate, disease control rate and time to treatment failure in patients with recurrent or metastatic squamous cell carcinoma of the head and neck compared to platinum-based chemotherapy alone and is an option to consider in the first line setting.^{31, 32} [Level 1 evidence]

Targeted small molecules against EGFR

Gefitinib (Iressa) and erlotinib (Tarceva) are orally active epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKI) that block the EGFR signalling cascade, thereby inhibiting the growth, proliferation and survival of many solid tumours. They have activity as single agents in patients with recurrent or metastatic head and neck cancer, and have an acceptable safety profile compared with conventional chemotherapy.^{33, 34} So far, results in locally advanced disease have not demonstrated additional benefit with these drugs.^{35, 36}

Inhibitors of angiogenesis

Angiogenesis (Figure 4.5) is the process of new blood vessel formation, triggered by hypoxia and regulated by numerous stimulators and inhibitors. It is vital for cancer development.

Figure 4.5 Schematic representation of possible anti-angiogenesis targets, including natural stimulators and inhibitors.

A tumour cannot exceed beyond 2–3 mm³ without inducing a vascular supply. New vessels develop on the edge of the tumour and then migrate into the tumour. This process relies on degradation of the extracellular matrix surrounding the tumour by matrix metalloproteinases such as collagenase that are expressed at high levels in some tumour and stromal cells. Angiogenesis is then dependent on the migration and proliferation of endothelial cells.

It has been found that anti-angiogenic agents tend to be cytostatic rather than a cytotoxic, hence stabilizing the tumour and preventing spread. As a consequence they may be valuable for use in combination with cytotoxic drugs, as maintenance therapy in early stage cancers or as adjuvant treatment after definitive radiotherapy or surgery. There is evidence to support the fact that suppressing angiogenesis can maintain metastases in a state of dormancy.³⁴

Vascular endothelial growth factor receptor

Vascular endothelial growth factor (VEGF) receptor VEGF is a multifunctional cytokine released in response to hypoxia and is an important stimulator of angiogenesis. It binds to two structurally related transmembrane receptors present on endothelial cells. High VEGF protein and receptor expression has been demonstrated in certain head and neck cancers and is associated with a higher tumour proliferation rate and worse survival.³⁷

Monoclonal antibodies against VEGFR

Bevacizumab (Avastin) is a humanized murine monoclonal antibody targeting VEGF. It is the first anti-angiogenic drug to have induced a survival advantage in cancer therapy.³⁸ The use of bevacizumab in head and neck cancer is supported by information derived in preclinical trials.³⁹ Currently clinical trials are exploring the feasibility and the therapeutic potential of a combination of bevacizumab and EGFR-targeted drugs.^{40, 41}

IMMUNOTHERAPY

Immune checkpoint inhibitors are a new class of systemic agents being increasingly used in oncology. They function by interrupting the immunosuppressive pathways, called inhibitory checkpoints, which are normally used by tumour cells to prevent detection and elimination by the host immune system.^{42, 43} Molecular targets of immune

checkpoint inhibitors are found on T cells and include cytotoxic T-lymphocyte antigen-4 (CTLA-4) and programmed cell death protein 1 (PD-1) receptor. A third common target is PD-L1, which is found on both tumour and immune cells and is the corresponding ligand to PD-1.^{42, 43} There is interest in the role of immune checkpoint inhibitors particularly in tumours with high levels of endogenous PD-L1 expression, which include some head and neck squamous cell carcinomas.⁴² Current available clinical trial-generated evidence suggests that immune checkpoint inhibitors present a promising new opportunity for a small number of patients with very advanced disease who progress on standard first-line chemotherapy. Objective response rates to immune checkpoint inhibitors are around 20% in patients who have progressed on first-line chemotherapy combinations for recurrent or metastatic squamous head and neck cancer irrespective of PD-L1 expression status.⁴² Data suggest that PD-L1 expression correlates with better efficacy to immune-checkpoint inhibitors; however, this correlation is not definitive and no other reliable biomarker has currently been identified for effectively selecting optimally responsive patient subgroups.^{42, 44} Ongoing studies are investigating the role of immune checkpoint inhibitors in patients with both locally advanced disease and metastatic disease.

CONCLUSION

The majority of conventional chemotherapeutic agents cause cell death by directly inhibiting the synthesis of DNA or interfering with its function. This means that they are often not tumour-specific and are associated with considerable morbidity. Trials have demonstrated that combination chemotherapy regimens can cause dramatic regression of head and neck tumours, especially when used concomitantly with radiotherapy. Unfortunately this has not been associated with an increase in survival rates.

There is now considerable excitement over the development of new target-directed cytotoxic agents. These have been developed to modulate or inhibit specific molecular targets critical to the development of or control of cancer cells. Particular interest has focused on the field of monoclonal antibody development, particularly in relation to the epidermal growth factor. Other drugs affecting signal transduction, programmed cell death, transcription regulation, matrix invasion, angiogenesis and immune modulation are currently involved in clinical trials. The results of these are eagerly awaited and will potentially radically change current therapeutic strategies.

FUTURE RESEARCH

The effect of chemotherapy on non-metastatic head and neck cancers is still being evaluated. The optimum combination of chemotherapeutic agents and the timing of their use in relation to surgery have not been defined, especially in combination with radiotherapy. As this continues to be assessed, significant

advances are being made in relation to more specific targeted therapies. The results of clinical trials with these new agents and their incorporation into management regimens are eagerly awaited.

KEY POINTS

- Traditional chemotherapy agents interfere with DNA synthesis and function and are classified according to their mechanism of action.
- Unfortunately they are associated with significant side-effect profiles.
- The role of chemotherapy in head and neck cancer is still being defined but there is increasing popularity of concurrent chemotherapy and radiotherapy regimens.
- Current research, however, is now focusing on more novel approaches including molecular targeted therapy and immunotherapy.
- Strategies recently have particularly looked at the use of monoclonal antibodies.
- There are also drugs being designed that specifically influence signal transduction, cell cycle regulation, apoptosis, matrix invasion and angiogenesis.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: neoplasms, radiotherapy, fractionation, radiation-sensitizing agents, chemotherapies, hypoxia and immunotherapies.

INTRODUCTION

Radiotherapy is the therapeutic use of ionizing radiation, typically usually high-energy X-rays (photons). Other modalities (e.g. protons) may be used to optimize the therapeutic effect by seeking to optimize the conformality to the target volume. As the name implies, the radiation interacts with matter by ejecting electrons from their orbits, resulting in ionization. The ejected particles interact with further atoms, ejecting further electrons and causing a cascade of ionizations after each initial interaction. In biological material, the free radicals that result, primarily from interactions with water molecules, are highly reactive and are particularly damaging to the cell when they interact with DNA. In total, about 100 distinct lesions have been identified amongst which strand breaks (i.e. sugar-phosphate backbone damage) predominate in terms of importance at the cellular level. Traditionally, the main cause of cell death following radiation was thought to result from direct damage to the DNA. This has gradually been modified over the last few years as an increasing number of studies have shown that ionizing radiation also targets the plasma membrane where it can initiate multiple signal transduction pathways, many of which lead to radiation-induced apoptosis (e.g. hydrolysis of the membrane phospholipid sphingomyelin by the enzyme sphingomyelinase resulting in the generation of ceramide). DNA damage in mammalian cells triggers three pathways: cell cycle arrest, DNA repair and apoptosis. Historically, three types of damage have been recognized: sublethal damage (SLD), potentially lethal

damage (PLD) and irreparable or lethal damage. These categories may not reflect different types of damage, but instead reflect the category of repair processes that act to modify the radiation-induced lesions. If the DNA damage is particularly severe then cell death may result, usually when the cell attempts to divide.

The fact that cell death occurs at a time after the actual exposure to irradiation, depending on the time of cell division (and also upon the tissue structure and life span of the mature functional cells), explains one of the most important clinical observations about radiotherapy, that tissues that are dividing rapidly manifest the effects of radiation sooner than those where cell division is slow. Tissues such as bone marrow, skin and the mucosa of the upper aerodigestive tract manifest the effects of radiation within days (i.e. they are classed as ‘acute-reacting’ tissues). Connective tissue, bone and neural tissue may only show the effect years later, hence being defined as ‘late-reacting’ tissues. Squamous head and neck cancers, as might be expected, behave as an acute-reacting tissue, like the squamous mucosa from which they originate. In addition to the kinetics (turnover rate) of the population as a whole, the response of tissues and organs is also dependent upon inherent cellular radiosensitivity. The sensitivity of the cell to radiation is determined to some degree by its state of maturity and its functional role. Generally speaking, immature cells are considerably more sensitive to radiation than mature cells and as mitotic activity increases (metabolic activity, proliferation), sensitivity also increases. There is general agreement as to which of the target cells is responsible for acute effects (stem cells of

rapidly dividing tissues), but the target cells that determine the late effects have not been defined clearly. In general, if any clonogens from acute responding normal (healthy) tissues survive they can rapidly repopulate and replace lost cells. Late-reacting tissues do not have this ability to repopulate rapidly and therefore whilst most acute reactions heal, most late reactions, if anything, may continue to progress with time. It is the severity of predicted late effects that can limit the delivered dose of radiation. Differentiating between acute and late effects is exploited in the concept of fractionation.

FRACTIONATION

The differences between ‘acute-reacting’ and ‘late-reacting’ tissues are thus very important to the science of fractionation in radiotherapy. At low single doses, tumour and early-responding tissues are more sensitive than late-responding tissues (more cells are in cycle). At high doses, the non-dividing late-responding cell response that compensates for tissue loss is slow and therefore organs appear more intrinsically radiosensitive than rapidly dividing tumour and early-responding tissues.

A fraction is the individual dose of radiation delivered at a single session of radiotherapy; in the treatment of head and neck cancer a total course of radiotherapy will take several weeks and consist of numerous fractions. The fraction size, measured in physical dose, is traditionally and almost invariably constant throughout a course of radiotherapy. In conventional radiotherapy, fractions are given once a day, five days per week typically for 4–6 weeks. This accords with normal working practices, rather than being founded on a sound scientific basis, and alternative fractionation schedules have been much studied in recent years.

In general, the relationship between the dose of radiation in a single fraction and the number of cells killed approximates closely to a straight line on a semi-logarithmic graph, conventionally drawing dose arithmetically on the x-axis and surviving fraction of cells on a declining logarithmic scale on the negative y-axis. This is shown in **Figure 5.1**. It should be noted though that while the general relationship is linear, at the lowest doses this is not so, and the line is curved (i.e. it has a ‘shoulder’). For most cells, the range in which this shoulder applies is close to most widely used fraction sizes (in other words around 2 Gy) and this has important implications for clinical practice.

The extent of the ‘curviness’ of the graph varies with many factors. Most importantly for day-to-day routine radiotherapy, late-reacting tissues generally have a more ‘curvy’ graph than do acute-reacting ones and therefore increasing the fraction size even modestly tends to have a greater effect on late-reacting as opposed to early-reacting tissues: in other words there is more ‘late-reacting’ tissue damage. The shoulder on the graph is a reflection of the capacity for DNA to repair damaged cells. Thus cells from patients with ataxia-telangiectasia show almost no curve. This is because these patients are deficient in certain mechanisms that act to repair DNA.

Figure 5.1 Typical radiation dose-response curve following a single radiation exposure. Note that the radiation dose (x-axis) is a linear scale, while surviving fraction (y-axis) is logarithmic. The effect for small doses is relatively ‘curvy’ compared to that for higher. The consequences of this are explained in the text.

The importance of this shoulder region to radiotherapy relates to the fact that as long as sufficient time elapses between fractions, a subsequent dose of radiation has the same shaped survival curve as an initial dose, including the shoulder (i.e. full repair of the initial damage has occurred). Thus, if the shoulder is considerable, the net effect of two doses is very much less than if the same total physical dose was given as a single fraction. The general shape of the cell survival curves, including the shoulder, is probably best described by the linear quadratic equation:

$$SF = N/N_0 = e^{-(\alpha D + \beta D^2)} \quad \text{or} \quad -\ln SF = \alpha D + \beta D^2$$

In this equation, N_0 is the number of cells in the population originally and N is the number surviving after irradiation with dose D , with N/N_0 representing the surviving fraction (SF). Only two parameters, α (the initial slope) and β (the terminal slope) are required to describe the dose–response curve. Absolute values of α and β are not well known, but the alpha/beta ratio (i.e. the dose at which the contribution to killing from the α component or nonreparable damage, is equal to that of the β component or reparable damage) has been identified with a reasonable degree of approximation for numerous tissues. In general, the α/β ratio tends to be low for late-reacting tissues, and for these the shoulder on the graph is considerable, whereas it is high for acute-reacting tissues, where the shoulder is less marked. When this is translated into practice, the total effect is more fraction size-dependent for late-reacting tissues than for acute-reacting tissues. Thus, for example, the effect achieved with a dose of 70 Gy in 2 Gy fractions given over 7 weeks will differ less from the effect of the same total dose in fractions of 1 Gy for acute-reacting tissues than it will for late-reacting tissues. There will be more ‘sparing’ of late-reacting tissues by breaking the same total dose up into a greater number of smaller fractions. Having said this, because of the

ability of early-reacting tissue to repopulate rapidly, these comparisons are only valid if the overall treatment time is the same for the different schedules. Otherwise the ability of head and neck squamous cell carcinomas (SCC) like acute-reacting normal tissues will negate the intended benefit. This will necessitate a shorter inter-fraction interval for the schedule of many small fractions. This interval still needs to be long enough though for adequate repair of sublethal damage to occur if the full sparing effect on late reactions by reducing fraction size is to be seen.

The corollary of this is that by using many small fractions it will be possible to give a higher total dose, but without increasing the amount of late damage, whereas a greater effect will be seen on acute-reacting tissues and thus squamous head and neck cancer cells themselves. This is the theory of 'hyperfractionation'.

The theoretical benefits of hyperfractionation were confirmed in clinical practice in a randomized trial comparing a 'conventional' schedule of 70 Gy in 7 weeks with a hyperfractionated schedule, in which two fractions of 1.15 Gy were given daily, also over 7 weeks, so that the total dose was 80.5 Gy.¹ Better local control was achieved in the experimental hyperfractionation arm, with no observed increase in late side effects. This approach to improve the therapeutic ratio, however, has not gained wide acceptance in the radiotherapy community largely on logistical grounds.

Other ways of modifying radiotherapy fractionation schedules have also been explored in head and neck cancer. The problem of tumour clonogen proliferation during a prolonged course of radiotherapy has already been alluded to. The consequence of this is that if radiotherapy schedules are prolonged for reasons such as holidays, machine breakdowns and so on, tumour control is adversely affected. A number of retrospective series have confirmed this (it cannot, of course, be ethically tested in a prospective randomized trial). The evidence has been strong enough for the Royal College of Radiologists in the UK to publish guidelines on how to minimize the harm done by such interruptions.² Of course, if prolongation of schedules is detrimental in terms of control of tumours, it might well be expected that to shorten the overall time ('acceleration') would result in better control. A number of trials have also been conducted to test this hypothesis. The evidence is convincing that shortening overall time is beneficial in terms of tumour control. One problem that all the trials of accelerated treatments have faced is that increasing the effect on the tumour by shortening the overall time also increases the effect on the adjacent normal mucosa, and severe acute reactions are to some extent unavoidable. The problem is compounded by the fact that very severe acute reactions sometimes lead, rather more than might be expected, to an increase in the extent of late reactions, and this has rather limited the extent to which improvements in outcomes can be achieved by shortening radiotherapy schedules. Even so, the many studies published in this area leave little doubt that it is indeed possible to employ the strategy of acceleration without incurring too high a penalty in terms of normal tissue effects, although the optimum strategy in terms of fraction size, interval, number

of fractions per day, number of treatment days per week, total dose and overall time, remains elusive.³ To some extent this debate has been superseded by efforts focusing on systemic agents and their interactions with conventional fractionation.

RADIOSENSITIZERS

As well as modifying the physical parameters of radiotherapy (time and dose through fractionation as well as the modality), other interesting avenues of exploration have involved using various agents to enhance its effects. It is reasonable to refer to all of these as 'radiosensitizers', although the scientific purists may argue about the appropriate use of this term. Numerous types of agent have been used, with varying degrees of success. The rapid advances that are currently occurring in molecular oncology have made and continue to make this an area of fruitful exploration.

The evidence that emerged from laboratory studies that hypoxic cells were relatively radioresistant to X-rays when compared with fully oxygenated ones prompted the earliest attempts at radiosensitization. As the centre of many tumours are necrotic, it was felt that this was evidence that the proliferation of cells within tumours led to growth outstripping blood supply (i.e. the diffusion distance for oxygen is <150–200 µm from an adjacent blood vessel) and that therefore it was logical to assume that there would be many chronically hypoxic cells within tumours (hypoxia can also be acute (momentary) due to the transient opening and closing of tumour blood vessels). It was hypothesized that chronic and acute hypoxia would make the centre of tumours relatively radioresistant. Modern technology has made it possible to precisely measure oxygen levels in tumour and normal tissues, and this hypothesis has indeed been confirmed. If this hypoxic effect could be overcome, radiotherapy would be more likely to be successful. A significant amount of time and effort has been expended over many years testing whether this could be achieved in clinical practice. Many diverse strategies have been employed and new strategies are continually being investigated.

The earliest avenue explored was probably the most direct. In an attempt to ensure greater oxygenation within tumours, patients were placed in hyperbaric oxygen tanks during radiotherapy. Clinical trial results failed to demonstrate that this approach yielded better results than 'standard' radiotherapy. There have been reports that increasing the haemoglobin level could be beneficial as anaemic patients may respond less well to radiotherapy.^{4, 5} Initial studies suggested that those patients given transfusions and hyperbaric oxygenation (HBO) did better than those given HBO alone. However, subsequent results from the DAHANCA study group did not support this.⁶ Similarly, studies with recombinant erythropoietin (EPO) have discounted the anticipated benefits of using EPO to correct anaemia with such patients actually faring less well.⁷

An alternative approach used the agent nicotinamide, which is thought to dilate small vessels to improve blood

flow through the vascularized parts of tumours (i.e. to deal with 'acute' hypoxia), in combination with patients breathing carbogen (a mixture of oxygen and carbon dioxide) during radiotherapy in an attempt to ensure good oxygenization (and thus deal with the 'chronic' hypoxia). Combined with accelerated radiotherapy this approach, called ARCON, was tested in a phase II trial with promising local control.⁸ A phase III trial showed locoregional benefits with acceptable toxicity but no gain in overall survival.⁹

A number of pharmaceutical approaches have been used in an attempt to make hypoxic tumour cells more radiosensitive through more direct actions on the cellular structure. True sensitizers have little or no cytotoxic action without radiation, but significantly enhance the efficiency of radiation killing when present during radiation. Apparent sensitizers include a variety of compounds, such as antibiotics, alkylating agents and antimetabolites, that act by diverse mechanisms. In general, sensitizers can be regarded as agents that increase the lethal effects of radiation. They should show a gain between tumours and normal tissues (i.e. to enhance the therapeutic ratio). Such a therapeutic gain could result from selective uptake (concentration), a differential absorption rate or biological half-life. Ideally they should be effective at systemically nontoxic dosages, thereby minimizing side effects.

Halogenated pyrimidines (IUDR, BrdUrd) work by being incorporated into actively dividing tumour cells to a greater degree than slowly dividing (cell maintenance) normal tissues. Appreciable quantities need to accumulate for several generations for them to be incorporated to set up stresses in the DNA and make them more susceptible to radiation damage. They therefore seem to be particularly useful with tumours having a high growth fraction and high labelling index. BrdUrd is also a sensitizer to ultraviolet (UV) radiation, therefore skin may be the limiting tissue. This is less of a problem with IUDR.

Hypoxic cell sensitizers are electron affinic and act to increase the sensitivity of radioresistant hypoxic cells by mimicking O₂. They are not rapidly metabolized and therefore have time to diffuse into poorly vascularized areas.

Cells are more responsive to sensitizers if they are depleted of their natural radioprotector, glutathione (GSH), a radical scavenger that eliminates reactive radicals before they have the opportunity of causing DNA damage. This may be accomplished by incubation with thiol binding agents, such as diamide and diethyl maleate, or inhibition of GSH synthesis with buthionine sulfoximine before delivering the radiation. The effectiveness of hypoxic cell sensitizers is measured in terms of the enhancement ratio (ER).

The nitroimidazoles have been extensively evaluated as potential radiosensitizers. One of the first compounds investigated was metronidazole, a trichomonacide. At 10 mM, an ER of 1.6 was obtained with no effect on aerated cells. The large concentrations required led to investigations for more effective derivatives and other nitroimidazole drugs appeared more promising in this respect.

Although many hypoxic cell sensitizers have been investigated (including misonidazole, metronidazole,

benznidazole, desmethylmisonidazole, etanidazole, pimonidazole, nimorazole, ornidazole and doranidazole), controversy exists regarding the role of these agents in conventional radiotherapy. So far only one major randomized trial of the many that have been performed has shown a therapeutic benefit and in this Danish trial, a benefit for nimorazole use during radiotherapy of pharyngeal and supraglottic laryngeal cancers when combined with conventional therapy was shown.¹⁰ Although nimorazole has been shown to be of potential benefit, these sensitizers generally show greater benefit in situations where large, single doses of radiation are given (e.g. intra-operative radiotherapy, interstitial radiotherapy, radiosurgery). As only this one trial out of many has shown a statistically significant benefit, the international clinical community remains unconvinced that there is a true benefit for the use of nitroimidazoles, and they are still not widely used outside Denmark to this day.

BIOREDUCTIVE DRUGS

Adjuncts to radiation, which are not true radiosensitizers, include bioreductive drugs and prodrugs. These agents, which are relatively non-toxic to cells under normal oxygenated conditions, when reduced intracellularly form cytotoxic agents. Bioreduction is favoured under hypoxic conditions due to cytochrome P450 and DT diaphorase reductases. The efficiency of bioreductive drugs may be increased further by inducing increased hypoxia in tumours through the use of vasoactive drugs, such as hydralazine. This induces vasodilation in normal tissues thus diverting blood from the tumour. Bioreductive drugs can be divided into three major groups: the quinones, nitroaromatics and organic nitroxides.

Specific examples of bioreductive drugs include mitomycin C (a quinone) and tirapazamine/SR-4233 (an organic nitroxide). The former is an antitumour antibiotic that is bioreduced to form products that cross-link DNA. It is cell cycle non-specific, is more toxic to hypoxic than aerated cells, is usually administered i.v. and is rapidly cleared from plasma (half-life, 10–15 minutes). The drug does not cross the blood–brain barrier and the major toxicity is myelosuppression. Indoloquinone EO9 is a synthetic analogue of mitomycin C (MMC), which was expected to have similar properties to MMC, but fundamental differences have emerged; for example, EO9 is a much better substrate for DT-diaphorase (DTD) and it has the ability to redox cycle more readily than MMC after reduction by purified DTD. In addition, EO9 has the ability to increase the cytotoxicity to hypoxic cells 49-fold over MMC. The overall capacity of the tumour to metabolize EO9 has been suggested to be the most important determinant for EO9 activity. This, along with the rapid clearance of EO9 in humans, has been suggested as one of the reasons for the disappointing results obtained from phase II clinical trials.^{11, 12} Another more efficient quinone, porfirimycin, when assessed in a phase III study showed no benefit over MMC.¹³

A more promising group of bioreductive drugs is the organic nitroxide of which tirapazamine (TPZ) is the most widely known. The benefits, however, in the phase II

trials have not been translated into clinical benefits in the phase III setting.¹⁴ It is thought that some of the failure to demonstrate clinical benefit in phase III trials may reflect the need to better identify patient populations with high levels of tumour hypoxia. In addition there is excessive metabolic consumption as it penetrates the extravascular space so that its apparently impressive selectivity for hypoxic cells from 50–300-fold *in vitro* diminishes to a more modest range of 3–5-fold *in vivo*.

To date, as with the hypoxic cell sensitizers mentioned above, there is thus little clinical evidence from large randomized trials of bioreductive agents showing increased efficacy when combined with conventional radiotherapy. There remains a fundamental need to develop drugs that balance small molecule stability against reactivity in a reduction/oxidation equilibrium, so that the intended toxicity is only imparted in tissues that are truly hypoxic. We also need to be mindful that hypoxia is not such a prominent prognostic factor in all forms of head and neck squamous cell carcinomata.¹⁵

A variety of emerging techniques with more tailored effects on hypoxic tissues are under active investigation:¹⁶

1. Vascular disrupting agents (VDAs) alter tumour blood flow via activity on the colchicine binding site on tubulin, leading to changes in endothelial cell shape and increased vascular permeability
2. ‘New’ radiosensitizing agents, e.g. Bevacizumab, a humanized monoclonal antibody specific for vascular endothelial growth factor (VEGF)
3. Drugs that target hypoxia-induced proteins, e.g., Immunomodulating drugs.¹⁷

CONCURRENT CHEMOTHERAPY

A clinically more successful (therapeutic) strategy than trying to overcome hypoxia thus far has in fact been the rather more empirical approach of simply combining ‘conventional’ chemotherapy with radiotherapy. Squamous head and neck cancers show a clinical response to a number of chemotherapeutic agents, so the strategy of combining such drugs with radiotherapy seems justifiable.

Many randomized trials have been conducted in which a combination of chemotherapy and radiotherapy have been compared with radiotherapy alone. Although the majority of these trials have been relatively small, when combined there are vast numbers of patients, and the technique of ‘meta-analysis’ has been applied. This has convincingly shown that the addition of chemotherapy, standardly cisplatin, does give better results than those achieved with radiotherapy alone¹⁸ and confirmed with longer follow-up and later studies.^{19, 20} The counterargument has been made that the same could be achieved by simply giving more radiotherapy. However, it is known that beyond a certain level the incidence of complications rises rapidly if additional radiotherapy is given, which is why the doses used in common practice are as they are. It has proved feasible to give chemotherapy in combination with such doses and, to date, there is no strong suggestion that this does

lead to an unacceptable increase in damage to normal tissue. The same cannot be said of the proposed strategy of simply giving higher doses of radiotherapy (other than in the context of fractionation trials, particularly hyperfractionation, as discussed previously).²¹

NEO-ADJUVANT CHEMOTHERAPY

Combined chemotherapy and radiotherapy schedules have been tested in randomized controlled trials against a policy of primary surgery for moderately advanced laryngeal and hypopharyngeal cancers. In fact, in these trials the drugs have been given before radiotherapy, so are certainly not acting as ‘true’ radiosensitizers but are mentioned here for completeness. They have been shown to be no less effective than radical surgery in terms of survival, but confer the advantage of enabling preservation of a functioning larynx in a substantial number of patients.^{22, 23} Such ‘organ preservation’ represents a significant advance in radiotherapy of head and neck cancer, and continues to attract a great deal of attention, with trials of different drug/radiation schedules, and involving other head and neck sites. However there is still no proven benefit in providing chemotherapy prior to definitive chemoradiotherapy for advanced head and neck cancer in terms of improved survival. As such, most consider that further studies are needed to identify potential patient subgroups that may benefit from this treatment intensification.

TARGETED THERAPIES

Our understanding of the molecular mechanisms that drive cancer cells has grown at an accelerating pace within recent years. This has led to the emergence of a range of drugs that act against cancer cells in a more targeted way than the cytotoxic agents that have been the mainstay of chemotherapy in the past. Because of their specificity, such agents hold the promise of being much less toxic than conventional chemotherapy.

Among these new classes of agents there are some interesting suggestions of synergy with radiation. In head and neck cancer, one target has so far attracted significant attention, the epidermal growth factor receptor, EGFR (*erbB1*, HER1). This is one of a family of transmembrane receptor tyrosine kinases, other members being HER2/*neu* (*erbB2*), HER3 (*erbB3*) and HER4 (*erbB4*). Ligand-binding receptor dimerization occurs, which induces a conformational change in the intracellular kinase domain, thereby inducing a cascade of phosphorylation events or activation of signal transduction (e.g. activation of the MAPK or ras signal transduction pathway). As implied by its name and as might be expected in a tumour arising from squamous epithelium, overexpression of this receptor is a very frequent event in head and neck squamous carcinomas and carries with it a worse prognosis.²⁴ Its overexpression, with or without gene amplification, is often associated with increased production of EGFR ligands, particularly epidermal growth factor (EGF)

and transforming growth factor alpha (TGF α). Selective compounds have been developed that target either the extracellular ligand-binding region of the EGFR or the intracellular tyrosine kinase region.

The first of these target the extracellular ligand-binding domain using a monoclonal antibody approach. Cetuximab is a chimeric ‘humanized’ monoclonal antibody that competitively binds to EGFR (it has a 2-log higher affinity for EGFR than TGF α and EGF). Once bound to the receptor, the complex is internalized and the receptor thereby rendered inactive. Cetuximab has undergone clinical trials in head and neck cancer used both as monotherapy and as combined therapy (radiation, chemotherapy). Results from a large randomized phase III trial were very impressive in that improved locoregional control (24.4 months versus 14.9 months) and improved survival (49 months versus 29.3 months) have been obtained with little increase in toxicity²⁵ as compared with radiotherapy alone. Cetuximab may, in addition to exerting antiproliferative effects by inhibiting the MAPK signal transduction pathway, act as an antiangiogenic agent and therefore exert radiosensitizing effects via mechanisms described above.²⁶ Despite these impressive results concurrent chemotherapy using cisplatin remains the gold standard for

locally advanced head and neck cancer unless renal function precludes the administration of platinum.

The second approach available to target receptor tyrosine kinases is via the use of small molecules that compete for the ATP binding site of the kinase domain. The low molecular weight of these molecules may allow them to penetrate tumours better and they can be administered orally making them suitable for chronic therapy. Several agents, including gefitinib and erlotinib, showed promise in clinical trials as monotherapy^{27, 28} and in combination with standard chemotherapy. Unfortunately these anticipated benefits do not appear to have been translated into studies with radiotherapy.²⁹

Another approach to targeted therapies is through the evasion of programmed cell death and immortalization. It is in this area that there is most excitement for new avenues of therapy for treating and improving the outcomes for head and neck squamous cell carcinomata as alluded to earlier.¹⁷ A recently published study in recurrent squamous cell carcinoma of the head and neck has shown the potential for significant activity with anti-PD1 monoclonal antibodies.³⁰ The question now being evaluated is whether such activity can be translated into the curative setting alongside radiotherapy.

KEY POINTS

- Conventional radiotherapy uses photons that both directly and indirectly damage the DNA, through the production of ions and free radicals. The majority of damage induced by photons is via this ‘indirect action’.
- Although the DNA is generally considered to be the most important target for radiation-induced damage, this dogma is gradually being amended to include effects on other cellular constituents, particularly cellular membranes.
- Tissues that are dividing rapidly manifest the effects of radiation sooner than those where cell division is slow. In addition to the kinetics (turnover rate) of the population as a whole, the response of tissues and organs is also dependent upon inherent cellular radiosensitivity. The sensitivity of the cell to radiation is determined to some degree by its state of maturity and its functional role, immature rapidly proliferating cells generally being more radiosensitive than slowly proliferating fully differentiated cells.
- The response of a tumour to radiotherapy is dependent upon inherent radiosensitivity, tumour cell repopulation, redistribution through the cell cycle (G2/M is the most sensitive phase of the cell cycle, late-S phase is the most radioresistant), repair of radiation induced damage and reoxygenation of tumour tissues between fractions. These parameters represent the ‘5 Rs of radiotherapy’.
- A fraction is the individual dose of radiation delivered at a single session of radiotherapy. In the treatment of head and neck cancer, a total course of radiotherapy will take several weeks and comprise numerous fractions. In conventional radiotherapy, fractions are given once a day, five days per week. The fraction size is, almost invariably, constant throughout a course of radiotherapy. Increasing the fraction size tends to have a greater effect (altered severity) on late-reacting as opposed to early-reacting tissues.
- Hypoxic cells (those under low O₂ tension) are relatively resistant to X-rays when compared with fully oxygenated ones. Chronic and acute hypoxia make tumours relatively radioresistant. If such hypoxia is overcome, radiotherapy is more likely to be successful.
- Many approaches to overcome tumour hypoxia have been evaluated – these include improving blood flow through the vascularized parts of tumours and pharmaceutical approaches to make hypoxic tumour cells more radiosensitive (radiosensitizer drugs).
- The nitroimidazoles have been extensively evaluated as potential radiosensitizers; however, controversy exists regarding the role of these agents in conventional radiotherapy. So far, only one major randomized trial, of the many that have been performed, has shown a therapeutic benefit (with nimorazole).
- Adjuncts to radiation, which are not true radiosensitizers, include bioreductive drugs. These agents are reduced intracellularly to form cytotoxic agents. A number have been evaluated in head and neck cancers.
- Perhaps a clinically more successful (therapeutic) strategy than trying to overcome hypoxia has been the rather more empirical approach of simply combining ‘conventional’ chemotherapy with radiotherapy. Meta-analyses have not been able to clearly identify which of the various adjuvant chemotherapy options is the best, although a strategy of giving cisplatin concurrently or in rapidly alternating sequences, with radiotherapy (perhaps with other drugs as well) has consistently emerged as the ‘front runner’.
- Novel, molecularly targeted, agents hold the promise of being much less toxic than conventional chemotherapy. Of the agents under evaluation, cetuximab, a humanized monoclonal antibody that competitively binds to EGFR, has undergone clinical trials in head and neck cancer used both as monotherapy and as combined therapy (radiation, chemotherapy). Results from a large randomized trial were very impressive in that improved locoregional control and reduced mortality have been obtained with little increase in toxicity. Other areas of optimism are in the field of immunotherapy where studies have demonstrated significant gains in the metastatic setting. Whether this will translate into clinical benefit in the curative setting with radiotherapy remains to be seen.

SEARCH STRATEGY

Data in this chapter may be updated by searching the following keywords used in PubMed: HNSCC, oropharyngeal, apoptosis, necroptosis, autophagy, senescence, radioresistance, p53, HPV (human papilloma virus), cetuximab and epidermal growth factor receptor (EGFR).

INTRODUCTION

The aim of this chapter is to summarize current understanding of apoptosis and cell death from a clinical perspective, focussing on the head and neck. Reviews cited here have been selected for importance or clear explanations. The basis behind some of the methods to measure cell death is explained to assist in evaluating primary research papers. Emphasis is placed on the role of evasion of apoptosis in head and neck squamous cell carcinoma (HNSCC), although the role of cell death in other processes may be of interest to the specialist clinician, for example: cancers of the head and neck; head and neck development; palatal shelf fusion and cleft palate; autoimmune disease; and hearing loss due to ageing, noise, or exposure to ototoxic agents.

INTRODUCTION TO APOPTOSIS

Apoptosis as a mechanism of programmed cell death regulates cell numbers in tissues and is a key response to cellular damage that cannot be repaired. Resistance to apoptosis is one of the hallmarks of cancer,^{1, 2} whereas increased apoptosis contributes to autoimmune and neurodegenerative conditions. In the ear, apoptosis of terminally differentiated sensory hair cells contributes to hearing loss caused by ototoxic agents such as aminoglycoside antibiotics and cisplatin chemotherapy, as well as that caused by excess noise over a prolonged time and general age-related hearing loss.³ Our understanding of apoptosis regulation provides cancer diagnostic and prognostic markers and is

leading to development of cancer therapies specifically targeting cell survival pathways or mimicking pro-apoptotic signalling molecules. Approaches involving sensitization to radiotherapy and chemotherapy are being taken as an alternative to the concept of single agent therapies for cancer. These highlight the need for personalized medicine, such that drugs are given to patients whose cancers, and indeed elusive ‘cancer stem cells’, can be predicted to respond by undergoing programmed cell death.

There are two signalling pathways that result in apoptosis, the mitochondrial (intrinsic) and the death receptor (extrinsic) pathways. Both involve activation of a family of enzymes called the caspases. Caspases are cysteine proteases that cleave after aspartic acid residues. Caspases are named in the order of their discovery, and while caspases 1, 4 and 5 are involved primarily in the processing of inflammatory mediators, caspases 2, 8, 9 and 10 have roles as initiator caspases for cell death signals, activating downstream effector caspases 3, 6 and 7, which target cellular proteins leading to the condensation of the cell and dissolution of the nuclear membrane. Hundreds of proteins are cleaved by caspases, usually at single sites. Some are cleaved as bystanders, but many structural and regulatory proteins are inactivated by caspases. Some substrates can be activated by cleavage – such as other caspases and Bid (see the section ‘Death Receptor Pathway to Apoptosis’ below). By cleavage of an inhibitor protein (ICAD), they release a caspase-activated deoxyribonuclease (CAD) that cleaves the DNA of the cell into oligomeric fragments that are integer multiples of 180–200 base pairs. This cleavage pattern can be detected on DNA electrophoresis as a

'DNA ladder'. The cleavage of DNA ensures that the cell is no longer capable of replication, and the destruction of the translational machinery restricts protein synthesis.

In haematoxylin and eosin stained sections of tissue, apoptotic cells are characterized by condensed chromatin that appears intensely purple stained in smooth shapes. Early stages show chromatin condensed around the periphery of the nuclear membrane, prior to its dissolution, frequently in crescent shapes. As the nuclear membrane disappears, apoptotic cells exhibit single smooth chromatin mass, which subsequently fragments to smaller smooth shaped chromatin masses that can be scattered throughout the cell. Loss of cell–cell and cell–matrix contact, along with shrinkage and rounding up of the cell as the cytoskeletal proteins are cleaved, results in the apoptotic cell appearing isolated among the tissue. The plasma membrane is seen to undergo 'blebbing' and the cell may fragment into apoptotic bodies following invagination of the plasma membrane. Cleavage of poly (ADP-ribose) polymerase (PARP-1) by caspases 3 and 7 gives two fragments of apparent molecular weights of 25 and 85kDa. These have since been designated as 24 and 89kD from sequence data. The p85/89 large fragment is a popular marker for identifying apoptosis, either by protein electrophoresis or by using antibodies that specifically recognize this fragment of the cleaved protein for immunostaining of cells or tissues. It is an earlier marker than DNA fragmentation (Figure 6.1).⁴

All caspases are produced as inactive zymogens, and are activated by either autocleavage (in the case of initiator caspases) or other upstream caspases. The procaspase is cleaved in two places – a prodomain is removed and two subunits are generated, a large subunit and a small subunit. These are assembled into the active enzyme which is a heterotetramer with head-to-tail alignment of the subunits. As a result of this, protein electrophoresis detection of the small and/or large subunits is indicative of caspase cleavage. *In vivo* detection of apoptosis by immunohistochemistry is facilitated by use of antibodies

that recognize only the cleaved, active form (Figure 6.1). DNA fragmentation has also been used as a way to detect apoptotic cells. The terminal deoxynucleotide transferase-mediated dUTP-biotin nick end labelling (TUNEL) assay detects both double and single strand breaks by adding labelled dUTP to free 3'-hydroxyl termini of fragmented DNA. The problem with this method is that it picks up DNA fragmentation occurring during necrotic cell death and should therefore be used in conjunction with other methods of apoptosis detection. Alternative *in situ* ligation (ISL) techniques label only 5' double-stranded DNA breaks with either blunt ends or a 3' single base overhang with terminal phosphates, allowing for more specific detection of apoptosis-mediated DNA fragmentation over either necrosis or repairable DNA damage.⁵

The ultimate fate of apoptotic cells *in vivo* is to be phagocytosed by macrophages or neighbouring cells acting as semiprofessional phagocytes. The membrane of apoptotic cells is altered to prevent leakage of intracellular material until phagocytosis, a process involving protein cross-linking by tissue transglutaminase. The lipid components of the membrane are also altered, in that phosphatidyl serine, normally only present on the inner membrane leaflet, is flipped into the outer leaflet and exposed on the cell surface, enabling macrophages to identify and engulf the dying cell. The engulfment of the cell prior to loss of plasma membrane integrity is key to the process of eliminating excess or damaged cells without eliciting an inflammatory response. If this does not occur, the plasma membrane becomes permeable, and the cell is said to undergo 'secondary necrosis', with the leakage of damage-associated molecular pattern molecules (DAMPs) able to elicit a non-infectious immune response. It is exposure of phosphatidyl serine on the outer leaflet that is recognized in the Annexin V assay. Annexin V is an anticoagulant protein from human placenta that binds to phosphatidyl serine lipids.⁶ Labelled Annexin V binding in conjunction with propidium iodide staining of unfixed cells distinguishes early apoptosis, as cells that

Figure 6.1 Cleaved caspase 3 staining highlights apoptotic cells in human tissue. Staining of apoptotic cells using an antibody that detects active caspase 3 in a human oral squamous cell carcinoma section. (a) Low magnification ($\times 10$ objective). (b) Higher magnification ($\times 40$ objective).

are not permeable to propidium iodide but are Annexin V positive. However, once the plasma membrane becomes permeable, it can no longer distinguish apoptosis and secondary necrosis, because Annexin V then has access to the inner plasma membrane leaflet. For use in fixed cells or *in vivo*, the cells are labelled before fixation.

OTHER TYPES OF CELL DEATH

Terminal differentiation

Apoptosis is a physiological event that contributes to maintenance of tissues with constant turnover of cells such as the gut epithelium. Tissue homeostasis is maintained by a balance between cell proliferation, differentiation and cell death. However, terminal differentiation in the skin, and indeed oral epithelium, is regulated by a process involving caspase 14. This is a distinct process from apoptosis.⁷

Necrosis

Apoptosis is distinct from necrosis, a pathological, passive process of cellular destruction (Table 6.1). Necrosis involves cell swelling and nuclear chromatin ‘flocculation’ where the swelling nucleus appears more diffuse than normal. Ultimately the cells lyse without detaching from their neighbours and the release of intracellular contents stimulates inflammation.

Necroptosis

Although necrosis is a passive process, a programmed cell death mechanism resulting in necrotic-like death has been identified that is termed ‘necroptosis’, specifically signalled by receptor-interacting serine/threonine-protein

kinases 1 and 3 (RIPK1 and RIPK3) in response to signalling through the tumour necrosis factor receptor (TNFR) family members, toll-like receptors (TLR3 and TLR4) or T-cell receptors (TCR), or in response to DNA damage and viral infection.^{9, 10} RIPK3 phosphorylates mixed lineage kinase domain-like protein (MLKL) which homooligomerizes and relocates to the plasma membrane. This appears to be key to the necroptosis signalling pathway, but RIPK1 may or may not be needed.¹¹

Necroptosis primarily appears to occur when caspases are inhibited, and one reason why apoptosis normally takes precedence over necroptosis is because active caspase 8 can cleave RIPK1 and RIPK3.⁹ Viral infection is a situation that can result in necroptosis because viruses inhibit caspases. Where tumour cells have become apoptosis resistant (perhaps through similar mechanisms to viral infection) necroptosis might be a useful way to eliminate tumour cells, although the consequences of the induction of inflammation to the tumour microenvironment will have to be considered.^{12, 13} While microscopically necroptosis appears as a swollen cell with formation of a balloon-like structure, known as oncosis, methods to identify necroptosis currently involve biochemical and fluorogenic assays on lysates or living cells, use of genetically modified mice or cells with RIPK3 or MLKL knockdown, or use of necrostatin and other more specific RIPK1 inhibitors to block the process.¹³

RIPK3^{-/-} and *MLKL*^{-/-} mice have revealed that necroptosis contributes to ischemia-reperfusion injury and chronic neurodegenerative disorders.¹¹ Necroptosis is not the only form of ‘regulated necrosis’ and if multiple pathways lead to cell death with similar morphology, clear understanding of these molecular pathways is needed to devise ways to distinguish these in human tissues as well as to distinguish RIPK3 activation in necroptosis from its role in inflammation.

TABLE 6.1 Summary of differences between apoptosis and necrosis⁸

	Apoptosis	Necrosis
Occurrence	Part of physiological or pathological processes	Always pathological
Initiating factors	Range of extracellular and intracellular factors	Direct result of injury and cellular anoxia
Distribution	Isolated apoptotic cells scattered widely throughout tissues	Occurs in groups/whole areas of tissue
Mechanism	Active process – ATP dependent Regulated mechanism	Passive Regulation lost
Cytoplasmic changes	Cytoplasmic shrinkage Blebbing of cell membrane into apoptotic bodies Many organelles preserved and bound into apoptotic bodies	Swelling of cell membrane Rupture of cell membrane with loss of contents to extracellular space Organelles lost
Nuclear changes	Endonuclease activation, cutting of DNA into oligosomal fragments Chromatin condenses into specific ‘crescents’ visible on light microscopy	Random digestion of DNA Chromatin flocculates
Effect on surrounding tissue	Little or none	Intense inflammation

Autophagy for survival – or autophagic cell death?

Macroautophagy is a process by which cytoplasm and organelles are engulfed into double membrane bound vesicles called autophagosomes (self-eating), which ultimately fuse with lysosomes for digestion and recycling of contents by lysosomal hydrolases. This process is utilized, for example, in situations of starvation, oxidative stress or hypoxia. Publications frequently specify that it is macroautophagy that is the form of autophagy being referred to (i.e. the use of autophagosomes to transport cargo to the lysosome) and then simply use the term ‘autophagy’ thereafter. Tumour cells are believed to utilize this process, promoting survival of tumour cells in unfavourable conditions. Autophagy contributes to chemotherapy resistance, for example in esophageal cancer cells treated with cisplatin or 5-fluorouracil.¹⁴ Some agents can induce excessive autophagy leading to cell death, but the consequence of autophagy can be context dependent and the microenvironment can adjust the threshold at which autophagy levels promote cell survival or cell death. There is now believed to be cross-talk between the processes of apoptosis, autophagy and ‘regulated/programmed necrosis’.¹⁵

Measurement of autophagy is difficult, as demonstration of flux of autophagosomes is currently the gold standard method, and this requires living cells in which flux can be blocked at different stages. The autophagy flux reporter mCherry-GFP-LC3 works on the principle that the GFP (green fluorescent protein) signal is sensitive to the acidic and/or proteolytic conditions inside the lysosome, whereas mCherry (red) fluorescence persists. This has been used to show autophagic flux in mouse neurones *in vivo* by adeno-associated virus delivery – autophagosomes appear as yellow dots and autophagolysosomes appear as red dots.¹⁶ A multiprotein class III phosphatidylinositol-3 kinase (PI3K) complex is needed to produce the isolation membranes that engulf cellular components and pinch off of membranes (usually the endoplasmic reticulum) to form the autophagosomes. Knockdown of active components of this complex can be used to demonstrate if autophagy is important in a particular cellular outcome, for example cell survival or cell death.

KEY POINTS

- Apoptosis eliminates damaged cells or cells in excess to requirement.
- Apoptosis involves destruction of the cell by caspases, but the cells are normally engulfed by phagocytes *in vivo*.
- Excessive apoptosis contributes to autoimmune diseases such as oral lichen planus and degenerative conditions such as apoptosis of the sensory hair cells of the ear, contributing to hearing loss.
- Resistance to apoptosis is a hallmark of cancer and contributes to therapeutic resistance.
- Necroptosis involves signalling by RIPK3 and MLKL and is known as ‘regulated necrosis or programmed necrosis’.
- Autophagy involves digestion of cellular material in autophagolysosomes for use as recycled metabolites and is generally a cytoprotective process; it can contribute to resistance to cancer therapy.

MECHANISMS OF APOPTOSIS REGULATION

Mitochondrial pathway to apoptosis

Bcl-2 was originally described as a protooncogene in B-cell lymphomas. In follicular lymphoma the t(8;14) translocation moves Bcl-2 to the immunoglobulin heavy chain locus, leading to its overexpression. Bcl-2 is located in the outer mitochondrial membrane but is also detected in the plasma membrane and endoplasmic reticulum. Its mitochondrial localization allows it to regulate the release of cytochrome c from the intramembrane space into the cytosol and it is this release that is required for the activation of the initiator caspase, caspase 9. Cytochrome c release can be measured as a characteristic marker of a cell’s early apoptotic response.¹⁷ A family of Bcl-2 proteins has been identified (Table 6.2), some of which are anti-apoptotic like Bcl-2; others are pro-apoptotic.¹⁸ Whereas Bcl-2 is localized constitutively to membranes, the anti-apoptotic Bcl-X_L, Mcl-1 and Bcl-w members of the family are located in the cytoplasm and localize to the mitochondria upon receipt of an apoptotic signal.¹⁹ Bax is a pro-apoptotic protein that was identified as a homologue that bound Bcl-2. When overexpressed, Bax accelerated cell death in response to cytokine deprivation. By contrast, overexpression of Bcl-2 allows cells to tolerate signals to undergo apoptosis. Bcl-2 and other anti-apoptotic family members do this by sequestering pro-apoptotic family members such as Bax and by regulating ion flux to prevent mitochondrial outer membrane depolarization which is required for cytochrome c release.¹⁷ Interestingly, Bax is not always bound to Bcl-2 in viable cells, but cycles on and off mitochondria in a dynamic equilibrium.²⁰ Bcl-X_L has also been shown to actively transport Bax from the mitochondrial membrane to the cytoplasm.¹⁹ The Bax homologue Bak serves a similar function. Both Bax and Bak function as homooligomeric complexes to release cytochrome c from the mitochondria. Although Bax and Bak mediate responses to different types of cellular stress, the outcome downstream of the mitochondrion is the same, and in fact there is some functional redundancy, as only cells lacking both Bax and Bak molecules fail to undergo apoptosis.²¹ By contrast to Bax, which translocates to the

TABLE 6.2 Most commonly studied Bcl-2 family members

mitochondrion in response to apoptosis signals, Bak is localized in the outer mitochondrial membrane.

Released cytochrome *c* binds to the adapter protein Apaf-1, causing a conformational change that allows it to bind dATP. In turn, this triggers oligomerization to a heptamer and exposes the caspase recruitment domain (CARD) of Apaf-1 allowing recruitment of procaspase 9. The heptameric wheel-like structure carrying procaspase 9 at its hub constitutes an activation platform for caspase 9 and is termed the apoptosome (Figure 6.2). Autocleavage of procaspase 9 generates active caspase 9,

the initiator of apoptosis, which subsequently activates further caspases.

While Bcl-2 and most anti-apoptotic proteins of the family have four domains of Bcl-2 homology (BH domains), Bax and Bak have three (BH1-3), which in the folded molecule comprise a hydrophobic groove used for dimerization with the anti-apoptotic proteins. Upstream of the mitochondrion, in addition to Bax translocation, so called 'BH3-only' proteins sense apoptotic signals and transmit these to the mitochondrion. They compete with Bax and Bak for Bcl-2 binding, and displaced Bax is free to

Figure 6.2 Apoptotic signalling. In the mitochondrial cell death signalling pathway, the molecules Bax and Bak can each form homooligomers that release cytochrome *c* from the inner membrane space of the mitochondrion. These are negatively regulated by anti-apoptotic members of the Bcl-2 family, represented here as Bcl-2. Once released, cytochrome *c* binds to monomeric Apaf-1, which in the presence of ATP can oligomerize into a heptamer called the apoptosome (blue). Procaspase 9 is recruited to the caspase recruitment domain (CARD) that forms the hub of the apoptosome. Here it autocatalytically cleaves to give rise to a highly active caspase 9 enzyme, which can then activate downstream executioner caspases, represented here by caspase 3. In the death receptor signalling pathway, trimerized receptors recruit the adapter molecule FADD, which recruits procaspase 8, which is autocatalytically processed to form the active enzyme. In type I cells this can result in caspase 3 activation and apoptosis. In type II cells, the BH3-only member of the Bcl-2 family, Bid, is cleaved to a form that can translocate to the mitochondria and interact with Bcl-2 to displace Bax or interact directly with Bax itself and by either of these mechanisms facilitate cytochrome *c* release, thus engaging the mitochondrial signalling pathway. In type II cells, Bcl-2 overexpression can block death receptor induced apoptosis but in type I cells it does not.

homooligomerize and release cytochrome c. This is the 'sensitizer' function of BH3-only proteins. Some can interact with Bax directly to facilitate conformation change, oligomerization, pore formation and cytochrome c release. This is the 'direct activator' function of BH3-only proteins and a model has been proposed whereby the BH3 protein binds transiently to a rear pocket on Bax distal to the hydrophobic groove.²² It is likely that Bak does not require this activation because it is already located in the mitochondrial membrane.¹⁹ Whereas Bad is only capable of sensitizer function, Bim, Bid and Puma can serve as direct activators.²³ Different BH3-only proteins mediate different apoptosis signals. In terms of the anti-apoptotic proteins, these may regulate cell life and death during tissue homeostasis at different stages in cellular differentiation, for example in the colonic crypt, Bcl-2 protects proliferative cells from apoptosis, whereas Bcl-X_L protects the post-mitotic cells in the upper regions of the crypt.²⁴ The BH3-only proteins also have preferred anti-apoptotic binding partners, for example Bad binds strongly to Bcl-2, Bcl-X_L and Bcl-w, whereas Noxa binds Mcl-1 and Al.²⁵

Small molecule drugs have been designed that mimic BH3-only proteins in their action. The most extensively clinically tested of these is ABT-263 (navatoclax; AbbVie), but this does not bind Mcl-1 or Al. Obatoclax (Gemin X) binds both Bad and Noxa targets and is being tested clinically for anti-cancer activity in advanced haematological malignancies. Others are being tested in preclinical models. Interestingly, obatoclax more efficiently induces apoptosis of HNSCC cell lines if autophagy is inhibited by choroquine.²⁶

Mitochondrial apoptosis induced by reactive oxygen species is believed to underlie ageing-related deafness and ototoxicity of some pharmaceuticals including aminoglycoside antibiotics such as gentamycin. Resistance to broad spectrum antibiotics and the increase in methicillin-resistant *Staphylococcus aureus* (MRSA) has led to reconsideration of gentamycin. The hair cells are the primary target of ototoxicity but auditory and vestibular ganglion neurons can also undergo cell death.²⁷ Different *in vitro* and *in vivo* models implicate apoptosis, necrosis or necroptosis as well as cell death subsequent to extrusion from the epithelium. Reactive oxygen species (ROS) generation is believed to induce mitochondrial apoptosis mediated by p53 or c-Jun N-terminal kinase (JNK).²⁷ Mutations in mitochondrial DNA encoding the 12S ribosomal RNA component of the mitochondrial ribosomes lead to its hypermethylation. Raimundo et al.²⁸ provided evidence for a model in which A1555G mutation, which confers susceptibility to aminoglycoside-induced deafness, led to enhanced ROS production, and AMP-kinase-dependent induction of the transcription factor, E2F1. E2F1 was expressed at levels high enough to induce pro-apoptotic genes rather than promote cell proliferation. In a mouse model, cleaved caspase 3 positive cells were detected in the stria vascularis and the spiral ganglion neurons, but not in the organ of Corti.²⁸ A T1095C mutation in the same gene also confers susceptibility to gentamycin mediated apoptosis in an *in vitro* model.²⁹ Therefore, patients susceptible

to gentamycin-induced ototoxicity could be identified by genetic screening. Free radical scavengers have been suggested to protect from aminoglycoside-induced toxicity.³⁰

Death receptor pathway to apoptosis

Cells can be induced to undergo apoptosis via engagement of cell surface death receptors (DR) with ligand molecules. These receptors form the tumour necrosis factor receptor family, the other members of which are Fas (APO1/CD95), DR3 (APO3), DR4 (TRAIL-R1) and DR5 (TRAIL-R2). Cell signalling was first elucidated for Fas, which is bound by Fas ligand (Fas-L). The source of Fas ligand may be in membrane-bound form presented on the surface cytotoxic T cells. The Fas ligand-Fas system normally eliminates excess T cells during an immune response, and defects in this signalling can be involved in autoimmune disease. Oral lichen planus involves epithelial apoptosis mediated by Fas ligand due to infiltration of inflammatory cells underneath the oral epithelium. Lichen planus is a condition with a high apoptotic index and is a useful positive control for apoptosis staining.

In apoptosis signalling, receptor trimerization leads to recruitment of FADD (Fas-associated death domain), which binds the intracellular death domain (DD) portion of Fas, and procaspase 8 molecules bind to the death effector domain (DED) of FADD (Figure 6.2). Hence, procaspase 8 molecules are clustered and activated by autocleavage on a platform known as the death inducing signal complex (DISC). Trimerized receptors may also cluster into receptor microaggregates. In some cell types (type I cells), caspase 8 activation at the DISC is sufficient for downstream effector procaspase cleavage, but in many cell types (type II cells), the mitochondrial pathway is engaged to amplify the death signal by caspase 8-dependent cleavage of the BH3-only protein Bid, converting it to a form that is able to transmit the apoptotic signal to the mitochondrion. In addition, cytotoxic T cells release perforin, which penetrates the epithelial cell membrane, and granzyme B, a serine protease that can cleave and activate Bid, hence engaging the mitochondrial pathway.

Expression of high levels of Fas ligand by tumour cells can allow them to evade infiltrating T cells that express Fas, so called tumour 'counter-attack'.³¹ Tumour-produced Fas may be soluble, as tumour cells may exhibit resistance to Fas-mediated apoptosis. Fas mutations have been found in sporadic myeloma and T-cell leukaemia leading to evasion of apoptosis. FLIP is a molecule that structurally resembles caspase 8 and is able to bind FADD and hence block death receptor signalling. Indeed for death receptors we now know that large complexes can be formed both at the receptors themselves or in complexes that are released into the cytoplasm, and the constitution of these determines downstream signalling consequence. For example, Fas ligand can induce cell survival and contribute to tumour promotion by inducing JNK, ERK (extracellular signal-regulated kinases), NF- κ B (nuclear factor kappa-light-chain-enhancer of activated B cells) and PI3K (phosphatidylinositol 3-kinase)

signalling pathways.³² Tumour necrosis factor-related apoptosis-inducing ligand (TRAIL) induces apoptosis through two of its receptors DR4 (TRAIL-R1) and DR5 (TRAIL-R2). Decoy receptors that bind ligand but do not signal apoptosis can be overexpressed in some cancers. For example, TRAIL-R3 is overexpressed in acute myeloid leukaemia, especially on cancer stem cells.³³ TRAIL-R4 can signal to activate Akt in HeLa cervical carcinoma cells independently of ligand binding, but the mechanism is not yet understood.³⁴

Agonistic antibodies that engage death receptors are in trials for various cancers in which the signalling pathway is intact – for example, the TRAIL-R1 antibody Mapatumumab and the TRAIL-R2 antibody Lexatumumab. As single agents these were initially disappointing, in part because TRAIL receptors must trimerize in order to signal effectively, and an antibody can only cross-link two death receptors.³⁴ However, their combination with other agents is looking more promising, at least *in vitro*. Agents inducing synergistic apoptosis include chemotherapeutic drugs, histone deacetylation inhibitors, proteasome inhibitors, NF- κ B inhibitors and BH3 mimetics. Moreover, new TRAIL receptor antibodies that will form higher order complexes are being developed.³⁵ Other recent strategies use more stable versions of the TRAIL trimer, targeted delivery of TRAIL in nanoparticles, and tumour-targeting of TRAIL constructs.³⁶

p53 ‘guardian of the genome’

Normally wild type p53 protein is rapidly turned over due to its binding to the ubiquitin ligase HDM2 (the human homologue of MDM2), which ubiquitin-tags it for destruction by the proteasome. In recognition of DNA damage, p53 is stabilized and can be detected as nuclear staining. p53 is extensively post-translationally modified and this regulates its binding partners and which gene promoters it engages with. Hence, p53 can activate transcription of either cell cycle arrest and DNA repair genes or genes encoding proteins that promote mitochondrial apoptosis such as Bax, Puma, Noxa and Apaf-1. p53 can also induce Fas, TRAIL, TRAIL-R2, hence modulating death receptor signalling. More recently, p53 has been shown to activate transcription of autophagy regulators under cell stress conditions.³⁷ p53 knockout mice are developmentally normal, and therefore p53 is thought to play a minimal role in development. However, defects in developmental genes can lead to p53-dependent apoptosis, for example the apoptosis of neural crest cells resulting in craniofacial hypoplasia syndromes such as Treacher Collins.³⁸

THE PI3K/AKT AND MAPK/ERK PATHWAYS TO CELL SURVIVAL

In response to engagement of tyrosine kinase receptors, G-coupled protein receptors, integrins, and toll-like receptors, the lipid kinase PI3K phosphorylates phosphatidylinositol 4,5-bisphosphate (PIP2) to generate

phosphatidylinositol 3,4,5-triphosphate (PIP3). PTEN antagonizes this pathway by removal of the phosphate at this position of the inositol ring.³⁹ PIP3 recruits Akt to the plasma membrane ready for activation. Then, upon its activation by phosphorylation, Akt can move to different locations within the cell to phosphorylate many molecular targets, some of which are key regulators of cell survival – for example, Akt-dependent phosphorylation contributes to Bad and caspase 9 inactivation. It also inactivates the Forkhead family of transcription factors that induce expression of pro-apoptotic factors and activates mTOR (mammalian target of rapamycin), a key regulator of autophagy and cell survival in situations of cell stress. The *PIK3CA* gene encodes p110 alpha (p110 α) subunit of PI3K and can be mutated in HNSCC.⁴⁰

The mitogen-activated protein kinase MAPK/ERK pathway downstream of Ras activates transcription factors promoting cell survival; however ERK phosphorylation can also lead to phosphorylation, ubiquitination and proteosomal degradation of the ‘extra long’ isoform of the BH3-only protein, Bim.

Apoptosis and head and neck squamous cell carcinoma

Although resistance to apoptosis is a hallmark of cancer, this does not mean that cancers do not exhibit apoptosis. Apoptosis is uncommon in normal squamous epithelium and eliminates damaged cells rather than contributing to normal tissue homeostasis. The apoptotic index is higher in dysplasia and in HNSCC than corresponding normal tissue.

The genetic changes in head and neck squamous cell carcinoma (HNSCC) have been reviewed by Rothenberg and Ellisen,⁴¹ in particular the exome sequencing results published in *Science* in 2011 by Agrawal et al.⁴² and Stransky et al.⁴³ These include changes that subvert the balance between proliferation, differentiation and apoptosis:

- *CDKN2A* loss (gene encoding tumour suppressor protein and cyclin-dependent kinase inhibitor, p16^{INK4a})
- *CCND1* amplification (gene encoding cyclin D1)
- loss of *TGFBR2* (gene encoding the type II transforming growth factor β receptor) or *SMAD4* (gene encoding the TGF β signalling molecule), which promote proliferation
- *NOTCH1* loss and/or abnormal expression of *TP63*, both of which deregulate keratinocyte differentiation
- alterations in *CASP8* (gene encoding caspase 8), *EGFR* (gene encoding the epidermal growth factor receptor (EGFR) and *PIK3CA* genes, which promote cell survival.

Loss or mutation of *TP53* is common, leading to defective cell cycle arrest and repair or apoptosis. Mutations in *TP53* can result in stabilized, mutant p53 that lacks function. Alternatively, tumours may lack p53 altogether. Hunter et al.⁴⁴ suggested that ~40% of HNSCCs may develop without acquiring immortality and retain wild type p53 and p16. These tumours would likely have

better prognosis. Interestingly, cisplatin induces senescence in HNSCC cells with wild type p53.⁴⁵

In development of HNSCC, *TP53* mutations appear early and contribute to ‘field cancerization’, whereby epithelium that is histologically normal actually carries mutation, and to around half of HNSCC cases. Hence, ways to kill cells harbouring mutant p53 or reconfigure mutant p53 to a transcriptionally active confirmation are being explored. ONYX-015 (dl1520) is an adenovirus modified to only replicate in and kill cells that harbour p53 mutations. Wild type adenoviruses must disable p53 before viral replication can occur and because ONYX-015 has a mutant E1B 55K gene, it cannot neutralize p53, therefore cannot replicate in cells with wild type p53 and does not kill them. Oncolysis of mutant p53-containing tumour cells leads to spread of viral particles and subsequent rounds of tumour-specific replication and cell killing. This virus is in phase III trials for head and neck cancer in the USA. H101, a similar virus to ONYX-015, is licensed in China for treatment of head and neck cancers.⁴⁶ An alternative is to use a replication-deficient adenovirus that expresses wild type p53. Phase II/III trials in HNSCC are showing increased patient survival.⁴³ Small molecules designed to directly reactivate mutant p53 protein are specific to the type of mutation; PRIMA-1(Met) stabilizes unfolded p53 and a ‘first in human’ study was published in 2012.⁴⁷

Risk factors for HNSCC are primarily smoking and alcohol consumption, with dietary contribution.⁴⁸ However, human papilloma virus (HPV) infection, particularly of subtype 16, can increase the risk of oropharyngeal cancer over 4-fold.⁴⁹ Unsurprisingly, human papilloma virus positive (HPV⁺) is genetically distinct from HPV⁻ HNSCC,⁵⁰ and patients have longer overall survival and respond better to treatment. Viral proteins E6 and E7 accelerate the degradation of p53 and p16 respectively,

resulting in cellular immortalization and reduced ability of cells to repair genetic damage or undergo apoptosis. HPV⁺ tumours rarely carry p53 mutations, as the E6 protein targets p53 for degradation, yet HPV⁺ cell lines are generally more radiosensitive than HPV⁻ cell lines, exhibiting a prolonged G2 arrest and increased apoptosis because of residual wild type p53.⁵⁰ It should be emphasized that apoptosis can occur by p53-independent mechanisms; for example, HNSCC cells can respond in this way to γ -irradiation.⁵¹

Since E7 decreases pRb, it frees the transcription factor E2F, normally sequestered by the pRb, permitting cell cycle progression. p16 increases in a negative feedback response. Therefore, whereas reduced p16 is common in HPV⁻ HNSCC, in HPV⁺ cases it tends to be enhanced. Grønhoj Larsen et al.⁵² found by systematic review that studies classifying ‘p16 positivity’ as tumours with a proportion of cells 70% or greater showed strongest correlation with HPV positivity. Using this scoring system, Rietbergen et al.⁵³ caution that there is also a possibility that p16 positivity may occur independently of HPV involvement, although they analysed HPV DNA and mRNA from formalin fixed paraffin-embedded tumour material and recommended that assays in fresh frozen tissue be conducted. They noted that p16⁺/HPV⁻ tumours had higher frequency of loss of heterozygosity on chromosomes 3p, 19p and 17p, similar to HPV⁻ tumours.

EGFR activation activates MAPK and PI3K/Akt signalling pathways (Figure 6.3). The EGFR and PI3K/Akt/mTOR signalling pathways are of current interest for molecular targeted therapeutics, as they are hyperactivated in HNSCC and contribute to radioresistance.⁵⁴ Although the EGFR is rarely mutated in HNSCC, increases in gene copy number do correlate with poor prognosis, and the possibility that EGFR ligands are present in the tumour microenvironment has been suggested.⁴¹ The monoclonal

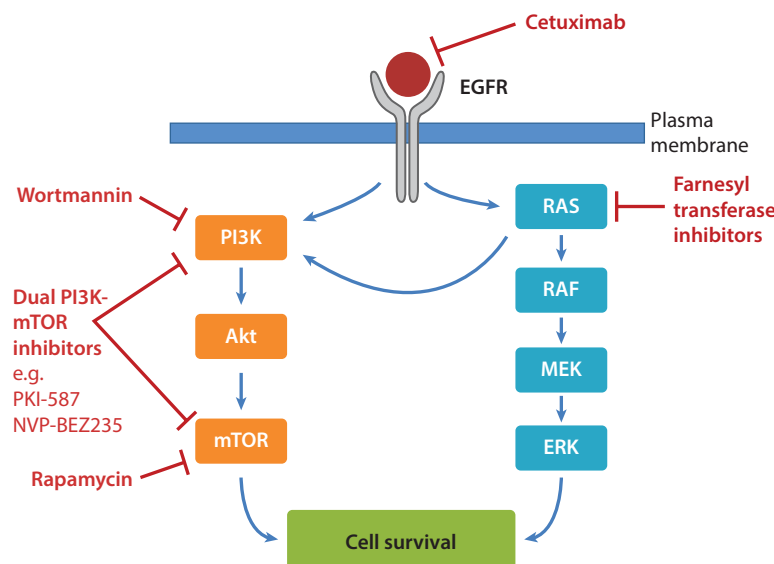

Figure 6.3 Survival signalling and potential targets for cancer therapy. The PI3K and Ras signalling pathways are hyperactivated in HNSCC. There is crosstalk between these two pathways; for example, Ras can potentiate PI3K activity. Targeting a single molecule is ineffective because of development of drug resistance and cells adapt their signalling pathways to overcome the block. Hence strategies are being developed that combine agents with different targets or use drugs with more than one molecular target.

antibody cetuximab targets the EGFR and is now used clinically to significantly enhance patient survival, but resistance remains a problem with downstream activation of PI3K/Akt/mTOR contributing to this. Similarly, resistance to PI3K inhibitors occurs due to the cancer cell's ability to adapt its signalling circuits and to engage feedback mechanisms. Hence, there is a move away from use of single target therapies towards evaluation of combination approaches. Use of PI3K or dual PI3K-mTOR inhibitors in combination with cetuximab is currently being explored.

Cancers with *HRAS* mutation are not likely to respond to EGFR-targeted therapies. Active Ras is needed for Akt activation in HNSCC cells.⁵⁵ Farnesyl transferase inhibitors that inhibit activity of Ras and Akt could be an area for research. Cetuximab combined with radiotherapy or chemotherapy is more likely to prolong survival for patients with oropharyngeal carcinomas rather than laryngeal or hypopharyngeal cancers. Although it has been speculated that HPV⁺ cancers may respond better to cetuximab, this has yet to be investigated.⁵⁶

FUTURE RESEARCH

Molecular targeting approaches are being developed to sensitize tumours to mitochondrial mediated apoptosis (BH3 mimetics at the forefront) and to optimize apoptosis utilizing TRAIL receptor signalling pathways, approaches that may potentially be applicable to HNSCC and nasopharyngeal carcinoma. Frequently, work on cancers of the head and neck lags behind that of other more common cancers. Knowledge can be applied across tumour types, if a full understanding of the molecular basis of the cancer is obtained. Even within HNSCC, subtypes

exist that need to be considered when testing agents and drug combinations, and in particular when dealing with the potential for resistance. The potential for inhibiting autophagic cell survival mechanisms could be explored further in these cancers. There is current interest in inhibiting PI3K and mTOR survival pathways. Given the increasing HPV⁺ HNSCC incidence and low take-up of HPV16 vaccination, targeting HPV DNA or E6 protein in HPV⁺ cancers to sensitize to p53-mediated apoptosis may be appropriate.

KEY POINTS

- Compromised p53 function leads to resistance to p53-mediated cell cycle arrest and DNA repair as well as apoptosis, leading to accumulation of genetic damage.
- HPV⁺ HNSCC is genetically distinct from carcinogen-induced HNSCC and is more likely to respond to traditional therapies; this may be in part because of residual wild type p53 that is not fully degraded in response to E6 binding.
- Targeting of overexpressed epidermal growth factor receptor (EGFR) using the monoclonal antibody cetuximab is currently used clinically.
- In HNSCC genetic changes resulting in defects in the PI3K/Akt and Ras/MAPK signalling pathways are common and because tumour cells adapt to single target therapies, a combination approach is being tested.
- The diversity of HNSCC tumours calls for screening approaches and personalized treatment to maximize cell death and overcome resistance to therapy.

SEARCH STRATEGY

Data in this chapter may be updated by Medline searches based mainly on various combinations of the terms 'stem cells', 'embryonic stem cells', 'tissue regeneration' and 'otolaryngology'. Other sources include published and unpublished information from the author's laboratories.

INTRODUCTION

Tissue abnormalities of the head and neck region, arising from disease, injury or developmental defects, often pose considerable regenerative problems. Historically, the efficacy of surgical reconstruction has been limited by a lack of suitable autologous tissues for reparative or regenerative procedures but the development of methods for *in vitro* and *in vivo* tissue expansion, together with advances in tissue engineering, now provide new therapeutic options.¹ It has become apparent that stem cells, of which there are several varieties, are the cells ultimately responsible for all normal tissue generation and regeneration. Therapeutic regeneration of new tissues therefore also typically depends on direct or indirect manipulation of stem cells and such cells are now a major focus for research. A relatively new aspect of stem cell biology relates to the roles of stem cells in malignancy. This too is of markedly increasing research interest that focuses on their roles in metastasis and the need to target them therapeutically.

Entering the search term 'stem cells' into the PubMed database indicates that more than 20 000 papers relating to stem cells were published in 2015 alone (<http://www.ncbi.nlm.nih.gov/pubmed>). This brief chapter can only outline some of the aspects of stem cells potentially relevant to otorhinolaryngology and head and neck surgery. The initial aim will be to put stem cells in perspective by outlining the different sorts of stem cells that exist and by describing their common features. The second aim will be

to outline current directions of stem cell research related to their potential clinical applications in otolaryngology.

GENERAL BACKGROUND: STEM CELL TYPES AND PROPERTIES

Adult tissue-specific stem cells

It has been known for well over a century that many tissues of the body are continuously renewed by cell division. Detailed studies of cell division in bone marrow, now over 50 years old, indicated that many blood forming cells have some ability to divide but that the ability to divide persistently, the key feature of stem cells, is possessed by only a subset of cells. Subsequent studies indicated that stem cells in the haematopoietic system can be identified by their expression of particular cell surface markers, are clonogenic *in vitro*, and have the ability to completely restore the haematopoietic system in mice whose bone marrow has been destroyed by irradiation.² These findings led to the concept of an adult (or 'somatic') stem cell as an immature cell that is capable of dividing indefinitely both to renew itself and produce cells maturing for tissue function. Cells with such properties have now been identified in most normal and malignant tissues.³

Although indefinite division is an essential stem cell property, the ability to produce differentiating cells is key to their function of tissue renewal and regeneration.

Some stem cells are able to generate cells entering several different lineages; haematopoietic stem cells, for example, generate cells that differentiate into the diverse range of cell types (e.g. erythrocytes, inflammatory and immune cells) found in blood.³ Stem cells with the ability to generate many different types of cells are considered ‘multipotent’. Other stem cells, for example those of the epidermis, normally produce cells of only a single lineage and are considered ‘unipotent’. However, even cells that are normally unipotent may under some conditions, such as wound healing, be capable of generating cells of different lineages.

The advantages of somatic stem cells for clinical use are that they are readily expanded *in vitro*, usually maintain a stable differentiation pattern and, as they can be expanded from autologous tissue, initiate no immune rejection. Examples of established therapeutic uses of somatic stem cells include the transplantation of donor haematopoietic stem cells for the treatment of leukaemia, and the grafting of *in vitro* generated autologous sheets of epithelial cells for the treatment of burns or repair of corneal damage. A large current range of clinical trials of regenerative stem cell procedures include neural stem cell grafting for treatment of spinal cord injuries, embryonic stem (ES) cell-derived retinal cells for treatment of macular degeneration, stem cell-derived β -cells for treatment of Type 1 diabetes, and the use of stem cells to enhance healing after coronary infarction. When somatic stem cells with an appropriate differentiation pattern can be generated from biopsies of autologous tissue this usually forms the simplest approach but, if not, then re-differentiation of a multipotent stem cell of one of the types described below provides an alternative method.

Embryonic stem cells

About 20 years ago, it was discovered that cells of the inner cell mass of mouse blastocysts, the cells that would normally go on to form the embryo, can be isolated, greatly expanded *in vitro* and then differentiated into multiple cell lineages.⁴ Such ‘embryonic stem cells’ (ES cells) were later also derived from human blastocysts. The controlled *in vitro* differentiation of ES cells into a required cell type can be directed using signals that mimic the tissue interactions that guide emergence of regionally appropriate cell lineages during embryonic development. Consequently, ES cells can provide an essentially unlimited source of relevantly differentiated cells.⁴ However, ES cells are generated by destruction of living human blastocysts and strong opposition to the use of ES cells has been expressed on ethical grounds. A further major complexity is that tissues produced from ES cells express the histocompatibility antigens genetically determined by the donor embryo and, consequently, their compatibility with recipients is restricted to some immune-privileged sites, requires manipulation of the recipient’s immune system, or modification of antigens expressed by the stem cell.

Induced pluripotent stem cells

Studies of ES cells led to the identification of genes associated with the maintenance of ‘stemness’ and it was found

that induced expression of ‘stem cell’ genes such as *Oct4*, *Sox2*, *cMyc*, and *Klf4* in differentiated cells results in their acquisition of stem cell properties similar to those of ES cells (i.e. the ability to divide indefinitely and the pluripotency that enables differentiation into multiple cell types by *in vitro* manipulation).⁵ The generation of such ‘induced pluripotency stem cells’ (iPSCs) demonstrates a degree of cellular plasticity beyond that previously thought feasible, and iPSC cells represent a class of cells able to regenerate a wide range of tissue types. The pluripotency of ES cells, and the possibility of their generation from autologous adult tissues, has greatly stimulated research into their potential clinical use for replacement of tissues that are genetically defective or have been lost to damage or disease.⁶ Concerns about potential carcinogenic effects of genetic alterations used to generate iPSC cells have been addressed by development of methods for their induction without permanent genetic alteration. In addition to their value for clinical tissue replacement, iPSC cells provide *in vitro* models of genetic diseases and for assays of drug effects.

Mesenchymal stem cells

Cells with multipotent stem cell properties can be isolated from various adult and foetal tissues, such as bone marrow, fat, dental pulp and umbilical cord, and it seems likely that similar cells are present in many adult tissues.⁷ These mesenchymal stem cells (MSCs) are fibroblast-like, have good expansion and differentiation potentials, and also possess immune-modulatory properties.⁸ Typically the cells differentiated from MSCs are osteoblasts or chondrocytes but greater plasticity with an ability to generate cells of non-mesenchymal lineages is suggested by reports of their differentiation into neurons or hepatocytes.⁹ The ability to derive MSCs from various tissues and to manipulate their differentiation for use as autologous transplants has generated extensive clinical interest.

TISSUE ENGINEERING: METHODS FOR GENERATION OF TISSUES AND ORGANS FROM CELLS

Methods for the isolation, amplification and differentiation of stem cells can provide the basic cellular materials for tissue reconstruction. However, these biological advances lead to new challenges of how to assemble such cells into functional tissues or organs. Clinical use has so far been largely limited to cells, such as epithelial or chondrocytic stem cells, that are able to self-assemble into an appropriate tissue either *in vitro* or after delivery to an *in vivo* site. The further aim of tissue engineering is to exploit biomaterials and biologically active molecules to facilitate the production of more complex structures. It includes using bioactive substances to control cell behaviour, together with synthetic matrices and engineered scaffolds that both provide physical support for growth and assist with the delivery of constructs. Currently, however,

the construction of tissues that are formed of multiple cell types, and of organs that are too large to rely on simple diffusion for the supply of gases and nutrients needed for cell survival provide many technical problems. Biological approaches to overcome problems of construct vascularization have included supporting the growth of cellularized scaffolds by transplantation to surrogate hosts and by complex genetic manipulations that allow implanted human stem cells to form organs during the embryonic development of other species.¹⁰ Rapid advances are, however, being made in three-dimensional cell culture with bio-printing, allowing patterned deposition of cells, and the development of novel perfusion bioreactors providing better support for cell growth.^{11, 12} However, the application of these procedures to the regeneration of large organs remains essentially experimental and the cost of such organ production is a significant factor.

APPLICATION OF STEM CELLS TO CLINICAL PROBLEMS IN OTOLARYNGOLOGY

The anatomical area of interest to otolaryngology contains a wide range of tissues but stem cell research has shown the feasibility of generating a range of appropriately differentiated cells for clinical use in regenerating and reconstructing epithelial, cartilaginous, osseous, neural and mucosal tissues.

The ear and nose

Regenerative stem cell properties have been investigated to rectify common structural or functional problems of the ear, nose, tympanic membrane, cochlea, trachea and other structures. Congenital, traumatic, and neoplastic tissue loss, as well as cosmetic reasons, may generate a need to replace or modify the existing structure of the external ear or nose and existing procedures for reconstruction may involve skin expansion, rib harvesting and multistage surgery. An alternative approach is to use autologous stem cells to produce cartilage after seeding onto appropriately shaped scaffolds.¹⁰ If needed, these can be invested in autologous epithelial sheets derived from epidermal stem cells provided by small epidermal biopsies, a well established technique long-employed for skin replacement of burns patients.¹³ Such procedures can be expected to provide consistent results that reduce surgical complexity and post-operative morbidity. Small biopsies of ear or rib tissue can provide cartilage stem cells for expansion and aesthetically successful nasal reconstructions have been reported using engineered cartilage grafts generated from cartilage stem cells in biopsies from the nasal septum.¹⁴ The uses of engineered cartilage for various other types of reconstruction are now being assessed. Augmented repair of chronic tympanic membrane perforation has focused mainly on the use of growth factors and biomolecules that have been demonstrated to enhance healing¹⁵ but this appears to be

a feasible area for the generation of matrices populated with autologous chondrocytes and epithelial cells.

Cochlea damage or degeneration

Sensorineural hearing loss resulting from inner-ear cochlear dysfunction involves the loss of sensory hair cells and/or spiral ganglion neurons. Loss of inner hair cells is currently irreversible but a range of stem cell procedures that aim to regenerate cochlea structures, such as hair cells and associated peripheral nerves, has been reported.⁹ A primary issue is identifying types of stem cells appropriate for differentiation into sensory and neural progenitor cells, but equally challenging secondary issues are the differentiation of stem cells into the desired structures *in situ*, or the delivery of *in vivo* or *in vitro* differentiated stem cells to the right location. Rodent MSCs and some other stem cell types have been shown to differentiate *in vitro* into cells with hair cell properties indicating the feasibility of stem cell use. Of particular interest, a stepwise *in vitro* process that mimics normal developmental interactions, can differentiate murine ES cells into both functional mechano-sensitive hair cells and into sensory neurones that interact to form specialized synapses.¹⁶

The trachea

Replacement of lost tracheal tissue has been a focus of successful stem cell research. Autologous cartilage has been harvested to replace small defects but malignancy may be associated with more extensive tissue loss that requires more extensive replacement. Larger constructs require the structural strength to withstand collapse due to the negative pressure of inspiration and the need for transplants to clear secretions points to the need for an appropriately differentiated luminal epithelium within a multi-layered functioning trachea.¹⁷ Successful five-year clinical results have been reported using a tissue-engineering strategy of bioreactor growth of a decellularized donor human trachea repopulated with cultured autologous epithelial stem cells and MSC-derived autologous chondrocytes prior to transplantation.^{1, 18} Further development that avoids the need for donor tissue has been construction of a bioartificial polymeric scaffold that models tracheobronchial size and morphology and which, after *ex vivo* seeding with autologous bone-marrow mononuclear cells and growth factor-induced mobilization of endogenous stem cells, was successfully transplanted as an airway replacement after cancer surgery.¹⁹

Larynx and vocal cords

Laryngeal injury and vocal cord (VC) disease can significantly impact upon vocal cord function and thus phonation. Current interventions in the management of vocal fold (VF) dysfunction focus on conservative and surgical approaches. However, the complex structure and precise biomechanical properties of the human VF mean that these strategies have their limitations in clinical practice

and may offer inadequate levels of success. Regenerative medicine has the potential to enhance VF recovery beyond that associated with conventional treatments.²⁰ So far, however, most investigations of the regenerative use of stem cells have been limited to assessment of various types of MSCs in animal models.²¹ Cell-free scaffolds of collagen, hyaluronic acid or fibrin enhance laryngeal wound healing and attempts have also been made to activate resident somatic stem cells.²⁰ MSCs support VC remodelling and reduce scarring when directly injected, either alone or as part of a cell-scaffold composite, and MSCs in hyaluronic acid hydrogels provide both biologically active material and volume allowing for accelerated healing in small animals.²² However, as VC remodelling can take up to six months in humans, it is uncertain whether MSCs persist long enough to benefit human repair.²² The non-keratinized epithelium covering the VCs can potentially be replaced by *in vitro* expansion of stem cells from small biopsies of adjacent mucosae but human iPS cells can be differentiated in the presence of matrix molecules and growth factors into an appropriate non-keratinizing epithelium.²³

Other tissues

Stem cell investigations to assist regeneration of a range of other tissues have been reported. For example, surgery of the head and neck can lead to peripheral nerve damage, with the facial and recurrent laryngeal nerves (RLNs) most commonly affected. Muscle-derived MSCs have been shown to improve outcomes in RLN injuries and work with facial nerve injuries has shown that neural regeneration following axotomy is enhanced by a combination of neural-induced MSCs and platelet-rich plasma.²⁴ Interestingly, several regions of the nose act as sources of autologous stem cells, such as olfactory ensheathing cells, which assist neural and other regenerative procedures. Large deficiencies of the maxillofacial skeleton can result from traumatic damage, or resection following malignant invasion, and direct injection of MSCs, together with appropriate materials or scaffolds, can assist regeneration. Stem cells have also been discussed with regard to improvement in scars following surgery or trauma and there is a large body of literature that considers MSCs and scars.

CANCER STEM CELLS: TUMOUR GROWTH, INVASION AND METASTASIS

Many solid tumours respond poorly to current therapies and, on average, only about 50% of HNSCC patients survive longer than five years from diagnosis. Recent work confirms that tumours contain subpopulations of altered stem cells, termed ‘cancer stem cells’ (CSCs) and that tumour growth is ultimately dependent on these cells.^{3, 25} Stem cell patterns have been identified in squamous cell carcinomas and also in the minority glandular tumours.^{26, 27} CSCs have unique properties

of direct clinical interest including resistance to therapy and the ability to invade locally and metastasize.²⁵ The mechanisms of the stem cell changes that lead to cancer remain unclear but, despite enhanced stem cell DNA repair,²⁸ tobacco and alcohol have mutational effects and an increasing number of oropharyngeal tumours result are associated with human papilloma viruses that act to increase the number of SCs and alter their behaviour.^{29, 30}

The homeostatic state of renewing tissues such as skin and mucosae is normally maintained by SC divisions that renew the SC population while also producing cells that differentiate. Many signalling pathways that affect division patterns (e.g. Notch, Wnt, Sonic hedgehog) are dysregulated in malignancy leading to a shift of CSC divisions towards greater self-renewal, which leads to an increasing number of CSCs and loss of tumour growth control.³ Normal stem cells (SCs) have several mechanisms to maintain their integrity and enhancement of these mechanisms in CSCs results in greater resistance when challenged with radiation or chemotherapeutic drugs and provides them with a survival advantage over non-CSCs.^{28–31} However, such mechanisms for enhanced tumour growth and resistance do not explain how CSCs escape from a tumour to invade locally or metastasize distantly, the events causing most cancer deaths. Basic research implicates epithelial-mesenchymal transition (EMT) as the process by which tightly cohesive epithelial cells acquire mesenchymal characteristics and lose mutual attachment to gain motility³² and it is proposed that this mechanism allows CSCs to escape from the tumour and migrate to distant sites where they then revert back to the proliferative epithelial phenotype to produce secondary tumours.³³ The mechanisms of reversion of cells back to the epithelial phenotype are not well understood but the molecular mechanisms of EMT indicate that the level of EMT occurring in a particular tumour depends partly on intrinsic tumour properties and partly on extrinsic stromal factors such as cytokines and hypoxia.^{34–36}

CSCs were initially defined by their ability to initiate tumours in immune-deficient mice after their isolation on the basis of their expression of cell surface markers.³ Such tumour initiating subpopulations of CSC have been identified in both fresh HNSCC and in passaged HNSCC cell lines.^{37, 38} Identification was initially achieved using the CD44 marker but a range of other cell surface or enzymatic markers has subsequently been employed. Analyses of CSC behaviour continue to support the conclusion that their elimination is necessary for successful therapy and many different therapeutic mechanisms are being explored to target CSCs.³¹ These include using antibodies against particular CSC surface markers to deliver cytotoxic agents,³⁹ development of drugs to inactivate CSC self-renewal pathways,⁴⁰ and reducing CSC resistance to radiation or drugs.⁴¹ However, concerning chemotherapeutic drugs, the plasticity of CSCs generates cells that differ in their drug or radiation responses and are also able to switch between phenotypes. Thus elimination of CSCs may require drug combinations and assays to assess drug effects on each of the CSC phenotypic manifestations and these are being developed.⁴²

KEY POINTS

- Stem cells are the ultimate origin of the wide variety of cells generated during embryological development and are responsible for all subsequent tissue growth and regeneration.
- Stem cells are also responsible for the growth and treatment resistance of malignant tissues.
- Recent research has disclosed many aspects of the control mechanisms underlying stem cell behaviour and has enabled their manipulation.
- This information is now being used to develop methods for clinical tissue regeneration and for cancer therapy.

Hormonal factors regulating thyroid growth	79		

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: thyroid, goitre, pathogenesis, aetiology, nodular and iodine. Reference lists for selected papers were examined for further sources.

INTRODUCTION

Thyroid enlargement is common, and has been recognized for almost two millennia. The exact definition of goitre has evolved over time, depending on the examination methods available. Based on autopsy studies, a thyroid was initially considered to be enlarged if weighing greater than 35 g, and the use of high-resolution ultrasound has led to the currently accepted definition of >18 mL in women and >25 mL in men.^{1,2} Variations in this cut-off globally have meant direct comparison between population studies is often problematic.

Previous autopsy studies reported the prevalence of thyroid nodules to be in excess of 50% in clinically normal thyroids;^{3,4} however, these studies were carried out prior to the iodization programs seen in many parts of the world and this is therefore probably an overestimation, with the current incidence lying between 25% and 50%.¹ Goitre can be classified as physiological or pathological – the former is found often in teenage girls and is without clinical significance. The latter comprises both benign and malignant; the focus of this chapter will be the benign multinodular goitre (Figure 8.1), with other causes of thyroid enlargement covered in other chapters.

Figure 8.1 A multinodular thyroid following excision.

FACTORS INFLUENCING GOITRE FORMATION

The aetiology of benign pathological goitre can be broadly split into environmental and genetic factors, although these rarely exist in isolation and a thorough understanding of each is therefore essential.

Environmental factors

IODINE DEFICIENCY

Iodine deficiency is the biggest contributor to goitre. In 2004 the World Health Organization estimated that 2 billion people were iodine deficient, including approximately 285 million school-aged children.⁵ It is thought around 45% of Europeans are iodine deficient,^{6,7} and in many parts of the world with universal iodine deficiency, goitre is endemic. The most common dietary sources of iodine are fish and dairy products, with a balanced diet being sufficient to maintain an adequate intake of 150mcg/day for (non-pregnant) adults.^{8,9} Iodine deficiency is measured using the surrogate marker of urinary iodine concentration (UIC), usually corrected for creatinine excretion. Iodine sufficiency is defined as UIC greater than 100µg/L, moderate deficiency as UIC below 50µg/L

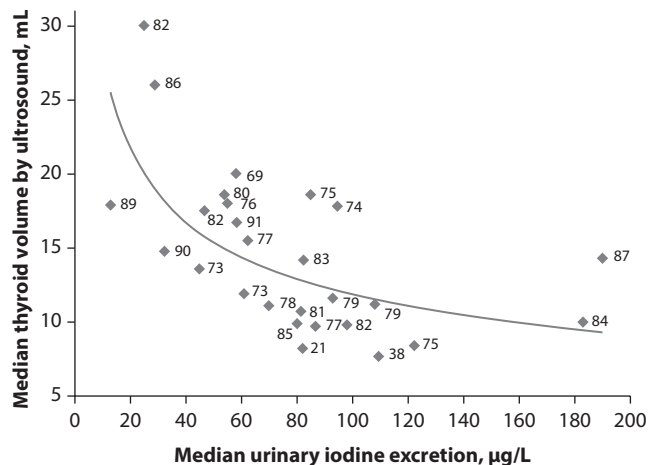

Figure 8.2 Graph demonstrating the fall in thyroid volume as urinary iodine excretion rises. From Carle A, Krejbjerg A, Laurberg P. Epidemiology of nodular goitre. Influence of iodine intake. *Best Pract Res Cl En* 2014; **28**(4): 465–79.¹

and severe deficiency as UIC below 25 µg/L.^{10,11} Thyroid volume directly correlates to UIC (**Figure 8.2**); in addition, increased UIC also negatively correlates with thyroid nodule prevalence.¹

Various programs exist across the developed and developing world to improve iodine status, one of the most effective being mandatory iodization of salt. This is not universal, however, and many countries including the UK do not enforce this. In 2006, the World Health Assembly recommended that countries carry out surveys of iodine status using sampling of UIC as a marker.¹⁰ The first national survey in the UK was carried out in 2011 and found that in female schoolchildren between the age of 14 and 15 years, the median UIC was 80.1 µg/L, with 67% of the cohort being iodine deficient (17% moderately or severely so).¹² The consequences of iodine deficiency in relation to prevalence of goitre among school children are shown in **Table 8.1**, and these findings therefore potentially pose a significant public health burden.

The consequences in pregnancy are also potentially severe. A recent study examining mother-child pairs in the UK measured maternal UIC in the first trimester of pregnancy and correlated this with the child's cognitive development at age 8 years. The researchers found that even mild iodine deficiency in early gestation was associated with lower scores for verbal IQ, reading accuracy and reading comprehension (**Figure 8.3**), emphasizing that even in developed countries there is a significant public health risk from iodine deficiency spanning several generations.¹³

Although there are several known environmental goitrogens, all of these must be examined in the context of iodine status of both the individual and the population, as some environmental causes will have significant effects when iodine is depleted, with some or no effect in iodine sufficiency (**Table 8.2**).

POLLUTANTS

Thiocyanate is found in cigarette smoke and also environmentally in cassava, which is a major source of carbohydrate in Africa and associated with an increased incidence of goitre.¹⁹ Nitrate sources include vegetables and drinking water; contamination of water with nitrate from agriculture leads to an odds ratio for goitre of 3 when assessed in iodine-replete Bulgarian school children,²⁰ although no link was found between urinary nitrite excretion and thyroid volume in a German study.²¹

TABLE 8.1 Relationship of iodine status to goitre prevalence in schoolchildren

Median UIE (µg/L)	Iodine status	Goitre among schoolchildren	Consequences
<20	Severe ID	>30%	Endemic cretinism, hypothyroidism, endemic nodular goitre
20–49	Moderate ID	20–29.9%	Endemic nodular goitre, low IQ, hyperthyroidism more often than hypothyroidism
50–99	Mild ID	5.9–19.9%	Hyperthyroidism more often than hypothyroidism, nodular goitre
100–199	Iodine sufficiency	<4.9%	Optimal balance between various thyroid disorders

Source: From WHO, UNICEF, ICCIDD. *Assessment of iodine deficiency disorders and monitoring their elimination*. 3rd ed. Geneva: World Health Organization; 2007.

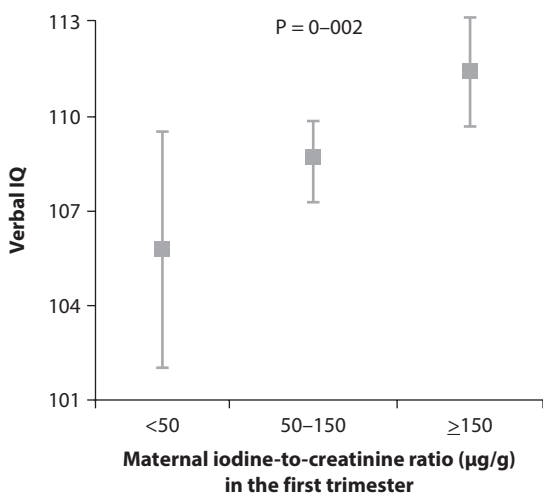

Figure 8.3 A deficient maternal iodine status is associated with poorer performance in a number of cognitive tests in offspring. From Bath SC, Steer CD, Golding J, et al. Effect of inadequate iodine status in UK pregnant women on cognitive outcomes in their children: results from the Avon Longitudinal Study of Parents and Children (ALSPAC). *Lancet* 2013; **382**(9889): 331–37.¹³

Isoflavones are found in soybeans and inhibit thyroid peroxidase; however, population studies give mixed results in terms of goitre formation.^{22,23} In our laboratory, we have used a soybean rich diet in our mouse models of goitre and see an increased thyroid size, a finding that reported by several other researchers.

Organochlorides present in solvents and pesticides have become less prevalent as most of these are now banned. They have, if any, only a mild goitrogenic effect and this should decline as their use tails off.²⁴

Perchlorate, a potent inhibitor of iodine uptake, is found in rocket fuel and accelerants, bleach and some fertilizers. It has not been shown to have any effect clinically on thyroid function at the levels encountered through environmental exposure, and it is therefore unlikely to have any effect on thyroid volume.²⁵ The US Environmental Protection Agency found perchlorate in 4% of drinking water samples tested nationally, and subsequently has issued notice that the perchlorate content of water will be regulated. The cut-off for detectable levels was, however, many orders of magnitude lower than that thought necessary to cause thyroidal effects.

TOBACCO

Tobacco smoking is another major risk factor for goitre development and is most marked in iodine deficient populations. Different studies report an odds ratio of between 1.5 to 3 for goitre in smokers, although variations in background iodine status make meta-analysis challenging.¹⁸ Thiocyanates are a major constituent of tobacco smoke and it is likely that these contribute to the increased risk.

SELENIUM

Selenium, like iodine, is necessary for thyroid hormone synthesis although to a much smaller degree. In addition, selenoproteins are important in the recycling of hydrogen peroxide generated by thyroid peroxidase. It is likely that selenium deficiency plays a cumulative role in nodule formation alongside iodine deficiency.²⁶

ORAL CONTRACEPTIVE PILL

While intuitively it may be thought that the OCP would be a risk factor for goitre development, the converse appears to be true. OCP use is associated with a lower thyroid volume (8.5 mL vs. 9.4 mL²) and low odds ratio (0.6)²⁷ for the development of goitre compared with no use; the mechanism for this is unexplained, but one theory is that exogenous oestrogens suppress the endogenous, goitrogenic ones. This is an avenue that warrants further exploration.

METABOLIC SYNDROME AND INSULIN RESISTANCE

Insulin resistance is becoming an increasingly studied risk factor given the rise in prevalence of metabolic syndrome across the Western world. Nodules were found in 53% of patients with insulin resistance compared to 19% without, and these results are mirrored in patients with metabolic syndrome, all in areas with a degree of iodine deficiency.^{28,29} Metformin has shown some positive effects in reducing thyroid volume in these patients, although results are not conclusive.^{30,31}

Genetic Factors

In addition to the well-studied environmental factors affecting thyroid growth, the familial clustering of goitres combined with the higher prevalence in females

TABLE 8.2 Relative contribution of genetic and environmental factors to goitre development with varying iodine status

Study	Country	Iodine status	Genetic factors (%)	Environmental factors (%)
Greig et al. 1967 ¹⁴	Scotland	Deficient	39	61
Brix et al. 1999 ¹⁵	Denmark	Mildly deficient	82	18
Hansen et al. 2004 ¹⁶	Denmark	Mildly deficient	71	29
Hansen et al. 2005 ¹⁷	Denmark	Mildly deficient	77	23

Source: Adapted from Knudsen N, Brix TH. Genetic and non-iodine-related factors in the aetiology of nodular goitre. *Best Pract Res Clin End* 2014; **28**(4): 495–506.¹⁸

suggests a genetic component to the disease, and this is becoming increasingly studied. While genetic factors are more significant in iodine deficient areas, families and small groups around the world show increased thyroid volume despite iodine supplementation, adding further evidence to a genetic cause. On a population level, discrete genetic causes are difficult to ascertain and therefore twin studies provide the best direct evidence of a genetic basis to goitre formation. In both endemic and non-endemic areas, monozygotic twins demonstrate a higher concordance for goitre development than dizygotic twins (Figure 8.4).

THYROID-SPECIFIC GENES

The identification of specific genes that predispose to goitre formation has mainly focused on those that are known to have a role in the normal physiology of the thyroid gland. Generally speaking, genetic mutations leading to suppression of thyroid hormone production/iodination have been associated with increased thyroid volume (i.e. gene alterations in those coding for the TSH receptor (TSHR), sodium iodide symporter (NIS), pendrin (PDS), thyroid peroxidase (TPO) and thyroglobulin (TG)) (Table 8.3).

NON-THYROID-SPECIFIC GENES

A number of putative non-thyroid-specific loci, associated with goitrogenesis, have been identified through genetic linkage analysis. This method uses the rearrangement of known chromosomal markers to identify candidate areas. The specific details are beyond the scope of this chapter but are summarized in Table 8.4; for further information see the review by Krohn et al.³² It remains to be seen whether the increasing use of next-generation whole exome sequencing will elicit more candidate genes; as yet benign goitre has not been a main focus of this research.

Although multiple genes have been identified that predispose to goitre formation, the majority of cases will be polygenic and heavily influenced by the environmental factors discussed above. These factors, inherent and exogenous, all feed into the pathogenic model for goitre formation discussed below.

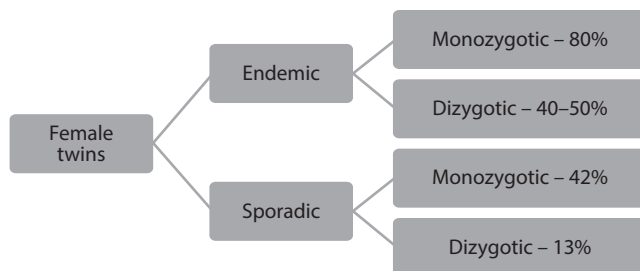

Figure 8.4 Preponderance to goitre in mono- and dizygotic twins. Adapted from Krohn K, Fuhrer D, Bayer Y, et al. Molecular pathogenesis of euthyroid and toxic multinodular goiter. *Endocr Rev* 2005; **26**(4): 504-24.³²

TABLE 8.3 Thyroid-specific genes with mutations linked to goitre formation

Mutated gene	Thyroid state
TG	Hypothyroid ^{33, 34}
TPO	Hypothyroid ³⁵ (/euthyroid ³⁶)
TSHR	Euthyroid ³⁷
PDS	Euthyroid ³⁸
NIS	Hypo/euthyroid ^{39, 40}

PATHOPHYSIOLOGY

Development of a multinodular goitre occurs in two phases: (i) a goitrogenic stimulus leading to global thyrocyte proliferation and increase in overall thyroid size, and (ii) focal increase in proliferation leading to nodules (Figure 8.5). Evidence for this is based largely on older animal studies,⁴⁵⁻⁴⁷ although the same principles do seem applicable to human disease.

Goitrogenic stimulus

Under the influence of (most commonly) iodine deficiency, or another goitrogen, global hyperplasia occurs with increased thyroid hormone synthesis (there is evidence that some patients will adapt to iodine deficiency with hypertrophy without hyperplasia,⁴⁸ although the mechanism for this is unclear). This increased production leads to a rise in hydrogen peroxide (H₂O₂) generation and free

Figure 8.5 The bimodal model for development of goitre. From Krohn K, Fuhrer D, Bayer Y, et al. Molecular pathogenesis of euthyroid and toxic multinodular goiter. *Endocr Rev* 2005; **26**(4): 504-24.³²

radical formation, resulting in a significant increase in spontaneous mutation rates.

Nodule formation

The combination of high spontaneous mutations coupled with increased cell replication rate results in an increased mutagenic load, and the chances of randomly generated mutations with a growth advantage are therefore significantly increased. The proliferating thyroid will be replete in growth factors (e.g. insulin-like growth factor (IGF), transforming growth factor (TGF), epidermal growth factor (EGF)), which will stimulate the division of all cells, including those with activating mutations. When the goitrogenic stimulus is removed, the proliferation of normal thyrocytes will cease whereas the activated cell clones will continue to proliferate, thus forming nodules. The nature of the mutation will determine whether the nodule is autonomously functioning or 'cold'; for example, an activating mutation of the cyclic AMP cascade will stimulate both growth and function, whereas one in the MAPK pathway will lead to proliferation only and a cold nodule. It follows, therefore, that multinodular goitre is a polyclonal entity, as opposed to a monoclonal one, with different nodules displaying different characteristics, which accounts for their heterogenous appearance on both imaging and pathological studies.

HORMONAL FACTORS REGULATING THYROID GROWTH

Thyroid growth and homeostasis is controlled by a number of factors other than iodine, through endo-, auto- and paracrine pathways. The principal stimulator of growth is TSH, the receptor for which is situated on the basal membrane of thyroid epithelial cells and belongs to the G protein-coupled receptor family. This in turn activates cellular processes including the adenylyl cyclase-cAMP system promoting growth. Similar to the Wolff-Chaikoff effect (reduced thyroid function in the presence of very high levels of circulating iodine), high serum TSH concentrations have been shown to have an inhibitory effect on thyroid cell proliferation *in vitro*⁴⁹ (Figure 8.6).

Figure 8.6 Reduction in iodide uptake by primary cultured thyroid cells with high concentrations of TSH.

TABLE 8.5 Growth factors acting on the thyroid gland to promote/inhibit growth

Activation pathway	Factors	Effect
AC-cAMP-PKA	TSH	Stimulatory and inhibitory
	Epinephrine	Stimulatory
Receptor tyrosine kinases	EGF	Stimulatory
	TGF- α	Stimulatory
	FGFs	Stimulatory
	Insulin	Stimulatory
	IGF-I	Stimulatory
	HGF	Stimulatory
	PDGF	Stimulatory
Phosphatidylinositol cascade	TSH	Stimulatory
	Esters	Stimulatory
	TGF- β	Inhibitory
	Iodides	Inhibitory

Other factors that act locally to promote growth and angiogenesis include insulin, EGF, TGF- α /TGF- β , IGFs, fibroblast growth factors (FGFs), hepatocyte growth factor (HGF) and platelet-derived growth factor (PDGF). The particular signalling cascades that involve these mitogenic factors are summarized in Table 8.5.⁵⁰

NOVEL THERAPIES

The surgical management of both benign and malignant thyroid disease is covered in depth in other chapters. It is, however, important to remember that globally, for many patients, surgery is not an option, either through patient non-suitability for general anaesthetic or lack of access to the appropriate facilities. Non-surgical treatment modalities are unfortunately lacking, although laboratory studies are ongoing to identify new therapies, usually by targeting specific growth factors receptors such as VEGF-R and FGF-R.⁵¹

SUMMARY

Goitrogenesis is a complex process reliant on an interplay of environmental and genetic factors, the extent of which is dependent on the underlying iodine status of the individual. While an understanding of these various processes is important, the most important factor to correct globally in order to reduce the prevalence of goitre is iodine deficiency, which continues to be a focus of the WHO – especially in developing countries. The role of iodine deficiency in the developed Western world, however, should not be ignored and continued efforts to ensure populations achieve their required intake should be supported.

FUTURE RESEARCH

- ▶ The role of iodination programs in the developing world to combat endemic goitre.
- ▶ Further understanding of the interplay between the metabolic syndrome and goitre formation, especially in view of the worldwide rise in obesity.
- ▶ Further characterization of the role of non-thyroid-specific genes in goitre formation and progression.
- ▶ Use of gene targeting therapies/recombinant adenovirus treatments in the non-surgical management of goitre.

KEY POINTS

- Benign thyroid enlargement is common.
- The biggest aetiological factor in the development of goitre is iodine deficiency.
- There is a complex interplay between environmental and genetic factors that determines the nature of the goitre.
- An understanding of the growth factors involved in thyroid hypertrophy and hyperplasia will aid the clinician in determining the likely progression of disease and best treatment options.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: thyroid cancer, molecular biology, parathyroid cancer, parathyroid adenoma and molecular genetics.

GENETICS OF THYROID TUMOURS

Introduction

Thyroid malignancy is the most common cancer of the endocrine organs. Most thyroid cancers originate from thyroid follicular cells and can be subdivided into well differentiated papillary and follicular carcinoma, poorly differentiated carcinoma and anaplastic carcinoma.¹ Medullary thyroid cancer (MTC) accounts for a small proportion of thyroid cancers.²

Understanding of the molecular pathogenesis of thyroid cancer has progressed rapidly in the last decade. The genetic aberrations and alterations in signalling pathways have helped reshape our insights into thyroid cancer aetiology and management of patients with thyroid nodules.

Oncogenes and tumour suppressor genes in thyroid cancer

Cancer is a complex, multistep process. However, recent years have seen major advances in understanding the role of two classes of genes that are of particular importance in carcinogenesis that provide a more comprehensive picture: oncogenes and tumour suppressor genes. Several of the known oncogenes have been consistently detected in differentiated thyroid neoplasms. Some are more strongly associated than others and, interestingly, few are limited to specific forms of thyroid tumours.

GENE MUTATIONS

B-RAF (BRAF) mutation

BRAF is a serine/threonine kinase and is a member of the mitogen-activated protein kinase (MAPK) pathway, involved in the transduction of mitogenic signals from the cell membrane to the nucleus within. *BRAF* gene mutations have been shown to be common in many different human cancers.³ Several studies have recently identified the most common *BRAF* (*V600E*) mutation, T1796A transverse mutation, in 29–69% of papillary thyroid cancers.^{4–8} *BRAFV600E* mutation has been demonstrated to be a novel prognostic biomarker that predicts poor clinic-pathological outcomes such as extra-thyroidal invasion, advanced pathological stage invasion, metastasis and relapse of PTC.^{8–9} *BRAF* mutation has also been associated with loss of radioiodine avidity and treatment failures.¹⁰

In contrast to classical genetic mutations in thyroid cancers such as *RET-PTC* and *RAS* mutations, which are also apparent in some benign thyroid lesions, this mutation has consistently been reported to be 100% specific for PTC. Consequently, *BRAF* mutation has been proposed as a specific molecular marker with high sensitivity for the diagnosis of PTC and represents a useful diagnostic adjunctive technique in the evaluation of thyroid nodules with indeterminate cytological findings.

RAS

The *RAS* proto-oncogene codes for a G-protein, p21, which is found within cell membranes. p21 plays a critical intermediate role in connecting the stimulatory signal

from tyrosine kinases such as EGF receptor and via Raf-1 to a mitogenic cascade involving the MAP kinases.¹¹ *RAS* mutations are found in 30% of human cancers, making this the most widely mutated human proto-oncogene. Activated *RAS* has been detected previously in 20% of papillary carcinomas and 53% of follicular carcinomas.¹² Three families of *RAS* oncogenes have been identified (*K-RAS*, *H-RAS* and *N-RAS*), each located in separate chromosomal locations. Although downstream targets of *RAS* mutations include MAPK and P13K signalling, there appears to be preferential activation of the P13K-AKT pathway.¹³

The prevailing view is that *RAS*-activation probably represents an early event in thyroid tumorigenesis and is itself not sufficient for malignant transformation. Studies have shown *RAS* to be present in a high proportion of the earliest forms of thyroid tumours. Others have noted normal cells immediately adjacent to *RAS*-containing tumour cells also to harbour *RAS*.¹⁴

C-Myc, *c-Fos*, *c-Met*

Mutations of several other proto-oncogenes such as *c-Myc* (nuclear transcriptional factor family), *c-Fos* and *c-Met* have also been demonstrated in differentiated thyroid cancers (see Reviews).^{15–16}

The *c-Myc* proto-oncogene encodes a nuclear protein that binds to DNA and acts as a transcriptional factor for genes involved in growth and differentiation. *c-Fos* is an immediate/early gene that regulates the expression of specific target genes by binding to their regulatory sequence of DNA. Aberrant activation of this transcriptional regulator has been demonstrated in thyroid tumours.¹⁷

Met protein is a transmembrane receptor with tyrosine kinase activity. Oncogene activation is associated with mitogenesis as well as motogenesis and has been suggested to contribute to tumour aggressive and metastatic behaviour.¹⁸ *Met* oncogene is seen in various cancer human types, including up to 70% of papillary and 25% of follicular carcinomas, although it is not detected either in MTC or in normal thyroid tissues.¹⁹

GENE TRANSLOCATIONS

RET-PTC gene rearrangements

The thyroid carcinoma gene, *PTC*, is an oncogene found in 25% of papillary thyroid cancers, which was initially described by Fusco et al.²⁰ Subsequently, it was discovered to be a fusion between a gene of unknown function (*D10S170*) and the TK domain of the *RET* proto-oncogene as a result of a chromosomal rearrangement.²¹ The *RET* proto-oncogene codes for a transmembrane protein with tyrosine kinase activity, the activity of which is normally restricted to a subset of cells derived from embryonic neural crest cells.²²

Although the *RET* proto-oncogene is not expressed in normal thyroid follicular cells, the rearranged *RET/PTC* oncogene is highly expressed in some papillary thyroid cancer cells.²³ *PTC/RET* rearrangements are generally specific for papillary carcinomas and have been found in

5–40% of papillary thyroid cancers (PTC) in adults and are more common in paediatric PTC, as well as in cancers from children exposed to ionizing radiation.^{24, 25–28}

There are more than 10 types of translocation, the most common being *RET/PTC1* and *RET/PTC3*.^{29–30} The oncogenic capabilities of *RET/PTC* are achieved through activation of both MAPK and P13K-AKT pathways.

PAX8/PPARG rearrangement

The paired box 8 (*PAX8*)–peroxisome proliferator-activated receptor- γ (*PPARG*) fusion gene (*PAX8/PPARG*) rearrangement occurs as a genetic translocation between chromosomes two and three. This inhibits the tumour suppressor activity of *PPARG* and also transactivates certain *PAX8*-responsive genes.³¹ The rearrangement occurs in up to 60% of follicular thyroid carcinoma (FTC) and follicular variant of papillary thyroid carcinoma (FVPTC).³²

TUMOUR SUPPRESSOR GENES

P53

The tumour suppressor p53 regulates cell response to DNA damage and allows for repair or apoptosis when cells are severely damaged. Inactivating mutations of p53 gene are common in human cancers; however, they are only present in 10% of thyroid malignancies.³³ The majority of such mutations are found in poorly differentiated and aggressive histotypes.³⁴ This suggests p53 plays a minor role in thyroid malignant transformation and in early stages of thyroid cancer, unlike many other human malignancies. However, evidence suggests that although p53 mutations may not occur in thyroid tumours, its activity may be inhibited by other mechanisms,³⁵ especially in early stage thyroid cancer.³⁶

SIGNALLING PATHWAYS

There are several important signalling pathways involved in the development and propagation of thyroid cancer. The common mutations described above are key genes in these signalling pathways.

The MAPK signalling pathway

The mitogen-activated protein kinase (MAPK) pathway plays a major role in the regulation of cell proliferation and survival and in human tumorigenesis. Activation is often due to mutated *RAS*, *BRAF* or by *RET-PTC* reported widely in papillary thyroid cancer.³⁷ Secondary molecular events amplifying this pathway such as hypomethylation and genome-wide hypermethylation, and upregulation of various oncogenic proteins can also occur. These include chemokines, nuclear factor κ B (NF- κ B), vascular endothelial growth factor A (VEGFA), matrix metalloproteinases (MMPs), and transforming growth factor- β 1 (TGF β 1).³⁸

The PI3K-AKT signalling pathway

The role of P13K-AKT pathway in thyroid tumorigenesis became apparent when the association of follicular thyroid adenoma and carcinoma was noted with Cowden's syndrome (caused by germline mutations of *PTEN*),³⁹

and high levels of AKT expression established in the latter (when compared to PTC or normal thyroid tissue).⁴⁰ Furthermore, evidence of AKT mutations and their occurrence in metastatic thyroid cancer⁴¹ has validated the central role of PI3K-AKT pathway in the invasive and metastatic capabilities of FTC. Aberration of the PI3K/AKT pathway appears to play a pivotal role in tumorigenesis in both FTC and ATC, promoting progression of adenoma to FTC, and subsequently ATC.

The NF- κ B signalling pathway

It has been suggested that activation of NF- κ B may promote dedifferentiation of PTCs and FTCs.⁴² Studies have demonstrated the NF- κ B pathway's role in anti-apoptotic and proliferative signalling pathways in thyroid cancer.⁴³ Emerging evidence of deregulated NF- κ B activity in ATC helps provide further insight into the molecular biology of thyroid cancer and identify it as a potential target to inhibit the pro-survival signalling in thyroid malignancy.⁴³

The WNT- β -catenin signalling pathway

The pathway plays a role in regulating cell proliferation and differentiation. Abnormal signalling and its role in thyroid tumorigenesis has been established. Activation of WNT- β -catenin pathway is secondary to mutations of *CTNNB1* (which encodes β -catenin),⁴⁴ a likely late event not evident in well differentiated carcinomas. Expression of β -catenin, a cytoplasmic protein regulating the coordination of cell-cell adhesion and gene transcription, is more prominent in ATC compared to DTC.⁴⁵

ABERRANT GENE METHYLATION

Epigenetic silencing through aberrant gene methylation are hallmarks of cancers including thyroid malignancy. Methylation of thyrotropin receptor (TSHR), E-cadherin (ECAD), sodium iodide symporter protein (NIS-L) are frequent in PTC.⁴⁶ The *BRAFV600E* mutation has been associated with a combination of hypermethylation and hypomethylation of genes involved in important metabolic and cellular functions in PTC.⁴⁷ Hypermethylation of several tumour suppressor genes are also associated with increased PTC aggressiveness.⁴⁸ Evidence shows down-regulation of PTEN tumour suppressor due to changes in methylation is associated with increased activity of the PI3K-AKT pathway, in thyroid cancer.⁴⁹

Genetic alterations in medullary thyroid cancer

Medullary thyroid cancer (MTC) is an aggressive form of thyroid cancer, accounting for less than 5% of thyroid malignancies.⁵⁰ It is a neuroendocrine carcinoma arising from the parafollicular C-cells and associated with secretion of calcitonin and various other hormones such as carcinoembryonic antigen (CEA). Sporadic MTC accounts for 75% of cases, with inherited MTC accounting for the remainder. The majority of the latter occurs

in association with multiple endocrine neoplasia (MEN) type 2A, MEN2B, and familial medullary thyroid carcinoma syndrome (FMTC) syndromes.

RET GENE

The various forms of hereditary MTC are caused by germline *RET* mutations and are all autosomal dominant with high penetrance. Somatic *RET* mutations are responsible for a subset of sporadic MTC.⁵¹ The *RET* oncogene plays a major role in MTC tumorigenesis, with *RET* mutations being identified in 98% of MEN2A patients, 95% of MEN2B patients, and 88% of those with FMTC.⁵² As noted previously, *RET* signalling activates both MAPK and PI3K-AKT pathways, playing a key role in cell growth, differentiation and survival.

ABERRANT GENE METHYLATION

Hypermethylation of *RASSF1A* (*RASSF1*), a known tumour suppressor gene within the PI3K-AKT pathway, has been noted in the majority of FTCs and less frequently in benign adenomas and PTC.⁵³ Due to its high prevalence in MTC (85%), it may indicate a role in MTC tumorigenesis.⁵⁴

MICRORNAS

MicroRNAs are small non-coding RNA genes (containing about 22 nucleotides) that function in RNA silencing and post-translational regulation of gene expression. MicroRNAs deregulation in MTC is thought to be an early event in parafollicular C-cell carcinogenesis.⁵⁵

Genetic alterations in anaplastic thyroid cancer

Anaplastic thyroid carcinoma remains a devastating disease. ATC constitutes 5% of all thyroid cancer and yet accounted for 50% of all thyroid cancer deaths in the United States in 2006.⁵⁶ Molecular research in anaplastic carcinoma has been limited due to its rarity and aggressiveness, relying mainly on *in vivo* cell line studies. Experimental models involving xenografts in athymic mice has allowed further study of this aggressive endocrine disease. Despite our limited understanding, it is generally accepted that anaplastic cancer does not arise *de novo*, but is likely to evolve from established well-differentiated thyroid cancer (PTC or FTC).⁵⁷

There are two groups of mutations evident in the ATC tumorigenesis. The first set of mutations is abundant within well differentiated thyroid cancer (WDTC) and ATC. Examples include *BRAF* and *RAS* point mutations and are likely to represent early changes.⁵⁸ The second group are found largely in ATC and are noted for their absence in WDTC. These are likely to represent late changes and are involved in dedifferentiation; p53 and β -catenin.

Mutations in p53 impairing transcriptional activity are found in 55% of ATCs⁵⁸ enabling accelerated genomic

instability, growth, angiogenesis and dedifferentiation. Redifferentiation of ATC tissue has been demonstrated with reintroduction of wild type p53 and the restoration of cellular responsiveness to physiologic stimuli (thyroid stimulating hormone) and re-expression of thyroid peroxidase.⁵⁹ E-cadherin and β -catenin are epithelial adhesion molecules in normal epithelium. There is reduced expression of both in ATCs when compared to the originating WDTC from which they evolve, suggesting the E-cadherin/ β -catenin complex plays a role in this transformation process.⁶⁰

KEY POINTS

- Several gene mutations and alterations in signalling pathways are now recognized as important events in the development and progression of thyroid cancer.
- *RAS* mutations appear to be an early event, as they are common to benign and malignant tumours. The subsequent pathways leading to follicular or papillary carcinoma are divergent.
- Mutational activation of *BRAF* and *RET/PTC* oncogenes are specific to papillary carcinomas. Conversely, loss of function of a gene on chromosome 11q13, possibly *MEN1* gene, may direct the tumour clone towards a follicular phenotype.
- Mutations of p53 are highly prevalent in anaplastic thyroid carcinomas, and together with mutations in the *RB* gene, may represent the critical transitional step in the progression of well-differentiated tumours into these aggressive thyroid cancers.

GENETICS OF PARATHYROID TUMOURS

Introduction

Primary hyperparathyroidism is a commonly detected endocrine disorder having a prevalence of 1–3:1000 in the general European population.⁶¹ The most common cause of primary hyperparathyroidism is a parathyroid adenoma accounting for ~85% of cases. Parathyroid adenomas are more commonly sporadic, or inherited as part of multiple endocrine neoplasia (MEN) syndromes, familial hyperparathyroidism or hereditary hyperparathyroidism with jaw tumours (HPT-JT). Parathyroid carcinomas are rare and account for less than 1% of cases of hyperparathyroidism.⁶²

Parathyroid adenomas

Previous investigations of the molecular pathogenesis of parathyroid tumours have only yielded mutations accounting for the minority of tumours. Investigations of the *PTH* gene, which is located on chromosome 11q15, detected restriction fragment length polymorphism (RFLP) abnormalities in sporadic parathyroid adenomas.⁶³ Further analysis demonstrated the rearrangement of part of the *PTH* gene onto chromosome location 11q13. The protein that was overexpressed as a result of this rearrangement was

designated PRAD 1 (parathyroid adenoma 1), and encodes a novel member of the cyclin-D family of cell-cycle regulatory proteins. Up to 20–40% of sporadic parathyroid adenomas have been shown to overexpress cyclin D1.^{64–65}

There has also been interest in the role of cyclin dependent kinase inhibitors (CDK1) genes conferring low-penetrance predisposition to hyperparathyroidism by providing a selective growth advantage to parathyroid cells.⁶⁶ Another genetic abnormality that appears to be important in the aetiology of parathyroid adenoma is the tumour suppressor gene associated with MEN type 1; 12–20% of patients with sporadic parathyroid adenomas have been shown to harbour bi-allelic defects in the *MEN1* gene.⁶⁷ Parathyroid adenomas are also associated with MEN syndrome type 2a. Although *C-RET* mutations are responsible for MEN2a, a search for the most common mutation at codon 634 has proved to be negative, suggesting a different mechanism responsible for the development of sporadic and inherited parathyroid adenomas.

Whole exome and direct sequencing of parathyroid adenomas has led to mutations being identified in the *ZFX* gene, a gene believed to have a role in the regulation of stem cell renewal. The identified mutations did not overlap with somatic mutations in the *MEN1* gene. Also implicated in other cancers such as that of the larynx, lung and prostate, the *ZFX* gene may as an oncogene provide gain of function in parathyroid tumour cells, possibly linked to cyclin D1.⁶⁸

Parathyroid hyperplasia

Comparison of genes between parathyroid hyperplasia and adenomas does demonstrate greater genetic heterogeneity and more complex expression of genetic mutations in hyperplasia, which is consistent with its polyclonal nature. Examples include the *CDH1* gene, which is not exclusive to but more highly expressed in hyperplasia versus adenoma (but not in carcinoma).⁶⁹

Parathyroid carcinoma

Although rare, parathyroid carcinoma is clinically aggressive. Whether it arises pre-existing adenomas or *de novo* remains controversial. As noted previously, cyclin D1 gene expression is overexpressed in parathyroid adenomas compared to normal parathyroid tissue. Recently, Zhao et al. examined seven parathyroid carcinomas and noted expression of *CCND1* (a gene encoding for cyclin D1) was significantly overexpressed in carcinomas when compared with adenomas.⁶²

The *RB* tumour suppressor gene responsible for the pathogenesis of retinoblastomas is involved in the pathogenesis of various other human tumours. Allelic deletion of *RB* gene was demonstrated in all parathyroid carcinomas in one study, with abnormal histological staining patterns for Rb protein in 50% of carcinomas but none in the adenomas.⁷⁰ Together, these observations suggests an important role for *RB* gene in the development of parathyroid carcinomas, and may help in the histological diagnosis of parathyroid carcinoma.⁶¹

Shattuck et al. directly sequenced the *HRPT2* gene (associated with hyperparathyroidism-jaw tumour syndrome) in 21 parathyroid carcinomas from 15 patients who had no known family history of primary hyperparathyroidism or the HPT-JT syndrome at presentation.⁷¹ Parathyroid carcinomas from 10 of the 15 patients had *HRPT2* mutations. In contrast, mutations of *HRPT2* are not evident in benign parathyroid tumours. Some have suggested that all patients with parathyroid carcinoma should be considered for germline testing for *HRPT2* mutations as up to 20% of them may have unrecognized HPT-JT.⁶⁶

INHERITED CANCER SYNDROMES AND GENETIC TESTING

In about 5–10% of individuals predisposition to a specific group of cancers is the result of a heritable mutation in a cancer predisposing gene, so-called germline mutation. The at-risk individuals tend to develop tumours at an earlier age than usual and are at risk of developing more than one primary tumour. In addition, the siblings and offspring of an affected individual each have a 50% chance of inheriting the cancer predisposing mutation, consistent with autosomal dominant inheritance.

Multiple endocrine neoplasia type 1 (MEN1)

MEN1, also known as Wermer's syndrome, represents the combination of more than 20 different endocrine and non-endocrine tumours. A practical definition is a case with two or three main MEN1-related endocrine tumours: parathyroid adenoma, entero-pancreatic endocrine tumour and pituitary tumour. MEN1 syndrome is usually an autosomal, dominantly inherited condition, although in 10% of cases arise *de novo*. The prevalence of MEN in the UK is estimated to be ~10 per 100 000 with equal sex distribution.⁷²

Parathyroid tumours occur in 95% of MEN1 patients and is the most common endocrinopathy with a typical age of onset of 20–25 years (reaching nearly 100% penetrance by the age of 50 years).⁷³ In contrast, MEN1 is rare and represents only 2–4% of all cases of primary HPT. Patients with MEN1 generally have parathyroid tumours in three or all four parathyroid glands. These tumours are asymmetric in size and are regarded as independent clonal adenomas. The issue of which operation is optimal remains controversial.^{72–74}

The gene causing MEN1 was localized to chromosome 11q13 by genetic mapping studies. Further studies defined the *MEN1* gene in 1997, consisting of 10 exons that codes a novel 610 amino acid protein named MENIN.⁶⁷ MENIN is a ubiquitously expressed nuclear protein that has been demonstrated to have roles in transcriptional regulation, genome stability, cellular proliferation, cell cycle control and apoptosis.^{67, 75}

More than 1000 germline mutations of the *MEN1* gene have been described and the majority (>80%) of these are

inactivating, and are consistent with its role as a tumour suppressor gene.⁷² More than 10% of the *MEN1* gene germline mutations arise *de novo* and may be transmitted to subsequent generations.⁷⁶ Importantly, 5–10% of MEN1 patients do not harbour mutations in the coding region of the *MEN1* gene, and these individuals may have mutations in the promoter and untranslated regions, which remains to be clarified. Correlations between *MEN1* mutations and the clinical manifestations are absent, and this contrasts with the situation in MEN2 and the *RET* gene.

MEN1 GENETIC TESTING FOR FAMILIAL MEN1 SYNDROME

The first step in the analysis is to identify the specific *MEN1* mutation in the germline DNA derived from a peripheral blood sample from the affected index case using direct DNA sequencing strategies. In most index cases of familial MEN1, a germline mutation of *MEN1* will be identified. However, many large studies have failed to find a *MEN1* germline mutation in 10–20% of index cases for familial MEN1.⁷⁷ Such failures are believed to be due to mutations in untested parts of the *MEN1* gene or large deletions that are transparent to PCR methods. Current recommendations suggest genetic testing should be performed in index cases with two or more MEN1 tumours, and first-degree relatives of a known mutation carrier. All individuals who are offered genetic testing should receive appropriate genetic counselling.⁷⁸

Multiple endocrine neoplasia type 2 (MEN2)

The MEN2 syndrome describes the association of medullary thyroid carcinoma (MTC), pheochromocytoma, and parathyroid tumours. MEN2 is an autosomal dominant syndrome caused by mutations in the *RET* proto-oncogene with variations in the penetrance resulting in three variants: MEN2a; MEN2b; and familial medullary thyroid cancer (FMTC). All variants show a high penetrance for medullary thyroid cancer; 90% of MEN2 carriers will eventually show evidence for MTC. MEN2a is the most common variant (95%), and the development of multicentric MTC (almost 100%) is associated with pheochromocytoma (50%) and parathyroid adenomas (20%). MEN2b, which represents 5% of all MEN2 cases, is characterized by the occurrence of MTC, pheochromocytoma in association with Marfanoid habitus and mucosal neuromas. Parathyroid tumours do not usually occur in MEN2b. FMTC is a variant in which only MTC is the sole manifestation and is the mildest subtype. MTC is the first neoplastic manifestation in most MEN2 patients because of its earlier and overall higher penetrance. Earlier studies reported mortality of 15–20% when treatment was initiated after identification of a thyroid nodule.⁷⁹ However, carrier diagnosis before adulthood allowing early thyroidectomy has lowered the mortality from hereditary MTC to less than 5%.⁸⁰

The *c-ret* proto-oncogene encodes a transmembrane tyrosine kinase receptor and is located on chromosome 10q11.2.⁸¹ The RET protein is involved in cellular

signalling pathways that regulate cell proliferation, differentiation, survival and regeneration (ref10). Specific activating mutations of *C-RET* have been described for each of the three MEN2 variants. The aggressiveness of MTC correlates with the MEN2 variant syndrome and with the mutated *RET* codon.⁸² Prevention or cure of inevitable MTC is by surgery, and should be performed before the age of possible malignant progress.

The presence of somatic *RET* mutations (which occur in up to 75% of sporadic MTC patients) confers a more aggressive clinical course when compared to *RET*-negative sporadic patients. The absence of *RET* mutations in some patients suggests that other loci may predispose to MEN1 and sporadic MTC.

MEN2 GENETIC TESTING

In 1997, a consensus was reached that the decision to perform prophylactic thyroidectomy in MEN2 should be based predominantly on the result of *ret* mutation testing, rather than CT testing.⁸³ Genetic testing for MEN2 has enabled detection of nearly 100% of carriers and is one of the few examples of a genetic test that mandates a highly effective clinical intervention. Sequencing DNA for *RET* mutation is effective and widely available. The likelihood

of a *ret* germline mutation in a patient with apparently sporadic MTC is 1–7%.⁸⁴ Despite the modest mutation yield, all cases of sporadic MTC should be tested for germline *ret* mutation because the critical clinical implications of finding a *ret* mutation. A germline *ret* mutation is more likely if the sporadic MTC is of early age onset or there is multiplicity in the thyroid gland. Further, the specific *ret* codon mutation correlates well with the MEN2 variant and with clinical behaviour. Genetic information allows stratification of MTC risk and provides a basis for a 3-level stratified thyroid management (Table 9.1).⁸⁵

Hyperparathyroidism-jaw tumour (HPT-JT) syndrome

The HPT-JT syndrome is an autosomal dominant disorder characterized by the development of parathyroid adenomas and carcinomas and fibro-osseous jaw tumours. In HPT-JT, patients usually have single adenoma or a carcinoma, whilst MEN1 patients will often have multigland disease.

The gene causing HPT-JT, *HRPT2*, is located on chromosome 1q25 and encodes for an ubiquitously expressed 531 amino acid protein PARAFIBROMIN.⁸⁷ To date,

TABLE 9.1 Genotype-phenotype correlations, risk levels for MTC and recommended interventions based on ATA risk level of genotype 2015⁸⁶

ATA group	RET genotype		MEN2 classification	Recommended start interventions

13 different heterozygous mutations translating truncated forms of parafibromin, have been reported in HPT-JT families. Although no consensus clinical guideline exists for *HRPT2* genetic testing, testing for germline *HRPT2* mutations are available commercially.⁸⁸

Cowden's disease

Cowden's disease (CD), also known as multiple hamartoma syndrome, is a rare autosomal dominantly inherited disease. Multiple trichilemmomas of the skin are common diagnostic features found in >90% of affected individuals. Patients with CD have an increased risk for carcinomas of the breast and thyroid; up to a 10% lifetime risk of follicular or papillary thyroid cancer. Approximately 70% of people with Cowden syndrome will have benign thyroid abnormalities, including multinodular goitre, adenomatous nodules and follicular adenomas. Marsh et al. identified *PTEN* mutations in 30 of 37 (81%) Cowden disease families.⁸⁹ The *PTEN* gene is involved in the previously PI3/AKT or PI3-AKT intracellular signalling pathway. Although no consensus clinical guideline exists testing for germline *PTEN* mutations are available commercially.

Other inherited syndromes

Mutations in the *APC* gene cause FAP and attenuated familial adenomatous polyposis (AFAP). FAP is inherited as autosomal dominant and is characterized by multiple adenomatous polyps in the colon and rectum with a natural history of progression to colorectal carcinoma in nearly 100% of cases, usually by the age of 40. People with FAP have up to a 2% lifetime risk of developing papillary

thyroid cancer (PTC). Women with FAP appear to be at greater risk than men (80:1) and develop a particular histological variant of PTC (cribriform morular variant of PTC) that demonstrates more indolent behaviour than the sporadic type.⁹⁰

Gardner syndrome (colonic polyposis, osteomas, and characteristic retinal lesion) is now known to be a phenotypic variant of FAP, caused by mutation in the *APC* gene. Herve et al. estimated that the incidence of thyroid carcinoma in patients with Gardner syndrome approached 100 times that of the general population. Genetic testing for mutations in the *APC* gene is available.⁹¹

KEY POINTS

- Our understanding of parathyroid tumour biology is less developed than thyroid; however, advancements in genetic testing have demonstrated areas of potential. Several genes have been studied (*MEN1*, *PTH*, *HRPT2*, *ZFX*) and have been postulated to play an important role in the development of parathyroid tumours.
- PCR and immunohistochemistry techniques based on products of specific genetic mutations may aid in differentiation of adenomas, hyperplasia and carcinoma.
- Genetic testing in endocrine disease relates to the MEN syndromes. Genetic testing plays a key role in the management of MEN type 2 and less prominent role in MEN type 1.
- *RET* mutational analysis is a key investigation in the management of patients with MEN type 2. *RET* analysis offers a risk stratification based on the codons mutated and guides clinical management.
- Further identification of genes may allow targeted anti-neoplastic agents in the age of targeted molecular therapeutics.

SEARCH STRATEGY

Data in this chapter may be updated by Medline and Embase searches using the key words: wound healing, tissue repair, tissue regeneration, chronic wounds and wound dressings. Information from these resources was critiqued and the information included is from levels of evidence 1 and 2.

INTRODUCTION

A wound is defined as a break in the integrity of the skin epithelium, often accompanied by concurrent disruption of the underlying dermis.¹ Having a clear understanding of wound healing is fundamental in all aspects of surgery. Whether small or large, acute or chronic, all wounds heal by a complex, dynamic, highly orchestrated biological process and a surgeon's success is largely dependent upon the uncomplicated successful procession through the different phases of normal wound healing.² In order to be able to both prevent wound formation and treat pathologic wounds, one must first appreciate the normal process of wound healing.

Wound healing has been divided into four overlapping stages: haemostasis, inflammation, proliferation and remodelling. However, this complex process is by no means constant, with genetics (susceptibility to abnormal scarring), age, site, tension, nutrition and disease all very important influencing factors. A wound is 'healed' when:

- connective tissue repair and complete re-epithelialization have occurred
- skin cover has been resorted with scar tissue without the necessity of drains or dressings.

When the process of wound healing fails to occur in an orderly and timely fashion, wounds become chronic and

non-healing, requiring continued management by drainage and dressing.¹

On the other hand, aberrant healing (excessive scar formation) may also result in the formation of abnormal scarring, such as in hypertrophic scarring or keloid disease.

TYPES OF WOUND HEALING

Primary healing (healing by first intention)

Healing by first intention is characterized by closure of a wound within 12–24 hours of its formation. These wounds are clean and well perfused, for example following surgical excision or a clean laceration. Wound edges are approximated using sutures, skin glue, steri-strips or other mechanical devices/instruments.¹ Apposition of wound edges reduces the distance for epidermal proliferation and wound closure (**Figure 10.1**).

Secondary healing (healing by secondary intention)

Healing by secondary intention usually occurs in large wounds where it is not possible to appose the edges or in wounds that are complicated by infection. Wounds may be

Figure 10.1 Diagrammatic representation of healing by primary, secondary and tertiary intention.

gaping and the edges lacerated. In these situations, sealing of the epithelium across the wound bed does not occur rapidly. Epithelial cells must grow both downwards and across the wound bed, with granulation tissue filling the defect. Healing of these wounds is achieved by wound contraction and subsequent epithelialization. Myofibroblasts play a key role in this process, usually appearing around 3 days following wound formation. Compared to healing by first intention, wound healing by secondary intention is a much slower process and may lead to subsequent contracture formation potentially resulting in functional impairment.¹

Delayed primary healing (healing by tertiary intention)

This process mainly occurs in contaminated wounds, for example following bites and in abdominal wounds after peritoneal soiling. The wound edges are left unopposed in order for host defences to aid in debridement of the wound. The wound edges are usually approximated after 3–4 days, during which host phagocytes are recruited and inflammatory cells destroy the contaminating bacteria.¹

Healing of superficial (partial-thickness) wounds

This process occurs following partial-thickness burns, split-thickness skin grafts and following abrasions, can extend through the epidermis and to the papillary dermis. The basal cell layer of the epidermis often remains intact and dermal regeneration can occur from epithelial cells within dermal appendages (hair follicles and sebaceous glands) and from the basal cell layer that replicate and migrate to the wound. The healing process occurs by re-epithelialization and is usually complete.¹

PHASES OF WOUND HEALING

The complex, co-ordinated cascade of wound healing (as occurs in primary wound healing) is characterized by a number of cellular activities, including phagocytosis, cytokine release, chemotaxis, inflammation and synthesis of the extracellular matrix (ECM).¹ Following tissue

Figure 10.2 Phases of wound healing. Adapted from Greaves et al., 2013.¹

injury, these processes have been described to occur in four phases: haemostasis, inflammation, proliferation and remodelling (Figure 10.2). Growth factors and cytokines are essential throughout the whole process of wound healing (Tables 10.1 and 10.2).

Haemostasis

Tissue injury results in disruption of the vascular endothelium, extravasation of blood constituents and exposure of the basal lamina. Constriction of endothelial cells and platelet activation then ensues. As well as initiating the coagulation cascade, aggregation, activation and degranulation of platelets leads to the release of several important growth factors that play important roles in chemotaxis (platelet-derived growth factor), deposition of the extracellular matrix (transforming growth factor-β), epithelialization (epidermal growth factor) and angiogenesis (vascular endothelial growth factor).²⁻³

TABLE 10.1 Major cell types and their roles in wound healing

Cell type	Role in wound healing
Platelets	<ul style="list-style-type: none"> • Clot formation • Release cytokines through degranulation (TGF-β, PDGF, platelet factor-4, β-thromboglobulin)
Neutrophils	<ul style="list-style-type: none"> • First cells attracted to wound site • Phagocytosis and intracellular destruction of bacteria
Macrophages/monocytes	<ul style="list-style-type: none"> • Phagocytosis of bacteria • Remove debris and necrotic tissue • Release important cytokines • Essential for fibroblast division, synthesis of collagen and angiogenesis
Lymphocytes	<ul style="list-style-type: none"> • Role unclear • May release some cytokines
Fibroblasts	<ul style="list-style-type: none"> • Produce most of the ECM • Form granulation tissue • Reorganize and structure the ECM • Wound contracture through formation of myofibroblasts
Keratinocytes	<ul style="list-style-type: none"> • Identification and destruction of foreign microorganisms • Wound re-epithelialization

TABLE 10.2 Major cytokines/growth factors, their sources and roles in wound healing

Cytokine/Growth factor	Sources	Role in wound healing
TGF-α	Macrophages, platelets, epithelial cells	<ul style="list-style-type: none"> • Stimulates epithelial cells and fibroblasts • Forms granulation tissue
TGF-β	Platelets, macrophages, fibroblasts, neutrophils, keratinocytes	<ul style="list-style-type: none"> • Stimulates fibroblast and smooth muscle proliferation • Chemotactic for macrophages
VEGF	Platelets, neutrophils	<ul style="list-style-type: none"> • Stimulates angiogenesis and collateral blood vessel formation in peripheral vascular disease
PDGF	Platelets, macrophages, endothelial cells	<ul style="list-style-type: none"> • Stimulates proliferation of fibroblasts • Stimulates angiogenesis • Stimulates wound contracture
FGFs	Fibroblasts, endothelial cells, smooth muscle cells, macrophages	<ul style="list-style-type: none"> • Chemotactic and mitogenic for fibroblasts and keratinocytes • Stimulates angiogenesis
IL-1	Macrophages, lymphocytes	<ul style="list-style-type: none"> • Activates granulocytes and endothelial cells • Stimulates haematopoiesis

Growth factors attract and activate fibroblasts, macrophages and endothelial cells. Four processes, essential to wound healing, are initiated following these events:

- Clotting cascade
- Complement cascade
- Kinin cascade
- Plasmin generation

The clot that forms acts as a matrix for subsequent cell migration. Vasoactive mediators released from the platelets lead to vasodilatation and increased vascular permeability.

Inflammation

This process usually lasts up to 4 days and can be divided into early and late phases. The cell type and response differ in these phases.

EARLY INFLAMMATION (DAYS 1–2)

Activation of the classical and alternative complement cascades leads to neutrophil infiltration of the wound usually within 24–48 hours of injury. These chemoattractants include:¹

- transforming growth factor- β
- complement constituents
- bacterial peptide products
- fragments of extracellular matrix proteins.

Neutrophils adhere to endothelial cells of the surrounding blood vessels (margination) and move through the vessel wall (diapedesis). Further neutrophils are attracted to the site and release proteolytic enzymes, which digest the bacteria and debris. Neutrophils also form oxygen-free radicals (through a myeloperoxidase pathway), which sterilize the wound of bacteria.⁴

Throughout this period, basal cells exhibit increased mitotic activity and epithelial cell migration and proliferation occurs across the dermis. Neutrophil activity usually stops within a few days of tissue injury, once the contaminating bacteria and debris have been removed. Macrophages also aid in this process by phagocytosing redundant cells. The main function of the neutrophil is to remove bacterial contamination and debris from the wound and thus prevent infection.

LATE INFLAMMATION (DAYS 2–3)

Monocytes are attracted to the wound by chemoattractants including cytokines, complement components and breakdown products of collagen and elastin. At the wound site, they differentiate into macrophages, which are the most important cell type of the late inflammation stage (48–72 hours). In addition to phagocytosis of bacteria and cell debris, macrophages play a key role in granulation tissue formation and proliferation by releasing important cytokines: PDGF (platelet derived growth factor),

TGF- β (transforming growth factor beta), TGF- α (transforming growth factor alpha), FGF (fibroblast growth factor) and IL-1 (interleukin one).⁵ Macrophages also play important roles in:

- formation of the ECM by fibroblasts
- proliferation of smooth muscle cells
- endothelial cell proliferation and subsequent angiogenesis
- phagocytosis and enzyme release in the early inflammatory phase.

Macrophage or monocyte depletion leads to poor wound healing with poor debridement, delayed proliferation of fibroblasts, delayed ECM synthesis, inadequate angiogenesis and poor fibrosis.⁶ During the late inflammatory stage, collagen fibres become evident at the incision margins of the wound but do not bridge the incision. A thickened epidermal covering layer is produced by continued epithelial proliferation.

Proliferation (day 3 to week 2)

This process, starting around day 3 and which can last up to 4 weeks, encompasses re-epithelialization and granulation tissue formation.

RE-EPITHELIALIZATION

This process involves replication and movement of the epidermal cells from the wound edges in order to reconstitute an organized, keratinized, stratified squamous epithelium. Increased mitotic activity within the basal cells of the wound edges occurs within 12 hours of wounding. Initially, migration of epidermal cells creates a delicate covering over the raw area, a process also known as ‘epiboly’. These cells then migrate, usually as a sheet, by extending lamellipodia (from the Latin *lamina* – thin sheet, *pod* – foot) from the free edge of the cut epidermis, across the defect. This process of migration is dependent on the oxygen tension present in the wound and is most rapid in hyperbaric conditions.⁷ ‘Contact inhibition’ prevents movement when epithelial sheets meet. Gradually, a continuous squamous cell epithelium is restored.

In partial-thickness wounds, the skin appendages (hair follicles and sebaceous glands) act as a source of epithelial cells for regeneration of the epidermis. During the process of migration, keratinocytes play an important role in bacteriological control. Foreign particles, once detected are phagocytosed and non-viable tissue is sloughed off.

Migration ceases once the sheets of epidermal cells meet. Re-epithelialization is complete and epidermal cells return to their normal morphology. Through this process, the barrier properties of the skin are restored, preventing the development of complications such as infection.

GRANULATION TISSUE FORMATION

Granulation tissue formation is composed of three important steps: fibroplasia, wound contraction and angiogenesis.

Fibroplasia

This process comprises of recruitment and proliferation of fibroblasts, which are essential in production of the ECM and the organization of components of the granulation tissue.⁸ Fibroblasts are attracted to the wound 2–4 days after injury by growth factors including PDGF and TGF- β . Once at the wound site, fibroblasts proliferate and produce a number of important proteins (fibronectin, hyaluronin, collagen and proteoglycans) used to construct the new ECM. After wounding, fibroblasts undergo phenotypic alterations with altered expression of fibronectin.⁹ These cells, called myofibroblasts, have capacity for contraction and increased motility and play an essential role in contraction during both normal and pathological wounding.⁹ Mechanical tension and PDGF are important factors reported in myofibroblast formation.⁹

Fibroblasts secrete the ECM matrix, composed of fibrous structural proteins (collagen, elastin) and an interstitial matrix (glycoproteins in a proteoglycan and glycosaminoglycan gel). The interstitial matrix becomes organized around the epithelial cells, smooth muscle cells and endothelial cells and forms a new basement membrane. Fibronectin is a glycoprotein secreted in the ECM that aids adhesion of fibroblasts to the ECM, stimulates fibroblast migration, provides support for collagen deposition and mediates wound contraction.

Structural proteins (collagen and elastin) are vital for providing structure and strength. Several growth factors stimulate collagen synthesis during both the proliferative and remodelling phases, including: PDGF, basic fibroblast growth factor, TGF- β , IL-1, and TNF (tissue necrosis factor). Around 18 different types of collagen exist. Collagen type III is secreted maximally within 5–7 days of wounding.

Wound contraction

This begins 7 days after wounding and peaks at 2 weeks. This process reduces the size of the defect and the need for scar tissue, usually occurring at a rate of 0.6–0.7 mm per day.¹⁰ The degree of contraction varies with depth. However, in humans, in whom the skin is relatively immobile, contraction alone rarely completely closes a wound. Contraction must be closely regulated; when there is limited contraction, this can lead to delayed wound closure, bleeding and infection whilst excessive contracture can cause contractures.

Angiogenesis

This is the process of new blood vessel formation, commencing 2–3 days after wounding. This is essential to healing, as metabolic activity in a healing wound cannot occur without a specific blood supply. Granulation is composed of proliferating fibroblasts and loops of capillaries in a loose ECM. Important steps required for angiogenesis include: degradation of the basement membrane of the parent vessel, endothelial cell migration towards the angiogenic stimuli, endothelial cell proliferation with subsequent maturation into capillary tubes.¹

Important factors inducing angiogenesis include: VEGF, PDGF, TGF- β and basic fibroblast growth factor. Invasion of the wound by capillaries creates a microvascular network within the wound. Chronic wounds, characterized by delayed healing, may occur when vascular supply to the wound is insufficient.¹¹

Remodelling and scar maturation (from week 1 to several weeks)

The ECM and collagen fibres are continually synthesized and remodelled throughout the process of wound healing (this occurs simultaneously with granulation tissue formation). As collagen is formed, it is also degraded. Metalloproteinases (collagenases, gelatinases and stromelysins) are proteolytic enzymes synthesized by fibroblasts, neutrophils and macrophages responsible for this process. Regulation of metalloproteinase activity is necessary to ensure that collagen degradation, which in excess may impair wound healing, is closely controlled. Typically, these enzymes are initially inactive and activation is necessary before they can act. Tissue inhibitors of metalloproteinases also prevent their action and allow for control of collagen breakdown. Around 21 days following injury, equilibrium is reached between collagen formation and degradation. Continued remodelling leads to eventual reduced activity of metalloproteinases, reduced macrophages and fibroblasts, reduced capillary outgrowth and reduced size of contractile connective tissue.

Scar maturation results in the breakdown of fibronectin and hyaluronan as well as a larger diameter of collagen bundles. Though increasing in strength through the process of remodelling, the collagen will never reach the same strength as that of unwounded skin and usually a maximum of 80% of the strength in unwounded skin is reached.

REPAIR OF HARD TISSUE/BONE

Repair of bone is similar to that of soft tissue, with an added osteogenic component. Following injury, haemorrhage occurs with clot formation. Neutrophils, macrophages and mast cells move into the injury site and release growth factors and cytokines, stimulating the process of healing. Cytokines of importance in bone formation include:

- TGF- β , which is a potent chemotactic cytokine for osteoprogenitor cells and macrophages. This also stimulates proliferation of mesenchymal and osteoprogenitor cells, osteoblasts and chondrocytes.
- TNF- α , which promotes recruitment of mesenchymal stem cells. Absence of TNF- α prohibits bone formation.
- Bone morphogenic proteins, which regulate the transcription of target genes, in particular playing a critical role in regulation of growth, differentiation and apoptosis of osteoblasts, chondroblasts, neural cells and epithelial cells.

Osteoclasts and macrophages remove wound debris and gradually granulation tissue is formed and replaces the clot. This process usually takes several days, but the duration is also dependent on the site and the severity of the injury.

Vascular endothelial cells and perivascular mesenchymal cells provide osteoprogenitor cells, which become osteoblasts. Several cytokines stimulate osteoblast activation including PDGF, TGF- β , FGFs and bone morphogenetic proteins (BMPs).¹² Chondroblasts may also become activated, particularly when oxygen levels are low. Within the new matrix, mainly at the site of the periosteum, cartilage cells begin to develop. Osteoblasts also release calcium, which is deposited into the new matrix and on to the cartilage. At this stage, the bone is flexible and is called soft callus.

Once the soft callus is formed, subperiosteal and endochondral ossification occurs continually. Hard callus is formed once the ends of the bone become united, after approximately 2 months. Once formed, the remodelling process continues leading to the formation of mature lamellar bone. This process requires osteoblasts and osteoclasts. Through further remodelling, the marrow cavity and the contour of the bone are restored. External forces applied to the bone can alter the remodelling process.

LINKING BASIC KNOWLEDGE TO PRACTICE – KEY QUESTIONS

A number of different pathological processes may lead to abnormal wound healing. Prompt diagnosis and appropriate treatment is key. When incorrectly diagnosed, delayed wound healing followed by other morbid complications may ensue.

1. What are the causes of abnormal wound healing?
2. Which local and systemic factors impede wound healing?
3. How do we assess wounds?
4. How do we manage wounds?

What are the causes of abnormal wound healing?

Several local and systemic factors may impede wound healing (Figure 10.3). This section will review some of these important factors in more detail.

PATIENT AGE

Local and systemic factors affecting wound healing are more common in elderly patients. Failure of wound healing can become a chronic disabling condition and may incur significant social and medical costs to the elderly population affected. Ageing has a number of effects on the different stages of wound healing including:^{13–15}

- delayed epithelialization
- altered inflammatory and cell adhesion molecule profile

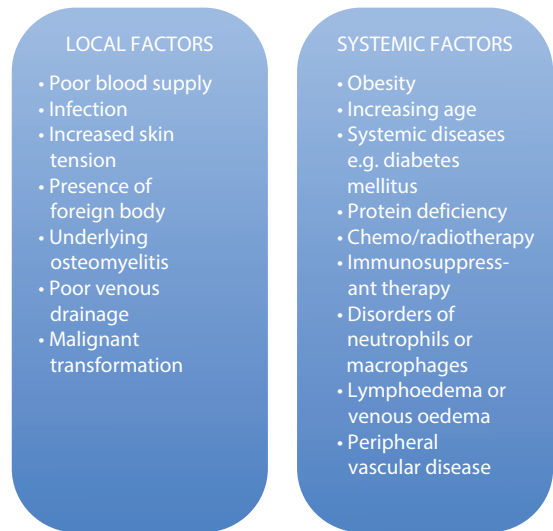

Figure 10.3 Local and systemic factors contributing to impaired wound healing.

- reduced collagen content and ‘fragmented’ appearing elastic fibres leading to reduced tensile strength
- reduced number of inflammatory cells
- impaired granulation tissue formation
- impaired angiogenesis.

NUTRITIONAL STATUS

Malnutrition adversely affects wound healing. In particular, dramatic degrees of protein calorie malnutrition delays the wound healing response.¹⁶ Additionally, several ‘pro-healing’ nutrients have been identified including: arginine, vitamins A and C and zinc.

Markers of nutrition identified in previous studies include:^{17, 18}

- serum albumin (<30 g/l), shown to predict delayed wound healing; however, albumin levels can be affected by other conditions such as fluid retention and distribution. It also has a long half-life
- pre-albumin (<10 mg/dl), an indicator of malnutrition and poor wound healing with a shorter half-life than albumin
- serum transferrin (<1.5 g/l) also shown to predict delayed wound healing; however, transferrin levels are also dependent upon body iron status.

Assessment of nutritional needs and supplementation is essential in those with or at risk of malnutrition. Dieticians play a vital role in the assessment and management of these patients.

Important screening questions when assessing nutritional intake include¹⁷ height, weight, recent unintentional weight loss, and change in food intake. It is also important to find out how physically active patients are and whether they have had any additional gastrointestinal symptoms such as chronic diarrhoea or vomiting.

Several formal screening tools have also been developed, such as ‘MUST’. This categorizes patients into low,

Figure 10.4 Mild, moderate and severe categories of malnutrition.

medium and high-risk groups according to their score. Those at high risk should be assessed by a dietician and receive nutritional support.¹⁹ Pre-operative nutritional support is recommended for patients with moderate to severe malnutrition (Figure 10.4).

UNDERLYING CHRONIC CONDITION

Diabetes mellitus, atherosclerosis, hypothyroidism, chronic venous insufficiency and obesity can all delay wound healing. The effect of increased serum glucose, in diabetic patients, on wound healing is multifactorial. Some of these effects include:²⁰⁻²³

- increased vascular permeability leading to pericapillary albumin deposition and impaired diffusion of oxygen and nutrients
- inhibition of function of structural and enzymatic proteins due to non-enzymatic glycolization
- glycosylated collagen resistance to enzymatic degradation.

Animal and human models have shown that as a result of these effects, diabetic wounds demonstrate decreased granulation tissue, decreased collagen, slow wound maturation and decreased numbers of fibroblasts.

Animal studies have also demonstrated that reduced thyroid hormone levels can adversely affect fibroblast function and subsequent wound strength. In addition to the specific effects of absent thyroid hormone, systemic complications of the disease such as heart failure can also compound these effects.²⁰ Treating the underlying condition is an essential step in wound management in patients with both diabetes mellitus and hypothyroidism.

INFECTION

Local wound infection and foreign bodies delay wound healing by prolonging the inflammatory phase. When the bacterial count is greater than $10^5/g$ of tissue or beta-haemolytic streptococcus is present, the wound will not heal. Bacteria prolong the inflammatory phase of wound healing and also deleteriously affect rate of epithelialization, contraction and collagen deposition.²⁰

MEDICATIONS

Patients with chronic wounds often suffer from chronic diseases for which they may take several medications.

These medications may contribute to delayed wound healing. It is thus vital to review a patient's list of medications. The following medications may contribute to delayed wound healing:²⁴

- steroids,²⁵ which arrest inflammation by interfering with wound macrophages, angiogenesis and wound contraction
- NSAIDs,²⁶ which reduce collagen synthesis, thought to be related to impaired prostaglandin metabolism
- chemotherapeutic agents,²⁴ which reduce wound contraction and fibroblasts proliferation.

CLASSIFICATION OF WOUNDS

Wounds can be categorized in a number of different ways. In this section we will describe some of the important classifications.

Acute vs. Chronic

Acute wounds most often occur secondary to trauma. These wounds generally heal very well.

Chronic wounds usually occur in patients with an underlying condition, for example diabetes mellitus, malignancy and chronic venous insufficiency. These wounds may start from an initial trauma and persist beyond 6 weeks, due to an abnormal underlying physiology affecting the process of wound repair, such as diabetes, or peripheral vascular disease. In addition, these wounds have the potential for malignant transformation, also known as Marjolin's ulcer.

ACUTE WOUNDS

Examples of acute wounds include:

- thermal wounds
- surgical wounds
- traumatic wounds.

Thermal Wounds

Both extremes of temperature and radiation may lead to thermal wounds. Radiotherapy is often used to treat head and neck cancers and leads to permanent damage to the skin's microvasculature. These wounds often heal poorly and can become infected.

Burns are the commonest type of thermal injury and exact assessment of the degree/level of depth of burn is critical. Most commonly burns are classified as:

- 1 Superficial:
 - Wound appears erythematous.
 - This affects the upper layer of the epidermis. Generally no intervention is necessary.
- 2 Partial-thickness:
 - Appear blistered.
 - Further subdivided into superficial partial-thickness, mid-dermal and deep-dermal.

- This affects the epidermis and part of the dermis. Generally minimal intervention may be required if only the most superficial part of the epidermis is affected, the so-called superficial partial-thickness wounds. Mid-dermal and deep-dermal should be closely observed as skin grafting may be necessary, particularly if these wounds extend.
- 3 Full-thickness:
- Appear charred/white and insensate
 - These wounds affect the epidermis, dermis and can extend into the subcutis. Skin grafts are always required in these wounds.

Surgical Wounds

There are many types of surgical wounds and examples include incisions, excisions, skin grafting (involving split-thickness skin grafts or full-thickness skin grafts), amputations and skin biopsies:

- **Incisions/excisions:** A scalpel is the most common device used to make these wounds. This extends through the whole thickness of the skin to the underlying tissues. If the incision involves removal of tissue, this will be considered an excision. Post-operatively the wound is sutured closed (healing by primary intention) or in the case of excision, this may require skin grafting or use of skin flaps.
- **Skin grafts:** These are commonly used following deep (full-thickness) burn injuries. The grafts can be either split-thickness or full-thickness depending on the depth of the harvest. Split-thickness includes the epidermis and the papillary dermis.
- **Amputations:** This type of wound is created following surgical removal of a limb, either as a result of disease, trauma or infection. Healing of these wounds is usually by either primary or secondary intention depending on the initial indication for the amputation.
- **Skin biopsies:** These wounds usually involved surgical excisional removal of a full-thickness area of skin for histological assessment. These wounds are normally left to heal and close by secondary intention although the larger wounds are closed directly using sutures following the biopsy and healing by primary intention.

Surgical wounds have also been classified according to the level of contamination during the operation from I–IV (Table 10.3).

Traumatic Wounds

These are other acute injuries, which usually result from a physical force. They may result from small, common cutaneous injuries to life-threatening limb/head/trunk injuries. Examples include:

- abrasions
- puncture
- laceration
- bruises
- gunshots
- blisters
- bites
- stab
- crush.

CHRONIC WOUNDS

The vast majority of chronic wounds can be classified into the following categories:

- diabetic ulcers
- pressure ulcers
- venous ulcers
- arterial ulcers.

Diabetic Ulcers

The effect of diabetes on wound healing was described previously. Diabetics have a 15% greater risk of amputations compared to the general population, due to chronic lower limb ulcers.²⁷ Wounds often form secondary to diabetic neuropathy. Loss of pain perception results and patients often develop wounds from repeated injury that they fail to notice.

Pressure Ulcers

These wounds typically occur over bony prominences where skin is subject to excessive pressure forces. Chronic conditions such as diabetes mellitus may also predispose patients to developing pressure sores. Common sites affected include the heels, shoulder blades and sacrum. Pressure ulcers can be classified according to the depth of the wound:

1. Stage I:
 - Non-blanching erythema
 - Skin temperature, tissue consistency or sensation may be altered

TABLE 10.3 Classification of surgical wounds

Class and type of wound	Description of wound	Wound closure
Class I Clean	<ul style="list-style-type: none"> • Wound made aseptically • No contact made with respiratory, alimentary or urinary tract 	<ul style="list-style-type: none"> • Closed by primary intention
Class II Clean-contaminated	<ul style="list-style-type: none"> • Wound made aseptically • Enters respiratory, alimentary or urinary tract 	<ul style="list-style-type: none"> • Closed by primary intention
Class III Contaminated	<ul style="list-style-type: none"> • Wound is open or involves major breaks in sterile technique or gross spillage from gastrointestinal tract 	<ul style="list-style-type: none"> • Closed by primary or secondary intention. • Requires significant washing before closure
Class IV Dirty	<ul style="list-style-type: none"> • Dirty infected wounds • This retains devitalized tissue or involves pre-operative existing infection or perforated viscera 	<ul style="list-style-type: none"> • These wounds are often left open for drainage

2. Stage II:
 - Partial-thickness skin loss
 - Involves epidermis and dermis
 - Appears as an abrasion, blister or shallow crater
3. Stage III:
 - Full-thickness skin loss
 - Extends to but not through the underlying fascia
 - Presents as a deep crater
4. Stage IV:
 - Full-thickness tissue loss
 - Extends to muscle, bone, or supporting structures (e.g. tendon or joint capsule)

Venous Ulcers

These are the most commonly occurring ulcers and result from venous insufficiency. Venous drainage and blood supply are reduced in the affected tissue, leading to extensive ulceration following a minor injury.

Characteristics of these ulcers include:

- often located around medial malleolus
- shallow depth
- large in size
- irregular edges
- sloughy base with pink granulation tissue.

Arterial Ulcers

These are caused by a lack of blood flow to the lower limbs. This leads to tissue hypoxia and ischemia. These ulcers occur more commonly in diabetics and smokers.

Characteristics of these ulcers include:

- often sited around the lateral malleolus
- small in size
- regular shape
- deep, often to bone
- no granulation tissue.

Types of wound tissue

GRANULATION TISSUE

This appears red, moist, shiny and granular. On biopsy, an abundance of capillaries, macrophages and fibroblasts may be seen.

EPITHELIAL TISSUE

Once wounds are filled with granulation tissue, a new epithelial layer grows from the edges of the wound moving towards the centre. This tissue appears pink/white in colour. As well as from the edges of the wound, epithelial cells may also be derived from skin appendages, producing islands of skin in the middle of the granulation tissue.

NECROTIC TISSUE

There are two types of necrotic tissue that may appear in a wound: slough and eschar. Slough is dead devitalized tissue that appears moist, loose and stringy. It is typically

yellow and found on the wound bed. It is commonly present in chronic or infected wounds. Eschar commonly occurs after burns and appears as dry, thick, leathery tissue. It may be black and should be promptly excised.

INFECTED TISSUE

A number of classical features can be used to identify infected tissue:

- Pyrexia
- Pus
- Erythema (particularly when spreading)
- Malodour
- Wound dehiscence
- Poor healing
- Increased pain
- Sinus formation

When a wound infection is suspected, the following steps should be taken:

- 1 Wound swab: Traditionally 10^5 bacteria per gram has been used as the cut-off point at which it is thought that bacteria inhibit wound healing. Wounds with this level or greater of bacteria are classed as being infected.
- 2 Sensitivities: From the wound swab, the sensitivities of the organisms to antibiotic treatment can be determined.

WOUND ASSESSMENT

Size of the wound

The wound size should be assessed on first presentation and regularly thereafter. The outline of the wound can be traced onto transparent acetate sheets. The surface area may be calculated by multiplying the longest diameter in one plane by the longest diameter in the plane at right angles (in a circular shaped wound).²⁸

Edges of a wound

Examination of the edges of a wound is useful in identifying the aetiology of the wound. Venous ulcers often have sloping edges whilst arterial appear well demarcated or 'punched out'. When rolled or everted edges are observed, malignancy must be excluded by biopsy.

Location of the wound

The site of a wound also aids in the diagnosis. Venous ulcers most commonly occur in the gaiter region, around the medial malleolus. Diabetic foot ulcers commonly occur over pressure areas such as under the hallux, under the first and fifth metatarsal heads and under the heel.

Wound bed

The appearance of the wound bed gives an indication of the type of wound. Healthy granulation tissue appears pink. Dark red and bleeding granulation tissue

Figure 10.5 Invasive and non-invasive techniques for assessing wounds.

may indicate infection. Excess granulation tissue may be present in chronic poorly healing wounds. This excess tissue must be debrided to aid wound healing. Techniques for assessing wounds may be either invasive or non-invasive (Figure 10.5).

EXCESSIVE WOUND HEALING

Hypertrophic scars and keloids occur as a consequence of excessive wound healing leading to abnormal fibrotic scar formation. These result from overproduction of fibroblasts, collagen, elastin and proteoglycans. These occur in up to 5–15% of all wounds, with rates much higher in the non-Caucasian population with pigmented skin.¹

Hypertrophic scars

These scars are more common in:¹

- wounds that are under tension
- deep dermal burns
- wounds healing by secondary intention.

Keloid

This is a benign fibroproliferative scar that continues to grow beyond the confines of the original wound, invading into healthy surrounding tissue.²⁹ No specific cause has been elucidated, although it is known that keloids have a strong genetic predisposition.³⁰ In most instances, the magnitude of the injury does not correlate with the size of the keloid scar, although in every case, a form of dermal injury has been associated with development of a keloid scar.

WOUND DRESSINGS

Ideal wound dressings sustain a moist wound environment for optimal wound healing. Dressings can be comprised of synthetic polymers (formed into fibres, wafers or membranes).³¹ These membranes are considered to be semi-permeable to gases (oxygen, CO₂ and moisture) and usually impermeable to liquids. These dressings are also named occlusive dressings. There are five types of such dressings:

- 1 Hydrogels
- 2 Hydrocolloids
- 3 Foams
- 4 Films
- 5 Alginates.

The principle reasons for applying a dressing include:

- to produce rapid and cosmetically acceptable healing
- to reduce pain
- to remove odour
- to treat or prevent infection
- to cover a cosmetically unpleasant wound.

Several factors should be considered when choosing a dressing including:

- wound-related factors:
 - size
 - depth
 - amount and characteristics of exudate
 - necrotic/viable
 - surrounding tissue appearance (pigmented, scarred or cellulitic)
- product factors.
- patient factors.

Dressings for acute wounds

Several dressings may be used for acute wounds. These include:

- low-adherence dressings (e.g. Mepore[®], Mölnlycke Healthcare), for example for skin tears
- transparent film (e.g. OpSite[™], Smith & Nephew), which is used in clean, dry wounds.

Dressings for chronic wounds

NECROTIC WOUNDS

The aim with these wounds is to rehydrate the skin so that the dead skin/scab will separate from the normal skin. Options include:

- wet dressings using saline or hypochlorite
- hydrocolloid when wounds are dry and necrotic
- hydrogel (e.g. Aquasorb[™]) when wounds are dry and necrotic
- surgical/mechanical debridement
- biological debridement (e.g. larvae)
- enzymatic debridement (e.g. collagenase).

SLOUGHY WOUNDS

These should be debrided in order to remove the abnormal matrix of slough (inflammatory cells and exudate). This can be done surgically or using an agent which soaks up the debris forming a moist gel. Dressing options include:

- hydrofibres
- hydrogels
- hydrocolloids
- polysaccharide dressings (beads or paste)
- alginate dressings
- mechanical debridement.

GRANULATING WOUNDS

Granulation tissue is highly vascular. It contains collagen and proteoglycans. The dressing choice depends on depth and exudate from the wound.

For light-medium exudative wounds consider:

- hydrocolloids
- thin foam dressings
- hydrogel, sheets or gels.

For shallow exuding ulcers:

- alginate dressings
- hydrophilic foam materials
- hydrocolloids.

For deep cavity wounds:

- alginate fibre ribbons
- foams
- silicone foam dressings
- hydrofibers (e.g. Aquacel®)
- vacuum-assisted closure (VAC) therapy.

EPITHELIALIZING WOUNDS

These are superficial wounds. Dressing choice depends on whether the wounds are dry or exude fluid. For dry superficial wounds, the following dressings are recommended:

- hydrocolloids
- film dressings
- perforated plastic film dressings
- knitted viscose non-adherent dressings.

For exudative wounds (e.g. burns and graft donor sites) dressing options include:

- paraffin gauze covered with gauze and cotton (Gamgee)
- hydrocolloids
- alginates
- hydrofibers (e.g. Aquacel®).

For very exudative wounds:

- impregnated gauze dressings may be used. Twice daily dressing changes may be required.

INFECTED WOUNDS

These wounds can have an unpleasant odour. For this reason and in order to prevent spread of infection, they should be covered. Antibacterial agents are included in a number of the dressings:

- framycetin
- fusidic acid
- chlorhexidene
- iodine

- honey dressings
- silver sulfadiazine dressings (e.g. Silvadene) or an ionic silver hydrofiber dressings (e.g. Aquacel-AG).

MANAGEMENT OF SPECIFIC WOUNDS

Over/hypergranulation tissue occurs when the inflammatory phase is prolonged unnecessarily. The most frequent dressing options include:

- change from occlusive to non-occlusive dressings
- light pressure application to wound bed with bandaging
- short-term topical steroid application.

For pressure wounds:

- comfortable dressing, for example an extra-thin hydrocolloid
- off-loading devices such as comfort boots in heel ulcers
- securing dressings in a very moist area such as the sacrum is challenging. A wafer hydrocolloid is a comfortable and highly adherent dressing.

For venous ulcers:

- the dressing type should be according to the tissue type in the ulcer bed
- compression bandages.

For diabetic foot ulcers:

- optimal blood sugar control
- appropriate comfortable footwear
- daily saline dressing to provide a moist wound environment
- debridement if necessary
- antibiotics if soft tissue infection or osteomyelitis present.

For burns or scalds:

- cold running water
- cling film prior to assessment.

For superficial burns:

- semipermeable films
- hydrocolloids
- Aquacel®
- Mepitel®
- foams.

For partial thickness burns:

- Flamazine®
- alginates
- Mepitel®
- Aquacel®.

For full-thickness burns:

- assessment at a specialist burn centre for need for skin grafting
- Flamazine®
- hydrogels
- Mepitel®.

Care of the surrounding skin:

- To secure a dressing when surrounding skin is fragile, hydrogel sheets and non-adhesive foams are useful.
- Topical creams such as Diprobase may be used to rehydrate the skin.

BEST CLINICAL PRACTICE

- ✓ Ensure a relevant history and careful examination is undertaken in order to elicit factors contributing to poor wound healing:
 - ✓ age: delayed wound healing with increasing age
 - ✓ nutritional status: malnutrition impairs wound healing
 - ✓ chronic disease: diabetes, peripheral vascular disease and chronic venous insufficiency all predispose to ulceration and poor wound healing
 - ✓ several medications impair wound healing, in particular: steroids, non-steroidal anti-inflammatory drugs, cytotoxic agents and immunosuppressants
 - ✓ pressure-prone anatomical areas can lead to ulcer formation
 - ✓ infection impairs wound healing.
- ✓ Wounds can be classified in a number of ways:
 - ✓ acute vs. chronic: (i) acute: thermal wounds, surgical wounds and traumatic wounds; (ii) chronic: diabetic ulcers, pressure ulcers, venous ulcers, arterial ulcers and mixed ulcers.
 - ✓ according to the type of wound tissue: granulation tissue, epithelial tissue, necrotic tissue or infected tissue.
- ✓ Wound assessment involves evaluation of: wound size, edges, and location (anatomical site) and status of wound bed and tissue. Invasive as well as a number of non-invasive techniques can be utilized in wound assessment.
- ✓ Five main types of wound dressing are used: hydrogels, hydrocolloids, foams, films and alginates.
- ✓ The following factors should be considered in order to choose the optimal dressing:
 - ✓ type of wound/ulcer
 - ✓ wound size
 - ✓ wound site
 - ✓ depth
 - ✓ amount and characteristics of exudate
 - ✓ necrotic/viable tissue
 - ✓ surrounding tissue appearance (pigmented, scarred or cellulitic).

FUTURE RESEARCH

Pre-clinical studies have demonstrated the potential benefit in the application of topical growth factors onto wounds.³² Future treatments may include gene therapy with insertion of human growth factors genes direction into wound cells using vectors.³³ Additionally research has demonstrated benefit in utilizing mesenchymal stem cells to promote wound healing.³⁴

In addition, the role of electrical stimulation (ES) in acceleration of cutaneous repair has gained recent scientific and clinical interest. A number of recent studies have shown that application of ES can enhance tissue repair not only by increasing angiogenesis but also by reducing inflammation.³⁵⁻³⁶

KEY POINTS

- Wounds may heal by primary, secondary or tertiary intention.
- Healing by primary intention involves:
 - clean wound edges closed within 24 hours
 - surgical incision/laceration
 - approximation using sutures, skin glue or steri-strips
 - hairline scar.
- Healing by secondary intention involves:
 - large gaping or infected wounds
 - epithelial cells grow downwards and across the wound bed
 - contraction and epithelialization occurs
 - slower than healing by primary intention and may lead to contracture formation.
- Healing by tertiary intention involves:
 - contaminated wounds
 - wound edges left unopposed for up to 4 days for phagocytosis to occur
 - wound edges then approximated, often loosely.
- Cutaneous wound healing may be divided into four stages:
 - 1 Haemostasis
 - 2 Inflammation
 - 3 Proliferation
 - 4 Remodelling.
- The following steps occur in the haemostasis phase:
 - disruption of the vascular endothelium
 - blood extravasation and clot formation
 - endothelial cell constriction and platelet activation
 - release of growth factors and cytokines by platelets.
- The inflammation phase comprises of early and late phases:
 - The early phase (days 1–2) comprises neutrophil infiltration within 24–48 hours of injury. These digest bacteria and debris.
 - The late phase (days 2–3) involves monocyte/macrophage attraction to the wound. Macrophages phagocytose bacteria and release essential cytokines including PDGF, TGF-β, TGF-α, FGF and IL-1.

- The proliferative phase:
 - Occurs from day 3 up to week 2.
 - Encompasses: re-epithelialization and granulation tissue formation (fibroplasia, wound contraction and angiogenesis).
 - Re-epithelialization starts within 12 hours of wounding and is the replication and reconstitution of the organized, keratinized, stratified squamous epithelium.
 - Fibroplasia is recruitment and proliferation of fibroblasts, which produce the extracellular matrix that acts as a scaffold for the healing tissue.
 - Fibroblasts, as well as releasing important cytokines and growth factors also produce important structural proteins (collagen, hyaluronin and proteoglycans). Phenotypic alterations in fibroblasts after wounding (day 7 to week 2) lead to myofibroblast formation. These contract and aid in wound closure.
 - Angiogenesis (day 2–3) is the process of new blood vessel formation and this is essential for the metabolic activity of the wound during healing. Several cytokines induce angiogenesis: VEGF, PDGF, TGF- β and basic fibroblast growth factor. A poor vascular supply leads to poor wound healing.
- Remodelling and scar maturation:
 - Occurs from week 1 to several weeks following tissue injury.
 - Involves collagen formation that is balanced closely with its degradation by metalloproteinases.
 - Continued remodelling eventually leads to scar formation.
 - Scar collagen is usually a maximum of 80% of the strength of unwounded skin.
- Healing of hard tissue/bone in soft tissue:
 - A similar process to that of soft tissue, with an added osteogenic component.
 - Important cytokines include: TGF- β , TNF- α and Bone morphogenic proteins.
 - Osteoclasts and macrophages remove wound debris and gradually granulation tissue is formed.
 - Chondroblasts and osteoblasts create a soft callus.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: skin flap, tissue transfer, free flap, physiology, biomechanics, vessel and skin.

Make a plan and a pattern for this plan.

Sir Harold Gillies (1882–1960)

DEFINITION

A skin flap is a block of tissue transferred from the donor site and inserted to the recipient site while maintaining a continuous attachment to the body (the pedicle). The flap may consist of skin and subcutaneous fat but could also include mucosa, fascia, muscle, bone, nerve or combinations thereof.

Traditionally, the term free flap refers to autologous tissue transfer from a distant donor site to reconstruct a defect after the pedicle has been completely detached. Blood supply is reinstated by means of microsurgical anastomoses of donor artery and vein(s) to the recipient artery and vein(s).

Flap viability is initially dependent on its robust blood supply via the pedicle so that metabolic demands of the mobilized tissue are met. Multiple anatomical and physiological factors that hamper adequate perfusion, before the collateral capillary network develops, can be detrimental for the flap survival.

Flaps currently represent the workhorses for head and neck reconstruction. However, allotransplantation holds promise for non-oncological reconstruction. Also, tissue engineering is another fast growing field in head and neck reconstruction.

HISTORY

The term ‘flap’ is alleged to originate from the Dutch *Flappe*, meaning something broad and loose that hangs attached only at one side.¹

Reconstructive skin flap surgery owes a great deal to the work of the Indian Ayurvedic medical practice of nasal reconstruction. *Sushruta Samhita*, the classical surgery textbook written around 600 BCE, describes the first cheek flaps utilized for nose repair.² The English surgeon Joseph Carpue (1764–1840) is given credit for introducing the Indian forehead rhinoplasty technique into the English language, based on a letter to the editor in 1794 relating the nasal reconstruction of a bullock driver called Cowasjee. An extremely well-referenced discussion of the history of this flap reconstructive technique is given by Nichter et al.³

Seminal studies in anatomical description of blood supply, pharmacological manipulation of the circulation and the advent of anaesthesia and aseptic techniques in surgery led to a better understanding of skin flaps. In this context, in 1889 Manchot published on many of the distinct cutaneous vascular territories served by identified named arteries.⁴ Spalteholz described the fasciocutaneous vessels, as well as those passing through muscle, and provided the origin of the concept of the musculocutaneous blood supply to flaps.⁵ In France, Salmon added to these ideas by performing radiographs on cadaver skin following intraarterial contrast injection.⁶

In 1921, Carl-Olof Siggesson Nylen, a Swedish ear, nose and throat (ENT) surgeon, built the first microscope. However, its use was confined to ENT and neurosurgical procedures. The first modern microscope is credited to Zeiss in the 1950s, and the first diploscope, operated by two surgeons simultaneously, was produced in 1961.⁷

Two years later, McGregor and Morgan described how skin flaps could be considered axial or random and therefore the length-to-width ratio was given an anatomical basis (drawing of random and axial flap). Having studied intra-arterial fluorescein injections in 14 patients, McGregor and Morgan deduced that an axial pattern flap could be safely raised beyond the standard dimensions of a random pattern flap of 1:1 length-to-width ratio and introduced the paramedian forehead flap.⁸ They went on to postulate that changes in pressure between one territory and an adjacent territory could create the effect of reverse flow in the adjacent axial vessels. This was further developed by Taylor and Palmer who postulated that each of the composite blocks (angiosomes) were connected by true anastomoses or reduced calibre 'choke vessels'.⁹ These choke vessels are analogous with the description by Salmon of 'retiform anastomoses' and as such are the defining limits of the vascular territories. They name the accompanying veins 'oscillating veins' in which flow could occur in any direction. In 1970, Milton reported that 'the surviving length of flaps made under similar conditions of blood supply is constant regardless of width. The only effect of decreasing width is to reduce the chance of the pedicle containing a large vessel'.¹⁰

The first attempts at free flaps without any magnification assistance were made in the late 1950s. Seidenberg et al. pioneered this by using a free jejunal autograft anastomosed to the superior thyroid artery and anterior facial vein via a stapling method, following a pharyngoesophagectomy for squamous cell carcinoma in 1959. The patient survived for 8 days post-op, apparently dying of an unrelated cerebrovascular accident, with the jejunal graft found to be completely viable on autopsy.¹¹

Nevertheless, the first reports of free flaps as we understand them today appeared in the early 1970s. Harry Buncke and Donald McLean used omentum, in 1972, to restore a large scalp defect following squamous cell carcinoma resection with exposed bone.¹²

As microsurgery field research advanced, it became evident that any clinically relevant perforator has the potential to be harvested as either a pedicle perforator flap or a free flap, depending on the diameter and length of the source artery and vein. The perforator flap era began in 1989, when Koshima and Soeda first described an inferior epigastric artery skin flap with the rectus abdominis muscle for reconstruction of floor-of-mouth and groin defects. Recently, Saint-Cyr et al. introduced the term 'perforasome' after conducting a three-dimensional (static) and four-dimensional (dynamic) computed tomographic angiography (CTA) in 40 fresh cadavers.¹³ Another breakthrough in the field of free-tissue transfer has been achieved by means of extracorporeal tissue perfusion. This method potentially opens avenues in cases of vessel depleted neck and severed limbs.¹⁴

FLAP DESIGN

In general, flaps are divided into two main categories, based on whether the pedicle remains attached to the donor site or not; pedicled and free flaps, respectively. The former are further subdivided based on the pattern of blood supply and tissue composition into random, arterial cutaneous (axial), fasciocutaneous, musculocutaneous and venous flaps. Similarly, free flaps are divided into fasciocutaneous, musculocutaneous, osteocutaneous, muscular or combinations thereof (chimeric free flaps). The latter allow for three-dimensional reconstruction of massive defects.

APPLIED ANATOMY AND PHYSIOLOGY

The skin is the outermost human organ in direct contact with the environment. It weighs approximately 3.8 kg and measures about 1.7 m² in surface area.¹⁵ The superficial part known as the epidermis is an impermeable, renewing, metabolically active, multi-layered, keratinizing, squamous epithelium. The epidermis consists of keratinocytes, melanocytes, Langerhans cells and Merkel cells. Hence, it serves as a sensory organ as well as a protective organ against insult and infection. Skin appendages, namely hair follicles, sebaceous glands, and eccrine and apocrine sweat glands derive from the epidermis. The epidermis and its appendages are all of ectodermic origin. Epidermis renewal is achieved by the so-called asymmetric division of the interfollicular stem cells located in the basal layer.¹⁶

The dermis, derived from mesoderm, is primarily a connective tissue layer between the epidermis and the subcutaneous (subdermal) fat and muscle. Being 15–40 times thicker than the epidermis, it invariably accounts for the skin bulk. It accommodates nerve and vascular networks, epidermal appendages, fibroblasts, macrophages and others. Collagen type I and type III to a lesser extent abound in the extracellular matrix. Elastin fibres and the ground substance (proteoglycans, glycosaminoglycans and filamentous proteins) are also found in dermis. All fibres and the ground substance are synthesized by fibroblasts and confer skin pliability, elasticity and tensile strength.

The superficial layer of dermis has a waveform pattern in proximity to the rete pegs, which is known as the papillary layer. The deeper counterpart is known as the reticular dermis. The papillary dermis has an enriched capillary network that is 10–20 microns in diameter. Deeper to it, there are several arteriovenous shunts (diameter of 10–30 microns), most notable in the reticular dermis. The capillary plexus provides nutritional support to the epidermis, whereas the arteriovenous shunt contributes to the thermoregulation and systemic blood pressure of the body. They are both connected with the deep subdermal plexus. Under normal skin conditions blood flow through the skin amounts to approximately 9 mL/min per 100 g of tissue, 10 times above the rate fulfilling the skin's metabolic needs. In extremely hot climates blood flow can increase up to 20 times with maximal vasodilation.

In contrast, when the body is exposed to cold, blood flow can reduce to levels that are marginal for skin nutrition.¹⁷

Two sphincter types regulate skin blood flow. The capillary system is controlled by a ring of smooth muscle, the pre-capillary muscle, located at the point where capillaries originate from metarteriole. It is mainly responsible for controlling nutritional support to the skin. Hence, skin hypoxia and metabolic by-products released into the microcirculation result in local vasodilation. However, blood flow can bypass by virtue of the arteriovenous shunts. The so-called pre-shunt sphincters are the main regulators of this system. Low blood pressure and extreme cold lead to pre-shunt sphincter contraction via norepinephrine released by the post-ganglionic sympathetic fibres. A similar effect is achieved by catecholamines released into the blood stream, as skin is perceived as a 'non-vital' organ in generalized hypoperfusion states.¹⁸

As mentioned above, Taylor and Palmer coined the term 'angiosome' in order to describe the spatial pattern of blood supply in various parts of the integument. Houseman et al. describe 13 angiosomes in the head and neck region mostly supplied from the external carotid, internal carotid and subclavian arteries. All 13 but the lingual, vertebral and ascending pharyngeal angiosomes contribute to the abundant subdermal vascular network (Figure 11.1). In the face and scalp, major contributing vessels radiate from fixed points, either from bony foramina or from sites where the deep fascia is attached to the bone. These arteries further arborize into smaller perforators that feed the subdermal plexus by penetrating the underlying muscle or bypassing through its fascia, hence are called musculocutaneous and fasciocutaneous perforators, respectively. Multiple arterial arches are encountered

Figure 11.1 The angiosomes of the head and neck coloured and numbered. The additional territories defined in the neck are the transverse cervical (7), deep cervical (8), inferior thyroid (9) and superior thyroid (10) (above, right). Sagittal section showing the three angiosomes, vertebral (11), ascending pharyngeal (12) and lingual (13), which do not reach the skin surface.

in midline by connection of paired arteries. The head and neck region is the smallest one with approximately 25 perforators greater than 0.5 mm in diameter. The average diameter and area of irrigation by a single perforator are 0.9 mm and 32 cm², respectively.¹⁹

In analogy to ‘angiosomes’, Saint-Cyr et al. recently introduced the term ‘perforasomes’ as well defined vascular territories nourished by a single perforator. They carried out static and dynamic CTA in order to study detailed vascular anatomy, flow characteristics, and the contribution of both the subdermal plexus and fascia to flap perfusion after raising 247 flaps in 40 fresh cadavers. Perforator flaps on the anterior trunk, posterior trunk, and extremities were studied. They concluded that:

- Each perforasome carries a multidirectional flow pattern that is highly variable and complex. These perforasomes are linked to one another by both direct and indirect linking vessels, which themselves are linked by communicating branches (Figure 11.2). These numerous vascular connections confer further protection

Figure 11.2 Interperforator flow occurs from the selected main perforator to multiple adjacent perforators by means of direct linking vessels and indirect linking vessels (recurrent flow from subdermal plexus). High perfusion pressures through the main perforator opens multiple direct and indirect linking vessels and allows perfusion of multiple other perforasomes. In this way, large flaps such as the anterolateral thigh flap can be harvested based on a single perforator. (Adapted from Saint-Cyr M, Wong C, Schaverien M, et al. The perforasome theory: vascular anatomy and clinical implications. *Plast Reconstr Surg* 2009; **124**: 1529–44. © American Society of Plastic Surgeons.)

from ischemia and vascular injury in case of trauma or flap raising. Linking vessels allow communication with adjacent perforasomes and follow a direction that is parallel to the direction of perforator flow. Therefore, perforator flap skin paddles should be parallel to the linking vessel orientation whenever possible. These linking vessels make it possible to harvest large perforator flaps based on a single perforator, such as the extended anterolateral thigh flap.

- When a perforator flap is harvested, all muscle and cutaneous branches from the source artery are ligated, which results in hyperperfusion of the selected perforator. Increased vascular filling pressures clinically dilate the perforator itself and allow extensive inter-perforator flow by means of opening and recruitment of additional linking vessels. These linking vessels, both direct and indirect, are subject to higher than normal filling pressures and are able to capture additional adjacent perforator vascular territories (perforasomes) (Figure 11.3).

Figure 11.3 Perfusion in multiple perforasomes via linking vessels. Vascular density is maximal within the cannulated perforator and its corresponding perforasome and decreases distally away from the midline of the trunk or an articulation. The orientation of linking vessels determines the orientation of vascular flow within the flap. Direction of flow is predominantly perpendicular to the trunk midline and parallel to the vertical axis of the limbs. (Adapted from Saint-Cyr M, Wong C, Schaverien M, et al. The perforasome theory: vascular anatomy and clinical implications. *Plast Reconstr Surg* 2009; **124**: 1529–44. © American Society of Plastic Surgeons.)

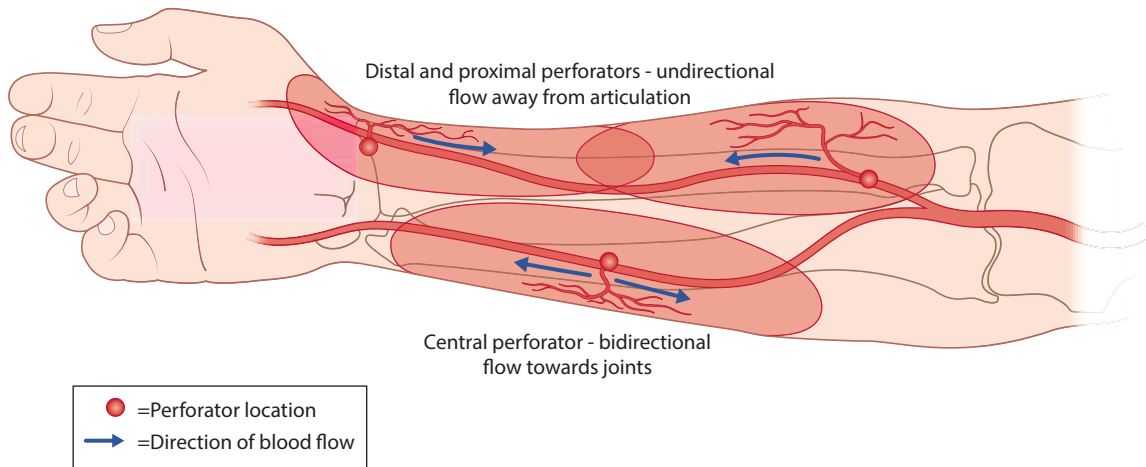

Figure 11.4 Direction of perforator flow between articulations. Perforators in the extremities that are found close to an articulation will have preferential flow away from that articulation, whereas midpoint perforators will have bidirectional flow. (Adapted from Saint-Cyr M, Wong C, Schaverien M, et al. The perforasome theory: vascular anatomy and clinical implications. *Plast Reconstr Surg* 2009; **124**: 1529–44. © American Society of Plastic Surgeons.)

- Perforator flaps designed at a midpoint between two articulations can be designed in multiple fashions because of the multidirectional perforator flow distribution. However, perforators located in proximity to one articulation seem to have unidirectional flow, i.e. distally located forearm perforators (wrist joint) course towards the proximal forearm (elbow joint), and vice versa (Figure 11.4).¹³

SKIN VESSEL BIOMECHANICS

Blood flow

Flap survival depends on flow through the pedicle of the flap.²⁰ Although the fluid mechanics of blood flow are complex, certain factors applicable to the small vessels supplying the flap are well established. Vessel blood flow (Q) is determined by:

- pressure difference (ΔP) between the two ends of the vessel
- the resistance to flow (R) produced in the vessel.

The mathematical expression of this blood flow is:

$$Q = \Delta P/R$$

where the letters are defined above.

The flow of blood through a smooth, straight vessel behaves as if there are concentric laminae, with the fastest flow in the centre creating a paraboloid wave front. The smaller the vessel becomes, the closer the central lamina becomes to the vessel wall. While this formula and lamina flow hold true for a straight, smooth vessel, any deformity such as vessel angulation, branching, obstruction or intraluminal irregularity will interfere with lamina flow. Disturbance in lamina flow is known as turbulence. Because all the flow is no longer in the same concentric laminae, fluid flowing across the direction of flow down

the vessel will increase resistance to the flow. Resistance to lamina blood flow in a vessel is created by marginal adherence of molecules to the vessel wall.

The smaller the vessel diameter, the closer the fastest flowing central lamina becomes to the margin. Therefore, these molecules become closer to the slow moving marginal molecules, which increases the resistance to flow. The effect of reducing the vessel diameter can be expressed as mean velocity (\bar{v}) and described in the formula:

$$\bar{v} = \Delta P r^2 / 8 \zeta L$$

where \bar{v} is velocity in cm/s; ΔP is pressure gradient (dynes)/cm²; r is the radius of the vessel in cm; ζ is the viscosity in poises; and L is the length of vessel in cm.

The rate of blood flow through a vessel (Q) is related to the velocity of flow (\bar{v}) multiplied by the cross-sectional area:

$$Q = \bar{v} \Delta P r^4 / 8 \zeta L.$$

Thus it can be seen that if $Q = \Delta P/R$ and $Q = \bar{v} \Delta P r^4 / 8 \zeta L$ such that:

- the resistance of a blood vessel (R) is directly proportional to the viscosity of the fluid and the length of the vessel
- the resistance is inversely proportional to the fourth power of the radius. Therefore the smaller the vessel (r), the greater the resistance of the flow. Thus, any interference with the resting tone in the blood vessel, which reduces the vessel radius, will have a detrimental effect on blood flow.

$$R = 8 \zeta L / \bar{v} r^4.$$

In general, radius (r) plays a major role in larger vessels, whereas viscosity (ζ) seems to determine blood flow in

smaller vessels. Viscosity varies with the speed of blood flow; the faster the flow, the lower the viscosity because Poiseuille's law does not apply fully *in vivo*. The Fahraeus-Lindqvist effect appears with reducing vessel diameter below 1.5 mm. The viscosity of blood in vessels narrower than 1.5 mm is so much smaller that viscosity in the capillaries is half that of large-calibre vessels. In a 100-micron arteriole, red blood cells randomly orientated whilst in a 15-micron vessel more regular orientation of the red cells occurs. Bloch postulated that the vessel flow has a marginal layer with few cells and red cells congregate in the centre of the stream, which reduces the viscosity of the layer in contact with the vessel wall. In the 10-micron capillary, the red cells travel in single file parabolooids, rather than the usual bioconcave shape.²¹

Vessel wall tension

From Laplace's law, the tangential vessel wall tension (T) is proportional to the vessel diameter (D) and the pressure exerted across the vessel wall (P) such that:

$$T \propto DP.$$

This has critical importance in a small vessel in which vessel diameter reduces, as does the pressure within the vessel. The vessel will collapse at the point elastic tension in the vessel wall exceeds the transmural pressure (P). This is known as critical closure pressure. Any increase in the resting tone in the blood vessel (spasm in clinical setting) that reduces the vessel radius, will thus have a deleterious effect on blood. Equally, any interstitial pressure increase (e.g. severe flap oedema) above the critical closure pressure can compromise the flap. As flap edges distal to the perforator are nourished by smaller calibre vessels they are more vulnerable to ischaemic necrosis. Laplace's law also applies to Milton's theory that 'the surviving length of flaps made under similar conditions of blood supply is constant regardless of width'. This is notably known as fallacy of the length-to-width ratio (Figure 11.5).¹⁸

SKIN BIOMECHANICS

As mentioned earlier, skin is a composite material consisting of a collagen-rich fibrous network embedded in a ground substance matrix. The proteoglycan-rich matrix provides skin its viscous nature at low loads, whereas collagen and elastin provide structural stiffness and elasticity to the skin. Skin exhibits anisotropic, non-linear, viscoelastic properties, in which the direction of minimal extensibility correlates with the fibrous network's principal direction. Skin is also a dynamic tissue, changing with age and influenced by gender.²²

Recently, finite element analysis (FEA) has been used in order to understand skin flap dynamics. It is a computerized technique that can determine the stresses, strains and displacements in solid body given the geometry, material behaviour and load/displacement boundary

Figure 11.5 Fallacy of the length-to-width ratio. Slope of decreasing perfusion pressure versus flap length does not change with incorporation of additional vessels (flap A versus flap B) with some perfusion pressure. Flap necrosis occurs when perfusion pressure falls below critical closing pressure of the capillary bed. (Adapted from Hom DB, Goding GS. Skin flap physiology. In: Baker SR (ed). *Local flaps in facial reconstruction*. 2nd ed. Philadelphia: Mosby Elsevier; 2007, pp. 15–30.)

conditions acting on that body. In this context, Lovald et al. performed FEA on a monopodcle (advancement) skin flap model concluding that the length of the flap should not exceed 3 times the size of the defect as benefit in reducing deformation is diminished beyond that point. Nevertheless, authors admitted that not all skin mechanical or local anatomical properties were studied. Although simulation models are useful instruments for a better understanding of skin flap biomechanics, success is dependent on the surgeon's ability to choose the best flap pattern on a given patient.²³

Non-linearity

This property refers to the limited lengthening of the skin when it is acutely stretched. It is ascribed to collagen, elastin, ground substance, capillaries, nerve fibres and lymphatics. Moreover, the relationship between the applied force (stress) exerted on a given skin length and its ensuing length increase (strain) is non-linear. Skin is initially resilient to the forced applied as fibres recruited along the lines of the stress have little resistance. However, in the intermediate stage, further

deformation requires much more stress as more collagen fibres are recruited into a load-carrying role. The final portion demonstrates almost complete rigidity of the skin regardless of the force applied as all of the collagen fibres are deployed in the direction of the stress. The rationale of skin non-linearity is to preserve its structural integrity especially under excessive stress. As eloquently shown in the stress-strain curve diagram, there are age dependent changes in skin deformation. Aged skin is less ‘malleable’ at initial stages due to the paucity of elastic fibres. However, young and aged skin stress-strain curves coincide in phase 3 alluding to the same degree of refractoriness at higher forces.

Although non-linearity confers protection to skin, lack of further deformation at high forces has a deleterious effect on blood flow. As mentioned above, peripheral (small caliber) vessels are more prone to occlusion due to their decreased diameter. Hence, increasing the amount of flap tension can hamper circulation, leading to necrosis of the distal part of any flap (Figure 11.6).²⁴

Anisotropy

Anisotropy refers to the directional qualities of the skin. In most regions of skin, there is tension in every direction, being greatest along the relaxed skin tension line (RSTL). Hence, an incision placed perpendicular to the RSTL will result in a wide gaping wound. Increased tension will also affect scarring and flap survival.

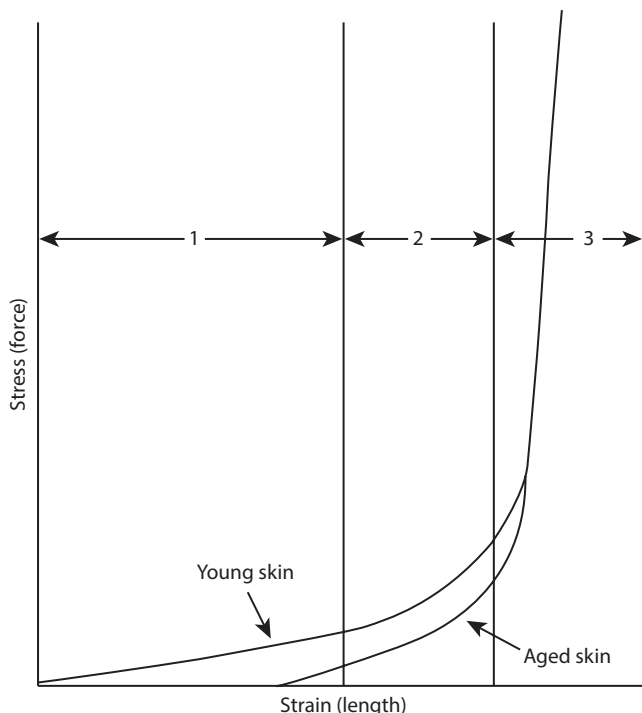

Figure 11.6 Stress-strain curve for isolated skin can be divided into three separate regions. Aged skin deforms under its own weight, shifting apparent origin of the curve along the x axis. (Adapted from Larrabee WF Jr. Immediate repair of facial defects. *Dermatol Clin* 1989; 7: 661–76.)

Viscoelasticity

Viscoelastic properties of the skin are better understood by the terms *creep* and *stress relaxation*. Creep refers to the increase in strain seen after a sudden constant load applied to the skin. Stress relaxation refers to a decrease in stress by means of stretching when a constant stress is applied to the skin. Viscoelasticity seems to be the background of the tissue expansion and serial sections.¹⁸

THE COMPROMISED FLAP

‘The after care is as important as the planning’ is the 15th principle postulated by Sir Harold Gillies.²⁵ His principle reads, ‘How futile it is to lose flap or graft for the lack of a little postoperative care. If in any doubt about the progress slip your hands out of your pockets and get down to the haematoma.’ This advice holds as true today as it did when it was published, the most common cause for the flap failure being failure to recognize a compromised circulation.

Indeed, Pohlenz et al. recently conducted a single-centre retrospective study looking at complications and outcomes of 1000 microvascular free flaps transplanted in the head and neck region for the interim between 1987 and 2010. Vascular occlusion (thrombosis) of one of the vessels was the primary (4.5% arterial, 6.8% venous) reason for flap loss, with venous thrombosis being more common than arterial occlusion. The majority of flap failures occurred within the first 36 hours. The main reasons for flap failure were the use of compression bandages, tapes around the neck or tracheal strips with extrinsic compression of the vascular pedicle (n = 7). Tight wound closure or wound haematoma may also compromise the flap by obstructing venous outflow. Major bleeding (4.9%) was a common cause of failure in microvascular free tissue.²⁶

Factors affecting flap survival can be considered as either extrinsic or intrinsic.

Extrinsic factors

External compression of the circulation to the flap is either due to a tight dressing, tension in the skin wound closure, which more commonly occurs if the flap is angulated over an underlying rigid bony surface, or soft tissue swelling; this can be due to oedema or a post-operative haematoma. The flap is usually blue and engorged, indicative of venous congestion. Haematomas seem to cause tissue injury even in absence of a pressure effect or pedicle thrombosis by a complex sequence of inter-related biochemical and cellular processes merging on a common pathway of local tissue ischaemia, which the overlying tissue is unable to regulate. In 2012, Glass et al. reviewed the literature relating haematoma to tissue compromise including free transferred tissue, vascularized flap models and brain injury. The authors acknowledged that all experimental data of this study were done in rat or pig modes. They postulated that degraded platelets release cytokines, which attract neutrophils. The latter release reactive oxygen

species (ROS) causing direct tissue damage. Additionally, the complement cascade is triggered by thrombin. Ferrous ions, freed by complement-mediated lysis of erythrocytes and degradation of haemoglobin, also promote generation of ROS. Reactive oxygen species, complement and activated neutrophils cause endothelial cell disruption, leading to activation of pro-thrombotic mechanisms and small vessel occlusion, with consequent tissue ischaemia, which in turn generates further ROS.²⁷

The prompt release of thigh bandages, dressings and removal of wound sutures and hematoma drainage may salvage the situation. If the free flap blood flow is compromised, urgent exploration of pedicle vessels is warranted. In general, earlier intervention confers better outcome in flap survival. In the case of a local flap, repositioning back on to the donor site should be considered if there is concern that the pedicle has been kinked, thus following the old adage, 'It is better to have a live flap out of position than a dead flap in position'.

Intrinsic factors

Reconstructive surgery for the head and neck is mainly aimed at elderly cancer patients with a long history of excessive smoking and drinking. These patients also suffer from other comorbidities (myocardial ischaemia, atherosclerosis/peripheral vascular disease, pulmonary diseases, diabetes mellitus (DM), cachexia, anaemia of chronic disease), hence are more vulnerable to flap-related as well as generalized complications.

Age per se should not be considered as an aggravating factor in terms of free-flap survival. Yang et al. conducted a retrospective cohort study on 53 head and neck cancer patients, aged >80 years, who underwent a free-flap reconstruction from 1996 to 2011 at an academic medical centre. There were zero flap failures or peri-operative deaths. Similar encouraging results were published by others.^{28–29}

Rosado et al. performed a systematic review and meta-analysis to determine whether diabetic patients have an increased rate of post-operative complications compared to non-diabetic patients after head and neck free-flap reconstruction. They reported that the prevalence of DM in patients with failed free flaps for head and neck reconstruction is 15%. The incidence of diabetes mellitus in these patients with failed free flaps is 2.3 times higher than in the general population.³⁰

Vasospasm in the flap following raising of the flap is a normal physiological response to reduce blood loss. Under normal circumstances, this vasospasm resolves without intra-vascular thrombosis because the spasm empties the lumen of the vessel. In addition, vessel lumen irrigation with heparin can resolve potential clots during anastomosis. In the presence of intact endothelium, the coagulation cascade is not activated. Hence, endothelial cell integrity plays a vital role in the maintenance of blood flow. Where flow to the flap is not established (or is compromised for a prolonged period of time) it has been shown experimentally in rabbits that 'no flow' occurs after a period of several hours of ischaemia. This has become known as

'no reflow phenomenon' coined by Ames et al. in 1968 and studied first in flap reperfusion in 1978.^{31–32} In the no reflow phenomenon, reperfusion of the ischaemic tissue results in the formation of oxygen-derived free radicals. Furthermore, it has been shown that the vasodilator effect of acetyl choline is mediated through endothelial production of nitric oxide.³³ The net effect of acetyl choline following reperfusion is the presence of damaged endothelial cells in vasoconstriction.

Nitric oxide is produced by nitric oxide synthase from the amino-acid L-arginine. Elegant experimental research in mice with targeted disruption of the inducible nitric oxide synthase (iNOS) gene (iNOS knockout mice) has shown pharmacological and genetic evidence that iNOS activity promoted survival of ischaemic tissue. The administration of nitro-L-arginine methyl ester (a constitutive NOS, endothelial NOS and neuronal NOS inhibitor) significantly increased flap survival in these mice.

In a pig ischaemia-reperfusion injury flap model, there was a disruption of constitutive nitric oxide synthase expression and activity, which may have led to decreased nitric oxide production.

A great deal of laboratory research has been undertaken to reduce flap failure by pharmacological means. Much attention has been paid to drugs that could act as 'free radical scavengers'. Superoxide dismutase has been shown to improve flap survival in animals^{34–35} but not in humans. Angel et al.^{36–37} have been at the forefront of superoxide radical scavenger therapy, publishing work on the beneficial effects of the iron chelator deferoxamine. These benefits, however, occur with significant toxicity that can be ameliorated (in pigs) by the conjugated form, deferoxamine-hesperan (DFO-H). DFO-H has a longer half-life, but with reduced efficacy in augmenting flap survival. This was postulated to decrease its ability to reach the intracellular oxygen free radicals.³⁸

It has also been shown that allopurinol can augment flap survival.^{39–40} Allopurinol is a xanthine oxidase inhibitor, although elevated levels of xanthine oxidase and malonylalddehyde have been noted to be elevated in ischaemic flap tissue in animals.⁴¹ A beneficial effect has yet to be shown in humans. Innumerable other animal experiments have been performed on such things as anti-adrenergic drugs⁴² and magnesium-ATP (a supply of high energy phosphometabolites),⁴³ both approaches being to increase the levels of ATP in the tissues.

Others researchers have looked at prostacycline (PGI₂) and prostaglandin-E₁ (PGE₁). Both cause peripheral vasodilatation and inhibition of platelet aggregation.^{44–47}

Endothelin-1 (ET-1) is an endogenous vasoactive (vasoconstrictor) peptide, produced in ischaemic flap tissues. In human microvascular breast reconstruction flaps, a statistically significant increase in (skin biopsy) tissue levels of endothelin-1 after clamping of the flap pedicle has been demonstrated. The authors concluded that endothelin-1 levels were elevated in free flaps following reperfusion.⁴⁸

Recent studies have shown that this detrimental effect can be blocked in experimental porcine transverse rectus abdominis myocutaneous (TRAM) flaps by tezosentan, an endothelin receptor blocker. The authors suggest that

tezosentan improves oxygenation and metabolism in the jeopardized contralateral flap tissue, probably as a result of a decrease in venous vascular resistance and fluid extravasation.⁴⁹

This beneficial effect on the venous outflow would fit with observations on the sensitivity of the human musculocutaneous perforator vessels to vasoconstrictors and vasodilators *in vitro*. The vasoconstrictor potency of norepinephrine, endothelin-1 and thromboxane-A2 mimetic were shown to be significantly higher in the vein than in the artery, hence the maximal venous effect of ET-1 blockade.⁵⁰ The severity of tissue necrosis correlated well with tissue levels of ET-1 in rat skin flaps, whilst topical nifedipine antagonized the vasoconstrictive effects of ET-1.

Topical nitroglycerin (GTN) has also been shown to exert a greater vasodilator effect on the venous circulation than on arterial vessels. Rohrich et al.⁵¹ reported improved survival of axial flaps in pigs and rats treated with nitroglycerin ointment. Topical GTN paste is used in clinical practice but with variable success. On the contrary, recent meta-analyses have shown that intra-operative use of vasopressors in free flap surgery is safe (hNJ).

Direct smooth muscle relaxants nifedipine and verapamil increased flap survival in rats.^{52–54} These are calcium-channel blockers that act on the vascular smooth muscles to cause vasodilatation but are restricted in clinical practice to topical application on to microvascular anastomoses, as there is no trial evidence to support their systemic use.

Surgically induced neutrophil recruitment in skin flaps has been shown to impair flap survival experimentally in the rat.⁵⁵ Myeloperoxidase (a marker for neutrophil recruitment) was significantly reduced by low-intraperitoneal calcitonin gene-related peptide (CGRP) without affecting the circulating neutrophil count, with improved random pattern flap survival.

One Japanese group⁵⁶ have studied sulphatide which binds to L-selectin and P-selectin, important in the initiation of neutrophil–endothelial interactions. Pre-treated experimental skin flaps showed little histological evidence of leukocyte invasion compared to that in the dermal layer of control flaps 48 hours after elevation. They went on to show augmented protection against ischaemia-reperfusion in rat skin flaps when combining sulphatide with anti-rat ICAM-1 and anti-rat LFA-1 antibodies.

The monoclonal antibody to the primary neutrophil adherence-mediating glycoprotein CD18 improves the survival length of the random pattern flap. Histological examination 24 hours after reperfusion in the treated group demonstrated only slight leukocyte invasion into the flap, and myeloperoxidase activity 24 hours after reperfusion was significantly reduced. This study indicated that sulphatide and monoclonal antibodies combined protect rat skin flaps from ischaemia-reperfusion injury.⁵⁷

The platelet glycoprotein IIb/IIIa receptor antagonist Abciximab promoted experimental skin flap survival secondary to blocked platelet activation/aggregation and decreased activated-platelet deposition on the vascular endothelium in the rat.⁵⁸ Thus, administration may save

the skin flap from reperfusion injury after a long period of ischaemia.

Dimethylsulfoxide (DMSO) is the only substance that has been shown experimentally to improve flap survival in animals and then been supported in a randomized control trial of mastectomy skin flap survival by Rand-Luby et al.⁵⁹ This is one of only two controlled trials referenced by the Cochrane database. The authors concluded that the topical application of DMSO safely reduced human mastectomy skin flap ischaemia.

The other clinical trial on the Cochrane database reported a selective phosphodiesterase III inhibitor (Amrinone), which prevents breakdown of cyclic adenosine monophosphate.⁶⁰ Statistically proven to improve positively the microcirculatory blood flow of transferred flaps, the authors proposed that this occurred by relief of intra-operative vasospasm.

Another work in rats by Pang et al. concluded that the administration of exogenous vascular endothelial factor (VEGF) ‘could protect flaps from ischaemia-reperfusion injury through the regulation of pro-inflammatory cytokines and the inhibition of cytotoxic nitric oxide production’.⁶¹

Adenovirus-mediated gene therapy with vascular endothelial growth factor delivered into the subdermal space of compromised epigastric skin flaps in a rat model has improved skin flap survival.⁶² Viral transfection with subdermal injections of adenovirus-encoding VEGF (Ad-VEGF) was performed two days before flap elevation. Compared with controls, a significant reduction in the area of necrotic and hypoxic zones of the flap was demonstrated following both local and midline subdermal injections of Ad-VEGF.

Others have reported that the survival of flaps treated with VEGF A165 or B167 cDNA was significantly greater than controls.⁶³ However, neither study could produce evidence that the mechanism was due to angiogenesis using light microscopy, microvessel count or angiography on the treated flap. This is in contrast with histologically demonstrated angiogenesis at the skin paddle-recipient bed interface following the subcutaneous administration of VEGF into the recipient bed of a skin tube flap.⁶⁴

Further support for VEGF therapy comes from Kryger et al., who showed that all routes of administration (systemic, subdermal into the flap, subfascial into the recipient bed) improved survival of a full thickness random pattern flap in the rat compared with controls.⁶⁵

By contrast, Rinsch et al. demonstrated that FGF-2, was more efficacious than either VEGF(121) or VEGF(165) in treating acute skin ischaemia and improving skin flap survival when delivered from encapsulated cells positioned under distal flap.⁶⁶

Thus, with improved delivery strategies, VEGF and FGF-2 may have a role in the management of surgical ischaemia. However, novel gene therapies to improve flap survival have not yet translated into clinical flap surgery.

Dextran and heparin have been shown to improve flap survival in experimental studies of microvascular anastomoses, but not in improving survival of a failing flap.^{67–68}

PHYSICAL INTERVENTIONS

Surgical delay

The only well-established technique to improve skin flap survival is by the 'delay procedure' with which all surgeons should be familiar. 'Delay' is a surgical procedure that renders a flap partially ischaemic several days prior to its transfer in order to increase its viability at transfer. Though much debate exists regarding the actual mechanism of vascular delay, most agree that changes in the microcirculation play a key role.

The latest work by Dhar and Taylor showed that when a flap is delayed, there is a dilation of existing vessels within the flap, not ingrowth of new vessels. The maximal anatomic effect on the arterial tree occurs at the level of the reduced-caliber 'choke' (or linking) anastomotic vessels that link adjacent adjacent vascular territories.

They describe 'an active process associated with both an increase (hyperplasia) and enlargement (hyper trophy) of the cells in all layers of the choke artery wall and a resultant increase in calibre of these vessels'.⁶⁹

Tissue expansion can be considered a form of skin flap delay, where expanded porcine flaps showed 150% greater length survival compared with acute non-delayed flap.⁷⁰ The expanded flaps had 50% greater length survival compared with the delayed flaps. Angiography showed increased axial vessel calibre in the tissue expanded flaps, subsequently confirmed by Taylor's work. A controlled clinical trial of TRAM flap breast reconstruction confirmed by colour flow Doppler showed an increase in the diameter of flap vessels in which surgical delay was performed one month prior to transfer.⁷¹ A lower flap necrosis rate was found using a delayed TRAM (7.1%) compare with a standard TRAM (30%).

Conditioning

This term describes an endogenous phenomenon in which the application of one or more brief cycles of sublethal ischaemia and reperfusion to an organ or tissue to protect itself or another one distant to it (remote ischaemic conditioning) from the detrimental effect of ischaemia-reperfusion injury (IRI). Depending on the timing of application in relevance to the actual IRI it is classified as ischaemic pre-, post- or conditioning.

Ischaemic preconditioning was first described in 1986 by Murry et al. in canine myocardial infarct models.⁷² In 2003, Zhao et al.^{73, 74} introduced ischaemic post-conditioning as a procedure to minimize acute myocardial infarction (MI) after applying alternate cycles of ischaemia and reperfusion. Both procedures require direct intervention on the tissue or organ. In contrast, remote ischaemic conditioning achieves a protective effect by applying the sublethal cycles to an easily accessed tissue or organ (i.e. arm).⁷⁴

Kraemer et al. studied the microcirculatory benefits of remote ischaemic preconditioning in 27 healthy individuals. The baseline cutaneous microcirculation of the left thigh (corresponding to ALT flap) was tested using combined Laser-Doppler and photospectrometry. Similar tests in the same skin region were performed after three 5-minute ischaemic cycles on the contralateral arm. Statistically significant increase in tissue oxygen saturation and capillary flow (29%, 35%, $p = 0.001$) was noted.⁷⁵

Extracorporeal perfusion

Recently, there have been attempts to revascularize severed limbs or free flaps in vessel-depleted necks both in animal models and humans via extracorporeal perfusion (ECP). This technique refers to a pump-assisted perfusion of the tissues in order to obviate the deleterious effects of prolonged ischaemia. In 2005, Newsome et al. presented a case report of a boy with chondroblastic osteosarcoma of the right hemipelvis with involvement of the common, internal, and external iliac vessels on the right side. The patient underwent hemipelvectomy and high above-knee amputation of the ipsilateral leg. The amputated extremity was placed on extracorporeal bypass using an extracorporeal machine oxygenation (ECMO) circuit connected to the femoral vessels for 162 min. at 32°C. While maintaining extracorporeal circulation, an anterior thigh free flap was created and later used for soft-tissue reconstruction.

In 2016, Wolff et al. reported successful free flap transfer using ECP in three consecutive cases with vessel-depleted neck.^{76, 77}

Lasers

Low energy helium-neon (He-Ne) laser irradiation has been shown to improve the viability of skin flaps in rats and in clinical flap repair after avulsion injury.^{78, 79} In rat capillaries and fibroblasts, proliferation was demonstrated histologically while clinical improvement was attributed to improved superoxide dismutase activity.

Leeches

Hirudo medicinalis, the medicinal leech, exerts its effect by injecting hirudin, a naturally occurring anticoagulant, into the affected part. In addition, leeches secrete hyaluronidase into the tissues, as well as a vasodilator, which contributes to prolonged bleeding. The main use for leeches is in the congested microvascular flap when there is no other way of improving venous outflow.⁸⁰ Useful in selected cases, there is nonetheless a serious risk of secondary infection with the leech enteric organism *Aeromonas hydrophila*, which can kill the skin flap. Antibiotic cover should be provided when using leeches.

KEY POINTS

- Skin is the largest organ of the human body and confers protection against mechanical and bacterial insults as well as thermoregulation.
- Better understanding of the pertinent anatomy and skin and vessel biomechanics can minimize mistakes and improve outcomes in reconstructive surgery.
- Several intrinsic and extrinsic factors may compromise flap viability.
- Conditioning, surgical delay and/or extracorporeal perfusion may optimize flap survival.

BIOMATERIALS, TISSUE ENGINEERING AND THEIR APPLICATION IN THE ORAL AND MAXILLOFACIAL REGION

Kurt Busuttill Naudi and Ashraf Ayoub

Introduction	119	Tissue engineering.....	122
Biomaterials	119	References	123

SEARCH STRATEGY

Data in this chapter may be updated by a Medline and Embase search using the keywords: biomaterials, tissue engineering, head and neck, and focussing on gold standard tissue engineering techniques as well as new developments. Clinical applications are limited due to the novelty of the subject; most of the published research is based on the preclinical applications of biomaterials.

INTRODUCTION

The reconstruction of large defects, particularly bony defects, in the head and neck region continues to be an area of significant debate. These defects are usually created after the surgical removal of cancer lesions or as a result of bone loss following major trauma. The critical size of the created surgical defect, combined with the detrimental effect of post-surgical radiation therapy on the blood supply of the surrounding tissues contribute to the limited healing capabilities of the surgical site and the challenging reconstructions. Most of the available data on the management of such defects are based on expert opinion; the comprehensive studies provide limited objective guidelines for successful treatment.¹

Bone provides the support and foundation for the overlying soft tissues so its replacement is essential for successful reconstruction. Various bone graft materials have been used for the restoration of head and neck bone defects. An ideal bone graft needs to promote osteogenesis, osteoinduction and osteoconduction.² *Graft osteogenesis* is provided by the cellular elements within a donor graft that survive the transplantation and synthesize new bone at the recipient site, an example of which would be mesenchymal stem cell-derived osteoblasts. *Graft osteoinduction* is new bone formation through the active recruitment of host mesenchymal stem cells from the surrounding tissue, which then

differentiate into bone-forming osteoblasts. This is a property held by various cytokines including bone morphogenetic proteins (BMP). *Graft osteoconduction* is achieved by new bone formation into a defined supporting scaffold (matrix) that can be the non-vascularized bone itself or with the application of allografts or synthetic substitute. Other important graft properties include biocompatibility, bioactivity, biodegradability and the ability to attain adequate mechanical properties. Because autogenous bone grafts possess all of the aforementioned properties they continue to be the gold standard for the repair of such defects but the morbidity associated with harvesting such grafts inspired the development of substitutes.³

This chapter looks at the main types of biomaterials that have been applied for the reconstruction of the oral and maxillofacial region and looks at the various bioengineering methods that have been developed to try and replicate as well as promote the body's natural healing capabilities.

BIOMATERIALS

The biomaterials that will be discussed in this section were developed to support the concepts described previously. The materials described will possess one or more of the three fundamental properties of osteoconduction, osteoinduction and osteogenesis.

Figure 12.1 The main types of alternative grafts available for use in the head and neck region. Hybrids of these different types are also available.

Scaffold biomaterials used for tissue engineering vary in porosity, composition and biodegradability to best mimic the requirements of the tissue to be replaced. For this reason a vast array of scaffold materials (available as powders, granules, dense blocks, putties, injectable pastes, gels and porous scaffolds) have been developed as they are able to provide osteoconduction and in some cases (e.g. porous block scaffolds) help restore the shape of the critical-sized defect.

Scaffolds can be broadly divided into three main types: allogenic, xenogenic and synthetic graft materials. Allogenic grafts are derived from donors of the same species as the recipient, xenografts are derived from donors that are from a species different to that of the recipient and synthetic grafts, as their name implies, are manufactured in a laboratory. These synthetic grafts are then further subdivided into ceramics and polymeric materials (Figure 12.1). Several hybrids (composites) of all the above scaffolds have also been developed. Most of these grafts only have osteoconductive properties providing a foundation for cells to migrate from the wound edges. Because of this limitation they are usually combined with osteoinductive materials.

Allografts

Allografts are grafts obtained from donors that are of the same species as the recipient. Demineralized bone matrix (DBM) is derived from human cadaveric bone that has been demineralized, processed and sterilized, leaving a denatured form of the protein matrix. This process is required to remove the risk of disease transmission to or an immunological response in the recipient. However, heavy processing can also result in the denaturing of the cytokines in the graft so that it loses its osteoinductive properties and remains only osteoconductive. It has been shown that DBM, when placed in sites where bone is not normally produced, can induce ectopic bone formation.⁴

Xenografts

Xenograft usage in the head and neck region is mostly limited to the use of bone minerals derived from the bones of pigs, cows and horses. The preparation of the materials results in the removal of all organic components leaving a

granular, porous material with good osteoinductive properties. Collagen xenografts are also commercially available where the collagen is extracted from porcine small intestine submucosa. Bio-oss is an example of a xenograft derived from bovine bone that is routinely used for augmentation of the jaw bones. The main barriers to the usage of these materials in the past have been the risk of disease transmission; this is now unlikely due to the processing methods. However, the ethical issues related to xenograft usage remain, so detailed informed consent is essential prior to their clinical use.

Synthetic grafts

The most researched synthetic grafts are the ceramics, of which hydroxyapatite (HA), tricalcium phosphate (TCP) or a mixture of the two (biphasic calcium phosphate, BCP) are most widely used (Table 12.1). Ceramics are brittle materials with limited tensile strength but are available in the form of blocks with more extensive interconnected porosity permitting faster bony ingrowth; the ideal pore size is thought to be between 150 and 500 microns.⁵ So as to overcome their inherent brittleness, ceramics are also available as composite materials where they have been combined with either polymers or allograft materials such as DBM.⁶

Cytokines

Cytokines are important low molecular weight, soluble cell signalling proteins that are released by cells to stimulate, 'induce', other cells through specific receptors. Usually cytokines act only over a short distance and for short periods of time and must therefore be newly produced. This has to be repeated frequently, usually in response to a stimulus. They are pleiotropic (can influence various cell types) as well as redundant (can share similar functions). Cytokines promote and control immune responses against

TABLE 12.1 Types of scaffolding materials used in tissue engineering

inflammation, infections and cancer, with the malignant transformation process being associated with an altered response to cytokine stimulation.⁷

Cytokines such as interleukins (IL-1, IL-3, IL-6, IL-11), tumour necrosis factor (TNF), platelet-derived growth factor (PDGF), fibroblast growth factors (FGF) and vascular endothelial growth factor (VEGF) have been linked with functions that range from further cytokine release, angiogenesis, metastasis and osteoblast/osteoclast development.

There is a complex interaction that takes place between the various bone modelling cells (osteoblasts and osteoclasts) and their haematopoietic precursors as well as the cytokines themselves that results in bone formation or deposition. Cytokines also play an important role in cell activation leading to chemotaxis and release of inflammatory mediators, help in vascular remodelling (neovascularisation) and promote the synthesis of matrix enzymes required for the remodelling of cartilage and bone.

BONE MORPHOGENETIC PROTEINS

Bone morphogenetic proteins (BMP) are probably the most effective cytokines in relation to bone formation and healing. There are more than 20 subtypes, all forming part of the transforming growth factor β (TGF- β) superfamily.⁸ BMPs induce stem and mesenchymal cell differentiation into osteogenic cells capable of producing bone. BMPs are secreted as signalling molecules that activate intracellular cascades by binding to cell surface receptors. The BMP signalling pathway has been shown to be involved in a number of developmental processes and is critical for the formation of the majority of the craniofacial elements including the cranial neural crest, the facial primordia, teeth, lips and palate.

With the use of recombinant gene technology, large quantities of recombinant human BMPs (rhBMPs) have become readily available. BMP-2 and BMP-7 (also known as Osteogenic Protein-1) are recognized to be the most effective cytokines in the maxillofacial region, inducing osteoprogenitor cells to produce bone, and resulting in chemo-attraction of mesenchymal stem cells to the defect area.⁹ They are both approved for clinical use and have been used for spinal fusion, the repair of long bone fractures and non-unions as well as the repair of craniomaxillofacial defects.⁹

Due to their nature cytokines need to be placed in a scaffold, such as the ones mentioned above, to control the shape of the regenerate. Even though they are widely available and appear to be very effective at inducing bone formation, cytokines continue to be very expensive. This is due to the very time-consuming purification and concentration steps before the produced dimer protein can be refolded into its functional form. This currently significantly limits their widespread use.

Mesenchymal stromal cells

The last important bone regeneration property is osteogenesis; this is a property potentially held by pluripotent

cells such as mesenchymal stromal cells (MSC). These cells are capable of differentiation into three main cell lineages – osteogenic, chondrogenic and adipogenic – as well as potentially into myogenic, neurogenic and tenogenic lineages. These cells, by their very nature, can therefore be *induced* to transform into bone forming cells if given the right stimulus and microenvironment.¹⁰ This microenvironment is implicated in both the support and maintenance of the MSCs. There are different elements that could affect the cells; these are oxygen tension, glucose concentration, growth factors, the physicochemical nature of the environment including the pH and ionic strength (e.g. Ca^{2+} concentration). Their roles are critical for the maintenance of stem cell properties and the possibility of reprogramming their commitment prior to application in the surgical defect. MSCs can be obtained from the bone marrow, spleen and thymus as well as several other sites including adipose tissue.¹¹

Autogenous bone marrow aspirate (BMA) is readily obtainable from the bone marrow of, for example, the anterior iliac crest. The aspirate is highly cellular containing osteoprogenitor cells (osteogenic) and provides a concentration of protein factors (cytokines) that stimulate bone growth (osteoinductive). For this reason it has become a cost effective alternative to the recombinant osteoinductive cytokines mentioned above.⁶

Platelet-rich plasma

Platelet-rich plasma (PRP) is blood that is taken from the patient, centrifuged, ultra-concentrated and then reimplanted after processing. It contains a mixture of platelets and growth factors such as platelet derived growth factors (PDGF), transforming growth factor- β (TGF- β), as well as insulin-like growth factor-I (IGF-I). These growth factors (cytokines) can stimulate mitogenesis of marrow stem cells and angiogenesis.¹² The expensive processing methods for the production of PRP limit its clinical use; for this reason, second generation platelet-rich fibrin (PRF), which requires no biochemical handling, has been developed.¹³

Bioreactors

In tissue engineering a bioreactor is a device that simulates the natural environment of a tissue so as to promote its growth. It is usually a perfusion chamber connected to a pump system that allows peristaltic pumping of fresh medium, and is kept at a controlled oxygen level. This allows the maintenance of ideal physiologic conditions that promote development of the required tissue. This helps to recreate the microenvironment that was described above. Other parameters that can be controlled include the application of forces or stresses to the tissues in both two or three dimensions, thus simulating the environment in which, for example, bone develops.¹⁴ These devices are becoming increasingly popular for the development of grafts for use in

the head and neck region as they are able to overcome one of the main problems in tissue engineering, which is the maintenance of a good oxygen supply and removal of cellular waste products. They also allow the maturation of the graft in the laboratory prior to its placement into the surgical recipient site.

TISSUE ENGINEERING

Bone is a complex tissue with highly porous central spongy bone and solid compact outer cortical bone. Therefore bone tissue engineering requires the design of three-dimensional (3D) scaffolds that closely mimic this anatomical organization of bone. Changes in scaffold geometry can impact on the flow of media across the scaffold and thus affect the supply of gases and nutrients and the removal of metabolites. An increase in pore number and size in various scaffolds is associated with increased vascularization and osseointegration *in vivo*, but the increased pore volume reduces the mechanical stability of the scaffold.¹⁵

A sufficient blood supply is required to achieve successful tissue regeneration. This remains a significant barrier to the effective reconstruction of large defects in the head and neck region. The stimulation of angiogenesis from endothelial precursors is therefore essential. The best-known angiogenic factor is vascular endothelial growth factor (VEGF), which creates an environment that promotes endothelial cell migration and proliferation.¹⁶

Clinical trials

The clinical application of the above mentioned novel materials is still in its early stages but some successful outcomes have been reported.

Fibroblast growth factors (FGFs) have been successfully applied for the repair of tympanic membrane perforations¹⁷ as well as the treatment of the ageing vocal folds,¹⁸ due possibly to the effect that this cytokine has on the key extracellular matrix components in the lamina propria.¹⁷

Recombinant human bone morphogenetic protein 7 (rhBMP-7) in a type I collagen carrier was used for the reconstruction of unilateral and bilateral alveolar cleft defects. The patients were followed up for an average of 6.5 years and objective radiographic evaluation demonstrated very good bone regeneration in the defects.¹⁹

Cultured bone marrow cells that were exposed to an osteogenic environment and placed in a mineral base of β -tricalcium phosphate and hydroxyapatite were used to treat three clinical cases. These cases had osteoradionecrosis of the maxilla and mandible with pathological fracture; a non-healed fracture with bone loss, and bilateral paraesthesia; and a very large maxillary bone deficiency. All showed signs of osteogenesis, nerve reinnervation and skin regeneration.²⁰

Thirteen consecutive cases of cranio-maxillofacial hard-tissue defects in the frontal sinus (three cases),

cranial bone (five cases), mandible (three cases) and nasal septum (two cases) were treated with autologous adipose stem cells derived from adipose tissue obtained from the abdominal wall. The cells were seeded onto bioactive glass or β -tricalcium phosphate scaffolds together with recombinant human bone morphogenetic protein 2. Ten out of the thirteen cases had successful outcomes.²¹

A large mandibular discontinuity defect was repaired with a custom bone transplant grown inside the latissimus dorsi muscle of an adult male patient. This was achieved using computed tomography scanning and computer-aided design techniques to produce a virtual replacement (in the form of a titanium mesh) for the mandibular defect. This was filled with bone mineral blocks, recombinant human bone morphogenetic protein 7 and the patient's bone marrow. Seven weeks after placement in the latissimus dorsi muscle the graft was successfully transplanted as a free bone-muscle flap to repair the mandibular defect.²²

FUTURE RESEARCH

Molecular therapy in bone bioengineering

Modification of the properties of cells at the molecular level can have significant potentially useful effects within tissue engineering. Liposome-mediated and adenovirus cell-mediated BMP-2 gene transfer into MSCs in pre-clinical studies has resulted in cells that are able to repair critical-size bony defects.²³ Gene-modified cells could potentially be given all the properties required for tissue regeneration and they could be then implanted into the surgical defect. Alternatively these cells could be placed in a bioreactor and allowed to create the required tissue 'bone' *ex vivo* after which it would be implanted into the surgical recipient site.

Biomimetic scaffolds

Scaffolds currently used for tissue engineering are either granular or manufactured in predetermined shapes. With the use of computer-based solid free form fabrication (SFF) using 3D printers it is possible to create custom-made scaffolds designed to specifically fit the defect that is being treated. Also the nano-topography and nano-chemistry of the scaffold can be structured in detail to try and reproduce the natural tissue that it is designed to replace, even at the cellular level. This would help promote the growth of all the required cellular elements for tissue regeneration (e.g. blood vessels and bone).

Improved vascularity

New methods that can improve the vascularity of the donor sites/grafts will significantly enhance the regenerative abilities. The bioreactors mentioned earlier can help in this respect but specific methods of inducing controlled vascular proliferation within the surgical site still need to be developed, possibly using synthetic polymers.

KEY POINTS

- The reconstruction of large defects, particularly bony defects, in the oral and maxillofacial region continues to be an area of significant development.
- An ideal bone graft should promote osteogenesis, osteoinduction and osteoconduction, as well as be biocompatible, bioactive, biodegradable and possess adequate mechanical properties.
- The harvesting of the autogenous bone graft 'gold standard' is associated with donor site morbidity; this is the main drive force for the search for synthetic substitutes and further investigation in tissue bioengineering.
- Biomaterial scaffolds can be broadly divided into three main types; allogenic, xenogenic and synthetic graft materials.
- Most synthetic scaffolds have only osteoconductive properties and are combined with osteoinductive materials.
- The ethical issues related to xenograft usage remain, so patient informed consent is essential prior to their clinical use.
- The most researched synthetic grafts are hydroxyapatite (HA), tricalcium phosphate (TCP) or a mixture of the two (biphasic calcium phosphate, BCP).
- Cytokines are important low molecular weight, soluble cell signalling proteins that have an effect on other cells through specific receptors affecting several processes that include tumour growth and bone remodelling.
- Mesenchymal stromal cells, which can be obtained from the bone marrow, spleen, thymus and adipose tissue, are capable of differentiation into the three main cell lineages; osteogenic, chondrogenic and adipogenic.
- The cytokine bone morphogenetic protein induces mesenchymal cell differentiation into osteogenic cells capable of producing bone.
- A bioactor is a device that simulates the natural environment of a tissue so as to promote its growth.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: innate immunity, adaptive immunity, antigen, B lymphocyte, T lymphocyte, antibody, immunoglobulin, antigen presentation, cytokine, complement, inflammation, hypersensitivity, allergy and autoimmunity.

INNATE AND ADAPTIVE IMMUNITY

The immune system has evolved for protection against infectious agents that invade the body. In order to achieve this, the immune system has recognition properties to locate and identify the invader, and to activate defence processes to repel or destroy the invader. There are an enormous number and variety of infectious agents within the main categories of viruses, bacteria, fungi, protozoa and parasitic worms. In order to provide effective immunity against each of these agents, the immune system has to be able to meet the challenges they pose: this is achieved by a diverse range of molecular and cellular components in the body that cooperate with each other in order to maximize their defensive activities. Some of these components generate innate immunity, whereas others provide adaptive (or acquired) immunity. The main cell types of the immune system are the leucocytes that develop from stem cells in the bone marrow.

The innate immune system is evolutionarily older than the adaptive system and provides generic defence against categories of microbes. It is composed of a range of cells and proteins found in the circulation and in tissues: these include macrophages (and their monocyte precursors), granulocytes (i.e. neutrophils, eosinophils, basophils), and mast cells, natural killer cells, complement proteins, regulatory proteins called cytokines. The innate system employs an inherited repertoire of receptor proteins (known as pattern-recognition molecules) that recognize characteristic structures that are commonly

expressed by microbes, and changes to cells induced by infection. The advantage of this innate system is that it is rapidly activated by infectious agents that penetrate tissues. However, it is only moderately efficient; hence, an adaptive immune response is also required to enhance the elimination of many pathogens.

Adaptive immunity is mediated by T lymphocytes and B lymphocytes (also known as T cells and B cells). Similar to the leucocytes involved in the innate system, lymphocytes develop from bone marrow stem cells. The precursors of T cells migrate to the thymus to complete their maturation. Each T or B cell expresses receptors that specifically recognize one particular chemical structure of a microbial molecule (known, in this context, as an antigen). Activated B cells also secrete a soluble form of their antigen receptors, known as antibodies or immunoglobulins (Ig). An enormously diverse repertoire of antigen receptors is somatically generated by recombination events involving the receptor genes during the development of lymphocytes, resulting in the potential to recognize millions of different antigens. The recruitment, activation and proliferation of resting lymphocytes specific for the antigens of an invading microbe takes time (possibly several days), but the lymphocytes generate a highly efficient defence. In addition, some of the lymphocytes activated by specific antigens are maintained in the body as resting cells after the elimination of the infection and constitute a memory population of cells that are able to generate a bigger and faster response upon subsequent exposure to the same antigens: this demonstrates the adaptive properties of lymphocytes.

The innate and adaptive systems interact and synergize to generate optimal immunity. Specifically, lymphocyte activation is dependent not only on antigen recognition, but also on co-stimulatory signals provided by cells and molecules of the innate system. Furthermore, the antibodies produced by B cells and the cytokines secreted primarily by T cells enhance the defensive activities of the innate system.

Stages of an immune response

The immediate response to an invading pathogen is mounted by innate components resident within the infected tissues (Figure 13.1a). In particular, tissue macrophages (and other cells with innate immune functions) express a range of pattern recognition receptors for microbial structures, including mannose receptor, scavenger receptors and Toll-like receptors, whose ligands include various microbial polysaccharides, lipids and nucleic acids. Complement proteins are also directly activated by microbes via the alternative pathway (see ‘The Complement System’ below). Inflammatory products of macrophages and complement, together with those released by tissue mast cells activated by the complement peptides C3a and C5a (known as anaphylatoxins), induce the migration of granulocytes, natural killer cells and more complement proteins from the blood stream into the infected tissues (Figure 13.1b).

Whilst these innate processes are providing early defence to limit growth and spread of the infection within the body, other processes are set in train to generate the antigen-specific adaptive response (Figure 13.1c). The activation of lymphocytes does not initially take place within the infected tissues themselves, but in specialized collections of lymphoid tissues such as lymph nodes, the spleen and mucosa-associated lymphoid tissues (MALT) that includes Waldeyer’s ring. Antigens therefore have to be transported from the infected tissues to local lymphoid tissues. Some antigens may be passively carried in the tissue fluid forming the lymph that drains into regional lymph nodes. However, a significant role is played by dendritic cells found in most tissues. These, like the macrophages described above, express pattern-recognition receptors for microbial structures and actively engulf microbial material. This induces maturation of the dendritic cells, which then migrate from the site of infection and carry the microbial antigens to the local lymphoid tissues where T and B lymphocytes have the opportunity to interact with the antigens leading to their activation. Only a very small proportion of the millions of lymphocytes in a particular lymphoid organ will have receptors that specifically recognize the antigens associated with a particular microbe. It is the antigen-activated lymphocytes that proliferate and mature into effector cells contributing to defence against the pathogen. These effector lymphocytes leave the lymphoid tissues and recirculate via the blood stream to the site of infection in order to enhance the destruction and elimination of the pathogen in cooperation with the innate components described above.

ANTIGEN RECOGNITION

Antigen recognition involves a high affinity interaction between an antigen and the specialized antigen combining site of a lymphocyte’s antigen receptor protein (or of an antibody molecule). The binding involves non-covalent intermolecular attractive forces that require the interacting surfaces to have complementary shapes that fit snugly together (rather like a lock and a key), allowing interactions to occur between complementary chemical groups of the antigen and the combining site. Each lymphocyte

clone (i.e. group of cells derived from a single parent lymphocyte) expresses antigen receptors with a single type of combining site that is unique in shape and amino acid composition to that clone contrasting with the millions of other lymphocyte clones in the body: this is why millions of differing antigens can be recognized by the adaptive immune system. Furthermore, the specificity of the adaptive response arises because those lymphocytes whose receptors have the highest affinity for an antigen that enters the body are the ones most likely to bind it and hence be activated by it: this is termed clonal selection.

B cells and antibodies (immunoglobulins)

The B cell's receptor is essentially a membrane bound form of the antibody that a particular B cell secretes, and is called surface immunoglobulin (sIg) (Figure 13.2). It is made up of two identical large polypeptides (heavy chains) and two identical smaller light chains (which can be one of two types called κ and λ light chains). Each chain is composed of a series of homologous globular regions called Ig domains: two in the light chains and four or five in the heavy chains.

The receptor has two identical antigen combining sites, each of which is composed of the amino terminal domains of a heavy and a light chain: these are called variable domains because they vary in structure between different B cell clones, thereby conferring the differences in antigenic specificity between B cells. Different types of chemicals can serve as antigens for direct interaction with different B cell receptors and antibodies, including proteins, carbohydrates, lipids and even nucleic acids.

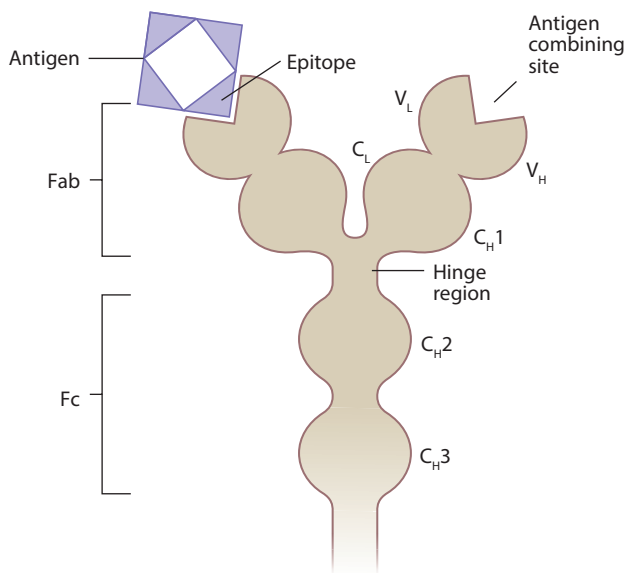

Figure 13.2 A schematic structure of a generic immunoglobulin (surface or secreted). (See text for details.) The variable domains of the heavy and light chains are labelled V_H and V_L , respectively. Similarly, the constant domains are labelled C_H1-3 and C_L . The pale region below C_H3 indicates the transmembrane region and cytoplasmic tail present in sIg, but not in secreted antibodies.

The combining site constitutes only a small part of a whole Ig molecule and can accommodate approximately four to six amino acids of a protein antigen: the precise region of an antigen molecule that interacts with a combining site is termed the antigenic determinant or epitope. Each variable domain contains three hypervariable loops, so called because they differ most in amino acid sequence between different clones of B cells; they are also known as complementarity determining regions, being complementary to the epitope and forming the main interactions with it. Following B cell activation, modifications can occur to the variable domains by somatic mutation. This involves nucleotide changes to the variable domain genes during B cell replication that affect the amino acid sequence (particularly of the complementarity determining regions) and therefore affect the antigenic specificity of the antigen combining sites. This can generate combining sites that fit even more tightly with the epitope, improving further the affinity for the antigen.

The other domains are called constant domains because they have the same structure in the sIg of different B cells. Human B cells can express one of nine different forms or isotypes of Ig (both surface and secreted) that differ in the structure and number of their heavy chain constant region domains, and constitute five immunoglobulin classes. These are called IgM, IgG (with subclasses IgG1, IgG2, IgG3 and IgG4), IgA (with subclasses IgA1 and IgA2), IgE and IgD. All B cells are initially programmed to express IgM (with IgD), but can undergo Ig class switching to produce one of the other isotypes following stimulation by antigen, without changing their antigenic specificity. They do this by changing the heavy chain constant region domains that they express, but maintain expression of the same variable domain on the heavy chain and the same light chain variable and constant domains.

The sIg is anchored in the surface membrane of a B cell by a transmembrane amino acid sequence at the carboxy terminus of the heavy chains. When a resting B cell is activated by an antigen, it can differentiate into a plasma cell that produces large numbers of Ig molecules that lack the transmembrane sequence. These are secreted from the cell as antibodies with the same antigenic specificity and isotype as the B cell's sIg. Because B cells initially express sIgM, the first antibodies produced during an immune response (i.e. on first exposure to a particular antigen) are also IgM (there is little, if any, secretion of IgD systemically), but IgG, IgA and IgE antibodies appear later in the response as activated B cells undergo class switching. Furthermore, the memory population is derived from B cells that have undergone class switching, so that IgG, IgA and IgE are produced at the start of a secondary response on repeated exposure to the same antigen. The advantages of producing a range of antibody isotypes are that they have different physiological and defensive activities.

T cells and antigen presentation

The T-cell receptor (TCR) for an antigen shows both similarities and differences to B cell sIg (Figure 13.3). The TCR is a much smaller molecule, being made up of two

Figure 13.3 Antigen recognition by T cells. (See text for details.) APC, antigen presenting cell; β_2M , β_2 -microglobulin; C, constant domain; MHC, major histocompatibility complex; Tc, cytotoxic T cell; TCR, T cell receptor; Th, helper T cell; V, variable domain.

polypeptide chains each of which is about the same size as an Ig light chain, with both expressing a transmembrane sequence. However, T cells do not produce a secreted form of the TCR (i.e. they do not release proteins equivalent to antibodies). The TCR polypeptides expressed by the majority of T cells are called α and β chains, whereas a minority express γ and δ chains. Each chain is composed of two domains that show strong structural homologies with those of the immunoglobulins. Similar Ig-like domains are found in many other surface molecules of lymphocytes and other cells: this indicates evolutionary genetic relationships between these molecules, constituting the immunoglobulin superfamily. The two amino terminal, membrane-distal domains of the TCR chains are variable between T cells and constitute the single antigen combining site. The membrane-proximal domains are constant in structure.

Unlike B cell immunoglobulins, conventional TCR cannot interact directly with antigenic epitopes of proteins; rather, they only bind to short peptides that are derived from protein antigens, and are expressed on the surface of other cells of the body that are known, in this context, as antigen presenting cells (APC). This is because the main function of T cells is to interact with other cells within the context of an immune response: binding to antigenic peptides held on the surface of a cell thereby directs a T cell to exert effects on that particular APC. There are two main functional types of T cell: helper T cells (Th) regulate the activity of other cells of the immune system, whereas cytotoxic T cells (Tc) kill cells that are infected. In order for this to happen, protein antigens that enter the cytoplasm of an APC are processed (i.e. degraded) into peptides, some of which associate with proteins of the major histocompatibility complex (MHC), known in humans as HLA (human leucocyte antigens). The MHC molecule/peptide complexes are then expressed on the surface of the APC where they can interact with T cells whose TCR have combining sites specific for the particular

antigenic peptides presented, much in the same way as an Ig combining site interacts with an antigen epitope. This interaction binds the T cell to the surface of the APC, enabling these cells to exert effects on each other.

There are two types of MHC molecule, called MHC class I and MHC class II (Figure 13.3). They have similar three-dimensional structures, but are made up of different types of polypeptide chains. The MHC class I protein is composed of a large α -chain non-covalently associated with the smaller β_2 -microglobulin, whereas MHC class II is composed of similarly sized α and β chains. Both class I and class II have two Ig-like domains adjacent to the cell membrane (i.e. they are members of the Ig superfamily), whereas distal to the membrane is the antigen peptide binding cleft. Two α -helices form the walls of the cleft and sit on a platform of β -pleated sheet; antigen peptide is held within the cleft in a linear conformation (rather like a hotdog sausage in a bun!) with its exposed surface available for interaction with a TCR. Peptides eight or nine amino acids in length can be accommodated within the cleft of MHC class I molecules, whereas the peptides that associate with MHC class II molecules can be between 12 and 20 amino acids in length because they can extend beyond the ends of the peptide binding cleft.

MHC class I molecules present antigens primarily to Tc cells because these cells express a protein called CD8 that binds to the side of the class I α -chain when the TCR interacts with the peptide and binding cleft (Figure 13.3a). Most tissue cells of the body express MHC class I molecules on their surfaces and thus have the potential to be targets for Tc cells if they become infected by microbes that enter the cytosol, such as viruses. The processing pathway for cytosolic proteins delivers the peptides to MHC class I molecules for binding and presentation. Tc cell clones that specifically bind to these peptides have various ways of killing infected cells by inducing them to undergo apoptosis (programmed cell death):

- The Tc cells secrete two types of proteins stored in cytoplasmic granules: perforins that polymerize to create pores through the plasma membranes of the target cells, and granzymes that enter the target cells through the perforin pores, inducing apoptosis.
- Fas-ligand expressed on the surface of Tc cells, or tumour necrosis factor (TNF alpha) secreted by Tc cells can induce apoptosis when they bind to their receptors on infected target cells (Fas and TNFR1, respectively).

MHC class II molecules present peptides mainly to Th cells because these cells express the CD4 protein that binds to the side of the MHC class II β -chain (Figure 13.3b). The expression of MHC class II molecules is mainly restricted to cells of the immune system whose functions are to activate, and be activated by, Th cells: these are dendritic cells, macrophages and B cells. These cells deliberately engulf exogenous antigens that, for example, bind to Toll-like receptors expressed on macrophages and dendritic cells, or specifically bind to the sIg of selected B cell clones. In either case, the surface-bound

Figure 13.4 Cytokine-mediated regulation by Th1, Th2, Th17 and Treg cells. antigens are endocytosed into membrane-bound vesicles within the cytoplasm. The processing pathway for these vesicular proteins delivers peptides to MHC class II molecules for binding and presentation. Th cell clones that specifically bind to these peptides can then be triggered by the APC to exert their regulatory activities. A range of cell surface and secreted molecules mediate the mutual effects of Th cells and APC. First, there are the interactions of TCR and CD4 with the peptide/MHC class II complex, with the signal resulting from TCR binding being delivered to the interior of T cells by the CD3 protein. Second, a number of other membrane proteins interact between the surfaces of the T cells and APC to deliver co-stimulatory signals; particularly important are interactions of CD28 with B7, and CD40-ligand with CD40, but others include the interactions of CD2 with LFA-3, and LFA-1 with ICAM (in each case on the T cells and APC, respectively). Third, both the APC and the T cells secrete cytokines as soluble regulatory proteins that bind to specific cell surface receptors. For example, interleukin-1 (IL-1) and IL-12 are important T cell activators secreted by dendritic cells.

When activated, different Th cells preferentially secrete differing combinations of cytokines (Figure 13.4). Th1 cells produce interferon- γ (IFN- γ), which is an important macrophage activator, and IL-2, which stimulates T cells (including Tc cells); hence, Th1 cells induce primarily cell-mediated immunity, although they do also stimulate B cells to produce IgG antibodies (subclasses 1-3). In contrast Th2 cells produce IL-4, IL-10 and IL-13, which stimulate B cells to produce antibodies, and particularly induce Ig class switching to production of IgG (subclasses 1-4), IgE and IgA; they also secrete IL-5, which stimulates eosinophils. Th1 and Th2 cells can in fact inhibit each other's activities via the cytokines they release. These patterns of type 1 and type 2 cytokine secretion are observed with other cell types, including Tc cells and B cells. Other subpopulations of T cells have been defined and include Th17 cells, which secrete IL-17, recruit neutrophils to infected tissues and induce the production of inflammatory cytokines

and chemokines. Regulatory T cells (Treg cells) inhibit the activity of T helper cells, thereby controlling adaptive immunity; they do this partly by secreting suppressive cytokines, a key example of which is transforming growth factor-beta (TGF- β).

There are several subpopulations of lymphocytes that display properties of both innate and adaptive immunity. These include NKT cells and $\gamma\delta$ T cells, whose antigen receptors show limited diversity and interact with ligands that differ from the peptide-MHC complexes recognized by 'conventional' T cells. Additional 'innate lymphoid cells' include the well-characterized natural killer (NK) cells and more recently identified lymphoid cells that lack antigen-specific receptors and rapidly produce cytokines when activated.

IMMUNITY TO EXTRA-CELLULAR AND VESICULAR INFECTIOUS AGENTS

Differing defence mechanisms are required to deal with infectious agents that occupy different compartments within the body. A major distinction is whether an infectious agent is in an extra-cellular environment or has entered the cytoplasm of cells, joining the intra-cellular environment (Figure 13.5). This distinction is important because extra-cellular organisms are directly accessible to defensive molecules secreted by cells of the immune system, whereas intra-cellular ones are not. Consequently, antibodies play a major role in the adaptive immune response to extra-cellular pathogens (Figure 13.5a).

Antibody effector functions

Antibodies are bifunctional molecules with one end having the antigen binding properties while the other end triggers the defensive activities. These functional regions are separated by a relatively flexible amino acid sequence between the first and second heavy chain constant

Figure 13.5 Immune responses to different types of infections.

domains called the hinge region (Figure 13.2). The two arms containing the antigen combining sites are called the fragment antigen binding (Fab) regions: each is composed of a light chain and the variable and first constant domain of a heavy chain. The other constant domains of the two heavy chains constitute the Fragment crystallizable (Fc) region (because it can form crystals when isolated experimentally).

As described under Antigen recognition above, there are five classes of Ig molecules expressed as B cell sIg, four of which are also secreted as antibodies (i.e. IgM, IgG, IgA and IgE, but not IgD). The classes have different heavy chain constant domains, and thus differ primarily in their Fc regions (Table 13.1). The heavy chains of IgG, IgA and IgD each have two constant domains in the Fc region, whereas IgM and IgE have three.

In addition, IgM forms pentamers (five Ig monomers) held together by a J (joining) chain polypeptide, whereas IgA can similarly form dimers. The large size of IgM results in it being predominantly restricted to the blood stream (except at sites of inflammation), whereas the other classes can more readily diffuse into tissues. IgG is the most abundant antibody class in the blood, and also is transported across the placenta from the maternal to the fetal circulation during the last three months of pregnancy. This maternal IgG in the newborn baby provides the protection against infection until the baby's immune system produces significant levels of antibodies. Very premature babies have limited maternal antibody. IgA in its dimeric form is transported across mucosal epithelia in large quantities and thus constitutes the main antibody class conferring protection in secretions and at mucosal surfaces. Part of the mucosal receptor that binds and transports IgA across the epithelium remains associated with it as the secretory piece. IgA is also secreted into milk and thus confers protection in the gastro-intestinal tract of suckling babies. In humans, IgD is present in secretions of the upper respiratory and digestive tracts where it may play important roles in neutralization of pathogenic microbes and exclusion of commensals.

Antibodies can neutralize microbes and their toxins simply by binding to them, hence inhibiting their functions and infectivity. However, antibodies can also contribute to the destruction of infectious agents by interacting with other defensive components, as described below.

The complement system

(See Figure 13.6.) The complement proteins found in the circulation and tissue fluids constitute an important defensive system that can be activated by the Fc regions of IgM and IgG antibodies in what is termed

TABLE 13.1 Functional properties of antibody classes and subclasses

the classical pathway of complement activation. This is triggered when IgM or several IgG antibodies that are bound to antigen, interact with the complement C1 protein complex, resulting in the formation of a C3 convertase enzyme from C4 and C2 (C4b2a). This same C3 convertase can be generated when the pattern recognition molecule mannan-binding lectin (MBL) interacts with mannose residues of microbial surfaces. (MBL is a member of a family of secreted carbohydrate-binding collagenous defensive proteins called collectins.) A different C3 convertase is produced when certain complement proteins directly form a stable complex (C3bBbP) on microbial surfaces in what is termed the alternative pathway of complement activation. IgA can also activate the alternative pathway.

The conversion, or splitting, of complement protein C3 by the C3 convertase enzymes into fragments C3a and C3b is the central and crucial event during complement activation and generates a range of biological effects. Some of the C3b can be used to generate more of the alternative pathway C3 convertase; it also modifies the activity of the C3 convertase enzymes to split C5 into C5a and C5b. As mentioned in ‘Innate and adaptive immunity’ above, C3a and C5a activate mast cells and thus promote inflammation: they also attract and activate neutrophils (particularly C5a). The C5b fragment forms the membrane attack complex (MAC) with C6, C7, C8 and several molecules of C9: this last

complement protein has structural and functional similarities to perforin and forms pores through lipid bilayers. Thus, the MAC has direct anti-microbial effects by disrupting microbial membranes. Finally, in addition to its other activities, C3b opsonizes (i.e. coats) infectious agents, which facilitates their interaction with leucocytes, as described below.

Digestive and inflammatory leucocytes

Some leucocytes have surface receptor proteins that bind to the Fc regions of antibodies (FcR), and others that bind to complement C3b (CR). As described above, the phagocytes (macrophages and neutrophils) express pattern-recognition molecules that enable them to bind microbes directly. However, they also possess FcR specific for IgG or IgA and CR that have particularly high affinities for their respective ligands. Thus, microbes such as bacteria can be firmly bound to the surface of phagocytes when opsonized by antibodies and C3b. This facilitates and activates phagocytosis (i.e. engulfing) of the microbes into membrane-bound cytoplasmic vesicles. The microbes can then be destroyed by lysosomal enzymes and reactive oxygen molecules.

Some microbes, such as the mycobacteria that cause tuberculosis and leprosy, are relatively resistant to the digestive activities of phagocytes and are able to survive and multiply within the cytoplasmic vesicles

of macrophages. In this environment the microbes are protected from the activities of extra-cellular antibodies and complement proteins. The effective control of such infections is then dependent on the activity of Th1 cells that, as described in ‘T cells and antigen presentation’ above, produce the potent macrophage activating cytokine IFN- γ : this promotes macrophage digestive activity against microbes in intra-cellular vesicles (Figure 13.5b).

Other infective agents, particularly parasitic worms like schistosomes and helminths, are much too large to be engulfed for intra-cellular digestion by phagocytes. In such circumstances, eosinophils are recruited to undertake extra-cellular digestion by releasing their digestive proteins (e.g. major basic protein) onto the surface of the parasites. Eosinophils possess FcR (specific for IgG or IgE) and CR, and so again will bind most avidly to opsonized targets.

The other main cells that express FcR for IgE are the tissue mast cell and blood basophils, whose defensive roles are to promote inflammation, rather than directly destroying pathogens. These cells are activated when an antigen binds and cross-links several FcR-bound surface IgE molecules. This induces the immediate release of pre-formed inflammatory mediators, particularly histamine, that are stored in cytoplasmic granules. It also induces the *de novo* synthesis and later release of leukotrienes. (As mentioned above, mast cells are also activated by the complement peptides C3a and C5a.) Furthermore, IgD produced in the upper aerodigestive tract can bind to receptors expressed by basophils, mast cells, monocytes and neutrophils. Cross-linking of IgD antibodies on the surface of basophils by the antigens to which they bind promotes basophil activity in promoting both innate and adaptive immunity.

IMMUNITY TO CYTOSOLIC INFECTIOUS AGENTS

(See Figure 13.5c) Some infectious agents, such as viruses, actively infect cells by entering the fluid cytosol. Viruses are obliged to infect cells in order to use the machinery of the cells they enter in order to replicate themselves. Although antibodies and complement can neutralize viruses whilst they are outside cells, other immune mechanisms are required to interact with intra-cellular viruses.

An innate mechanism of anti-viral defence is the production and secretion of IFN- α and/or IFN- β by the infected cells. These type 1 interferons are structurally unrelated to the IFN- γ (type 2 interferon) that is produced by activated T cells and natural killer (NK) cells. Both types derive their name from their ability to *interfere* with viral replication. Type 1 interferons secreted by virally infected cells induce an anti-viral state in neighbouring non-infected cells by stimulating these cells to produce enzymes that block viral replication. In addition, type 1 interferons enhance MHC class I

expression, which is necessary for Tc cell recognition of target cells, and they activate NK cells. Both these types of killer cells are important in the immune response to intra-cellular viruses as killing the infected cells inhibits viral replication and hence spread within the body. NK cells are the first killer cells to be activated, and they employ the same mechanisms of cytotoxicity as those described for Tc cells under the ‘T cells and antigen presentation’ above. However, unlike Tc, NK cells do not possess antigen-specific receptors; rather, they detect abnormalities in the expression of a cell’s own surface molecules that may be indicative of the cell being virally infected. NK cells possess two types of receptors that interact with potential target cells: killer activating receptors; and killer inhibitory receptors, with the latter providing a dominant inhibitory signal that prevents NK cells from killing normal (uninfected) cells. The ligands for killer inhibitory receptors are often MHC class I molecules, whose expression may be reduced by viral infection of a cell: this makes the cell susceptible to the activity of NK cells because they then bind predominantly via their killer activating receptors. The ligands for some of the killer activating receptors are MHC class I-like molecules whose expression on target cells can be induced by infection, malignant transformation or other forms of cellular stress, thereby increasing the susceptibility of these cells to killing by NK cells.

NK cells also express FcR specific for IgG and so can interact with, and kill, target cells via antibodies that have bound to antigens expressed in the surface membranes of the target cells, as may happen during the process of budding by viruses. This is termed antibody-dependent cellular cytotoxicity (ADCC).

Interferons and NK cells are very important in limiting the replication and spread of a virus during the early stages of an infection, but may not be able to eliminate the infection. The adaptive Tc cells will take longer to be activated, as described under ‘Stages of an immune response’ above, but can then specifically and efficiently target the infected cells, as described under ‘T cells and antigen presentation’ above.

INFLAMMATION AND HYPERSENSITIVITY

Inflammatory processes are necessary to recruit components of the immune system to sites of infection. The importance of tissue mast cells as a source of inflammatory mediators has been discussed in previous sections, but many cell types can produce a range of inflammatory mediators, including cytokines and other proteins as well as other types of chemicals (e.g. prostaglandins and leukotrienes). A number of these have particular effects on the vessels that supply blood to infected tissues, promoting vasodilatation and increased vascular permeability, and enhancing endothelial expression of adhesion molecules (particularly selectins and integrins). The interaction of

circulating leucocytes with the adhesion molecules facilitates their migration across the blood vessel walls and into the infected tissues in response to chemotactic factors.

In addition to localized inflammatory events within infected tissues, systemic effects are induced by cytokines that enter the blood stream, particularly IL-1, IL-6 and tumour necrosis factor (TNF). These have effects on the hypothalamus to induce fever, on the bone marrow to promote leucocyte release, and on the liver leading to the release of acute phase proteins: in particular the liver-derived pentraxins called C-reactive protein and serum amyloid P possess innate anti-microbial activities.

The enormous destructive potential of the immune system that is unleashed against invading microbes can be equally damaging to the body's own tissues. Thus, during every immune and inflammatory response, a balance must be struck between beneficial and tissue damaging effects. The immune system has evolved regulatory processes to limit the latter but, in some instances, immunological tissue damage becomes the main clinical feature, generating the problems of hypersensitivity.

Allergy and autoimmunity

Tissue damaging adaptive immune mechanisms can be triggered by foreign antigens or the body's own components. The former can be microbes, inducing the immune-mediated tissue damage associated with infective diseases, or can be inert (non-infective) materials that cause allergies. Up to 30% of the population is affected by allergies in developed countries, with a host of different allergens affecting different individuals (e.g. pollen, house dust mite, insect venom, food proteins, latex). Conversely, reactivity to self-components can lead to autoimmune diseases. Collectively, these affect over 3% of the population, with a much higher incidence of sub-clinical autoimmunity. In organ-specific autoimmunity, the stimulating autoantigens are restricted to particular tissues or organs, such as thyroid peroxidase and thyroglobulin in autoimmune thyroiditis, insulin and glutamate decarboxylase in type 1 diabetes mellitus. By contrast, systemic autoimmunity involves reactivity against widely spread tissue components, such as DNA, histones and ribonucleoproteins in systemic lupus erythematosus and IgG and citrullinated proteins in rheumatoid arthritis.

Mechanisms of hypersensitivity

Although allergic and autoimmune disorders differ in the nature of the stimulating antigens, they involve similar mechanisms of tissue damage, referred to as the four mechanisms of hypersensitivity (Figure 13.7).

Type I (immediate or reaginic) hypersensitivity occurs in a variety of atopic allergies (Figure 13.7). It involves activation of tissue mast cells when an inducing allergen specifically binds to at least two IgE antibodies on the surface of mast cells. The IgE cross-linking induces the release of inflammatory

mediators, as described under 'Digestive and inflammatory leucocytes' above, which induce vasodilatation, increased vascular permeability and smooth muscle contraction. For example, inhaled allergens that induce immediate mast cell activation commonly cause allergic rhinitis and extrinsic asthma. These conditions may be seasonal (e.g. hay fever), or perennial in allergies to house dust mite and cat, for example. Severe systemic acute forms of type 1 hypersensitivity are seen in anaphylaxis (e.g. to nuts, insect stings, drugs).

Type II (cell or membrane reactive) hypersensitivity involves antibodies of the IgG, IgA or IgM classes that bind to antigens associated with cell surface membranes or basement membranes (Figure 13.7). The antigen-bound antibodies then activate complement, which may damage the membranes directly via the membrane attack complex, but also attract and activate neutrophils via the actions of C5a and C3a. The release of digestive enzymes and reactive oxygen species by the neutrophils can then exacerbate the membrane damage. Bullous pemphigoid is an example of a disease involving antibodies to basement membrane antigens. By contrast, in pemphigus, autoantibodies bind to desmoglein in the epidermal intra-cellular cement, and clearly correlate with tissue damage. Goodpasture's syndrome is a further example of a disease where autoantibodies bind to basement membranes; in this case, the autoantigen is type IV collagen in alveolar and glomerular basement membranes, causing the typical haemoptysis and haematuria. The muscle weakness of myasthenia gravis is induced by autoantibodies to the acetylcholine receptors in the post-synaptic membranes of muscles: these antibodies induce complement-mediated damage, receptor internalization and blockade, leading to inhibition of neurotransmission by acetylcholine.

Type III (immune complex mediated) hypersensitivity, like type II hypersensitivity, involves IgG, IgA and IgM antibodies, but in this case reacting with soluble antigens to form cross-linked molecular lattices containing multiple antibody and antigen molecules known as immune complexes (Figure 13.7). These complexes can become too large to remain soluble and so precipitate within tissues where they can activate complement and neutrophils, leading to tissue damage. Allergic immune complex disease is exemplified by extrinsic allergic alveolitis that is triggered by inhalation of allergens that form immune complexes in the alveolar walls leading to tissue damage and fibrosis. Common allergens are fungal spores (e.g. in farmer's lung) and avian plasma proteins (e.g. in bird fancier's lung). In systemic lupus erythematosus immune complex deposition can occur in various tissues, including the skin, joints, lungs, brain and kidneys: these complexes are frequently composed of DNA and anti-DNA antibodies, with contributions from other nuclear and cytoplasmic autoantigens.

Figure 13.7 Mechanisms of hypersensitivity. (See text for details.) APC, antigen presenting cell; Ig, immunoglobulin; MC, mast cell; Th1, T helper 1 cell.

Type IV (cell-mediated) hypersensitivity is distinguished from the other three types by not involving antibodies. It is principally dependent on the activities of T cell and macrophages with Th1 cells producing cytokines like IL-2 and IFN- γ that activate cytotoxic T cells and macrophages, respectively (Figure 13.7). Much of the tissue damage in autoimmune diseases is brought about by cell-mediated mechanisms, although autoantibodies are also present (e.g. thyroiditis in the autoimmune thyroid diseases, insulinitis in type 1 diabetes and synovitis in rheumatoid arthritis). Sjogren's syndrome is characterized by lymphocytic destruction of exocrine

tissues, particularly the lacrimal and salivary glands, resulting in dry eyes and mouth. Much of the pathology associated with certain infectious diseases is also due to immune-mediated tissue damage. For example, in tuberculosis, infection of lung macrophages by *Mycobacterium tuberculosis* – which is resistant to intra-cellular digestion – leads to chronic T cell activation and cytokine production.

Despite the clinical problems of hypersensitivity diseases, the severe, persistent, unusual and recurrent infection problems associated with immunodeficiency disorders highlight the vital defensive role of the immune system.

KEY POINTS

- Immunity provides protection against pathogenic organisms, and the functions of the immune system are recognition of these foreign pathogens and defence of the body against them.
- Innate and adaptive immunity constitute the two main arms of the immune system which differ in their recognition and activation properties. Adaptive immunity improves with repeated exposure to the same antigens.
- The early innate response to infection stimulates an inflammatory response and initiates the processes that result in the adaptive lymphocyte response.
- Adaptive immunity involves the specific recognition of antigens by B and T lymphocytes.
- B-cell antigen receptors and antibodies can bind antigen in its native, unmodified form, recognizing accessible surface epitopes. In contrast, T-cell receptors recognize antigenic peptides bound to HLA molecules expressed on the surface of antigen-presenting cells or target cells; this requires processing (fragmentation) of the antigen, and epitopes may be derived from any part of the antigen.
- A typical immunoglobulin/antibody is composed of two identical heavy chains and two identical light chains. The amino-terminal variable domains of a heavy and a light chain form an antigen-combining site within one of the two Fab portions of the molecule. The Fc portion is composed of the heavy chain constant regions on the carboxy-terminal side of the hinge region.
- Cytotoxic function is associated with CD8⁺ T cells and HLA class I-associated antigen recognition. This facilitates T-cell recognition and killing of abnormal tissue cells.
- Helper function is associated with CD4⁺ T cells and HLA class II-associated antigen recognition. This facilitates T cell help by interaction with cells such as interdigitating dendritic cells, macrophages and B cells.
- Th1 and Th2 cells secrete cytokines that promote principally cell-mediated immunity and antibody-mediated immunity, respectively. Th17 cells promote inflammatory responses, whereas various types of Treg cells suppress Th cell-driven responses.
- Immunoglobulin isotypes (i.e. classes and subclasses) are defined by differences in their heavy chain constant regions. These determine their biological characteristics, e.g. complement activation, cellular association via Fc receptors and tissue distribution.
- Complement consists of several plasma proteins that operate as an enzyme cascade giving rise to various biological activities, including immune adherence, inflammation and membrane lysis.
- Macrophages and neutrophils are called phagocytes because of their ability to ingest and destroy microbes.
- Mast cells and basophils are activated by multivalent antigens cross-linking surface-bound IgE molecules; this induces the release of inflammatory mediators. Certain mast cell and basophil mediators are preformed and stored in granules (e.g. histamine) and are released immediately upon activation, whereas other mediators are synthesized *de novo* (e.g. leukotrienes and prostaglandins).
- There are two types of killer lymphocytes: cytotoxic T cells (Tc cells) and natural killer cells (NK cells). They are cytotoxic to target cells that have become infected or malignant.
- The immune system can cause inflammatory damage to the body's own tissues that may be triggered by infection, non-infective foreign antigens (in allergies), or the body's own autoantigens (in autoimmune disease).
- The mechanisms of immunologically mediated tissue damage are classified into four main types: Type I, IgE-mediated immediate hypersensitivity; Type II, antibody-mediated; Type III, immune complex-mediated, Type IV: T cell-mediated, DTH. More than one mechanism may operate in an inflammatory process.

Introduction	137	Tests in allergy diagnosis.....	143
Aetiology of sensitization	137	References	148
Basic mechanisms.....	138		

SEARCH STRATEGY

Data in this chapter may be updated by PubMed and Ovidsp Medline searches using the keywords: allergy basic mechanisms, allergic rhinitis, anaphylaxis, skin prick tests, specific IgE, allergen component, basophil activation test, immunotherapy, mast cell signalling. The references of relevant articles were also checked. In addition, major immunology and allergy journals, and immunology textbooks were scanned. The evidence in this chapter is mainly levels 2/3 with some level 1 evidence. The clinical and laboratory recommendations are based on guidance from the UK and international professional associations, grade A and B.

INTRODUCTION

Allergy is defined as a hypersensitivity reaction initiated by specific immunologic mechanisms.¹ By a specific definition, it describes objectively reproducible symptoms or signs initiated by an exposure to a defined stimulus at a dose tolerated by normal persons.¹ *Hypersensitivity* is an altered immune response to an antigen that can cause damage. Immunologically four types of hypersensitivity reactions are generally recognized (Table 14.1).

An *allergen* is an antigen (usually protein) that causes allergic diseases. Allergic airway diseases including rhinitis are due to inhaled allergens (Table 14.2). *Atopy* is a tendency to become sensitized and produce allergen-specific immunoglobulin E (sIgE) in response to ordinary exposures to allergens. Clinically this is demonstrated by positive skin prick tests and/or increased serum sIgE concentration to one or more allergens. Not all sensitized individuals are symptomatic. Therefore allergy is a disease manifestation of sensitization.

We will consider the basic mechanism of allergy initially in which an individual is predisposed to allergy by sensitization to allergens. Then we will consider the immunological process involved in some allergic diseases and the effect of treatment including current understanding of specific allergen immunotherapy. Finally the principles of diagnostic tests will be considered.

AETIOLOGY OF SENSITIZATION

Type 1 immunoglobulin E (IgE) mediated immediate hypersensitivity occurs only in a sensitized individual. Immune responses to innocuous antigens leading to sensitization are multi-factorial. In general these include host factors such as genetic predisposition and environmental factors such as pollution.

Up to 40% of the population in the industrialized countries have been reported to have a tendency to atopy. An atopic person usually has a high total IgE level, a strong familial tendency and increased susceptibility to allergic diseases such as allergic rhinitis and atopic dermatitis. Many genetic loci have been shown to be associated with allergic diseases. These include chromosome 11q12-13 (encodes β subunit of high-affinity IgE receptor) and chromosome 5 (encodes Th2 promoting cytokines such as IL4, TIM gene family that regulates Th1/Th2 balance, p40 subunit of IL12, β 2 adrenergic receptor). Polymorphism in these genes altered disease susceptibility of a person to allergic diseases. Another inherited variation seen in IgE response to specific antigen is human major histocompatibility complex (MHC) class II region (e.g. HLA DRB1*1501 in ragweed pollen sensitization). Therefore an allergic individual can be associated with both general tendency and allergen-specific predisposition to develop a stronger Th2 response than their normal counterpart.

TABLE 14.1 Types of hypersensitivity (adapted from Coombs and Gell Classification)

Features	Type I	Type II	Type III	Type IV
Mechanism	Immediate hypersensitivity	Cytotoxic hypersensitivity	Immune complex reaction	Cell-mediated hypersensitivity
Immune reactant	IgE	IgG	IgG	T cell
Effectors	Mast cells, basophils, eosinophils	Complement, phagocytes	Complement, phagocytes	Macrophages
Disease examples	Allergic rhinitis	Haemolytic anaemia	Serum sickness, SLE	Contact dermatitis

TABLE 14.2 Inhaled allergens

Environmental factors such as exposure to infectious diseases in early childhood, environmental pollution and dietary changes also contribute to allergic diseases. *Hygiene hypothesis* has been one of the well-known discussions since 1989. Early life exposure to infectious diseases has been shown in mice models as being associated with promoting Th1 rather than Th2 response. Th1 response is proinflammatory and responsible for killing intracellular pathogens and for perpetuating autoimmune responses. Th2 response is not only essential in defence against pathogens such as helminths (e.g. hookworm) but also promotes allergic conditions. Therefore the prevalence of allergic diseases is higher in children who grew up in a hygienic environment (e.g. industrialized Western countries) than in less hygienic regions where infectious diseases are more common.

A *counter-regulation hypothesis* has proposed that regulatory cytokines (e.g. IL10, TGF- β) are upregulated in the presence of infection. As a result atopy is less common despite Th2 response being predominant in infections. In addition proinflammatory cytokines (e.g. interferon- γ) resulting from infection also stimulate dendritic cells (DC) to suppress Th2 inflammation and promote regulatory cytokines.

Regulatory T cells are also considered to have an important role in allergic diseases. This has been supported by a FoxP3 deficient mice model that develops manifestations seen in allergic conditions such as eosinophilia, increased IgE level and allergic airway inflammation suggesting Treg (CD4+CD25+) cell deficiency can predispose to this phenotype.

BASIC MECHANISMS

Mast cells and basophils are the principle effector cells that produce mediators (Table 14.3) responsible for allergic diseases. IgE mediated immediate allergy can be associated with early and late responses. The early phase is due to preformed mediators release (e.g. anaphylaxis). The late phase is due to newly synthesized mediators and infiltration of other leucocytes that can be followed by a chronic

allergic inflammation in some conditions (e.g. allergic asthma). Late phase response involves Th2 cytokines resulting in activation of eosinophils and other leucocytes. Chronic allergic inflammation is characterized by tissue destruction and remodelling and is essentially type IV hypersensitivity in nature.

Effectors of allergic diseases

The essential effector cells of immediate hypersensitivity are cells expressing high affinity IgE receptors (Fc ϵ RI) such as mast cells, basophils and eosinophils. Other effectors include antigen presenting cells (e.g. dendritic cells) and Th2 cells that promote allergen-specific IgE synthesis by B cells.

MAST CELLS

Mast cells are haemopoietic stem cell derivatives and mature locally. They reside near the surface where our body is exposed to pathogens and allergens. Based on the distribution they are known as either mucosal mast cells or tissue mast cells. They are often found in close proximity to blood vessels. Fc ϵ RI is capable of being tightly bound to sIgE even in the presence of a very low serum concentration. On exposure to their specific allergens, cross-linking of the receptor and signalling follow to produce clinical phenomena (Figure 14.1). Fc ϵ RII is a low affinity IgE receptor (CD23). It is present in many cells including B cells, activated T cells, monocytes, eosinophils, platelet and follicular dendritic cells. The role of Fc ϵ RII in an allergic reaction is not fully understood.

Mast cells granules contain preformed mediators that are responsible for the immediate symptoms of allergic reactions. Mast cells also produce other mediators upon Fc ϵ RI signalling. Mediators that are rapidly synthesized are involved in the immediate symptoms of allergic reactions. Other mediators may lead to late phase responses and chronic allergic inflammation (Table 14.4).

BASOPHILS

Basophils develop from bone marrow granulocyte-monocyte progenitor. There is increasing evidence that basophils involve significantly in allergic diseases. They respond to many stimuli including cytokines, antibodies, proteases and antigens. Cross-linking of IgE bound Fc ϵ RI receptors on basophils have been shown to produce mediators (Table 14.4). Basophils have been identified in nasal washes of patients with allergic rhinitis.

TABLE 14.3 Physiologic actions of mediators

Types of mediator	Effects
Enzymes: <ul style="list-style-type: none"> • tryptase, chymase, carboxypeptidase A • eosinophil peroxidase • eosinophil collagenase • matrix proteinase 	<ul style="list-style-type: none"> – tissue destruction – toxic to target, histamine release from mast cells – connective tissue remodelling – matrix protein degradation
Eosinophil major basic protein	– toxic to parasite, histamine release form mast cells
Proteoglycans - histamine, heparin	– increase vascular permeability, smooth muscle contraction
Cytokines: <ul style="list-style-type: none"> • TNF-α • IL4, IL13 • IL3, IL5 • TGF-α, TGF-β 	<ul style="list-style-type: none"> – promote inflammation – amplify Th2 response – activate eosinophil – epithelial proliferation and myofibroblast formation
Chemokines: CCL3, CXCL8	– influx of leucocytes
Platelet-activating factor (PAF)	– attracts leucocytes and increases lipid mediators production
Arachidonic acid metabolites: <ul style="list-style-type: none"> • prostaglandins D2 (PgD2), leucotrienes C4 (LtC4) 	– smooth muscle contraction and increase vascular permeability

**Figure 14.1** Development of sensitization.

EOSINOPHILS

Eosinophils are granular leucocytes that mainly reside in submucosal connective tissue in respiratory, gastrointestinal and urogenital tracts. They play an essential role in defence against helminths. Eosinophils also express Fc ϵ RI receptors and are capable of releasing mediators (Table 14.4).

T LYMPHOCYTES

T cells are central to the pathogenesis of allergic diseases since they are the only cells capable of recognizing antigens presented by antigen presenting cells. Maturation of a naive T cell takes place on activation by signals including specific peptide-MHC via T cell receptor and costimulatory signal via CD28. T helper cells (CD3+CD4+) differentiated into many types depending upon the type of immune response taking place and cytokine environment. Th1 cells differentiate in the presence of interferon gamma (IFN- γ) and IL-12, and produce predominantly IFN- γ and interleukin 2 (IL-2). Th2 cells differentiate in the presence of IL-4 and produce IL-4, IL-5 and IL-13 cytokines preferentially. Recruitment of Th2 cells, their activation in tissues and generation of Th2 cytokines are main features of both allergic rhinitis and asthma. Low dose antigen exposure via mucosal surface with inhaled allergen is typical of Th2 response in allergic rhinitis, where as high dose allergen delivered by injection favour Th1 response.

DENDRITIC CELLS

Dendritic cells are professional antigen presenting cells (APC), which are abundant in the epithelium and submucosa of both upper and lower respiratory mucosa in patients with allergic diseases. Traditionally dendritic cells have been classified as myeloid derived DC1 cells (derived from human blood monocytes) or DC2, plasmacytoid cells (derived from lymphoid cells). DC1 cells produce a high level of IL-12 and favour Th1 development. DC2 cells are low IL-12 producers and support preferential Th2 differentiation. However, in dendritic cells subpopulations, differential function may depend on their location, their degree of maturation and local cytokines milieu.

Immature cells express high levels of immunoglobulin receptors and are highly endocytic in keeping with

TABLE 14.4 Mediators of effector cells

Types of mediator	Mast cells	Basophils	Eosinophils
Preformed mediators	tryptase, chymase, carboxypeptidase A, histamine, heparin, TNF- α	histamine, TNF- α	eosinophil peroxidase, eosinophil collagenase, matrix proteinase, eosinophilic cationic protein
Newly synthesized cytokines and lipid mediators	IL4, IL13, TNF- α , IL3, IL5, PAF, Pgd2, LtC4	IL4, IL13, PAF, LtC4	IL3, IL5, TGF- α , TGF- β , LtC4, PAF

efficient antigen capture. In contrast, mature cells express high levels of MHC class II and have upregulated CD86 expression and produce abundant cytokines, features consistent with their role in allergen presentation and immune modulation. Rapid maturation (within 2 hours) was observed in dendritic cells within the bronchial wall and not peripheral lung. Rapid dendritic cells recruitment to the bronchial mucosa in atopic asthmatic patients has also been observed within the time frame of late asthmatic responses following local segmental allergen challenge. Plasmacytoid dendritic cells (CD123) IL-3R α -chain+CD45RA+ cells increase dramatically in number following local allergen challenge repeatedly for 7 days. This is of particular interest since plasmacytoid dendritic cells matured *in vitro* can induce preferential Th2 development.

IMMUNOGLOBULIN E (IGE)

IgE concentration is the lowest immunoglobulin isotype (approximately 100–400 ng/mL) in human serum. The majority of IgE is tissue-bound with a half-life of approximately 2 days. Fc ϵ RI is a high affinity receptor for IgE, which is mainly present on mast cells, basophils and eosinophils. But low-level expressions are detected in dendritic cells, monocytes, and macrophages that are in different molecular structures. Their significance remains uncertain. IgE also bind to a low affinity receptor Fc ϵ RII (CD23) on B cells, monocytes and macrophages.

IgE is developed from isotype switching of IgM. B cells secrete IgM following antigen recognition (Figure 14.2). Isotype switching is influenced by specific Th2 cells and the cytokine environment. IgE production is favoured by IL-4 and IL-13 derived from Th2 cells. It is also perpetuated by IL-4 and IL-13 from mediator release as a result of degranulation in allergic reaction. IgE production generally occurs in the bone marrow and the draining regional lymph nodes. But local IgE production has been reported in local forms of allergic conditions (e.g. allergic rhinitis). Local IgE synthesis has been considered as the cause in some situations – allergic symptoms without sensitization on skin prick test and increased sIgE; some atopic individuals develop rhinitis whereas other develop asthma or eczema, and others may have sensitization without any clinical manifestation.

HISTAMINE

Histamine is generated from histidine decarboxylase and stored in granules of mast cells and basophils. Elevated

Figure 14.2 Th2 development and IgE production. APC, antigen presenting cell; MC, mast cell.

histamine levels correlate well and indicate higher sensitivity than tryptase in anaphylaxis. Tryptase level is elevated in 60% whereas histamine and PAF are elevated in 70% and 100% respectively in anaphylaxis.² However, histamine is highly soluble and rapidly diffuses away after the release. The majority of histamine is metabolized within minutes of release by many enzymes such as histamine N-methyl transferase, monoamine oxidase and diamine oxidase. The short plasma half-life and sample handling issue are major limiting factors for histamine measurement in routine laboratory use. Urinary metabolites (N-methyl histamine) can be detected several hours after anaphylaxis. But there are potential confounding factors for this measurement such as the effect of histamine producing bacteria, histamine containing foods and so on. In scombroidosis, the urinary histamine level can be increased despite a normal serum tryptase level.

SERUM TRYPTASE

Tryptase is produced by mast cells and basophils. In humans, tryptase exists in two isotypes (alpha and beta), which are in two forms – mature and immature. Beta tryptase is the predominant isotype in mast cells. Protryptase is the immature form and is spontaneously secreted by unstimulated mast cells. Mature tryptase is stored in the intracellular granules and released on degranulation. Therefore it is normally undetectable. The normal reference range of total tryptase is 1–13 ng/mL in our laboratory. The total tryptase levels peak 30–60 minutes after the onset of symptoms due to degranulation, and reduce afterwards with a half-life of about 2 hours. Tryptase levels can be measured in both serum and plasma but in a sample left at room temperature for more than 1–2 days may give falsely low values.

Normal tryptase levels do not exclude anaphylaxis. Other causes of increase tryptase levels include mastocytosis, acute myelocytic leukaemia, myelodysplastic syndrome and the myeloid variants of hypereosinophilic syndrome. Elevated total tryptase has also been reported in some conditions such as onchocerciasis treatment and administration of recombinant stem cell factor.

There are two mechanisms leading to mediators release in mast cells and basophils. The FcεRI signalling as a result of the sIgE-antigen complex is the underlying mechanism in the IgE mediated hypersensitivity. However, mediator release can also occur by other factors that are capable of IgE independent direct stimulation. These include viral proteins (e.g. HIV gp120), bacterail proteins (e.g. LPS), drugs (e.g. opiate), chemical and physical stimuli, complement activation and neuropeptides, cytokines and so on.

High affinity receptor (FcεRI) signalling in allergic reaction

Allergic reactions are overlapping and synergistic physiological effects resulting from mediators release due to the activation of mast cells and basophils through a mechanism generally understood to involve FcεRI signalling. This signalling has been extensively investigated using passive cutaneous and passive systemic anaphylaxis models.³

Unlike other immunoglobulin isotypes, the majority of IgE is tightly bound to FcεRI. There is no signalling until these receptors are cross-linked by their specific antigens. The high level of IgE has potential to enhance IgE dependent effector function. FcεRI is a tetrameric receptor consisting of three subunits: a IgE binding unit (α chain); a signal transducing unit (β chain); and two signal regulator units (γ chain).

Allergen-sIgE binding is followed by early signalling events including phosphorylation of cytosolic domains of the receptor known as immunoreceptor tyrosine-based activation motif (ITAM). This phosphorylation is mediated by Src family proteins. There are two types of Src family protein in these events, namely signal-initiating kinase (Lyn) and signal-propagating kinase (Syk). This is followed by the recruitment of many signalling proteins to form multi-molecular signalling complexes. The downstream

effect of this signalling results in an activation of protein kinase C and liberation of intracellular calcium. These lead to degranulation within minutes. In addition eicosanoid generation and activation of transcription factors for the production of cytokines and other mediators of allergic reaction follow within hours (Figure 14.2).

ROLES OF SENSORY NERVES

Activation of sensory nerves is an important mechanism in rhinitis in many ways. These include generation of acute rhinitis symptoms, nasal hyper-reactivity to non-specific triggers, release of neuropeptides such as substance ‘p’ and neurokinin from inflamed sensory nerves. Neurogenic inflammation is self-perpetuating and represents an important component of the allergen-IgE interaction. Nerve growth factor can be detected in nasal fluids in chronic allergic rhinitis. It is increased after allergen challenge. Therefore immediate response is due to a complex interaction between mediators release and target organs such as the sensory nerve, the vasculature and mucus secreting glands. Hyper-responsiveness of target organs associated with late response and day-to-day allergic disease is likely to relate to a combination of both inflammation and increased sensory nerve activation. The contribution of these components varies in different individuals.

Clinical features of IgE mediated hypersensitivity^{4–6}

The American College of Allergy, Asthma and Immunology Epidemiology of Anaphylaxis Working Group has estimated that a lifetime prevalence of anaphylaxis is 0.05–2.0%. The clinical features of allergic reactions are the effects of mediator release and may involve many systems. Most commonly, these include cutaneous, respiratory, cardiac and gastrointestinal systems (Table 14.5).

The onset of immediate allergy depends on the route of exposure to an allergen but it is usually within minutes. An anaphylaxis due to intravenous allergen (e.g. drug) occurs within seconds. Electrocardiographic abnormalities such as T inversion, supraventricular arrhythmias and bundle branch blocks have been reported in anaphylactic reactions during anaesthesia. In general an immediate allergy develops within 60 minutes of allergen challenge. Myocardial infarctions following anaphylaxis have also been reported. The late-phase reactions (LPR) have been described in respiratory and cutaneous allergy. Biphasic reaction patterns have been reported when both immediate and LPR have occurred.

Post-mortem finding of fatal anaphylaxis often shows few pathologic changes but may reveal oedematous obstruction of the airways, laryngeal oedema, pulmonary hyperinflation, pulmonary oedema, eosinophilic infiltration around the bronchi, and swelling of liver, spleen and intestine.

LOCAL ALLERGIC RHINITIS⁸

Local allergic rhinitis (LAR) has been described as a localized nasal allergic response. In contrast to generally

TABLE 14.5 Clinical features of immediate allergy (adapted from Ring and Messmer)

System	Manifestations			
Prodromal	– feeling of anxiety, paresthetic sensations on palms and soles			
Cutaneous	– pruritus, flush, urticaria, or angioedema			
Respiratory	– sneezing, rhinorrhea, dyspnoea due to laryngeal obstruction or bronchospasm, hoarseness, feeling of ‘tight throat’, cough or wheezing, cyanosis and respiratory arrest			
Cardiac	– early tachycardia, changes in blood pressure (sometimes an initial rise, followed by hypotension), arrhythmia, shock, cardiac arrest			
Gastrointestinal	– nausea and cramping (uterine cramps may also occur), vomiting, diarrhoea, urination			
Non-specific	– sweating, headache and disorientation			
Severity grading of an allergic reaction				
Severity	Cutaneous	Cardiac	Respiratory	Abdominal
Grade 1	Urticaria, flushing, angioedema			
Grade 2	Urticaria, flushing, angioedema	Tachycardia, blood pressure change (>20 mmHg systolic)	Rhinorrhoea, hoarseness, breathlessness	Nausea
Grade 3	Urticaria, flushing, angioedema	Shock	Laryngeal oedema, wheezing, cyanosis	Nausea, vomiting, diarrhoea
Grade 4	Urticaria, flushing, angioedema	Cardiac arrest	Respiratory arrest	Nausea, vomiting, diarrhoea

known allergic rhinitis (AR), allergic sensitizations are not detectable by serum-specific IgE or skin testing in LAR. LAR is usually diagnosed by a positive nasal allergen provocation test (NAPT). Many patients previously diagnosed with non-allergic rhinitis are now being classified as having LAR. In one of the Spanish cohort, LAR accounts for 15% of all cases of rhinitis.

A local specific IgE production in the nasal mucosa with a TH2 inflammatory pattern response has been considered as a pathophysiologic mechanism in LAR. A proportion of patients with LAR have detectable basal aeroallergen sIgE (e.g. house dust mite, cat, dog, grass etc.) in their nasal secretion. These sIgE levels rapidly increase after NAPT in 22% of LAR with perennial symptoms and 35% of those with seasonal symptoms. Measurement of nasal sIgE in LAR has a high specificity but low sensitivity (up to 40%). Clinically patients with LAR often present with typical symptoms of AR including ocular symptoms and good response to oral antihistamine and nasal corticosteroid.

RHINITIS AND ASTHMA LINK

The link between rhinitis and asthma has been highlighted in a World Health Organization report, *Allergic rhinitis and its impact on asthma* (ARIA).⁹ Approximately 30% of patients with rhinitis develop asthma and up to 80% of patients with perennial asthma have rhinitis. However, the causal link between these conditions is not fully understood (Table 14.6).

It is important to recognize and treat asthma in patients presenting with allergic rhinitis. Airflow obstruction should be assessed in an ENT clinic including using peak expiratory flow, spirometry and reversibility testing. If these are unavailable, patients should be referred to a respiratory physician.

Basic mechanisms of treatment of allergic diseases

The majority of current drug treatments for allergic diseases are symptomatic therapies targeting the mediators (e.g. antihistamines and adrenaline) or general immunosuppressive drugs (e.g. corticosteroids). New approaches are now developing to modify the pathogenesis of allergy. The most promising is specific allergen immunotherapy such as pollen desensitization for seasonal allergic rhinitis.

Antihistamines act through histamine H1 receptors. They are effective in the partial suppression of immediate allergic responses in the skin and respiratory tract in AR. However, they have little or no effect in late response in allergic asthma and bronchial asthma.

Corticosteroids bind to intracellular receptors, leading to an anti-inflammatory effect due to alteration in transcription factors. Allergen-induced Th2 proliferation and cytokines secretion are exquisitely sensitive to corticosteroids in low 10^{-10} to 10^{-8} molar concentration. They also act on membrane receptors that lead to non-genetic mechanism, resulting in more rapid action. Corticosteroid has no effect on immediate response but is highly effective in inhibiting allergen-induced late response and bronchial asthma. The topical steroid effects of corticosteroid have been extensively studied in AR. These can be summarized as follows:

- Reduction of inflammatory mediators such as cytokines, prostaglandins, nitric oxide
- Inhibition of inflammatory cells migration by inhibiting the expression of adhesion molecules
- Promotion of apoptosis of leucocytes due to upregulation of endonucleases.

TABLE 14.6 Features of allergic rhinitis and asthma

Features	Similarities	Differences
Anatomical features	Pseudostratified epithelium	<ul style="list-style-type: none"> • Prominent erectile venous sinusoids and submucosal glands in the nose • Disruption of epithelium with thickening of the sub-basement membrane zone in asthma but intact epithelium with normal basement membrane zone in rhinitis • Airway smooth muscles are present in bronchi and increase in asthma
Pathogenesis	Th2 driven inflammation	Airway remodelling in chronic asthma
Treatment response	Corticosteroid, antileukotriene, anticholinergic	Selective effectiveness of antihistamine in rhinitis and β_2 agonists in asthma

Allergen-specific immunotherapy is the only curative approach for allergic rhinitis, allergic asthma and venom allergy. This involves a step-wise administration of increasing doses of an allergen, in order to suppress symptoms on subsequent re-exposure to that allergen. Allergen-specific immunotherapy has been reported to be highly effective in allergic rhinitis in a Cochrane systematic review.¹⁰

Subcutaneous immunotherapy (SCIT) has an earlier onset of the therapeutic effect than sublingual immunotherapy (SLIT) in seasonal allergic rhinitis. Both have been shown to give long-lasting benefit after stopping treatment. Alternative methods of administration of allergen have been used in smaller cohort to improve the uptake and reduce the side effects. These include nasal immunotherapy, epicutaneous immunotherapy, intra-lymphatic immunotherapy and oral immunotherapy.

The precise mechanism of allergen-specific immunotherapy is being elucidated. Current understanding is based on evaluating benefits and immunological changes following the immunotherapy.¹¹⁻¹³ These can be summarized as follows:

- Inhibition of mediators release due to rapid desensitization of mast cells and basophils by allergens. The exact molecular pathway is not well understood. However, the susceptibility of these cells to degranulation decreases but the subsequent threshold for activation increases. Upregulation of histamine receptor expression on basophils were observed in venom immunotherapy. Rapid upregulation of histamine receptor strongly suppresses Fc ϵ RI induced activation of basophils
- Upregulation of blocking specific IgG4 antibodies that reduce the antigen presentation by the relevant cell types as a result of binding to epitopes on the surface of the allergen
- Inhibition of IgE-facilitated antigen presentation due to immunotherapy-induced specific IgG antibodies and subsequent reduction in the activation and proliferation of allergen-specific T-cells that are responsible for the production of cytokines (IL-4, IL-13) and further IgE synthesis
- Skewing effector cells towards regulatory phenotypes due to induction of T-reg and B-reg cells. Numbers of tissue mast cells and eosinophils, and subsequent mediators release decrease.

The clinical effects of immunotherapy have been shown in many studies. It induces an early and further reduction

in symptoms/need for medication and reduction in hyper-responsiveness that persist after the end of the treatment period. It has been proposed as a prevention of new sensitivities and progression of disease (e.g. rhinitis into asthma). Therefore immunotherapy has been considered as a potentially curative treatment in allergic rhinitis due to its immunomodulatory effect.

A subcutaneous anti-IgE antibody (omalizumab) has been shown to be effective in a proportion of patients with severe perennial allergic asthma and in seasonal allergic rhinitis. Other therapies such as anti-CD23 monoclonal antibody (IDEC-152) and CCR3 targeted therapy have not been proved with clinical significance so far.

New knowledge arises for more targeted strategies in AR that inhibits Th2 cytokines IL4 and IL5 to prevent the activation of B cells from producing IgE. IL4 induces B cell class switching, upregulates IgE receptors on mast cells, increases VCAM-1 expression on vascular endothelium, induces mucus secretion and promotes Th2 polarization. In a small study, using an inhaled soluble IL-4 receptor during the withdrawal of inhaled corticosteroids has been shown to be effective in preventing relapse in moderately severe atopic asthma.

IL5 is a major factor responsible for terminal differentiation of eosinophils. Inhaled IL5 induces airway hyper-responsiveness and sputum eosinophilia. Anti-IL5 blocking monoclonal antibody was effective in reducing allergen-induced eosinophilia and deposition of extracellular matrix proteins in the bronchial subepithelial basement membrane zone in patients with mild asthma.

TESTS IN ALLERGY DIAGNOSIS

Allergy diagnosis includes an assessment of clinical presentations followed by *in vivo* and/or *in vitro* tests to identify the culprit allergen responsible for the immunologic mechanism of immediate hypersensitivity. Demonstration of sensitization to a suspected allergen (i.e. the presence of allergen-specific IgE) is required for the diagnosis. But not all sensitized individuals are clinically allergic. Therefore confirmation of allergy diagnosis requires either a convincing relevant history or a reproducible allergic phenomenon by a 'controlled challenge test' (provocation test). Hence, 'challenge test' is accepted as the gold standard test in allergy diagnosis.

Skin testing

Skin testing is a bioassay. When specific allergens are introduced into the skin, cross-linking of the FcεRI occurs if allergen-specific IgEs are present in sufficient quantities on the cutaneous mast cells. Transient wheal and flare responses develop as a result of mast cell activation and mediators release. These represent the immediate phase of the allergic reaction. However, the size of the wheal does not directly correlate with the amount of histamine released. In some individuals deep tissue swellings with warmth, pruritus and erythema at skin test sites may develop 1 to 2 hours after testing and resolve in 24 to 48 hours (late phase responses). But they are not used in allergy diagnosis.

Skin testing is widely used in the diagnosis of a variety of IgE-mediated allergies (Table 14.7). The performance of skin testing in allergy diagnosis is influenced by many factors (Table 14.8). Skin testing and interpretation require specific training and knowledge. The diagnostic utility of

skin testing depends on the pre-test probability. It should be performed by an allergy expert, because there is a small but definite risk of a systemic allergic reaction.

The two major methods of skin testing currently in use are the skin prick test (SPT) and the intra-dermal test (IDT). SPT is the most appropriate initial test with overall positive predictive value (PPV) of less than 50% for all allergens but negative predictive value (NPV) is very high ($\geq 95\%$) (Table 14.9). IDT has much higher sensitivity (100–1000 folds) but lower specificity with a greater risk of a systemic reaction. IDT should only be performed after a negative SPT.

Skin prick test

After cleaning with a 70% alcohol solution, 1:10 or 1:20 weight/volume allergen extract solutions are placed at least 2 cm apart on the volar surface of the forearm or upper back. A separate commercially available test device (lancet) is used to prick through each droplet of allergen.

TABLE 14.7 Indications, cautions and contraindications of skin testing

Indications	Notes
1. Aeroallergy (e.g. rhinitis, allergic asthma)	Well validated
2. Food allergy (e.g. nut, milk, egg)	Well validated
3. Drug allergy (e.g. penicillin)	Often used in the evaluation of many other drugs including antibiotics, chemotherapeutic agents and anaesthetic drugs but the significance of results are less well defined
4. Venom allergy (e.g. wasp, bee)	The diagnostic test of choice; well-validated
5. Latex allergy	The diagnostic test of choice when using standardized test preparations
Cautions and contraindications	Notes
1. High risk patients	Poorly controlled asthma, clinical histories of severe reactions to minute amounts of allergen, significant cardiovascular diseases such as coronary heart disease, cardiac arrhythmias
2. Recent anaphylaxis	The skin can render temporarily non-reactive after anaphylaxis for 2 to 4 weeks
3. Interfering medications	Recent antihistamine use
4. Unsuitable skin conditions	Dermatographism, urticaria, dermatitis, cutaneous mastocytosis

TABLE 14.8 Factors affecting results of skin testing

Factors	Notes
Medications	Many drugs can interfere with skin testing and should be stopped prior to skin testing: <ul style="list-style-type: none"> • Antihistamine – stop 3 days for non-selective short acting, 7 days for long acting (e.g. Cetirizine) • H2 receptor antagonists – stop 48 hours • chronic and relatively high dose systemic corticosteroids (>20 mg/day) may partially suppress skin testing • omalizumab may depress skin reactivity for up to 6 months or longer • tricyclic antidepressants, phenothiazines may decrease skin reactivity for up to 2 weeks • other drugs may affect skin testing – some muscle relaxants and antiemetic drugs with antihistamine action.
Physiologic factors	Extreme age may reduce skin reactivity. Forearms produce smaller wheals than the skin of the back.
Technical factors	The quality of allergenic extracts, testing devices, and techniques: <ul style="list-style-type: none"> • the major inhalant allergens are well characterized and standardized, except for moulds • although extracts of milk, eggs, peanuts, soy, fish, shellfish, and tree nuts are reliable, most commercially available food extracts are not standardized (e.g. commercial extracts of fruits and vegetables).
Allergen preparation	Allergen extracts used in current clinical practice are obtained mainly from natural sources. There is immense variability in the commercial preparation of these products – season, growth conditions, genetic differences between geographic regions, etc.

TABLE 14.9 Reported diagnostic values of SPT^a

Preparation	Wheal mm	PPV %
HDM	≥3	95
Peanut	≥8	95
Egg	≥4	95
Grass	≥3	80
Hazel	≥4	80
Dog	≥10	80
Cat	≥7	80
Birch	≥3	80
<i>Cladosporium</i>	≥7	80
<i>Alternaria</i>	≥8	80

PPV = positive predictive value.

Prick by prick testing is a skin prick test (SPT) when a fresh food is used as a source of the allergen. The test device is used to prick the food initially and then the patient's skin. A positive prick prick test (PPT) should be confirmed on a non-allergic individual, to exclude an irritant effect.

Histamine dichloride (10 mg/mL) and a negative control of diluent identical to that of the allergen extracts (usually glycerinated saline) should always be included in the test.^{id}

A wheal ≥3 mm with flare after 15 to 20 minutes is considered positive – the presence of sensitization. For research purposes, a more precise measurement is usually used – the mean of the longest wheal diameter (D) and the diameter perpendicular to D (d) expressed as (D + d)/2.

Potential systemic reactions are reported to be about 33:100,000 (SPT) and 0.5% of PPT using fresh food in infants. One fatality due to SPT has been reported in a large survey (American Academy of Allergy Asthma & Immunology).¹⁵ Appropriate training and full emergency equipment and medications are essential when skin testing is used.

End-point dilution technique (a variant of IDT) to identify the concentration of an extract that produces a reaction of a defined size is not routinely used in the clinical practice. Potential systematic reactions (0.5%) and fatalities (6) have been reported with IDT without prior SPT.

Serum-specific IgE measurement

Allergen-specific IgE (sIgE) measurement is an *in vitro* test to demonstrate sensitization.¹⁶ Serum sIgE can be measured by sensitive immunoassays such as radioimmunoassay, enzyme immunoassay or fluorescent immunoassay. In these assays a serum is incubated with an allergen of interest bound solid phase. IgEs with the specificity to the allergen of interest will remain on the solid phase, which is then detected by a labelled anti-IgE antibody (Figure 14.3). The level of signal is proportionate to the concentration of sIgE. sIgE can be falsely elevated if total IgE > 1000 kU/L due to non-specific binding. Solid phase varies in different assay systems – the ImmunoCAP by Phadia (cellulose

Figure 14.3 Enzyme immunoassay diagram of serum sIgE measurement.

sponge matrix in the form of a small cap), the Immulite System (avidin solid phase) and the HYTEC-288 system (cellulose wafer). Similarly reagents used in the different systems vary. Therefore sIgE results from different systems are not interchangeable. The ImmunoCAP system is currently most widely used for sIgE measurement in the UK.

sIgE measurement is indicated in the following situations: high risk for anaphylaxis; use of medications that can cause interference in SPT; skin lesions unsuitable for SPT; small children; and so on. The level of sIgE is not directly correlated with the severity of allergy.

Until recently allergen sources have usually been based on the conventional extract. Allergen extract is a mixture of proteins (components) from the allergen source. More recently component resolved diagnostics (CRD) are used in detecting sIgE to allergen components. CRD has improved our knowledge in risk assessment and treatment such as allergen-specific immunotherapy.

Multiple component-specific IgEs can be detected using microarray techniques (e.g. ImmunoCAP ISAC). This can be useful by providing a sensitization profile for risk assessment. Allergen components can be categorized into species-specific and cross-reactive component. Cross-reactive components labile proteins (e.g. profilin) can be associated with multiple sensitivities and symptoms but are less likely to cause systemic symptoms. In contrast, cross-reactive stable proteins such as non-specific lipid transfer protein (nLTP) are often associated with more systemic symptoms. This knowledge is increasingly being applied in the management of multiple fruit/food allergy (Table 14.10).

Basophil activation test (BAT)

The Basophil Activation Test (BAT) (Figure 14.4) is an *in vitro* study of peripheral basophils responses to stimuli.^{18–20} BAT can use whole blood and therefore is more accessible than mast cells to study IgE mediated

TABLE 14.10 Allergen components and clinical relevance[†]

Component	Allergen source	Protein nature	Clinical relevance
Ara h 2	Peanut	Species-specific	Severe peanut allergy
Ves v 1	Wasp	Species-specific	Wasp allergy
Api m 1	Bee	Species-specific	Honey bee allergy
Gal d 1	Egg	Species-specific	Persistent egg allergy
Tri a 19 (O5g)	Wheat	Species-specific	Food dependent exercise induced anaphylaxis
Phl p 1	Timothy grass pollen	Cross-reactive (profilin)	Seasonal allergic rhinitis
Ara h 8	Peanut	Cross-reactive (PR-10)	Oral allergy syndrome
Pru p 3	Peach	nsLTP	Peach allergy/oral allergy syndrome

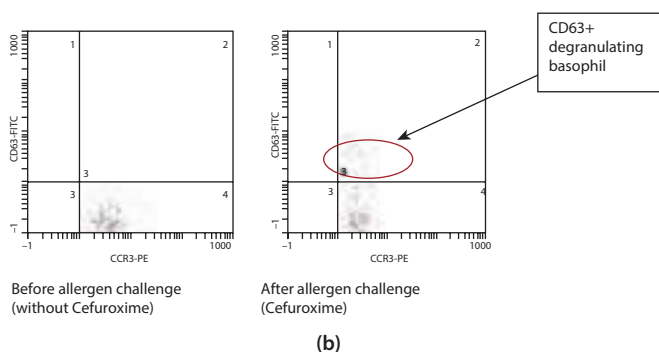

Figure 14.4 (a) Assay principle diagram of basophil activation test. (b) BAT histogram from flow cytometry using activating markers CD63. This patient has a history of anaphylaxis following intravenous cefuroxime. SPT, strongly positive to cefuroxime.

responses in allergic reaction. These can be assessed mainly by two methods: measurement of mediator release (e.g. histamine); or detecting the increase in cell surface molecules or newly expressed cell surface molecules (e.g. CD63, CD69, CD203c).

The whole blood of the patient is incubated with the allergen of interest. Basophils are stimulated due to the cross-linking of the specific IgE-FcεRI on basophil. Degranulation of basophils leads to the expression of molecules (e.g. CD63) on the basophil cell surface. In an unstimulated phase these molecules are anchored on the membrane of intracellular basophil granules, which contain histamine. CD63 expression closely correlates with histamine release in the degranulation. These can be detected by the flow cytometry method.

The assay performance from many studies and reports indicates BAT is comparable to serum sIgE in allergy diagnoses. For house dust mite sensitivity, BAT has claimed to have sensitivity of 85% (allergic rhinitis) and 50% (local allergic rhinitis), specificity of 93%, positive predictive value of 0.92 (allergic rhinitis) and 0.89 (local allergic rhinitis), and negative predictive value of 0.87 (allergic rhinitis) and 0.62 (local allergic rhinitis). BAT has been used to assess allergic response for allergens that are not commercially available for sIgE measurement. These include aeroallergens, drugs, venom and food allergens.

There are limitations in BAT. It is not well standardized (e.g. allergen concentration). It requires a fresh sample and highly skilled technicians. Interpretation of the test demands a highly trained immunologist/allergist given there is a concern about false positive related CD63 expressing platelet. Therefore BAT is currently available in limited numbers of diagnostic laboratories.

Non-validated tests

The following tests have not been validated to be used in allergy diagnosis:

- vega test
- kinesiology
- hair analysis
- provocation-neutralization
- iridology
- leucocytotoxic testing
- auriculo-cardiac reflex.

BEST CLINICAL PRACTICE

- ✓ Diagnosis of allergic disease is principally on a careful clinical history. An approach to allergy diagnosis is outlined in **Figure 14.5**.
- ✓ Allergic rhinitis can cause significant morbidities, and the impact of the disease upon the patient's work and leisure activities should be considered. Respiratory symptoms may indicate the presence of associated asthma.
- ✓ The examination of allergic rhinitis should include nasoendoscopy to exclude other conditions or exacerbating factors (nasal polyps, septal deflection or chronic rhinosinusitis).
- ✓ The presence of sensitization can be demonstrated by *in vivo* or *in vitro* tests, which must be interpreted with the clinical history.
- ✓ The routine panel of skin prick testing to demonstrate atopy includes house dust mite, animal danders (cat fur, dog hair, horse hair), moulds (*Aspergillus*, *Alternaria*, *Cladosporium*) and pollens (birch, timothy grass, weeds), positive control (histamine 10 mg/L) and negative control (allergen diluent).
- ✓ Serum sIgE measurement is preferred when SPT is likely to be equivocal in certain conditions such as severe eczema or use of medications that may interfere with the SPT (**Table 14.6**). Serum sIgE has a wider spectrum of allergens than SPT.
- ✓ Pharmacotherapy is the mainstay of treatment for allergic rhinitis. Most medications are designed to target mediators.
- ✓ Antihistamines are H1 receptor antagonists that are effective in early symptoms of allergic rhinitis.
- ✓ Intra-nasal corticosteroids are considered first-line treatment for more severe allergic rhinitis and are highly effective provided they are administered correctly. Training and health education of patients regarding the timing, technique and adequate dosing are essential in order to achieve the maximal benefit.
- ✓ A short course of prednisolone (e.g. 20mg daily for 5 days) may be prescribed and is highly effective at relieving all nasal symptoms including nasal obstruction in the majority of patients.
- ✓ Sodium cromoglycate is a mast cell membrane stabilizer. It reduces nasal discharge and congestion but is less effective than topical corticosteroids. The eye drop preparations are useful for allergic ocular symptoms.
- ✓ Intra-nasal cholinergic relieves rhinorrhoea but is less effective for other symptoms of allergic rhinitis.
- ✓ Leucotriene receptor antagonists (e.g. montelukast) have beneficial effects in asthma but are less effective in rhinitis.

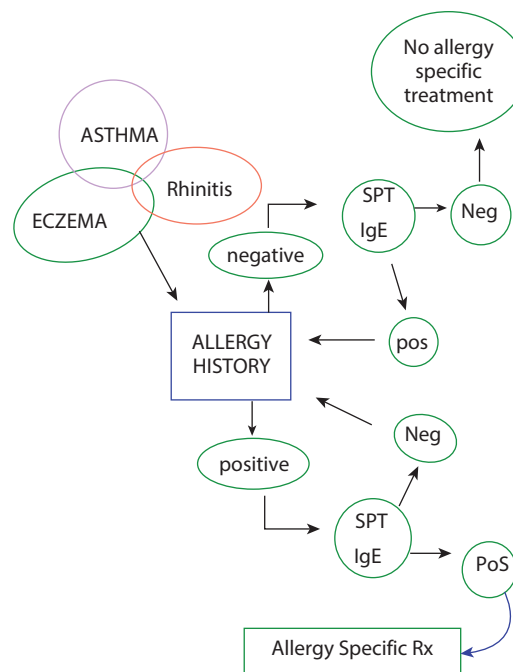

Figure 14.5 An approach to allergy diagnosis.

- ✓ Allergen avoidance is possible and essential for some allergens (e.g. peanut, cat fur, latex) but less effective in allergic rhinitis due to ubiquitous allergen (e.g. grass, house dust mite).
- ✓ House dust mite avoidance is often recommended. However, trials to date have been small and of suboptimal methodology.
- ✓ Allergen-specific immunotherapy is an effective intervention that can modify the disease process and long-lasting benefit has been reported. There are potential side effects including anaphylaxis, especially in patients with concomitant asthma. Efficacy can be limited in patients with multisensitivities. Therefore allergen-specific immunotherapy should be delivered in specialist centres and comply with the clinical guidelines (e.g. British Society for Allergy and Clinical Immunology).

FUTURE RESEARCH

- Improve understanding of mechanism of different methods of specific immunotherapy
- Multicentre studies for better application of component resolved diagnostics (CRD) in risk assessment
- External quality assurance of tests – CRD, BAT
- Multicentre studies for translation of new biomarkers, use of specific immunotherapy other than SCIT and SLIT
- Prevention of allergic diseases development

KEY POINTS

- Genetic and environmental factors interact as causes of allergic disease.
- Type 1 IgE mediated immediate hypersensitivity occurs only in a sensitized individual.
- Allergic inflammation is characterized by IgE dependent activation of mast cells and tissue eosinophils infiltration. These events are under the regulation of Th2 cells.
- Biomarkers are useful in allergy diagnosis. Normal levels of tryptase do not exclude anaphylaxis.
- The majority of IgE is tightly bound to FcεRI. There is no signalling until these receptors are cross-linked by their specific antigens.
- Skin testing and sIgE indicate sensitization only and must be interpreted in the context of the clinical history.

- Allergic rhinitis and asthma are commonly associated.
- Corticosteroids are general immunosuppressive agents.
- Allergen-specific immunotherapy is the only curative approach for allergic rhinitis, allergic asthma and venom allergy.
- Of the new novel therapeutic targets in clinical trials only anti-IgE therapy has been successful.

SEARCH STRATEGY

Data in this chapter are taken from standard UK immunology laboratory practice. They reflect expert opinion (level 4 evidence) with regards to immunology tests currently performed in the UK.

INTRODUCTION TO EVALUATION OF THE IMMUNE SYSTEM

Evaluation of the immune system broadly encompasses the investigation of immunodeficiency, autoimmune disease including vasculitis, allergy and lymphoproliferative disease. Diagnosis results from studying the combination of clinical presentation and investigations including immunological, haematological, microbiological and histopathological, with increasing recognition of the place of genetic and molecular biological approaches. However, immunology tests in isolation are rarely diagnostic. Some understanding of the sensitivity (proportion of true positives correctly identified), specificity (proportion of true negatives correctly identified), positive predictive value (likelihood an individual has a disease given a positive result) and negative predictive value (likelihood an individual does not have the disease given a negative result) for each test is required.

Interpretation of results is dependent upon the age of the patient. This is particularly important for the investigation of childhood immunodeficiency when, for example, a lymphocyte count that would be normal for an adult could be well below the age-related normal range and may signify an underlying immunodeficiency in an infant. Similarly, a weak positive anti-nuclear antibody (ANA) titre may be a common incidental finding in a middle-aged female whereas may signify an autoimmune process in a child.

The choice of investigations will ultimately depend on the clinical presentation and may be guided through discussion with a clinical immunologist. Whilst rare immunological diseases will only be recognized by the appropriate investigation, consideration must also be given to commoner diseases with a similar presentation, for example, cystic fibrosis.

IMMUNOLOGICAL TESTS

Immunodeficiency

Immunodeficiency should be considered in any patient with persistent or recurrent infections not responding to antibiotics, or patients with unusual or opportunistic infections.¹ Immunodeficiency may be either primary or secondary to therapies such as immunosuppressive drugs or chemotherapy or secondary to diseases such as haematological malignancies, diabetes or HIV infection; in many patients the secondary cause will be clearly apparent but in others, infection will be the presenting feature. Primary immune deficiency can arise from defects in any part of the immune system so may manifest in a myriad of ways across a wide age range but with the common hallmark of increased susceptibility to infection. Sinopulmonary infections are a common feature of primary antibody deficiency and ENT clinical staff should look out for these individuals and initiate the appropriate investigations. It is estimated that half of the patients with primary antibody deficiency in the UK remain undiagnosed.² Remember that early diagnosis of primary immunodeficiency does lead to an improved outcome, emphasizing the need to consider this diagnosis.

When considering immunodeficiency, the type of pathogen may provide a clue to the underlying disease and appropriate tests required (Tables 15.1 and 15.2). Certain tests, especially those involving functional assays, require rapid transport of samples and prior laboratory preparation. Accordingly early discussion with the local laboratory is recommended.

TABLE 15.1 Outline of associations between pathogens and specific immunodeficiencies

Pathology	Immunodeficiency
Bacterial infections	Antibody deficiency
	T cell deficiency
	Complement
	Neutrophil disorders
Viral infections	T cells
	Antibody deficiency
Fungal infections	Neutrophil disorders
	T cells
Neisserial infections	Complement
Abscess formation	Neutrophil disorders
Mycobacterial infection	T cells
	Macrophage/cytokines

C-REACTIVE PROTEIN

C-reactive protein (CRP) levels reflect the acute phase response and are particularly elevated in bacterial infections and active vasculitis. An elevated CRP may indicate intercurrent infection in immunodeficiency and individuals on high dose steroids. Rarely the lack of an appropriate acute phase response in the face of invasive bacterial infection can be a feature of certain rare immune deficiencies such as Hyper IgE Syndrome.

IMMUNOGLOBULINS

Serum immunoglobulins (IgG, IgA and IgM) are a useful first line test for investigation of immunodeficiency although normal or even high levels do not exclude all forms of immune deficiency. Very low levels of all immunoglobulins are typical in boys with X-linked agammaglobulinaemia (XLA). IgG and IgA levels are typically low in children and adults with common variable immunodeficiency, although, as the name suggests, the pattern can vary and in some patients immunoglobulin levels may only be slightly below the normal range. Other types of immune deficiency such as HIV infection and defects of neutrophil function such as chronic granulomatous disease are characterized by raised immunoglobulin levels. Other indications for immunoglobulin testing include infective and inflammatory diseases in which polyclonal increases in immunoglobulins are often seen and the evaluation of lymphoproliferative disease when serum and urine electrophoresis should also be requested to identify any paraproteinaemia.

SPECIFIC ANTIBODIES (ALSO TERMED FUNCTIONAL ANTIBODIES)

Assessment of dynamic antibody responses to immunization plays an important part in the assessment of antibody deficiency especially in patients with borderline or normal immunoglobulin levels. Specific antibody levels are measured before and 4–6 weeks after immunization with

TABLE 15.2 Outline of immunological tests for primary immunodeficiency

Deficiency	Tests
T lymphocytes	HIV serology
	Lymphocyte subsets - numbers of CD4 and CD8 T cells, B and NK cells
	Lymphocyte proliferation studies
Antibody deficiency	Immunoglobulins (IgG, IgA and IgM) and serum electrophoresis
	Specific antibodies and responses to immunization
	Lymphocyte subsets
Phagocyte disorders	Differential white cell count (neutrophil numbers)
	Neutrophil respiratory burst analysis
	Neutrophil adhesion markers
Complement disorders	Functional complement assays
	Assay individual complement components

tetanus toxoid, pneumococcal, Haemophilus influenza b or other non-live vaccines depending upon local immunization schedules and availability of specific antibody tests. Failure to mount an adequate response is a pointer to an underlying immunodeficiency. Of course, live vaccines must not be given to any patient with a suspected immunodeficiency.

IMMUNOGLOBULIN G SUBCLASSES

IgG subclasses are sometimes useful in the investigation of possible antibody deficiency where IgG subclass deficiency may be associated with selective IgA deficiency and/or failure to respond to pneumococcal immunization. However, isolated low IgG2 levels may be found in asymptomatic individuals especially in childhood. Increasingly the main indication for the measurement of IgG subclasses is now suspected autoimmune pancreatitis and other IgG4-related diseases. This group of inflammatory disorders, which may affect a wide range of organs including sinuses, salivary glands and thyroid, is characterized by an infiltrate of IgG4 positive plasma cells, fibrosis and raised IgG4 levels.

LYMPHOCYTE PHENOTYPING (ALSO TERMED LYMPHOCYTE SUBSETS)

A reduced lymphocyte count in the full blood count may provide an early clue to the presence of immune deficiency; indeed in infants a persistent unexplained lymphocyte count of $<2.8 \times 10^9/l$ should prompt consideration of severe combined immune deficiency. Lymphocyte phenotyping by flow cytometry allows accurate measurements of the different lymphocyte subsets by detection of cell surface markers. The two main T cell subsets are evaluated by assessing CD3⁺CD4⁺ and CD3⁺CD8⁺ numbers whilst CD19⁺ cells identify B cells and CD3⁺CD16/56⁺ cells represent NK cells. Very low T cells are characteristic of severe combined immunodeficiency whereas absence of B cells is a feature of X-linked agammaglobulinaemia. However, these findings are not diagnostic and may be affected by drugs or intercurrent infection.

Low CD3⁺CD4⁺ cell numbers are characteristic of human immunodeficiency virus (HIV) infection. However, a normal CD4 count does not exclude HIV nor should it be used as a covert screening test. A wide range of additional cell surface markers and lymphocyte subsets can be measured and so close dialogue with the laboratory is advised in order to select the most appropriate panels for individual patients and also to interpret the results. Lymphocyte phenotyping is also valuable in the diagnosis of lymphoproliferative disease.

LYMPHOCYTE PROLIFERATION AND OTHER FUNCTIONAL ASSAYS

These specialized tests are reserved for the investigation of suspected cellular immunodeficiency usually following discussion with an immunologist. The proliferation of lymphocytes can be measured following *in vitro* stimulation by mitogens such as phytohaemagglutinin, or antigens such as tetanus, to which the patient has previously been exposed. Additional more specialized functional tests are possible, for example to assess production and function of cytokines in the gamma interferon and interleukin 12 pathways in patients with recurrent atypical mycobacterial infections.

COMPLEMENT PATHWAY LEVELS (C3-, C4-, C1-INHIBITOR)

Measurement of C3 and C4 levels is helpful in the assessment of patients with systemic inflammatory disorders. As complement components are acute phase proteins, levels of both C3 and C4 are typically raised in systemic vasculitides, sepsis and other inflammatory disorders. However, complement is consumed in systemic immune complex disorders so levels of both C3 and C4 are typically low in active systemic lupus erythematosus (SLE) and levels may vary with disease activity. Isolated low C3 levels with normal C4 levels are a feature of certain glomerulopathies including post-streptococcal nephritis. Complement levels also play a vital role in the investigation of angioedema. Patients with C1-inhibitor deficiency (hereditary angioedema) have low C4 levels (but normal C3 levels) due to uncontrolled turnover of the classical complement pathway; a normal C4 level during an attack of angioedema essentially excludes this diagnosis. C1-inhibitor levels are low in the majority of hereditary angioedema patients but a small proportion have type 2 C1-inhibitor deficiency whereby they have normal levels of a dysfunctional C1-inhibitor. Functional C1-inhibitor assays can be undertaken in those patients with angioedema without urticaria and a low C4 level. Appropriate care must be taken in handling and transport of the sample to avoid *in vitro* degradation of C1-inhibitor function.

HAEMOLYTIC COMPLEMENT ACTIVITY

Deficiencies in the classical complement pathway typically present with early onset atypical or severe lupus-like illness or invasive bacterial infection with encapsulated organisms such as pneumococcus. Deficiencies in the alternate and

terminal pathways predispose to meningococcal infection especially with unusual serotypes. The CH100 (or CH50) haemolytic complement test assesses activity of the classical and terminal complement pathways and the AP100 (or AP50) haemolytic complement test assesses activity of the alternate and terminal pathways. Thus the combination of these tests can identify the presence and likely location of any deficiency that can be followed up by measurement of the appropriate individual complement components. As haemolytic complement tests rely upon complement function, samples should be taken when patients are clinically stable and blood samples must be separated and frozen within a short time of venepuncture to avoid *in vitro* depletion of complement causing false positive results.

NEUTROPHIL FUNCTION

Patients with chronic granulomatous disease (CGD) have deficient neutrophil respiratory burst and their neutrophils are unable to kill ingested organisms, especially catalase positive organisms such as staphylococcus aureus, serratia and also fungi such as aspergillus. Therefore assessment of neutrophil respiratory burst is indicated in patients presenting with recurrent abscesses and lymphadenitis, deep seated abscesses or recurrent bacterial infections. The traditional nitro blue tetrazolium (NBT) test, which assessed the ability of patient neutrophils to oxidize pale yellow NBT into a dark blue precipitate, has now mainly been superseded by flow cytometric assays. Female carriers of the X-linked form of CGD may also be identified using the flow cytometric test. Neutrophils have a short life span so analysis needs to be carried out within a short period of time after venepuncture whilst cells are still viable, so prior discussion with local laboratory is recommended.

MOLECULAR AND GENETIC STUDIES

Mutations in more than 300 genes are now known to cause primary immune deficiency with the number of causative genes increasing each year. Genetic testing for primary immune deficiency by means of Sanger sequencing of the suspected faulty gene is now routinely available for many disorders and also allows carrier detection and prenatal diagnosis where appropriate. However, with this new genetic knowledge has come the recognition that many primary immune deficiencies have overlapping and wider clinical phenotypes than were initially described. The advent of next generation sequencing technologies is paving the way for new approaches to genetic investigation of suspected immune deficiency by enabling large panels of immunological genes to be examined simultaneously. As well as providing a means to identify lesions in multiple genes known to cause immune deficiency, this approach can also enable the discovery of new genetic conditions.

Allergy

A brief discussion of allergy tests follows, although this subject is discussed further in [Chapter 14](#), Allergy: basic mechanisms and tests. When diagnosing allergy,

a clear and detailed history is paramount. Evidence of sensitization to specific allergens can be detected *in vivo* by skin prick tests or *in vitro* on serum by measuring allergen-specific IgE levels.

SKIN PRICK TESTS

Drops of aqueous solutions of relevant allergens, negative (allergen buffer) and positive controls (histamine) are applied to the skin. A pinprick is made through the drop placed on the epidermis and excess solution removed with tissue. The size of any localized skin reaction is measured at 15 minutes, and results >2–3 mm diameter larger than the negative control are considered positive. Antihistamines should be stopped before testing, to prevent false negative results. Positive results indicate sensitization but do not necessarily indicate clinical allergy, emphasizing the need to correlate with the patient's history.

IgE

Total IgE levels may be raised in allergic diseases, particularly eczema, and also with certain parasitic infections, immunodeficiencies and lymphomas. Therefore a raised total IgE level does not necessarily imply allergic disease and a normal level does not exclude allergic disease. Very high total IgE levels such as those found in severe eczema can result in many weak false positive allergen-specific IgE levels.

ALLERGEN-SPECIFIC IgE

These are now measured by enzyme-linked immunoassay rather than radioallergosorbent assay test (RAST) although the latter term remains in common usage. A wide range of aeroallergens, food and other allergens is available. Choice of appropriate allergens should be based on the clinical history, for example in patients with seasonal allergic rhinitis the most useful allergens will be the pollens in season at the time of the patient's symptoms; in patients with perennial rhinitis allergens such as house dust mite or household pets are more likely to be informative. The presence of specific IgE indicates sensitization but does not necessarily indicate clinical allergy, emphasizing the importance of correlation with the patient's history. Results also depend upon the sensitivity and specificity of the tests which does vary between individual allergens. *In vitro* tests are especially useful if patients are unable to undergo skin testing (e.g. because they are unable to stop antihistamine therapy, have widespread skin disease or are dermatographic).

ANAESTHETIC REACTION TESTING

Anaphylaxis occurring during surgery may be difficult to differentiate from other simultaneous haemodynamic events. Tryptase is released from mast cells during anaphylaxis and can be measured by laboratories and may be helpful in this setting. Serum tryptase levels typically peak 1–2 hours after onset of an anaphylactic event with levels falling towards normal within 24 hours. Accordingly a series of timed and clearly labelled samples for tryptase is required. However a rise in tryptase is only seen

in approximately 60% of anaphylactic events so normal results do not completely exclude anaphylaxis. Allergen-specific IgE can be measured to a limited range of anaesthetic drugs, antibiotics, chlorhexidine and latex but there is an increased risk of false negative results within the first 6 weeks after the acute event. Further specialist assessment and skin testing is often required to identify the most likely culprit allergen.

Autoimmune disease including vasculitis

The detection of serum autoantibodies is a helpful aid in the investigation of autoimmune diseases and vasculitis and should be considered in the light of the clinical history and the outcome of appropriate tissue biopsies.⁴ Some autoantibodies such as anti-glomerular basement membrane (GBM) and acetyl choline receptor antibodies play a direct role in disease pathogenesis; these antibodies generally have very high sensitivity and specificity for the disease in question. In contrast, other autoantibodies such as anti-nuclear antibodies (ANA) are thought to be secondary to tissue damage or represent epiphenomena but are nevertheless useful disease markers; these antibodies are often less specific. Autoantibodies may be useful for diagnosis, assessment of prognosis and disease monitoring, and in some cases may be detected prior to the development of disease.

ANCA AND VASCULITIS

The investigation of suspected vasculitis requires integration of clinical, laboratory and biopsy information. Antineutrophil cytoplasmic antibodies (ANCA) play a critical role in identifying ANCA-associated vasculitis (AAV). ANCA is detected by indirect immunofluorescence on human neutrophils. Two main patterns of fluorescence may be seen; cytoplasmic staining denotes a C-ANCA and is usually due to reactivity against proteinase 3 (PR3) and are associated with polyangiitis with granulomatosis (formally called Wegener's granulomatosis). Perinuclear staining denotes a P-ANCA which is usually due to myeloperoxidase (MPO) antibodies and associated with microscopic polyangiitis, rapidly progressive glomerulonephritis or Churg–Strauss syndrome. Other atypical staining patterns of ANCA may be seen but these are usually due to reactivity against other antigens and are rarely associated with systemic vasculitis. Care is needed in interpreting ANCA results. Negative results can be found in AAV, especially localized polyangiitis with granulomatosis, and false positive results can be found in a range of conditions including HIV infection, infective endocarditis and atrial myxoma, which may mimic vasculitis (Table 15.3). Other tests are also useful in the investigation of suspected vasculitis. Complement levels may be useful. For example, if both C3 and C4 are low, SLE, subacute bacterial endocarditis and hypocomplementaemic vasculitis should be considered; if C4 alone is low cryoglobulinaemia should be considered; and if C3 alone is low, then post-streptococcal nephritis should be considered in the differential diagnosis. Other autoantibodies may be useful, for example, anti-nuclear, anti-glomerular basement membrane and anti-phospholipid antibodies, depending upon the clinical picture and organ involvement.

TABLE 15.3 Guide to interpretation of ANCA

Result	Guide to interpretation
Positive C-ANCA with PR3 antibodies	Polyangiitis with granulomatosis
Positive P-ANCA with MPO antibodies	Microscopic polyangiitis
	Churg–Strauss syndrome
Positive C-ANCA without PR3 antibodies	Inflammatory bowel disease
	Infection, malignancy
Positive P-ANCA without MPO antibodies	Vasculitis, connective tissue disease

ANTI-NUCLEAR ANTIBODIES (ANA), DOUBLE-STRANDED DNA ANTIBODIES AND ANTIBODIES TO EXTRACTABLE NUCLEAR ANTIGENS (ENA)

Anti-nuclear antibodies (ANA) are found in systemic lupus erythematosus (SLE). ANA is a useful screening test, as a negative ANA makes SLE very unlikely. However, positive ANAs are also found in other connective tissue disorders and autoimmune hepatitis, as well as a wide range of other autoimmune, inflammatory and infective disorders. ANAs are also found in healthy individuals especially older females. Different patterns of ANA are seen and reflect reactivity against different nuclear antigens including centromere, dsDNA and ENA (Ro, La, Sm, ribonucleoprotein, Scl70 and others) and may help categorize the connective tissue disease present. Whilst antibodies against centromere, dsDNA and ENA are much more specific for individual connective tissue disorders, they are less sensitive. [Table 15.4](#) shows the main disease associations. Advances in technology mean that many multiplex assays are now readily available and often termed ‘connective tissue disease screens’. These typically comprise a mixture of the main ENA and dsDNA antigens enabling patient samples to be screened more rapidly with detection of only the more disease-specific autoantibodies. However, there may be a loss of sensitivity and some patients with clinically relevant positive ANA but negative ENA and dsDNA abs may be missed. Clinicians are encouraged to become familiar with the details of the tests offered by their local laboratory as the different methods may differ significantly in sensitivity, specificity and range of autoantibodies included in the screen.

RHEUMATOID FACTOR (RF) AND CYCLIC CITRULLINATED PEPTIDE (CCP) ANTIBODIES

RF and CCP antibodies may both be found in a proportion of patients with rheumatoid arthritis. CCP antibodies are more specific than rheumatoid factor, which is also found in many healthy individuals. Rheumatoid factor is also found in Sjogren’s syndrome and cryoglobulinaemia.

CARDIOLIPIN ANTIBODIES AND ANTIPHOSPHOLIPID SYNDROME

Anti-phospholipid syndrome presents with features including recurrent venous and arterial thrombosis, recurrent pregnancy loss, thrombocytopenia and neurological

TABLE 15.4 Interpretation of ANA, centromere, dsDNA and ENA antibodies

Autoantibodies	Interpretation
Anti-nuclear antibody (ANA)	SLE Other connective tissue diseases – Sjogren’s syndrome, scleroderma, undifferentiated connective tissue disease Autoimmune hepatitis Other autoimmune, inflammatory and infective disorders, malignancy Healthy individuals – incidence increases with age, females > males
dsDNA antibodies	SLE Autoimmune hepatitis
Ro (SSA)	SLE, Sjogren’s syndrome, neonatal heart block in the fetus of a Ro positive mother
La (SSB)	SLE, Sjogren’s syndrome
Sm	SLE
Ribonucleoprotein (RNP)	SLE, overlap syndromes eg mixed connective tissue disease
Scl70	Systemic sclerosis
CENP-B	CREST syndrome (calcinosis, Raynaud’s, oesophageal dysmotility, scleroderma, telangiectasia)

disease due to both small and large vessel occlusion plus the presence of phospholipid antibodies. These consist of a group of related autoantibodies – anti-cardiolipin antibodies, anti- β -2 glycoprotein 1 antibodies and lupus anticoagulant. Patients may have one or more of these autoantibodies. Repeat testing may be indicated to exclude transient autoantibody production (e.g. secondary to infection).

CRYOGLOBULINAEMIA

Cryoglobulins are immunoglobulins that form gels or precipitates on cooling. Clinical features include purpura, Raynaud’s syndrome, thrombosis, neuropathy and vasculitis. They are associated with infections, connective tissue disease and lymphoproliferative disease. Detection relies on the appropriate collection into a prewarmed blood tube in a waterbath/vacuum flask. Cold agglutinins are autoantibodies that reversibly agglutinate erythrocytes in the cold and should not be confused with cryoglobulins.

COELIAC DISEASE

Coeliac disease is characterized by malabsorption and weight loss but can present with oral ulceration, anaemia and malaise. The presence of villous atrophy on duodenal biopsy remains the gold standard for diagnosis but serological tests are an invaluable screen. Over 95% of patients with Coeliac disease have positive IgA tissue transglutaminase or IgA endomysial antibodies; these are essentially the same autoantibodies, the different terminology reflecting the different test methodology. Serology typically becomes negative on a gluten-free diet so it is important to ensure that the patient has been consuming gluten regularly (typically at

least twice a day for at least 6 weeks) prior to testing to avoid obtaining a false negative result. Paradoxically individuals with IgA deficiency (defined as $IgA < 0.06 g/l$) have an increased incidence of Coeliac disease but of course the usual IgA based serology is of no value. IgG tissue transglutaminase or IgG endomysial antibodies can be measured instead but sensitivity and specificity may be less than that of the IgA based serology.

BULLOUS PEMPHIGOID AND PEMPHIGUS

Bullous pemphigoid and pemphigus are blistering disorders associated with autoantibodies to desmoglein in the basement membrane zone or intercellular type VII collagen respectively. These may be detected in blood or in tissue biopsies using direct immunofluorescence.

LIVER AUTOANTIBODIES

Several autoantibodies are associated with autoimmune liver disease. Typical screens based on indirect immunofluorescence on rodent liver/kidney/stomach multi-block can detect mitochondrial, smooth muscle, liver kidney microsomal (LKM), liver cytosolic 1 (LC1) and anti-nuclear antibodies. M2 mitochondrial antibodies are associated with primary biliary cirrhosis, ANA and smooth muscle antibodies are associated with autoimmune hepatitis, LC1 and LKM antibodies may be associated with more aggressive forms of autoimmune hepatitis. However, overlapping serology and clinical pictures may be seen.

GASTRIC PARIETAL CELL AND INTRINSIC FACTOR ANTIBODIES

Gastric parietal cell antibodies are present in the majority of patients with pernicious anaemia and may pre-date onset of disease. They are also found in up to 15% of the healthy elderly. Intrinsic factor antibodies are much more specific but less sensitive for pernicious anaemia. In the past, recent B12 treatment could interfere with the intrinsic factor antibody assays but this is much less of a problem with modern methodologies.

ACETYL CHOLINE RECEPTOR ANTIBODIES, MYASTHENIA GRAVIS AND THYMOMA

Myasthenia gravis is characterized by increased skeletal muscle fatigability. Facial and bulbar muscle involvement may cause nasal speech, ptosis, diplopia and difficulty in swallowing. Generalized weakness occurs in approximately 85% of patients. Autoantibodies to the acetyl choline receptor (AChR) at the neuromuscular junction are detectable in 90% of patients. Myasthenia gravis is associated with thymoma and other autoimmune diseases.

Lymphoproliferative disease

Many of the immunological tests required to investigate lymphoproliferative disease have already been mentioned and are used in combination with bone marrow and lymph node biopsies.

IMMUNOGLOBULINS, SERUM AND URINE ELECTROPHORESIS AND SERUM-FREE LIGHT CHAINS

Multiple myeloma is a malignancy of plasma cells that produce monoclonal immunoglobulin (paraprotein). Paraproteins may be detectable in both serum and/or urine. Twenty percent of myelomas only produce monoclonal light chains, which may only be detectable in urine as Bence Jones protein or in serum using a serum-free light chain assay. Therefore a full myeloma screen requires both blood for immunoglobulins and electrophoresis plus either serum-free light chains or urine for electrophoresis. This combination of tests will detect all but the very rare non-secretory myelomas. These tests are also required for the investigation of possible AL amyloid. As paraprotein levels may be relatively low and difficult to detect in AL amyloid, close liaison with the laboratory is recommended as more sensitive detection methods such as immunofixation may be required. Although paraproteins are the hallmark of myeloma, Waldenström's macroglobulinaemia and AL amyloid, the majority of paraproteins detected in routine clinical practice are not associated with any identifiable lymphoproliferative disorder and are termed monoclonal gammopathy of uncertain significance (MGUS). Some MGUS may progress to lymphoproliferative disease with an overall rate of 1–2% per annum.

BEST CLINICAL PRACTICE

- ✓ Immunological tests always need to be interpreted in the context of the clinical case.

FUTURE RESEARCH

- The majority of current tests are performed on peripheral blood due to its accessibility. Tests that reflect activity at local surfaces, for example defensins, and tests that are more reflective of *in vivo* pathology, such as intracellular cytokine analysis, may enter clinical practice.
- Many patients have severe, persistent, unusual and recurrent infections yet no immunological cause is identified. Advancing knowledge, particularly regarding the innate immune system (e.g. toll receptors), may account for such disease and diagnostic tests will subsequently follow.
- Increasing use of molecular diagnosis and development of tests looking at functional pathways will occur. It is becoming increasingly apparent that individuals with the same genetic mutation may have diverse disease phenotypes, e.g. btk mutation associated with complete absence of B cells or IgG subclass defect. Identification of genetic polymorphisms may predict patients at risk of severe disease requiring a more aggressive management strategy.

KEY POINTS

- Immunodeficiency may present to ENT specialists with severe, persistent, unusual or recurrent infection. Early diagnosis may reduce morbidity and mortality.
- Immunological tests may help in diagnosis and monitoring of disease but must always be considered in association with clinical presentation and biopsy findings.
- Liaise with your clinical immunologist/immunology laboratory to ensure the appropriate tests are being requested. If clinical history is particularly suggestive of a disease, further tests may be required even in the presence of initial negative investigations.

SEARCH STRATEGY

This chapter provides an overview of the main concepts involved in the immunology of head and neck tumours, including disease progression, monitoring and immunotherapy. Data in this chapter may be updated by a PubMed search using the keywords: head and neck cancer, tumour microenvironment and Immunotherapy.

INTRODUCTION

Major technical and conceptual advances in immunology and cancer immunology in particular over the last two decades has led to a better, although by no means as yet complete, understanding of the complex relationship between the immune system, tumour initiation and progression, and immunotherapy. Specifically much attention has focused on changes in individual immune profiles of patients treated with conventional, biological or combination therapies; such work is underpinned by high-throughput proteomic and genomic platforms. This has led to a huge amount of interest in using immune biomarkers to both diagnose and monitor tumour response to therapy, as well as acting as a potential therapeutic option alone or in combination with chemo- or radiotherapy.

In this chapter, we endeavour to explore the fundamentals of the complex interactions within the tumour microenvironment and how malignancies effectively ‘escape’ immune detection. The roles of key immune cells and proteins will be discussed with a focus on tumour biomarkers and the application of anti-tumour immunity knowledge that underpins recent immunotherapeutic trials.

This chapter will discuss concepts of tumour immunobiology that will be of help to clinicians and their patients, focusing on head and neck squamous cell carcinomas (HNSCC), as tumours head and neck originating from squamous epithelia are the most prevalent tumour type within the head and neck region.

TUMOUR MICROENVIRONMENT (TME)

In general, cancers arise from the accumulation of genetic and epigenetic changes, together with abnormalities in the cancer-associated signalling pathways causing the acquisition of cancer-related phenotypes. These changes include limitless replicative potential of tumours, self-sufficiency in growth signals and insensitivity to anti-growth signals, ability to evade apoptosis, increased angiogenesis, invasion and metastasis.¹ However, tumours are complex tissues that not only contain malignant cells but surrounding stroma, which comprises various types of mesenchymal cells, extracellular matrix and immune cells. Collectively, these tissues are referred to as the tumour microenvironment (TME).²

As tumours progress, the surrounding microenvironment co-evolves into an activated state through continuous tumour–host interactions.¹ The TME contains many different cell types including normal fibroblasts, carcinoma-associated fibroblasts (CAFs), myofibroblasts, smooth muscle cells, endothelial cells and their precursors, pericytes, neutrophils, eosinophils, basophils, mast cells, T and B lymphocytes, natural killer cells, macrophages and dendritic cells.² Many components of the immune system contribute to the rejection of tumours; however, under the influence of the malignancy, they can actually act to promote tumour growth and invasion (**Figure 16.1**). Several studies have shown that tumour stroma contains growth factors and

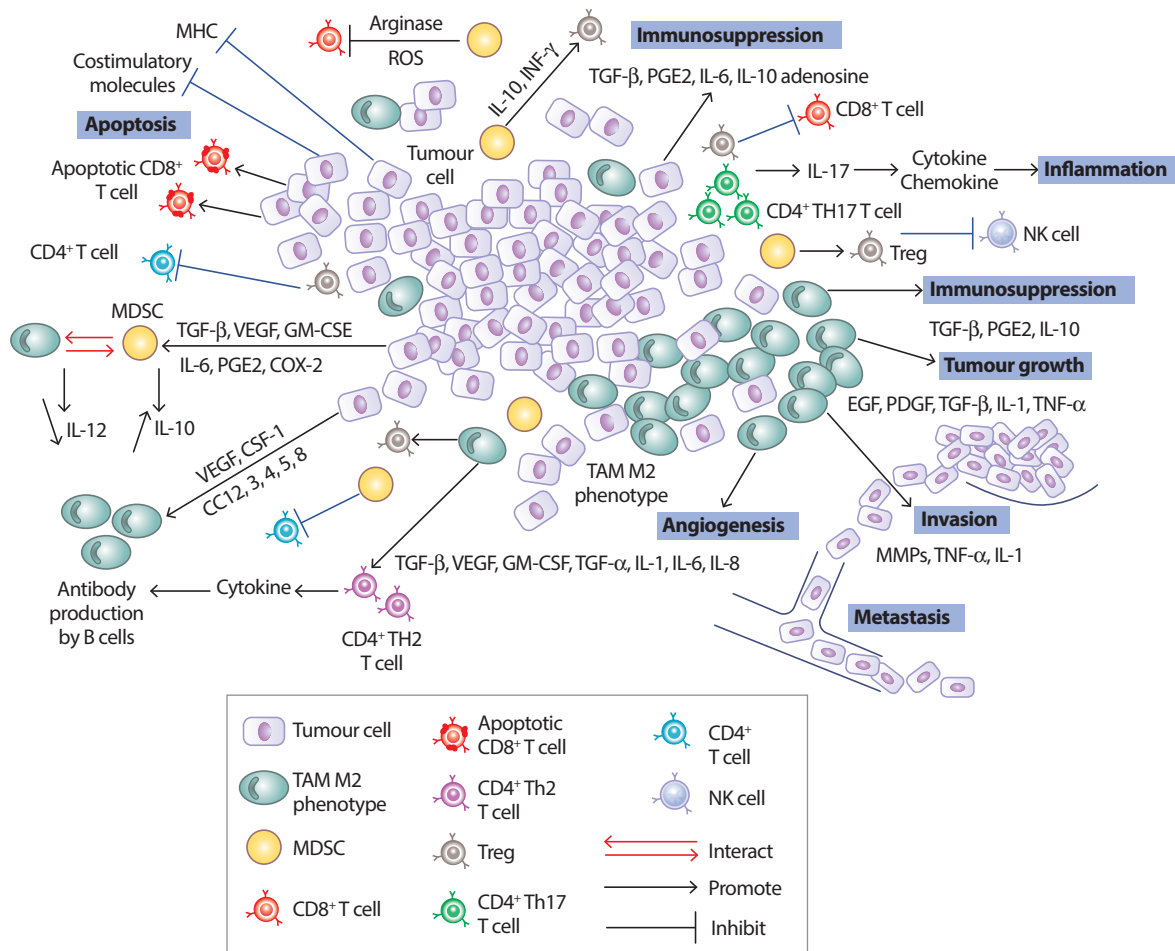

Figure 16.1 Immunosuppressive mechanisms in the tumour microenvironment.

cytokines that can promote angiogenesis, tissue invasion and metastasis. In addition, it has become evident that the stroma provides a chemoresistant capability to the tumour, most likely due to the presence and function of CAF and tumour associated macrophages (TAM) that promote resistance to oncological therapies.^{3–5}

The cellular component of TME

T lymphocytes are considered an essential component of anti-tumour immunity. *In vitro*, malignant cells presenting ‘altered self’ peptides (molecules that have undergone mutations or are aberrantly expressed in the tumour cell) in association with major histocompatibility complex (MHC) class I molecules, can be recognized by CD8⁺ T cells causing tumour cell-lysis and/or apoptosis through the release of toxic molecules such as perforin and granzymes. Conversely, CD4⁺ T cells are programmed to release cytokines and may differentiate into one of an ever growing type of T helper cells (i.e. Th1, Th2, Th17) or regulatory T cells (Treg cells), which differ in the cytokine repertoire they produce and therefore their function⁶ when interacting with antigen-presenting cells such as dendritic cells or macrophages expressing altered self peptides by host MHC II molecules. In general the CD4⁺ Th1 cells serve to

‘help’ and enhance the magnitude and duration of the anti-tumour response.⁷ However, CD4⁺ Th2 cells and CD4⁺ Treg cells are capable of suppressing effective CD8⁺ anti-tumour responses.⁵ *In vivo* studies by several groups have found dysfunctional circulating and tumour-infiltrating T cells in HNSCC patients, with functional assays identifying multiple defects in T-cell activation and effector functions, suggesting that the tumour has successfully suppressed an otherwise robust lymphocytic response.^{8–11}

The TME can become dominated by CD4⁺ Treg cells that suppress anti-tumour effector T cells by the production of suppressive cytokines such as TGF- β , interleukin-10 (IL-10), prostaglandin E2 (PGE2) and adenosine.⁵ Although the full relevance of different subsets of Treg cells is not yet known one subtype, inducible Treg cells (iTreg cells or Tr1 cells), have been shown to very effectively suppress cytotoxic T cell activity both in the TME of several cancers and the peripheral circulation.^{12–13} It is becoming increasingly clear that the balance between inflammatory effector cells and Treg cells is critical in producing an effective immune response. A relatively crude measure of the effectiveness is to determine the ratio between cytotoxic CD8⁺ T cells and Treg cells within the tumour microenvironment. Higher CD8⁺/Treg cell ratios have been shown to be associated with a favourable prognosis in a range

of human cancers including ovarian,¹⁴ hepatocellular,¹⁵ breast,¹⁶ lung¹⁷ and HNSCC.¹³

Tumour infiltrating lymphocytes (TIL) have been shown to promote angiogenesis and therefore tumour progression and metastasis. Cells with such activity in HNSCC include mast cells,¹⁸ CD34 progenitor cells,¹⁹ Th17 cells²⁰ and TAM.²¹ A high level of infiltration of TAM within HNSCC defined by the overexpression of macrophage content, monocyte chemoattractant protein 1 (MCP1) and macrophage inflammatory protein (MIP)-3 α levels was also found to be a strong predictor of lymph node metastasis, extracapsular spread and advanced stages of the disease; all considered as poor prognostic markers.^{22–23} Stromal cells have been shown to secrete cytokines and growth factors including vascular endothelial growth factor (VEGF), platelet derived growth factor (PDGF) and IL-8, which are strong inducers of angiogenesis and tumour progression.^{24–26} VEGF expression, which is responsible for facilitating proliferation of endothelial cells and neo-vascularization, correlated significantly with adverse prognosis in HNSCC patients.²⁷ VEGF-C, a member of the VEGF family, plays an important role in tumour lymphangiogenesis; raised tumour-tissue levels of VEGF-C are associated with a worse prognosis due to increased tumour lymphatic vessel density that correlates with lymph node metastasis in HNSCC.²⁸

Carcinoma-associated fibroblasts are the major cell population in the tumour stroma.^{2, 29} Within the TME, there is evidence suggesting that CAF use protease and mechanical remodelling of the extracellular membrane to lay tracks along which HNSCC tumour cells invade.³⁰ When compared with normal oral cavity fibroblasts, CAF were found to exhibit rapid growth, increased proliferation and viability and produce α -smooth muscle actin (α -SMA) and membrane metalloproteinase 2 (MMP-2), which represent markers of chronic inflammation that normal tissue fibroblasts do not produce.³¹

Cytokines and chemokines in TME

Cytokines are small molecular weight molecules that regulate all aspects of the immune response (e.g. inflammation, immunity and haematopoiesis). This group of molecules is divided into subfamilies according to their structure or function and includes: interleukins (IL), interferons (IFN), cytokines, tumour necrosis factors (TNF) and other cell-specific growth factors.⁷ Chemokines are a superfamily of small proteins with chemoattractant and activation properties for different cell types involved in inflammatory reactions and are considered the main facilitators of cell trafficking.³² Cytokines and chemokines are key in controlling communication within and between individual cells in the TME.

Tumours produce cytokines in a dysregulated manner that contributes to an ineffective host immune response.^{33–34} One such cytokine is tumour growth factor beta (TGF- β), which acts broadly to suppress cell-mediated immunity and is released by tumour cells and Treg cells conferring inhibitory action.³⁵ Further observations in HNSCC, as well as in many other cancers,

have shown that tumour development can significantly alter serum levels of key Th1 and Th2 type cytokines in the body. Commonly there appears to be an imbalance, towards a Th2 cell cytokine profile that becomes more pronounced at later stages of tumour growth.^{36–37} The Th2 cell profile is characterized by the production of IL-4, IL-5, IL-6, IL-10, IL-13 and granulocyte-macrophage colony stimulating factor (GM-CSF) whilst Th1 responses are characterized by the production of interferon gamma (IFN- γ), IL-2, IL-12 and IL-18. Some of the Th2 cell cytokines, particularly IL-10, have been clearly shown to suppress the cellular immune response effectively, thus permitting tumour growth.³⁸

Immune suppressive cytokines, whether produced by tumour cells or by stromal cells, seem to control the cross-talk between cells within the TME during tumour progression (Figure 16.1). Furthermore the release of such cytokines induces ECM remodelling, basement membrane degradation, tumour cell proliferation and angiogenesis, and hence favours tumour progression and metastasis. In studies on HNSCC cell lines, fibroblasts and stromal endothelial cells have been shown to express a suppressive cytokine/chemokine milieu when co-cultured with HNSCC cells.³⁹ CAF showed an increase in the expression of a number of pro-inflammatory cytokines and chemokines including CCL7, CXCL1, CXCL2, CXCL3 and CXCL8 when compared with CAF cultured alone.⁴⁰ Similarly, type I collagen was found to markedly stimulate immune-suppressive cytokine expression such as IL-1 α , IL-1 β , IL-6, TNF- α , TGF- β and MMP-2 in metastatic HNSCC cell lines compared with that of the primary cancer cell lines.⁴¹

Chemokines co-ordinate the trafficking, migration and organization of cells to various tissue compartments.^{42–43} Thus understanding alterations in chemokine levels within HNSCC is likely to offer useful prognostic information. Initial work by Muller and colleagues demonstrated that upregulation and activation of CXCR4 and CCR7, facilitate leukocyte migration to regional lymph nodes; in breast cancer this is capable of inducing actin polymerization, migration and invasion both *in vitro* and *in vivo* studies.⁴⁴ Upregulation of CXCR4 and CCR7 expression has been observed in tumour tissue and lymph nodes of HNSCC patients.^{45–48} Overexpression of CXCR4 was shown to be a significant prognostic indicator for poor survival in patients with oral squamous cell carcinoma⁴⁶ while upregulation of CCR7 was also found to correlate with poorer survival in patients with HNSCC.⁴⁹ Furthermore, it was reported that hypoxia, a major stimulator of tumour progression, enhances CXCR4 expression by activating hypoxia inducible factor 1 alpha (HIF-1 α) in tissue from oral squamous cell carcinoma patients.⁵⁰

A recent systematic review of cytokine/chemokine profiles and their clinical significance in various cancers has shown that, despite tumour heterogeneity, patients with advanced-stage cancer seem to experience a simultaneous immune-stimulation and immune-suppression, with increased concentrations of cytokines Macrophage Inhibitory Factor (MIF), TNF- α , IL-18, IL-8, IL-6, TGF- β , and IL-10. The result of the described cytokine pattern is local immunostimulation and inflammation with

synchronous functional immune-suppression and attraction of immune cells that are then tolerized, thus protecting tumour cells locally from detection and destruction. The review concluded that, independent of tumour histological changes, the immune-suppressive cytokine cascade links the functional status of the immune system with the extent of cancer disease and patients prognosis and ultimately is an expression of the systemic disease in cancer.⁵¹

Inflammation in TME

A chronic inflammatory environment is associated with neoplastic transformation and progression in many malignancies including HNSCC.^{52–54} Oncogenes that are activated early in the development of tumours can incite strong inflammatory responses. For example, lung tumours that are initiated by a mutation in the K-ras oncogene produce chemokines that attract immune cells to the TME;⁵⁵ or the *RET*–*PTC* protein, that causes constitutive activation of the RET tyrosine kinase domains in thyroid tumours, modulates nuclear factor- κ B, a transcription factor that controls the production of immune-regulatory cytokines. The *RET*–*PTC* protein increases the production of GM-CSF and monocyte chemoattractant protein 1, that contribute to a pro-inflammatory microenvironment.⁵⁶ Products of dying tumour cells (e.g. heat-shock proteins and monosodium urate) are some of the many inflammatory substances that further exacerbate immune responses in a relatively non-specific manner.⁵⁷

The pro-inflammatory conditions within the TME have also been shown to contribute to tumour progression, proliferation and metastasis. Cyclooxygenase (COX)-2 and 5-lipoxygenase (5-LOX) pathways, which both produce derivatives from arachidonic acid, are activated during HNSCC development.⁵⁸ The COX-2 enzymes specifically catalyze the production of prostaglandins (PG). PG are increased in HNSCC (e.g. raised PGE2 in HNSCC is known to promote tumour growth and inhibit apoptosis by upregulating Bcl-2 expression). PGE2 is also known to increase the production of angiogenic factors such as VEGF and MMP, resulting in the promotion of invasion and tumour metastasis. Higher expression of COX-2 in tumour cells is seen in parallel with an increased PGE2 expression in HNSCC.^{59–60}

TUMOUR ESCAPE MECHANISMS

In order for the immune system to identify and eliminate tumours, it needs to recognize the malignant growth in some way. Some antigens are solely presented by tumour cells and never by normal cells, thus are called tumour-specific antigens (TSA); for example, MAGE-1, a melanoma-specific antigen,⁶¹ or NY-ESO-1 antigen, a molecule that belongs to a family of cancer–testis antigens.⁶² Other antigens are presented by tumour cells but at raised levels when compared with normal cells; these are termed tumour-associated antigens (TAA).⁶³ Examples of TAA in HNSCC include the epidermal growth factor receptor (EGFR)⁶⁴ and wild-type p53.⁶⁵ Tumours associated

with viral infection display viral antigens that can serve as tumour markers. Good examples are the products of the E6 and E7 genes of the human papilloma virus, the causative agent of both cervical^{66–67} and oropharyngeal carcinoma,⁶⁸ and EBNA-1, the Epstein–Barr virus nuclear antigen expressed by Burkitt’s lymphoma and nasopharyngeal carcinoma cells.⁶⁹

The discovery and identification of tumour antigens has helped scientists begin to understand the key steps in an anti-tumour immune response. In animal models, the encounter between the immune system and tumours initiates a process termed ‘immunoediting’.⁷⁰ This process can bring about three outcomes: elimination of the tumour; tumour equilibrium, in which there is immune selection of less immunogenic tumours during an anti-tumour immune response;⁷¹ and tumour escape, the growth of tumour variants that resist immune destruction.

Tumour escape mechanisms have been broadly divided into two main groups. Either the tumour cells are poor stimulators of immune cells and hence are simply not recognized, and/or they actively interfere with immune function and survival of the immune cells.^{72–73} Tumour-escape from immune-surveillance in HNSCC is due to a combination of multiple mechanisms involving tumour cells, cytokines and immune cells (Table 16.1). The most common mechanism is the loss of MHC class I molecules that reduces/prevents TAA expression, which, coupled with deficient antigen-presenting and processing mechanisms by immature dendritic cells and overexpression of Treg cell, all contribute to avoidance of the immune system. Major regulators behind dysregulated cytokine and chemokine function include imbalanced STAT1/STAT3 signalling within tumour cells,⁷⁴ hepatocyte growth factor (HGF) production by tumour-associated fibroblasts,^{75, 76} and production of immunosuppressive molecules by TAM such as VEGF, IL-10 and TGF- β .^{77, 78} Finally, effector cell dysfunction allows tumour escape through an increased level of spontaneous apoptosis and anergy, as well as signalling defects in the T cell receptor signalling complex (Table 16.1).

TABLE 16.1 Immune-suppressive tumour-escape mechanisms in HNSCC

• Spontaneous apoptosis/anergy of tumour infiltrating and circulatory T cells ^{10, 105, 106}
• Imbalanced and decreased absolute counts of T cell subsets ^{107, 108}
• Signalling defects in effector cells ^{109, 110}
• Cytokine imbalance favouring immunosuppression ^{51, 111, 112}
• Poor expression of co-stimulatory molecules and high expression of co-inhibitory receptors on tumour cells ^{106, 113, 114}
• Deficient antigen-presenting and processing mechanisms ^{115–117}
• Loss of HLA class I molecules by HNSCC cells ^{118, 119}
• Inhibition of NK cell activity ^{73, 120, 121}
• Overexpression of Treg cells both in the circulation and intra-tumourally ^{6, 122}

HLA: human leukocyte antigen; NK cells: natural killer cells; Treg cells: regulatory T cells; HNSCC: Head and neck squamous cell carcinoma.

TUMOUR BIOMARKERS

As our knowledge of the anti-tumour response increases the idea of using biomarkers as surrogate endpoints of clinical response is becoming a reality.²

Tumour biomarkers can be divided into either disease-related ones (i.e. at the time of diagnosis prior to any therapy) or therapy-related ones (i.e. prior to, during and after therapy).⁷⁹

Seminal work in colorectal cancer (CRC) by Golan and colleagues,^{80–83} reporting on TIL using modern techniques of systems biology, and an objective scoring system based on image analysis data, showed that the type, density and location of immune cells within tumours predicted clinical outcome. T cell infiltrates emerged as the strongest independent prognostic factor, more significant than the conventional clinicopathological criteria such as tumour size, depth of infiltration, differentiation, or the nodal status. Based on these results, a proposal has been drafted for a routine evaluation of the tumour microenvironment for the density, location, phenotype and function of T cells in order to define an ‘immune score’ for each tumour as a part of the standard pathological examination. Although not yet incorporated in routine pathological practice, this approach represents the first serious immunological marker of risk in cancer with a potential to be incorporated into prognostically relevant immune classification of human CRC equal to or better than the conventional TNM classification.⁸¹ In HNSCC, the value of tumour-infiltrating CD4+ T cell subpopulations is under evaluation as a prognostic marker; however, this too has not yet been incorporated into clinical practice.^{84–85}

One of the other validated biomarkers is the B cell signature, which has emerged as the most robust prognostic factor in breast cancer.^{86–87} A multicentred trial has identified the immunoglobulin G kappa chain (IgGκC) as an immunological biomarker of prognosis and response to chemotherapy breast cancer, ovarian cancer, non-small cell lung cancer, and CRC. The IgGκC was microscopically identified as a product of plasma cells present in the tumour stroma and was validated as a prognostic biomarker by RNA and protein-based expression studies independently performed in thousands of formalin-fixed, paraffin-embedded specimens at 20 different centres.⁸⁷ However, the most important finding was that IgGκC predicted responses to neo-adjuvant therapy in breast cancer and thus qualifies it as the first immune marker of response to cancer treatment. Supporting the key role of the B cell signature in HNSCC is a study by Pretscher et al. where intra-tumoural CD20+ B cells were significantly more frequent in metastatic lesions than in primary tumours when 193 tissue cores from 33 patients were examined. Further, large numbers of peri-tumoural B cells together with increased numbers of intra-epithelial CD8+ T cells in metastatic tumours were associated with favourable outcome in patients with oro- and hypopharyngeal carcinoma.⁸⁸

Recent evidence has suggested that the total white blood count and especially the elevated neutrophil count

compared with a depressed lymphocyte count (i.e. high neutrophil-to-lymphocyte ratio (NLR)) measured prior to oncological therapies predicts adverse clinical outcome in patients with lung, breast, renal, ovarian and HNSCC. Further, high NLR was found to be a significant but not yet validated marker of poor response to chemotherapy in these cancers.⁸⁹ These observations are in agreement with previous studies that reported low lymphocyte counts in patients with HNSCC, for example spontaneous apoptosis of circulating CD8+ antigen-responding effector T cells, leading to rapid lymphocyte turnover and depressed absolute numbers of T cell subsets tested prior to any form of treatment, have been reported.⁴

Multiple other biomarkers have been identified in various cancers including HNSCC, but are not yet validated. Examples include the frequency and function of circulating Treg cells,^{13, 90} markers of CD8+ T cell apoptosis such as Fas L+ microvesicles and their immunosuppressive cytokines PDL-1 & TGF-β,⁹¹ the frequency of circulating CD8+ CCR7+ cells,⁹² and the functional status of tumour peptide-specific CD8+ T cells.⁹³ A recent review summarizes the biomarkers measured by immunohistochemistry in the different anatomical subgroups of HNSCC and their clinical relevance;⁹⁴ as yet no marker is sufficiently robust to become a routine test in HNSCC.

IMMUNOTHERAPY

Early clinical trials of immunotherapy in the majority of cancers were troubled by systemic toxicity or difficulties in local administration. Now, interest in immunotherapy has been revitalized by mechanistic insights into immune evasion, coupled to ongoing developments of novel immunotherapies.⁹⁵

Any form of immune-based therapy must overcome the main factors hindering an effective immune response; a representative selection of ongoing trials is detailed in **Table 16.2**. Multiple components of the immune system, such as immunization with tumour antigens, cytokines and T cells, have all been studied in multiple immune-based therapies. The aim of these therapies is to cause the tumour to be targeted in a specific fashion by the host immune defences.

Immune-based therapies are classified according to their target cell or molecule. Targeting specific elements of the immune system such as tumour antigens with antibodies and therapeutic cancer vaccines have all shown promising results.⁹⁶ Some of the most promising immune-based therapies involve the administration of monoclonal antibodies against tumour antigens (e.g. Trastuzumab, an antibody against the HER2 receptor expressed on 15–25% of breast cancers;⁹⁷ rituximab that binds CD20 expressed on 90% of Non-Hodgkin B-cell lymphomas;⁹⁷ or cetuximab, that binds to EGFR that is upregulated in HNSCC, lung and colorectal cancer);^{98–100} these have all been shown to be clinically effective and are already incorporated into mainstream treatment modalities.

TABLE 16.2 Key areas and promising immunotherapies in HNSCC

Key area	Example of drug mechanisms	Phase of development
TA-specific monoclonal antibodies	Cetuximab: Anti-EGFR chimeric IgG1 mAb ⁹⁸ blocks growth factor signalling	NICE and FDA approved
	Nimotuzumab: Anti-EGFR IgG1 humanized mAb ¹²³ blocks growth factor signalling	II
Targeting cytokines	IL 12: Cytokine agonist causes NK cell activation ⁹⁵	II
	Bevacizumab: Anti-VEGF IgG1 humanized mAb ¹²³ a drug that inhibits angiogenesis	III
	IRX-2: various cytokines including IL-1b, IL-2, IL-6, IL-8, GM-CSF, IFN γ and TNF α , to enhance anti-tumour immune responses ¹²⁵	I/II
Targeting T cell checkpoint inhibitors	Ipilimumab: Anti-CTLA4 IgG1 humanized mAb ⁹⁵ that prevents co-stimulatory signals	I
Therapeutic cancer vaccines	MAGE-3 and HPV-16 vaccine: Trojan construct peptide vaccine ¹²⁶	I
	HPV pNGVL4a-CRT/E7 (Detox) DNA vaccine: Detoxified E7 DNA in a pNGVL4a plasmid backbone ¹²⁷	I
	Multi-epitope p53 vaccine: Wild type peptide/autologous dendritic cell vaccine ⁹⁵	I

Examples of key areas during anti-tumour immune responses, where immunotherapeutic agents are being utilized and trialled. TA: tumour associated; EGFR: epidermal growth factor receptor; IgG: immunoglobulin G; mAb: monoclonal antibody; IL: interleukin; NK cells: natural killer cells; VEGF: vascular endothelial growth factor; GM-CSF: granulocyte macrophage-colony stimulating factor; IFN γ : interferon gamma; TNF α : tumour necrosis factor alpha; CTLA4: cytotoxic T-lymphocyte antigen 4; MAGE-3: melanoma-associated antigen-3; HPV: human papilloma virus. (For a current list of immunotherapy-based trials, please refer to clinicaltrials.gov.)

Several mechanisms are developed by cancerous cells to escape the immune system such as a loss or a reduction of the expression of MHC class 1 molecules and co-stimulatory molecules, the expression of FasL to induce apoptosis of tumour-infiltrating lymphocytes and the production of immunosuppressive molecules such as TGF- β , PGE₂, IL-6, IL-10 and adenosine. Among the subpopulations of naïve CD4⁺ T cells, CD4⁺ Th17 T cells promote inflammation by secreting IL-17 whereas CD4⁺ Th2 T cells promote antibody production by B cells. Tregs promote tumour progression by inhibiting the functions of CD4⁺ and CD8⁺ T cells and NK cells. TAMs/M2 phenotype induce the expression of CD4⁺ Th2 T cell and Tregs. Moreover, M2 phenotype promotes growth tumour (EGF, PDGF, TGF- β , IL-6, IL-1 and TNF- α), angiogenesis (TGF- β , VEGF, GM-CSF, TGF- α , IL-1, IL-6 and IL-8), invasion (MMPs, TNF- α , IL-1), immunosuppression (TGF- β , PGE₂ and IL-10) and metastasis. MDSCs induce Treg cells, secrete IL-10, and inhibit CD4⁺ and CD8⁺ T cells. (Adapted from Duray et al.¹²⁸)

Seminal work by Bonner et al. reported that the administration of cetuximab with radiotherapy, when compared to radiotherapy alone, has significantly prolonged progression free survival without increasing the common toxic effects associated with radiotherapy to the head and neck in a multicentred phase III clinical trial.⁹⁸ So far, cetuximab is the only approved antibody by FDA and NICE for use in patients with locally advanced HNSCC. In addition, a variety of other anti-EGFR agents such as the small molecule tyrosine kinase inhibitors (TKI) lapatinib, dacomitinib and afatinib and the anti-EGFR mAbzalutumumab, nimotuzumab and panitumumab, are currently under investigation in phase II and III clinical trials in different HNSCC therapeutic settings. The EGFR-targeting TKI erlotinib is currently in phase III development for oral cancer prevention (NLM Identifier NCT00402779), while bevacizumab, an anti VEGF monoclonal antibody, has been shown to produce favourable efficacy when combined with chemoradiotherapy for locally advanced HNSCC.¹⁰¹ Numerous other biological agents are in early stages of development for HNSCC treatment, including novel anti-EGFR mAb such as necitumumab, small-molecule TKIs (vandetanib, icotinib and dasatinib), and drugs (temsirolimus and everolimus). Overall, a wealth of clinical trial data are expected in the coming years, with the potential to modify significantly the approach to anti-EGFR therapy for HNSCC.¹⁰²

The key areas for targeting the immune system through immune-based therapies with promising results in HNSCC are summarized in [Table 16.2](#). It is worth noting that in HNSCC the degree of immune-suppressive

cross-talk suggests that single immunotherapies will be inadequate. Thus, integration of immune therapies with standard treatments for cancer is seen as the best avenue and revealing promising results.⁹⁵

CONCLUSIONS

It is evident now that cancer creates an immunosuppressive environment locally and systemically. This tumour microenvironment interferes with maturation and activation of antigen-presenting cells and naïve cytotoxic T cells,¹⁰³ hence creating immune-suppressive conditions that favour tumour proliferation and progression. As our understanding of the TME grows, specific key areas and immune end points can be explored with the ultimate goal that they may act as potential targets for tumour detection, prognosis and ultimately therapy.

In HNSCC, several reports have shown that immune cells within the peripheral circulation, associated lymph nodes and tumour tissue are responsible for suppressing effective CD8⁺ anti-tumour responses and are associated with poorer prognosis in patients. Such cells include CD4⁺ Th2 cells, TD4⁺ Treg cells, TAM and CAF. Products of these cells in the form of cytokines and chemokines have also been linked to immune suppression and poor prognosis in HNSCC patients, for example IL-10, TGF- β , CXCR4 and CCR7.

Most tumour biomarkers, whether reflecting cancer presence, progression or response to therapy, have a potential to serve as intermediate biomarkers of outcome.

However only a few, including T-cell and B-cell immune signatures or the NLR, have been validated in independent clinical studies encompassing sufficiently large cohorts of patients with different tumour types to give statistically valid data. In HNSCC, a histopathological 'immune score' of TIL as a robust clinical prognostic marker is under evaluation based on work in colorectal cancer that has been reported recently. HPV p16 status in HPV-associated head and neck tumours is the only validated biomarker in HNSCC to date. Treatment protocols of HNSCC, especially oropharyngeal tumours, have now fully incorporated HPV p16 status in their guidelines.¹⁰⁴

Precise clinicopathological analysis and clinical follow-up in well-defined, relatively uniform cohorts of patients in each subunit of the head and neck offers the best option for confirming immune endpoints as biomarkers of outcome. This is particularly important in tumours of the head and neck as multiple anatomical subsites with different molecular biology and immune reactions are usually studied and reported together. This point has clearly been shown to be relevant in oropharyngeal tumours, and more precisely tonsillar and tongue base tumours that are HPV related, and nasopharyngeal tumours that are EBV related.¹⁰⁴ Much work remains to confirm the reliable association of immune biomarkers with clinical endpoints and to validate each of these potentially promising biomarkers in a series of prospective clinical trials appropriately powered to determine effects on each head and neck subsite.

Much has been learned about the potential of the immune system to control cancer and the various ways that immunotherapy can boost the potential of the immune system for the benefit of the patient. This knowledge has stimulated the invention of many new therapeutic antibodies, cell-based treatments, and vaccines, which are starting to be used in clinical practice, either alone or in various combinations. Cetuximab, the only immune-based therapy incorporated in the treatment of advanced HNSCC so far, has paved the way for a wealth of ongoing and future trials exploring multiple agents in key areas during tumour progression and spread. Future immune-based therapies in HNSCC specifically, and solid tumours generally, are expected to result in improved cancer treatment.

KEY POINTS

- The tumour microenvironment strongly influences tumour development and outcome through a combination of cell activities; Tumour Associated Macrophages and Treg cell populations appear to play prominent roles.
- Currently, no biomarkers have been identified which possess prognostic or diagnostic value above TMN classification, but it is likely that tumour subtype-specific molecules will be identified in the future.
- The number of trials involving immunotherapies in HNSCC continues to increase; the use of novel checkpoint inhibitors has shown positive preliminary data.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed searches using keywords related to human papillomavirus, molecular biology, cancer pathogenesis and epidemiology.

INTRODUCTION

In recent years there has been increasing evidence related to head and neck cancer pathogenesis and viral infections, particularly human papillomavirus (HPV). In 1907 Giuseppe Ciuffo was able to demonstrate the viral origin of common warts, with the potential for human–human transmission.¹ Subsequently in 1976 Harald zur Hausen was the first to suggest a link between HPV infection and cervical cancers,² with HPV now considered a sexually transmitted disease. Our current knowledge of HPV and disease pathogenesis is based mainly on cervical cancer models. This chapter will review the molecular biology of HPV and related cancer pathogenesis.

HPV belongs to the papovaviridae family of viruses, which also includes the polymaviruses. The HPV virion is composed of an 8 kb double-stranded DNA genome contained within a protein capsid, and forms a non-enveloped icosahedral structure measuring 55 nm in diameter. The virus only infects epidermal cells, such as skin or mucosa.

HPV GENOTYPES

To date, more than 120 HPV types have been identified.³ These can be divided into mucosal or cutaneous genotypes, with approximately one-third causing mucosal infections. Furthermore the HPV types can be classified into low- or high-risk, depending upon their malignant potential. Low-risk HPV includes types 6 and 11, which are traditionally associated with genital warts but are also related to laryngeal papillomatosis. The high-risk HPV types 16 and 18 have

been implicated in head and neck squamous cell carcinomas (HNSCC), such as laryngeal and oropharyngeal cancers. Reported HPV prevalence in HNSCC varies between studies, and is dependent on anatomical subsite. For example, the RTOG 0129 randomized controlled study reported 63.8% HPV prevalence among patients diagnosed with oropharyngeal cancer, of whom 96% were HPV 16 positive.⁴

HPV GENOME AND PROTEINS

The HPV genome is composed of approximately 8000 base pairs coding for eight main viral genes, which are subdivided into early and late gene products (**Figure 17.1**). The LCR (long control region) contains *cis*-regulatory elements, which control and regulate viral DNA replication. The functions of the early and late genes are summarized in **Table 17.1**. The key viral proteins involved in cancer pathogenesis are E6 and E7.

HPV LIFE CYCLE

Transmission

HPV is transmitted between individuals by direct contact of skin or mucosa. While HPV can be considered a sexually transmitted disease this is by no means the only mode of transmission. Studies have demonstrated HPV infection in children, which is likely caused by vertical transmission from the mother during birth. Indeed there is evidence that risk of HPV transmission from mother to infant is

Figure 17.1 Schematic diagram of the HPV 16 genome.

TABLE 17.1 HPV gene products and functions^{4,5}

Viral protein	Functions
E1	Initiates viral DNA replication via ATP-dependent helicase activity
E2	Combined activity with E1 to initiate viral replication Regulates viral transcription Suppresses E6 and E7 activity
E4	Disrupts host cell keratin structure Supports viral amplification and maturation
E5	Enhances E6 and E7 activity Role in evading host immune response
E6	Binds to p53 and causes its degradation by proteolysis, leading to inhibition of apoptosis
E7	Binds to and inactivates pRb, causing loss of cell cycle regulation
L1	Major capsid protein
L2	Minor capsid protein

Figure 17.2 Life cycle of HPV. 1) HPV gains access to basal stem cells through areas of micro-trauma in the epithelial cell layer, 2) Entry into basal cells via endocytosis, 3) Maintenance phase with low viral replication, 4) Differentiation-dependent phase with high viral replication, 5) Complete HPV particles are released during normal epithelial desquamation.

reduced in caesarean sections.⁷ Transmission may also occur by autoinoculation or indirectly via fomites.⁸ The HPV particles are shed by the outermost epithelial layer of skin or mucosa, and are highly infectious. The life cycle of HPV (Figure 17.2) is ideally adapted to the host cell cycle, ensuring evasion from the immune system.

Epithelial exposure

The HPV particle has a tropism to epithelial surfaces but must first acquire access to the dividing basal stem cell layer. This can occur via micro-trauma to the epithelial layer, for example during sexual contact. As the normal host cell response to injury is recruitment of dividing epithelial cells, this enhances the infectious ability of the virus.⁹ However, the exact mechanism of establishing HPV infection is not clearly understood, particularly in head and neck sites.

Attachment and entry

In order to gain access into the basal stem cells the virus requires attachment to surface receptors, the L1 and L2 viral capsid proteins are believed to be involved in this process. Initially the L1 capsid protein binds to exposed heparin sulfate proteoglycans and causes a conformational change leading to cleavage of L2 capsid protein by furin.¹⁰ Further interaction with host cell receptors occurs, with $\alpha 6$ integrin proposed as one of the main target receptors.

Entry into the host cells then occurs via endocytosis utilizing various pathways. These include clathrin-mediated and caveolar endocytosis.¹⁰⁻¹¹ Once internalized the viral particle migrates to the host cell nucleus. The incubation period of the virus can last for weeks, months or even years after initial exposure.

Replication

The replication stage can be subdivided into the maintenance and differentiation-dependent phases.¹² The HPV particle utilizes the host cellular mechanisms to initiate DNA replication within the host cell nucleus and cause persisting infection. During the maintenance phase there are a low number of episomal viral copies produced within the basal stem cells, between 50–100 copies per cell.¹³ The E1 and E2 viral proteins function together to maintain viral DNA replication. Dividing stem cells produce daughter cells that either remain within the basal layer or move towards the suprabasal layer. The low number of viral copies within the basal layer ensures evasion from the host immunity. Within the suprabasal layer the cells begin to differentiate, with E6 and E7 viral proteins encouraging further cell proliferation. Cells moving into the suprabasal layer lose their ability to divide and therefore undergo terminal differentiation, with HPV replication entering the differentiation-dependent phase. Activation of late viral promoters during this phase causes a dramatic increase in viral copies to several thousand per cell.¹⁴ The E1, E4 and E5 viral proteins function to support viral amplification and maturation at this stage. While E6 and E7 function to promote cell proliferation the E2 viral protein suppresses their activity to allow cell differentiation and completion of the HPV life cycle. The delayed expression of large viral numbers within terminally differentiated cells prevents an immune reaction and ensures long-term persistence of the virus.

Shedding

Expression of L1 and L2 capsid proteins is the final step prior to release of the viral particles from the host cells. Maturation of HPV occurs in the most superficial layer of the epithelium. Release of complete viral particles occurs during normal epithelial shedding. Unlike other viruses, which lyse the host cells for viral release, the papillomavirus has adapted to utilize the normal epithelial cell cycle. Release of viral particles by this method prevents host cell immune recognition and ensures no abnormal inflammatory response.¹²

Persistence and clearance

Following initial infection the majority of individuals will clear the virus, although the period of active infection is unknown in head and neck sites. Cell-mediated immune response and activation of Langerhans cells play a role in viral clearance from the host cells.¹³ However, considering the life cycle of HPV, undetectable infection may persist for an extended period with possible reactivation. Several factors, such as host cell immune status and hormonal levels, are likely to contribute to persistence and future reactivation.

HPV AND CANCER

Pathogenesis

Infection with HPV, particularly high-risk types, increases the risk of developing cancer. Failure to clear

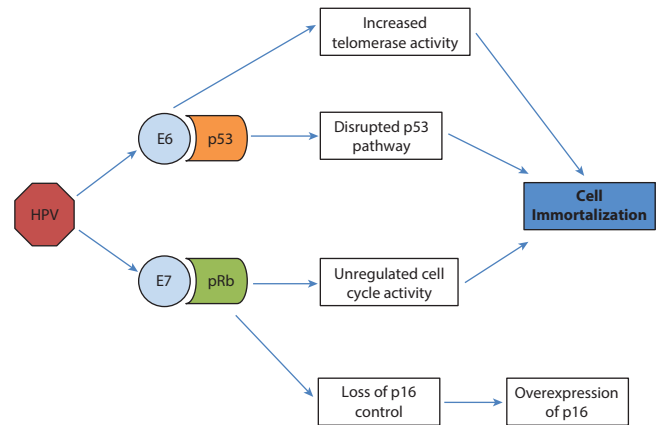

Figure 17.3 Illustration of HPV E6 and E7 interactions with host cell pathways.

the virus is likely to result in unregulated cell proliferation, accumulation of mutations and cancer formation. While the various HPV proteins contribute to viral replication, the E6 and E7 viral oncoproteins are critical in malignant transformation (Figure 17.3). Working together they can lead to epithelial cell immortalization. E6 binds to p53 and promotes its degradation via ubiquitin-dependent protease pathways.¹⁵ The wild-type p53 is normally activated by DNA damage or cellular stress, and acts as a tumour suppressor. P53 functions include modulation of cell cycle, regulation of apoptosis and cell senescence.¹⁶ E6 also activates the hTERT promoter to induce telomerase activity, which also leads to cell immortalization.¹⁷

The E7 viral protein binds to and inactivates pRb (retinoblastoma protein). The pRb is also an important tumour suppressor. The normal function of pRb is to block cell cycle progression by binding to E2F transcription factor and therefore blocking progression from G1 to S-phase.¹⁸ Disruption of pRb-E2F complex therefore leads to unregulated cell cycle entry into S-phase causing increased cell proliferation. Interestingly unregulated S-phase activity would normally cause apoptosis via the p53 pathway. However, suppression of p53 activity by E6 interrupts this pathway and prevents cell death. Consequently immortalized cells lose the ability to repair DNA damage and therefore accumulate mutations and chromosomal instability. This can eventually lead to cancer formation.

During the complex interactions between E6 and E7 and the host cell pathways numerous cellular proteins can be disrupted, including p16. The p16 gene was first discovered in 1993 and codes for a cyclin-dependent kinase (CDK) inhibitor.¹⁹ The CDK family plays an important role in cell cycle control. The p16 protein acts to prevent G1 to S-phase cell cycle progression, and also interacts with the pRb pathway.²⁰ The pRb function varies according to its phosphorylated state, which is controlled by the cyclin D-CDK4/6 complex. The p16 protein inhibits CDK4/6 and prevents phosphorylation of pRb. Hypo-phosphorylated pRb binds to and inactivates E2F transcription factors, leading to cell cycle

arrest as described. Activity of p16 is controlled by functional pRb via a negative feedback mechanism.²¹ Considering the effect of E6 on pRb function, an overexpression of p16 is expected in HPV active infections.

Epidemiology and risk factors

Among the head and neck cancers there appears to be a significant increase in the incidence of oropharyngeal cancer (OPC). In a large retrospective study examining incidence rates of OPC within 23 countries between 1983 and 2002, increasing incidence was observed mainly in developed countries such USA, UK and France.²² In England the incidence rate of OPC more than doubled between 1990 and 2006,²³ with similar trends observed in Sweden and Scotland.^{24–25}

Traditional risk factors of HNSCC include smoking and alcohol. However, increasing evidence has implicated HPV in cancer pathogenesis. The majority of HPV-related head and neck cancers occur within the oropharynx. In one systematic review there was a 26% overall prevalence of HPV infection within HNSCC cases, with the greatest proportion in the oropharyngeal cohort with a prevalence of 36%.²⁶ Other studies have also shown a strong association between HPV positivity and the oropharynx.²⁷ Recent evidence also appears to show prevalence of HPV infection in oropharyngeal cancer is increasing, whilst prevalence in non-oropharyngeal sites has remained static.²⁸

Recently a geographic variation in prevalence has been demonstrated, with high prevalence in oropharyngeal cancers demonstrated in Western Europe (37%) compared with Eastern Europe (6%) and Asia (2%).²⁹ The increasing prevalence of HPV-related cancers can be attributed to changes in sexual practices. Risk factors for high-risk HPV infection in oropharyngeal cancer include younger age group (<55 years), higher number of sexual partners, early sexual contact, oral-genital and oral-anal sex.^{30–31}

Prognostic markers

There has been increasing interest in the role of HPV in HNSCC and the prognostic significance of HPV-related tumours. Various studies have correlated improved overall survival and disease-specific survival in HPV positive cancers.^{27, 32, 33} In a retrospective study of the RTOG 0129 data, 3-year overall survival was 82.4% in HPV positive OPC cases compared to 57.1% in HPV negative cases.⁴ Further analysis of the data showed HPV status was the most important determinant of survival, followed by number of smoking pack years. Recently a number of systematic reviews and meta-analyses have confirmed the improved prognostic outcomes in HPV positive HNSCC.^{34–36}

Other prognostic markers proposed for HPV infection include p16 overexpression. The use of p16 testing as a surrogate marker for HPV-related OPC is now

commonplace.³⁷ Overexpression of p16 is considered an independent prognostic marker, with improved overall survival and disease-free survival.³⁸

Diagnosis

HPV detection can involve several methods including direct and indirect assays. Direct methods include polymerase chain reaction (PCR), in-situ hybridization (ISH), Southern blot analysis and HPV antibody detection. The common detection methods included PCR and ISH. The PCR assay is highly sensitive but not specific, requiring only a low level of viral DNA. However, traditional PCR is time and resource intensive and is unable to distinguish between episomal and integrated HPV infection.

In contrast to PCR, the ISH assay is highly specific but not sensitive. An estimated 10 viral copies per cell are required for a positive reaction.³⁹ The advantages of ISH are the ability to differentiate between episomal and integrated HPV infection, and it can be a fully automated process.

Indirect HPV testing includes p16 detection, which utilizes monoclonal antibodies against p16. Staining patterns and cut-off values vary between studies and are observer-dependent. HPV testing algorithms incorporating these various methods have been proposed.⁴⁰

FUTURE RESEARCH

- Current knowledge of HPV infection and cancer pathogenesis is based on cervical cancer studies. Further studies are required to determine the exact life cycle and natural history of HPV in head and neck sites.
- Initial infection mechanisms in the upper aerodigestive tract remain unknown.
- Receptors involved in HPV epithelial cell attachment and exact cell entry pathways are yet to be identified.
- Further studies are needed to determine the incubation and latency period of HPV infection in head and neck sites.
- Epidemiological studies into incidence and prevalence rates of HPV infection in the healthy population are required.
- Exact mechanisms of malignant transformation are yet to be elucidated.
- The interaction between host immune system and HPV is not fully understood, particularly the reasons why infection can persist in some individuals.
- Accurate biomarkers are required to determine a causal link between HPV infection and cancer pathogenesis. Ideal assays should be highly sensitive, specific and cost effective.
- The best methods of HPV detection have not been determined, particularly a consensus on accurate p16 testing among researchers.
- Models of risk stratification based on HPV status can have the potential for personalized prognosis and treatments.

KEY POINTS

- The HPV virion is a small, non-enveloped virus composed of an 8 kb double-stranded DNA contained within a protein capsid.
- HPV only infects skin or mucosal epidermal cells.
- Human papillomavirus is considered a sexually-transmitted disease, although transmission can occur by other methods such as vertical transmission between mother and infant.
- More than 120 HPV types have been described and divided into low-risk (e.g. 6 and 11) and high-risk (e.g. 16 and 18).
- The majority of HPV positive oropharyngeal cancers are caused by HPV 16.
- HPV proteins are classified into early and late gene products.
- E6 binds and degrades p53, E7 binds and inactivates pRb. Both E6 and E7 contribute to cell immortalization.
- Persisting HPV infection is likely to cause accumulated mutations and chromosomal instability, leading to cancer pathogenesis.
- p16 overexpression occurs via pRb inactivation, and is considered a surrogate marker of HPV infection.
- Recent evidence suggests improved prognosis for HPV positive HNSCC, particularly oropharyngeal cancer.
- Risk factors for HPV-related OPC include younger age group, increased sexual partners and oral-related sex.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: ENT complications of autoimmune rheumatic disease, rheumatoid arthritis, spondylarthropathy, sarcoidosis, SLE, Sjögren's syndrome, juvenile idiopathic arthritis, scleroderma, systemic sclerosis, Behçet's disease, dermatomyositis, polymyositis, periodic fever syndromes, PFAPA, mouth ulcers, TMJ arthritis, jaw growth, vasculitis, Wegener's granulomatosis, Churg-Strauss syndrome, microscopic polyangiitis, Kawasaki vasculitis, relapsing polychondritis, lymphadenopathy and polychondritis.

INTRODUCTION

Many rheumatological disorders are multi-system in nature where ENT symptoms and signs may provide a fundamental diagnostic clue to the overall condition, for example, mouth ulcers and lymphadenopathy often seen in systemic lupus erythematosus (SLE). On the other hand, ENT complications may constitute a life-threatening emergency, as in arthritis of the crico-arytenoid with associated vocal cord dysfunction. Long-term secondary damage may occur in under-treated granulomatosis with polyangiitis (GWP), the old Wegener's granulomatosis, where late tracheal stenosis or collapse of the nasal bridge are pathognomic. Sudden onset deafness, trigeminal nerve or facial nerve dysfunction can be seen in many autoimmune and chronic inflammatory rheumatological conditions.

The key to assessment is a whole patient screening review of systems and general examination by the ENT specialist, as well as good ENT assessment by the physician or paediatrician. This ensures that a second or multiple presentation is noticed enabling an early, accurate diagnosis without delay of definitive treatment.¹

Constitutional symptoms of general malaise, tiredness, weight loss, unexplained fevers, rashes, hair loss, photosensitivity, arthralgia, arthritis, myalgias or muscle weakness,

neurological features such as neuropathies, hypertension or unexplained haematuria or proteinuria, mouth ulcers, lymphadenopathy, hepatosplenomegaly, shortness of breath, chronic cough, crepitations on chest auscultation, heart murmurs and absent pulses all occur in rheumatic disorders such as in SLE, the vasculitides, complicated rheumatoid arthritis, and in overlap connective tissue disorders.

Localized arthritis of the temporomandibular joints, cervical vertebrae and the cricoarytenoid can present with local and referred pain, or specific signs. Erosion or collapse of vertebrae from arthritis or secondary osteoporosis can present with torticollis (more often in childhood) or loss of movement and/or neurological signs.

ENT PRESENTATIONS IN AUTOIMMUNE RHEUMATIC DISEASE

The clinical symptoms and signs of many conditions may overlap and appear similar so that it is the patterns and combinations of symptoms, signs and subsequent investigations that will lead to the most likely diagnosis. However, as these diagnoses are made by clinical pattern recognition it is important that the expert opinion of a rheumatologist is sought as early as possible to avoid any dangerous delays in making an accurate diagnosis.

ENT management needs to be in conjunction with an expert specialist rheumatology or paediatric rheumatology team depending on the age of the patient.

1. Mouth ulcers and nasal ulcers may be found in Behçet's disease, systemic lupus erythematosus (SLE).
2. Sore throat may be the presenting symptom in:
 - a. Acute rheumatic fever
 - b. Systemic onset juvenile idiopathic arthritis (JIA)
 - c. Macrophage activation syndromes (MAS)/haemophagocytic lymphohistiocytosis (HLH), either primary or secondary to other autoimmune inflammatory states
 - d. Periodic fever syndromes including periodic fever, aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome.
3. Lymphadenopathy may be associated with many rheumatological disorders:
 - a. SLE
 - b. Systemic onset JIA, with or without MAS/HLH
 - c. Sarcoidosis or Blaus syndrome
 - d. Kawasaki disease
 - e. Rosai-Dorfman disease
 - f. Kikuchi syndrome.
4. Nasal disorders: GWP, eosinophilic granulomatosis with polyangiitis (Churg-Strauss syndrome), relapsing polychondritis and sarcoidosis.
5. Sinusitis: GWP, eosinophilic granulomatosis with polyangiitis, relapsing polychondritis and sarcoidosis.
6. Vasculitic lesions: petechial lesions, ulcerated non-healing lesions (e.g. in pinna, on the palate, nasal mucosa, perforated nasal septum).
7. Hearing disturbances (either through autoimmune neuropathy or with vasculitic damage to small vas-nervorum). Seen in SLE, GWP, relapsing polychondritis, polyarteritis nodosa, Cogan's syndrome, Sjögren's syndrome, and less frequently in eosinophilic granulomatosis with polyangiitis and Behçet's disease.
8. Stridor:
 - a. Arthritis of the synovial joints of the cricoarytenoid joint with an emergency presentation of vocal cord dysfunction. Occurs in rheumatoid arthritis, ankylosing spondylitis, juvenile idiopathic arthritis and gout. Osteoarthritic changes have also been described.
 - b. Mucosal inflammation and swelling in GWP, Churg-Strauss vasculitis, rheumatoid arthritis, SLE, extranodal mucosal disease with lymphoid hyperplasia as in lymphomas.
 - c. Myaesthesia gravis including neonatal disease with transplacental transfer of anti-Musk antibodies.
9. Dysphonia and vocal cord paralysis is found in association:
 - a. Cervical cord changes due to osteophyte
 - b. Cervical cord damage associated with cervical vertebral erosion with JIA
 - c. Hoarseness from anatomical and functional problems.
10. Sjögren's syndrome. Xerostomia or a dry mouth is a common feature of primary and secondary Sjögren's syndrome (occurring with most autoimmune rheumatological disorders). Salivary gland enlargement may be also seen in these patients, as well as in patients with sarcoidosis. In childhood parotid gland enlargement is the most frequent presentation of Sjögren's syndrome. People with Sjögren's are at increased risk of developing non-Hodgkin lymphoma.
11. Trigeminal nerve dysfunction may occur in patients with Sjögren's syndrome, systemic sclerosis, SLE and mixed connective tissue disease.
12. Peripheral facial nerve palsy may complicate Sjögren's syndrome and sarcoidosis.
13. Motility disorders of upper and/or lower portions of the oesophagus have been reported in patients with dermatomyositis/polymyositis, systemic sclerosis and SLE.
14. Chondritis of the pinna in relapsing polychondritis.
15. Skin thickening, dyspigmentary changes, hemi-facial hypertrophy (Parry Romberg syndrome), gum retraction, tympanic membrane involvement in localized scleroderma.
16. Swallowing difficulties:
 - a. Due to weakness in dermatomyositis, myasthenia gravis
 - b. Due to oesophageal constriction in scleroderma.

SYSTEMIC SYMPTOMS AND SIGNS THAT ARE RED FLAGS OF AUTOIMMUNE RHEUMATIC DISEASES

- Joint pain, stiffness especially early morning stiffness and joint swelling seen in inflammatory arthritis
- Fevers
- Malaise, tiredness, weakness, weight loss
- Mouth ulcers, nasal ulcers, genital and perianal ulceration
- Rashes:
 - psoriasis
 - photosensitive, malar erythema in SLE
 - salmon pink, urticarial in systemic onset juvenile idiopathic arthritis
 - purple/black ulcerated vasculitic rashes
 - scalp rash or ulceration
 - skin thickening or hardening with dyspigmentary changes in localized scleroderma
 - erythema nodosum in sarcoidosis and streptococcal infection
- Alopecia either with or without scalp rashes in SLE
- Sclerodactyly, sclerodermatous facial pinching with decreased mouth opening in systemic sclerosis
- Puffy eyelids, heliotrope violaceous look around eyelids in diabetes mellitus (DM)
- Skin ulceration in vasculitis
- Nail fold capillary changes in systemic sclerosis, DM, SLE
- Lymphadenopathy (e.g. Kikuchi syndrome, massive lymphadenopathy with histiocytosis)
- Cardio-vascular features in SLE, vasculitis:
 - Raynaud's phenomenon
 - hypertension

- peripheral vascular pulses loss of diminished, or peripheral aneurysms
- pericarditis, endocarditis, myocarditis
- Thromboembolic phenomenon from primary or secondary anti-phospholipid syndrome
- Respiratory symptoms (e.g. shortness of breath, chronic cough, interstitial pneumonitis, pulmonary arterial hypertension in SLE, scleroderma, DM)
- Nephritis with haematuria, proteinuria, renal impairment, hypertension in SLE or vasculitis
- Gastrointestinal abdominal pain, dysphagia, altered bowel habit, bloody diarrhoea SLE or vasculitis
- Neurological features of neuropathies, myopathies, CNS direct involvement with various presentations including headaches, reduction in intellectual function, loss of memory in SLE or vasculitis
- Ophthalmological disease of uveitis, retinal vasculitis, retinal vein thrombosis
- Laboratory features: raised ESR and or CRP, thrombocytosis, cytopenias, haemolytic anaemia, raised ferritin, abnormal U and Es, LFTs, raised CK, LDH. Abnormal thyroid function tests and thyroid antibodies, raised immunoglobulins, abnormal antibodies antithyroid peroxisomal, antinuclear factor, positive extractable nuclear antibodies, anti-ds DNA, positive p and c ANCA, positive anti-MPO and anti-proteinase 3 (PR3) antibodies, anti-centromere antibodies, anti-scl 70 antibodies.

LABORATORY FEATURES OF SPECIFIC RHEUMATOLOGICAL DISEASE

SLE features include positive antinuclear antibodies (ANA), positive extractable nuclear antibodies (ENA) especially anti-Ro and anti-La, anti-Smith, anti-dsDNA, abnormal thyroid tests, raised immunoglobulins, abnormal antibodies (i.e. antithyroid peroxisomal, raised ESR and/or CRP), thrombocytosis, cytopenias (e.g. lymphopenia, Coombs positive haemolytic anaemia), systemic sclerosis positive ANA, positive anti-centromere antibodies, positive anti-scl 70 (topoisomerase antibodies).

Vasculitic suggestive features include raised inflammatory markers, positive ANCA. Raised serum angiotensin converting enzyme may be seen in sarcoidosis. Sjögren's syndrome positive ANA, positive extractable nuclear antibodies, especially anti-Ro and La. Other causes of raised ACE include Hodgkin disease, diabetes, alcoholic hepatitis and hyperthyroidism.

RHEUMATOLOGICAL CONDITIONS WITH ENT FEATURES OR COMPLICATIONS

Vasculitides

There are many ways of classifying vasculitis including the size of the blood vessel involved, whether there is a granulomatous histology, whether there is ANCA positivity, immune complex deposition. **Table 18.1** lists most named types of vasculitis. Presentation is often specific with

TABLE 18.1 Classification of vasculitis

I Predominantly large vessel vasculitis	a) Takayasu arteritis b) Giant cell arteritis
II Predominantly medium sized vessel vasculitis	a) Childhood polyarteritis nodosa b) Cutaneous polyarteritis c) Kawasaki disease
III Predominantly small vessel vasculitis	Granulomatous: a) Granulomatosis with polyangiitis (Wegener's granulomatosis); eosinophilic granulomatosis with polyangiitis (Churg-Strauss syndrome) b) Microscopic polyangiitis Non-granulomatous: a) Microscopic polyangiitis b) Henoch-Schonlein purpura/IgA vasculitis c) Isolated cutaneous leucocytoclastic vasculitis d) Hypocomplementemic urticarial vasculitis (possibly drug induced) e) Cryoglobulinaemic vasculitis associated with RA, SLE, Sjögren's syndrome f) Anti-GBM disease
IV Variable	Cogan's syndrome Behçet's disease
V Other vasculitides	a) Behçet's disease b) Vasculitis secondary to infection (including polyarteritis nodosa associated with hepatitis B or streptococcal infections), malignancies, drugs (including hypersensitivity vasculitis) c) Vasculitis associated with connective tissue disease (systemic lupus erythematosus, dermatomyositis, rheumatoid arthritis) d) Isolated vasculitis of the central nervous system e) Unclassified

low-grade fever, tiredness, malaise with rashes, arthritis and multi-organ disease.

NOTES ON SPECIFIC VASCULITIDES WITH ENT IMPLICATIONS

Kawasaki disease

Kawasaki disease is the most common vasculitis seen in childhood. Typical features of Kawasaki disease are fever persisting for at least 5 days (mandatory criterion) plus four of the following five features:

- changes in peripheral extremities or perineal area
- polymorphous exanthema
- bilateral conjunctival injection
- changes of lips and oral cavity: injection of oral and pharyngeal mucosa
- cervical lymphadenopathy.

In the presence of coronary artery involvement (detected on echocardiography) and fever, fewer than five additional features are required to be certain of the diagnosis. Note that atypical cases occur that do not fulfill all criteria.

In terms of ENT features, the mucosal inflammation may present with swollen red tongue and lips, cracked lips, and angular stomatitis enough to make swallowing impossible. Clinically this can look similar to Stevens Johnson syndrome

The eyes may be red with aseptic conjunctivitis. Peripheral oedema of the dorsum of hands and feet may occur with or without rashes. The most frequent feature not in the diagnostic criteria is irritability and may signify cerebral irritation. The illness can be life-threatening acutely from myocarditis or later from coronary artery aneurysms. Treatment is evidence-based with intravenous immunoglobulin and aspirin, although steroids and immunosuppressants may be needed in non-responsive and severe cases. Coronary artery aneurysms can occur in atypical cases with incomplete diagnostic criteria where treatment is still needed.

Granulomatosis with polyangiitis (Wegener's granulomatosis)

Necrotizing granulomatous inflammation usually involves the upper and lower respiratory tracts with rhinosinusitis leading to bloody discharge, chronic nasal ulceration, nasal chondritis (Figure 18.1) leading to a saddle nose, laryngeal stenosis, chronic destructive sinusitis, proptosis, orbital wall damage leading to orbitonasal fistulas. Conductive hearing loss caused by middle ear inflammation, or eustachian tube dysfunction, pulmonary granulomata, necrotizing glomerulonephritis, skin rashes, arthritis, neuropathies, CNS, heart and GI involvement can all occur. In the localized phase of the disease 50% are ANCA negative whereas when generalized disease is present 90% are positive for PR3 ANCA.

The disease has a high mortality and requires urgent intensive treatment with high dose steroids, cyclophosphamide, plasma exchange for severe cases with methotrexate and/or rituximab in milder cases.

Eosinophilic granulomatosis with polyangiitis (Churg-Strauss syndrome)

This is a vasculitis characterized by asthma, hypereosinophilia, pulmonary infiltrates with eosinophilia rich granulomatous inflammation in the respiratory tract. Sinuses are affected with allergic rhinitis, sinusitis and polyps. Myocarditis, neuropathies, arthritis, skin purpura, renal and gut disease can occur. ANCA, usually with anti-MPO specificity, is detected in 40% of patients.

ENT manifestations of Behçet's disease

Behçet's disease (BD) is a multi-system vasculitis characterized by recurrent oral and genital ulceration, skin lesions

and ocular inflammation. Diagnostic criteria are based on recurrent oral ulcers occurring three times in 12 months plus two of the following: scarring recurrent genital ulcers, ocular involvement (uveitis or retinal vasculitis), skin lesions (such as erythema nodosum, pseudofolliculitis/pustolosis) and positive pathergy test (skin reaction to needle insertion). Other observed manifestations are arthritis, neurological disease and ENT involvement.

Audiovestibular involvement is frequent with sensorineural hearing loss in 23–32% of patients.² This is usually bilateral, affecting high frequencies and may be due

Figure 18.1 The changes in crusting found inside the nose from a patient with active granulomatosis with polyangiitis: (a) shows early changes with an angry mucosa and mucous hypersecretion; (b) demonstrates the end result of gross activity.

to vasculitis of vessels supplying the cochlea. Recurrent vertigo, bilateral vestibular hypofunction causing instability and bilateral Meniere's syndrome can occur. Neuro-Behçet's may present with vestibular neuronitis. Although CNS involvement is infrequently seen, peripheral nerve involvement with isolated case reports of facial paralysis and vocal cord paralysis are reported.

Ulceration of the oral cavity is common but oropharyngeal ulceration may be misdiagnosed as tonsillitis or pharyngitis. Rarely, laryngeal or oesophageal ulceration can lead to pharyngolaryngeal stenosis. Infrequently nasal symptoms such as nasal ulceration, dysosmia, obstruction and pain are experienced.

MAGIC syndrome

There is an association of autoimmune disorders such as Behçet's disease with relapsing polychondritis and inflammation of the auricular cartilages seen as part of the MAGIC syndrome (mouth and genital ulcers with inflamed cartilage).

Cogan syndrome

This is an autoimmune disorder of young people characterized by³:

- ocular symptoms with non-syphilitic interstitial keratitis
- audio-vestibular symptoms similar to those of Meniere's syndrome (sudden onset of tinnitus and vertigo accompanied by gradual hearing loss)
- an interval between the onset of the ocular and audio-vestibular features of less than 2 years.

Atypical cases occur without any inflammatory ocular manifestations, with interstitial keratitis and with delays of more than 2 years between the eye and ear symptoms. There are often neurological or systemic features of vasculitis with possible infectious or autoimmune triggers. Anti-HSP 70 antibodies may be a marker for the autoimmune nature of the hearing loss. ANCA positivity may occur. Treatment is with corticosteroids followed by immunosuppressive therapy with cyclophosphamide, methotrexate, azathioprine, cyclosporine or anti-TNF blockers such as etanercept and infliximab. Rituximab is also used.

Relapsing polychondritis (RP)

RP is a rare autoimmune disease with episodic flares of progressive inflammatory destruction of cartilage either as a primary condition or overlapping with rheumatoid arthritis, spondyloarthropathies, vasculitis or as a paraneoplastic condition. Acute phase reactants are raised and biopsy of affected tissues is characteristic. Elastic cartilage of the ear, hyaline cartilage of the tracheo-bronchial tree and joints, and fibrocartilage of the axial skeleton are involved. Because of significant morbidity and mortality systemic immunosuppression is required.

Systemic lupus erythematosus (SLE)

SLE is truly a multi-system inflammatory disorder affecting every organ with multiple presentations, a true masquerading condition where diagnosis can be difficult requiring specialist advice. Recently the Systemic Lupus International Collaborating Clinics (SLICC) classification 2012 has been proposed in addition to the 1997 American College of Rheumatology (ACR) diagnostic criteria (Tables 18.2 and 18.3). Both include a glossary of detailed definitions of component parts but are a start in making sense of a multifaceted disorder.

From an ENT perspective mucosal presentations occur in up to 45% of cases. In the mouth these include irregular raised white plaques with areas of erythema, silvery white scarred lesions, actual ulcers with surrounding redness occurring on soft or hard palates or on the buccal mucosa. These have a wide differential diagnosis including lichen planus, candidiasis, aphthous stomatitis, intra-oral herpes, Behçet's disease, bite induced lesions, leukoplakia and malignancy.

Oral and nasal ulcers occur. These are usually painless and may be the first presentation of the SLE. Discoid lesions may occur on the lips with erythema, swelling or atrophy and depigmented areas. Lymphadenopathy occurs in around 40% of cases with soft, non-tender discrete glands in the cervical, axillary or inguinal regions. These may warrant a biopsy to exclude other causes.

TABLE 18.2 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for systemic lupus erythematosus

Clinical criteria	Immunologic criteria
Requirements; 4 or more criteria (at least 1 clinical and 1 laboratory criteria) OR biopsy-proven lupus nephritis with positive ANA or Anti-DNA.	
1. Acute cutaneous lupus	1. ANA
2. Chronic cutaneous lupus	2. Anti-DNA
3. Oral or nasal ulcers	3. Anti-Sm
4. Non-scarring alopecia	4. Antiphospholipid Ab
5. Arthritis	5. Low complement (C3, C4, CH50)
6. Serositis	6. Direct Coombs test (do not count in the presence of haemolytic anaemia)
7. Renal	
8. Neurologic	
9. Haemolytic anaemia	
10. Leukopenia	
11. Thrombocytopenia (100,000/mm ³)	

From Petri et al., 2012⁴

TABLE 18.3 American College of Rheumatology revised criteria for diagnosis of systemic lupus erythematosus 1997

Criteria	Definition
Malar rash	Fixed erythema, flat or raised, over the malar eminences, tending to spare the nasolabial folds
Discoid rash	Erythematous raised patches with adherent keratotic scaling and follicular plugging; atrophic scarring occurs in older lesions
Photosensitivity	Skin rash as a result of unusual reaction to sunlight, by patient history or physician observation
Oral ulcers	Oral or nasopharyngeal ulceration, usually painless, observed by a physician
Arthritis	Non-erosive arthritis involving two or more peripheral joints, characterized by tenderness, swelling or effusion
Serositis	a. Pleuritis: convincing history of pleuritic pain or rub heard by a physician or evidence of pleural effusion, or b. Pericarditis: documented by ECG or rub or evidence of pericardial effusion
Renal disorder	a. Persistent proteinuria >0.5g per day or 3+ if quantification is not performed or b. Cellular casts: may be red cell, haemoglobin, granular, tubular or mixed
Neurological disorder	a. Seizures: in the absence of offending drugs or known metabolic derangements (eg. uraemia, acidosis, or electrolyte imbalance) b. Psychosis: in the absence of offending drugs or known metabolic derangements (eg uraemia, acidosis, or electrolyte imbalance)
Haematological disorder	a. Haemolytic anaemia with reticulocytosis, or b. Leucopenia < 4000/mm ³ , or c. Lymphopenia < 1500/mm ³ , or d. Thrombocytopenia < 100 000/mm ³ in the absence of offending drugs
Immunological disorder	a. Anti-DNA antibody to native DNA in abnormal titre, or b. Anti-Sm, presence of antibody to Sm nuclear antigen, or c. Positive finding of antiphospholipid antibodies based on: (1) an abnormal serum concentration of IgG or IgM anticardiolipin antibodies, (2) a positive test result for lupus anticoagulant using a standard method, or (3) a false positive test for syphilis known to be positive for at least 6 months and confirmed by Treponema pallidum immobilization or fluorescent treponemal antibody absorption test
Antinuclear antibody	An abnormal titre of antinuclear antibody by immunofluorescence or an equivalent assay at any point in time and in the absence of drugs known to be associated with 'drug-induced lupus' syndrome

Autoinflammatory diseases/hereditary periodic fever syndromes (HPFSs)

These rare genetic conditions are characterized by short and recurrent attacks including fever, often with a sore throat, tonsillitis, lymphadenopathy and general debility, with a severe inflammatory reaction (with raised leucocytosis, ESR, CRP, fibrinogen, serum amyloid A protein) with the patient well between attacks. Infection has to be excluded as it is clinically indistinguishable in an individual attack and often it is only after multiple courses of antibiotics that the pattern of the disorders is clear. Genetic testing needs to be through specialist clinics and specialist laboratories. Clinical clues are in recurrent or continuous symptoms, especially fever, rash, joint pain or arthritis, accompanied by very high acute phase reactant with a wide differential diagnosis. If attacks recur for longer than a year and especially if there is a family history, HPFS should be considered. Some may present very late into adult life.

They are disorders of the inflammasome with triggers including emotional and physical stress, the menstrual cycle and pregnancy, vaccination reactions in hyper-IgD syndrome (HIDS), local mucosal trauma (e.g. in PFAFA), cold as in some cryopyrin-associated periodic syndromes (CAPS) syndromes:

- **Familial Mediterranean fever (FMF)** is due to a gene mutation *MEFV*, location 16p13.3 proteins affected pyrin and marenosttrin. FMF may cause sensorineural hearing loss.

- **Hyperimmunoglobulinemia D (or hyper IgD syndrome)** with periodic fever syndrome (HIDS) gene mutation *MVK* located at 12q24, proteins affected mevalonate kinase deficiency. Most cases have marked reactions to immunizations. Febrile episodes with lymphadenopathy, rashes sometimes with hepatosplenomegaly, arthralgia, abdominal pain, irritability.
- **Tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS)** gene *TNFRSF1A* located 12p13, proteins affected TNF-receptor Type 1

Cryopyrin-associated periodic syndromes (CAPS):

- **This is a group of hereditary periodic fever syndromes with the same gene mutations but with very different phenotypes.** The gene *NLRP3 (CIAS1) mutation* at 1q44 affects the protein cryopyrin (NALP3/PYPAF1).
- **Muckle-Wells syndrome (MWS)** gene *NLRP3 (CIAS1)* at 1q44 inheritance protein affected cryopyrin (NALP3/PYPAF1). Clinical presentation with conjunctivitis in 44%, hearing loss in 32% with recurrent urticaria and uveitis.
- **Familial cold autoinflammatory syndrome (FCAS)** *NLRP3 (CIAS1)*, 1q44 protein affected Cryopyrin (NALP3/PYPAF1). Symptoms such as lip swelling after cold contact.
- **Chronic infantile neurologic cutaneous articular syndrome (CINCA)**, also known as neonatal-onset multi-system inflammatory disease (NOMID) *NLRP3 (CIAS1)*, 1q44 protein affected, Cryopyrin (NALP3/PYPAF1). Although onset is from the

neonatal period, diagnoses may not be made until adult. Features include daily fever, a measles-like macular rash (very like that in systemic onset arthritis), lymphadenopathy, splenomegaly and sensorineural deafness with ocular optic neuritis papillitis, intermittent oligoarticular arthritis with pathognomic patellar overgrowth and learning difficulties preventable with treatment. Treatment is with daily anakinra injections or with canakinumab, both IL1 receptor antagonists.

- **Shnitzlers syndrome** is like CAPS but late onset with no family history. Diagnosed only in adults. Consisting of an IgM gammopathy, chronic urticarial rashes, acute phase reactants, intermittent fever, arthralgia and arthritis, splenomegaly, lymphadenopathy, some deafness. There is a long-term risk of Waldenstrom's macroglobulinemia. It is interleukin-1 (IL-1) driven with 100% of cases responding to anakinra.
- **PFAPA syndrome** (periodic fever, aphthous stomatitis, pharyngitis and adenitis syndrome). The most frequent disorder in childhood accounting for around 50% of recurrent fever syndromes. There is no identifiable gene associated with this so the diagnosis is clinical. This disorder often responds to tonsillectomy; however, PFAPA may recover spontaneously. The evidence for adenoidectomy in addition to tonsillectomy is not established.⁷ Short courses of oral corticosteroids may help this condition. Although PFAPA is usually self-limiting attacks can occur frequently throughout childhood from a median age of 2.5 years and can last for a decade.
- **Blau syndrome and sarcoidosis:** sarcoidosis is a systemic disorder characterized by non-caseating granulomata affecting the lungs, skin, joints with arthritis, bony changes of osteitis, eyes with uveitis, calcium metabolism causing hypercalcaemia, muscle, and heart with skin lesions of lupus pernio, papules, nodules in infiltrated scars and erythema nodosum. Neurosarcoid can result in cranial nerve palsy and obstructive sleep apnea. Lymphadenopathy occurs in 15%. Salivary gland involvement (e.g. solitary parotid enlargement) occurs. Other ENT presentations include nasal perforation, sinonasal disease (where the nasal mucosa resembles apple jelly; (Figure 18.2)), laryngeal disease, and vocal cord deposits, trigeminal nerve or facial nerve mediated pain. Chest X-ray to look for perihilar lymphadenopathy or pulmonary infiltrates, and urinalysis for proteinuria or haematuria suggestive of a nephritis as the rare renal involvement should always be done. Patients should be sent for ophthalmological review for signs of uveitis that may be subclinical. In childhood, chest and kidney involvement is rare. Blau syndrome is associated with CARD15/NOD 2 mutations and is very like young onset sarcoidosis. Most patients develop polyarticular arthritis, with cutaneous and eye manifestations.

Systemic sclerosis

This condition is caused by a combination of low-grade inflammation with increased fibrosis in soft tissues and in blood vessels. As well as Raynaud's phenomenon, the skin becomes stiff and vascular insufficiency can lead to

Figure 18.2 Examination of the nasal mucosa from a patient with sarcoidosis reveals apple jelly nodules.

finger-tip ulcers. The antinuclear factor is usually positive. Lung and renal disease and pulmonary hypertension are significant causes of death. From an ENT perspective the soft tissues of the mouth can become stiff with decreased mouth opening.

EFFECTS OF IMMUNOSUPPRESSION FROM DISEASE OR TREATMENT

Many of the rheumatological conditions are immunosuppressive in themselves, as are the drugs, including steroids, used to treat the conditions. ENT infections may be increased in these situations. Immunizations against winter flu, pneumococcus and any killed vaccines are safe and are important to reduce infection risk although the efficacy may vary according to the time between vaccination and drug treatments.

TREATMENTS INCLUDING DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS) AND BIOLOGIC THERAPIES

Treatments of the rheumatic disorders include steroids, disease-modifying anti-rheumatic drugs (DMARDS – methotrexate, ciclosporin, azathioprine, leflunamide) cyclophosphamide and biologic drugs against specific

cytokines (e.g. anti-TNF blockers – etanercept, infliximab, adalimumab), anti-IL6 blocker (tocilizumab), anti-IL1 blockers (anakinra or canakinumab and rilonacept), anti-B cell drugs such as rituximab and belimumab and the anti-costimulatory molecule blocker abatacept. Immunomodulatory doses of intravenous immunoglobulin may be used. Colchicine may be used. Several drugs in combination are often required.

FUTURE RESEARCH

- ▶ Long-term outcome studies of childhood ENT diseases such as GWP with laryngeal stenosis
- ▶ Trials of early aggressive treatment of isolated ENT autoimmune disease

KEY POINTS

- Airway and anaesthetic risks occur:
 - arthritis of the TMJ and decreased jaw growth
 - arthritis of the cricoarytenoid joint
 - arthritis of the cervical spine
 - disorders with tracheal stenosis.
- Patients with systemic sclerosis with tight soft tissues and decreased mouth opening.
- Many rheumatological disorders have a relatively high mortality rate and high morbidity rates if treatment is delayed.
- Multi-system disorders may have ENT features as the clue to diagnosis.
- Lymphomas and leukaemias can be associated with autoimmune presentations with raised auto-antibodies occurring as an epi-phenomenon and unless tissue diagnosis is sought misdiagnoses can occur.

MICROORGANISMS

Ursula Altmeyer, Penelope Redding and Nitish Khanna

Introduction	181	Classification of bacterial organisms	183
Basic concepts in microbiology	181	References	193

SEARCH STRATEGY

This chapter collates basic consensus knowledge of bacteriology. Laboratory practices described are based on Public Health England's Standards for Microbiology Investigations (SMI). Data in this chapter may be updated by a PubMed search using the keywords: basic concepts in microbiology; classification of bacteria based on gram staining; gram positive; gram negative; staphylococci, streptococci, enterobacteriaceae, anaerobes; mycobacteriae; spirochetes.

INTRODUCTION

The human body is a habitat that supports single-cell microorganisms in numbers that by far exceed the number of its own cells. Most of these organisms have evolved over millions of years in close association with our own species, forming what is referred to as the human microbiome.

Contained in their ecological niche, these bacteria can be essential for the survival of the host body, although if given the opportunity to leave their niche, for example through injury or surgery, their presence may equally lead to disease. Some of these beneficial, or at least harmless, tenants also have the potential to cause opportunistic infections in host organisms that are particularly susceptible, whether that be due to overall poor health, extremes of age, or constitutional or iatrogenic immunosuppression.

In comparison, the number of pathogens whose presence is always abnormal and will always lead to disease is relatively small.

The advent of antimicrobials in the first half of the 20th century has been one of the most transformative developments in medicine for both good and bad.

The emergence of antimicrobial resistance and the increasing number of resistant strains in circulation together with a lack of new antimicrobial agents means that modern healthcare is under pressure to reassess its attitude towards infection and develop alternative diagnostic and therapeutic approaches.

BASIC CONCEPTS IN MICROBIOLOGY

The human body is colonized with a wide range of microorganisms and different body sites will have a very characteristic normal or resident flora ([Table 19.1](#)).

A few sites are considered sterile ([Table 19.2](#)) and recovery of any bacterial growth from such a site should merit consideration of systemic treatment if infection is clinically suspected. In this context it is important to be able to differentiate between possible contamination and infection; this becomes easier if multiple samples can be submitted and examined ([Table 19.3](#)).

Most organisms commonly recovered from clinical specimens can be identified on the basis of few simple tests:

- Gram staining and light microscopy
- growth requirements (e.g. aerobic or anaerobic growth)
- metabolic properties.

The best known of these techniques is the Gram stain, which was developed by the Danish microbiologist Hans-Christian Gram (1853–1938) as a stain that is able to differentiate between human and bacterial tissue more readily than the histological stains in use at the time. The presence or absence of an outer membrane leads to differences in uptake of methylene blue, and has coined the terms 'Gram positive' and 'Gram negative' ([Figure 19.1](#)).

This technique is still in daily use and is performed on any positive blood culture and any sterile site sample submitted for bacterial culture.

TABLE 19.1 Resident flora of selected body sites

Site	Examples of resident flora
Skin	Predominantly Gram positive organisms: <ul style="list-style-type: none"> • staphylococci • streptococci • corynebacteriae Gram negatives may be present on lower body half
Oral cavity	Mixed flora: <ul style="list-style-type: none"> • staphylococci • streptococci • anaerobic organisms • bacillus species • yeasts Consider cover of oral flora in both human and animal bite wounds.
Upper respiratory tract	Predominantly Gram positives: <ul style="list-style-type: none"> • staphylococci • streptococci, incl <i>S. pneumoniae</i> and <i>S. pyogenes</i> Some Gram negative organisms, e.g.: <ul style="list-style-type: none"> • <i>Haemophilus influenzae</i> • <i>Moraxella catharrhalis</i> • <i>Neisseria meningitis</i>
Digestive tract, especially colon	Mixed flora: <ul style="list-style-type: none"> • anaerobic organisms • Gram negatives – ‘coliforms’ • some Gram positive organisms – enterococcus species • yeasts

TABLE 19.3 Contaminant versus infection

More likely contaminant	More likely to represent infection
Few organisms present on microscopic examination	Large number of organisms present on microscopic examination
Lack of white blood cells on microscopic examination	White blood cells present on microscopic examination
Growth absent from routine culture, present in enrichment only	Abundant growth in routine culture
No clinical signs of infection	Patient displays clinical signs of infection

**Figure 19.1** Gram positive and Gram negative cell wall structure in comparison.

Depending on the sample site and its resident flora, different sets of bacterial culture media are inoculated and incubated overnight. By careful choice of medium and incubation environment (e.g. CO₂, anaerobic, different incubation temperatures) it is possible to encourage growth of a wide range of potential pathogens.

Clinical information often provides clues about potential pathogens and may therefore play a crucial role in selection of appropriate media, for example selective media for mycobacteria or *Actinomyces* (Table 19.4).

For some organisms (e.g. *Staphylococcus aureus* or *Streptococcus pyogenes*), a formal identification is possible

by performing very simple tests on the first day a growth is observed on the culture medium.

The majority of Gram negative organisms, however, will look very similar in culture and require further differentiation on the basis of their metabolic profiles. This is usually done by automated or semi-automated systems that are able to perform an entire range of different reactions in one step and often also carry out antibiotic susceptibility testing at the same time.

Some tests, especially susceptibility testing, whether performed manually as disc testing or by automation, require the organism to be grown in pure culture and can,

TABLE 19.4 Different types of media used for bacterial culture

Medium type	Use	Example
Enrichment medium	Improves recovery of organisms from sterile sites when only few organisms may be present in the sample and there is no resident flora	Robertson's Cooked Meat Broth Blood culture medium
Nutrient medium	Improves recovery of fastidious organisms	Chocolated blood agar
Selective medium	Selectively allows growth of organisms of interest while suppressing growth of normal flora	Hoyle's tellurite medium for recovery of corynebacterium species

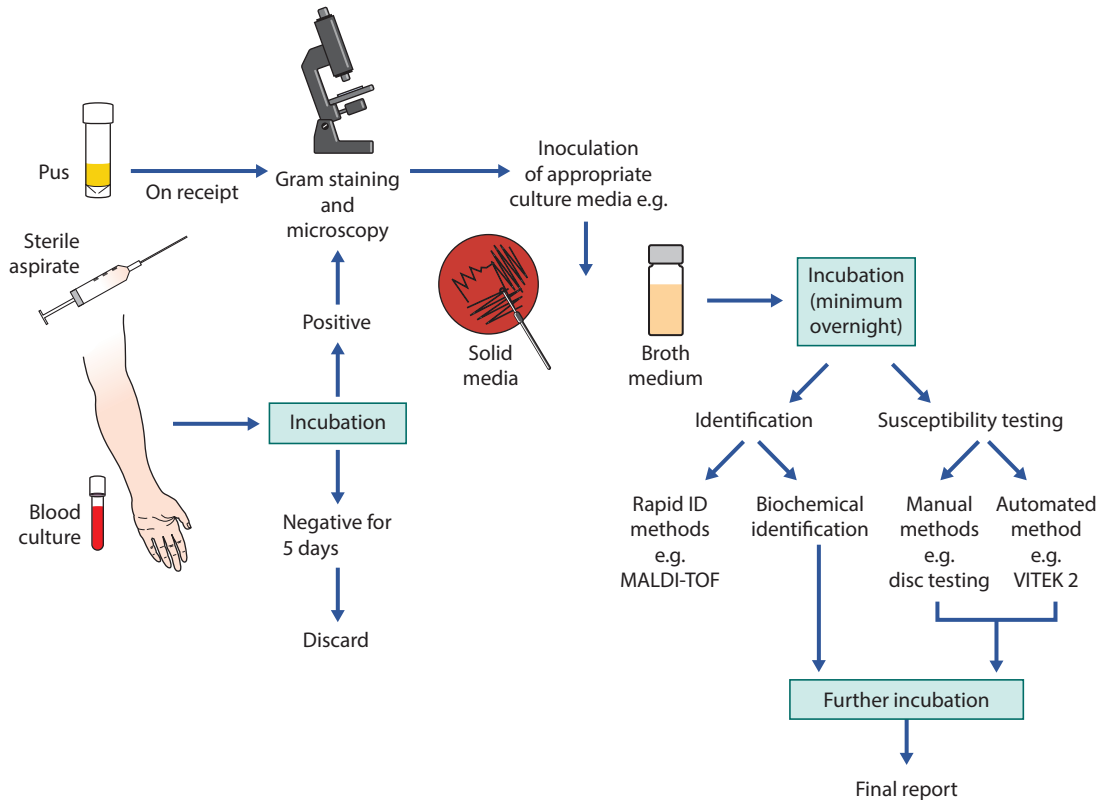

Figure 19.2 Processing of sterile site samples involves several overnight incubation steps. If organisms are not present in pure culture in the original sample a further step of subculture and incubation may be required in order to be able to perform formal identification and susceptibility testing. On average 48 hours are required to produce a final report on a sterile site sample.

at the earliest, be performed after overnight incubation of a sample (Figure 19.2).

Polymerase chain reaction (PCR) has been a mainstay technique in virology for some time and is also available for bacteriological diagnosis. It is widely employed in reference laboratories for typing purposes and CSF is often tested for presence of genomic material from *Streptococcus pneumoniae*, *Haemophilus influenzae* and *Neisseria meningitidis*.

Another more rapid diagnostic technique that has recently come into routine use in many laboratories is matrix-assisted laser desorption/ionization and time of flight analysis, or MALDI-TOF, which uses mass spectrometry to measure species-specific profiles of biomolecules, such as peptides and sugars, and larger organic molecules following laser ionization of a sample absorbed onto a specific test matrix. This is currently only possible from a pure culture, but may become available as a technique usable directly on clinical samples.

In the future, whole genome sequencing may come to supersede conventional culture techniques entirely, as it is able to not only identify bacterial species directly from clinical samples, but is also able to deliver a full profile of antimicrobial resistance. This has the benefit of identifying genes responsible for resistance (genotype) as opposed to current conventional susceptibility testing that detects phenotypic resistance.

CLASSIFICATION OF BACTERIAL ORGANISMS

The Gram stain continues to be one of the most frequently used and simple tests performed in clinical microbiology laboratory practice, and gram staining of pus and tissue samples can provide vital early information on possible causative organisms in an infective process. Figure 19.3 provides an overview of gram positive organisms and gram negative organisms (Figure 19.5) commonly encountered in clinical practice.

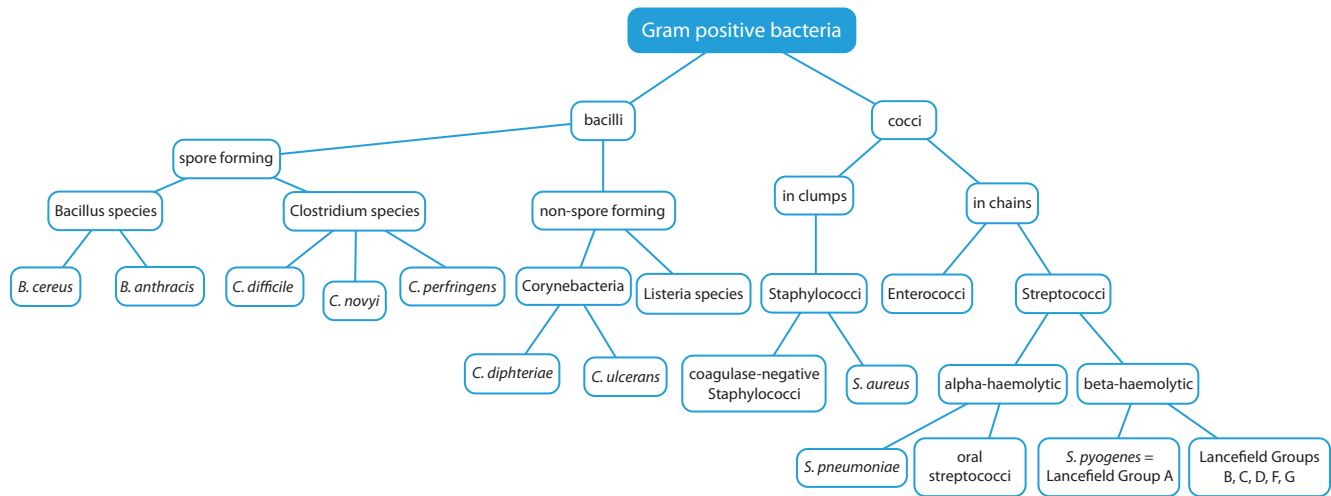

Figure 19.3 Overview of medically important Gram positive organisms.

Gram positive organisms

STAPHYLOCOCCI

Staphylococci are Gram positive, catalase positive organisms that on microscopy after Gram staining lie together in clusters, reflecting the fact that they are able to divide in more than one geometrical plane. Staphylococcal species form part of the normal skin flora.

There are several species of coagulase negative staphylococci. Most are skin commensals with low pathogenic potential, although they are able to cause indolent infections of intravascular devices and implants. An exception to this is *Staphylococcus lugdunensis*, which although coagulase negative, produces infections which present clinically much like infections with *Staphylococcus aureus*.

S. aureus is the major human pathogen in this group and it can be distinguished from other staphylococci by presence of a coagulase, which clots plasma.

This allows the organism to become coated in plasma and evade detection by phagocytes. It also plays a role in the formation of abscesses, which sequester the organism from access by the host immune system. *S. aureus* also produces a hyaluronidase, which facilitates spreading of the organism through host connective tissue.

Some strains are capable of producing exotoxins, among which are several enterotoxins, an exfoliative toxin and a toxin capable of producing staphylococcal toxic shock. Another important exotoxin is the Panton-Valentine leukocidin (PVL) toxin, which is associated with an increased ability to cause disease, usually in the form of skin and soft tissue infection with recurrent abscesses. In the UK, about 2% of all *S. aureus* isolated from clinical samples are PVL positive.¹

Rarely, strains carrying this exotoxin can cause severe necrotizing pneumonia with a high mortality rate. Specific infection control measures should be adhered to if a patient carries a PVL positive strain and guidance regarding this is available from public health authorities.

S. aureus most commonly colonizes the anterior nares; about 20% of the population are permanent carriers and

60% carry it intermittently; the remaining 20% are non-carriers which are almost never colonized.²

The main manifestations of community-acquired disease caused by *S. aureus* are superficial skin and soft tissue infections, purulent infections in the form of folliculitis and deep tissue abscesses. Enterotoxin carrying strains are a cause of food poisoning.

In the hospital environment, the organism plays a major role in hospital-acquired infection, most commonly in surgical site infection, infection of surgical implants and intravascular device infection.

S. aureus bacteraemia (SAB) is a severe complication of *S. aureus* infection, which has a mortality rate of up to 30% and frequently involves secondary deep foci of infection, such as solid organ abscesses, spondylodiscitis and endocarditis. Even if treated adequately with intravenous antibiotics and removal of the focus of infection, a significant number of cases will experience a relapse or develop metastatic infection.

The majority of strains of *S. aureus* currently in circulation produce a penicillinase that renders them resistant to benzyl-penicillin, making penicillinase-stable penicillins, such as flucloxacillin, the first-line treatment. Unless the patient is penicillin allergic, intravenous treatment with one of these agents is the gold standard treatment of invasive *S. aureus* infection.

For penicillin allergic individuals, or if the isolate is methicillin-resistant (MRSA), vancomycin is the agent of choice for invasive infection.

If the infection is clinically severe or likely to involve a biofilm, as in prosthetic joint or intravascular device infections, a second anti-staphylococcal agent is sometimes added. The choice of this second agent will depend on the antibiotic susceptibility profile, but may include agents such as gentamicin, rifampicin, fusidic acid, trimethoprim, and clindamycin. However, there is scant clinical evidence that dual therapy for SAB is any more efficacious than single agent therapy.³

Methicillin-resistant *S. aureus* (MRSA) first emerged in the 1960s, but since has become widespread, both within the hospital environment as well as in the community and

causes the same range of infections as the methicillin-susceptible strains (MSSA).

All strains of MRSA are resistant to penicillinase-stable β -lactams such as flucloxacillin; this is mediated by carriage of a resistance gene cassette, *mecA*, which codes for altered cell wall components which the β -lactam agents are unable to bind to.

Susceptibility to other anti-staphylococcal agents varies, but in contrast to initial concerns, vancomycin resistant strains are extremely rare (case reports only from the United States, Japan and most recently Portugal)⁴ and the agent remains the intravenous treatment of choice for MRSA infection.

Biofilms

Like many other organisms, *S. aureus* is capable of forming a biofilm, in which the organisms form an aggregate within a slime-like extracellular matrix.

These are well known to form on non-biological surfaces which are immersed in a liquid, such as an intravascular device immersed in the blood stream, but may also exist on mucosal surfaces within the body, such as the tonsils or the mucosa of the sinuses and the middle ear.⁵

The importance of biofilms is becoming recognized in a range of fields, from treatment of intravascular device infections, in marine engineering and shipbuilding, to use of biofilms for removal of oil spills from marine environments (Table 19.5).

The formation of a biofilm initially involves a stage of reversible attachment of the planktonic (free-living) form of the organism to a surface. As the biofilm develops, this attachment becomes irreversible and the bacterial community becomes covered in an extracellular matrix slime. Within this matrix the individual cells communicate with each other via a process called quorum sensing, which allows regulation of gene expression throughout the colony. A fully mature biofilm is able to release planktonic organisms back into the environment. Biofilms may involve more than one bacterial species.

Treatment of infections involving a biofilm are complicated by both the presence of the extracellular slime, which makes penetration of antimicrobials difficult, and the fact that the bacteria themselves will exhibit reduced metabolic activity and divide less frequently than as their free-living planktonic forms. This renders many antimicrobials ineffective. Agents that act on the ribosome,

such as rifampicin or macrolide agents, remain effective in these organisms, unless a resistance mechanism is present. Successful treatment of infections involving a biofilm may require mechanical debridement of the biofilm and if a device is involved, this may ultimately require removal. Development of improved device surfaces that do not allow attachment of the organisms to initiate biofilm formation is a focus of research that may in the future prevent device-related infections.⁷

Research into treatment strategies involving disruption of the biofilm by mechanical measures and eradication of the biofilm with topical agents such as mupirocin or manuka honey may also result in more effective new treatments of biofilm infection.⁸

STREPTOCOCCI

Streptococci form the second group of medically important Gram positive cocci. On microscopy, they appear to lie in chains, the length of which can vary. In the laboratory, they are initially classified by examining growth on a blood agar plate for the presence and type of haemolysis (Figure 19.4 and Table 19.6).

Figure 19.4 Alpha, beta and gamma haemolysis on blood agar.

TABLE 19.6 Streptococci by type of haemolysis

Type of haemolysis	Examples
α -haemolysis	<i>S. pneumoniae</i> Oral streptococci - 'viridans' group Some enterococci
β -haemolysis	<i>S. pyogenes</i> <i>S. agalactiae</i> <i>S. anginosus/milleri</i> Some enterococci
γ -haemolysis	Denotes a lack of haemolytic activity

β-haemolytic streptococci

The β-haemolytic streptococci are usually further classified by using a latex agglutination test to determine their Lancefield group.

Medically relevant streptococci usually belong to Lancefield groups A–D, F and G (Table 19.7).

Of the β-haemolytic streptococci, *Streptococcus pyogenes* is particularly worth noting, partly due to the range of clinical presentations caused by this organism, but also due to its particular virulence (Table 19.8). It not only expresses a wide range of proteins which enable it to evade host defence mechanisms, but certain strains also produce an exotoxin capable of acting as a superantigen, leading to streptococcal toxic shock syndrome. This represents a true medical emergency with a high mortality and a substantial number of patients with this presentation require transfer to an intensive care facility as they frequently require circulatory and ventilatory support as well as renal replacement therapy.⁹

S. pyogenes causes a range of suppurative infections from tonsillitis to skin and soft tissue infections, but is also capable of eliciting a number of non-suppurative immunological complications (Table 19.9), with certain M-protein type strains showing association with specific presentations.

S. pyogenes remains sensitive to penicillins and is usually also sensitive to macrolide antibiotics and clindamycin. Clindamycin has a particular role in the treatment of severe infection with *S. pyogenes*, as it reduces toxin production by interrupting protein synthesis at the bacterial ribosome.

Streptococci of the Lancefield groups C and G are also capable of causing severe skin and soft tissue sepsis that is clinically indistinguishable from infections with *S. pyogenes*.

Group F streptococci, also commonly referred to as the *Streptococcus milleri* group, are part of the normal flora of the gut and occasionally the oral cavity. They have a particular propensity to cause deep-seated abscesses and infection should be treated by drainage of the abscess, followed by a prolonged course of antibiotics to minimize the rate of recurrence.

α-haemolytic streptococci

Streptococcus pneumoniae is the clinically most important organism amongst the α-haemolytic streptococci. It colonizes the healthy upper respiratory tract, more often in children (carriage rate up to 53%) than in adults (carriage rate 4%).¹⁰

S. pneumoniae can be more difficult to grow in culture than other streptococci, but when it does it can readily be identified in the laboratory by a characteristic 'draughtsman' shape of the individual colonies, alpha-haemolysis on blood agar and an inhibitory zone to a disc containing optochin, which disrupts the fragile cell wall.

Prior to introduction of the heptavalent pneumococcal vaccine into paediatric vaccination schedules, *S. pneumoniae* was the most common bacterial cause of otitis media in children. It has now been replaced by

TABLE 19.7 β-haemolytic streptococci by Lancefield group

Lancefield group	Species

Necrotizing fasciitis	Sydenham's chorea
Surgical site infection	
Puerperal sepsis	

Haemophilus influenzae, but still remains the second most common bacterial cause.¹¹

Overall, the introduction of the vaccine has led to a shift of circulating strains from those included in the vaccine to previously less common strains.

In the adult population, *S. pneumoniae* is most commonly found in the classic lobar pneumonia, but also plays a role as a causative agent of bacterial meningitis which may arise from an infected mastoid or sinus cavity and has a high rate of neurological sequelae, especially permanent hearing loss.

Contiguous infection from the mastoid or sinuses may also result in formation of intra-cerebral abscesses. These are a radiological diagnosis, and ideally drainage and sampling should precede initiation of antimicrobial treatment. Drainage itself is mandatory to achieve cure of disease and intravenous treatment with an agent that penetrates well into the brain tissue should be extended to at least 6 weeks.

Invasive strains of *S. pneumoniae* are usually capsulated, rendering asplenic individuals particularly vulnerable to infection and therefore available vaccines against capsulated organisms (i.e. against *S. pneumoniae*, *H. influenzae* and *N. meningitidis*) should be administered to any patient undergoing splenectomy.

High dose intravenous benzyl-penicillin is the treatment of choice of pneumococcal sepsis, but in some countries, especially in southern Europe, strains with a raised minimum inhibitory concentration for penicillin (MIC) are in circulation, which display intermediate susceptibility or resistance to benzyl-penicillin. Invasive infection with these strains should be discussed with an infection specialist, who may recommend treatment with a third generation cephalosporin, vancomycin and rifampicin or a fluoroquinolone with activity against *S. pneumoniae*, such as levofloxacin or moxifloxacin.

Ciprofloxacin has little useful activity against *S. pneumoniae* and should be avoided.

Other α -haemolytic streptococci, often referred to as viridans streptococci alluding to the green tinge of the blood agar caused by the α -haemolysis, mainly play a role in medicine as causative agents of sub-acute bacterial endocarditis.

ENTEROCOCCI

Enterococci are relatives of the streptococci most commonly found as gut commensals. They are indistinguishable from streptococci on Gram stain and haemolysis on blood agar can be variable. They frequently react with the reagent for the Lancefield group D.

In clinical samples, they often represent colonization rather than infection, especially in samples from chronic wounds or the nasopharynx of patients currently on antimicrobial treatment. They can contribute to intra-abdominal infections and cause urinary tract infections. Enterococcal bacteraemias may lead to infective endocarditis and merit further investigation with an echocardiogram; they should be treated with an appropriate course of intravenous antimicrobials.

Enterococci are commonly sensitive to amoxicillin or vancomycin, but can carry multiple resistance genes, including resistance to glycopeptides (i.e. vancomycin), making treatment difficult.

Gram positive bacilli

The main distinction between the different Gram positive bacilli lies in the presence or absence of spore formation.

Bacillus species, such as *Bacillus anthracis* and *Bacillus cereus* and *Clostridium* species, like *Clostridium tetani*, *Clostridium perfringens* and *Clostridium difficile*, all form spores, which preserve the organism in unfavourable conditions and can remain viable for considerable amounts of time. This has implications for both treatment and infection control aspects – treatment may have to be prolonged, taking into account that spores may reactivate after antimicrobials have been discontinued (e.g. post-exposure prophylaxis of inhalatory anthrax)

and any disinfecting agents have to be active against the spore form (e.g. lack of activity of alcohol hand gels against spores of *C. difficile*).

CLOSTRIDIUM DIFFICILE

Toxin-producing strains of this spore forming anaerobic Gram positive rods are the causative agent of a form of toxin-mediated bacterial diarrhoea (now called *C. difficile* infection (CDI), previously referred to as *C. difficile* associated diarrhoea (CDAD)), which may lead to the development of potentially lethal pseudomembranous colitis.

Carriage rates of *C. difficile* vary in different age groups – in infants the carriage rate can be as high as 70%, in healthy adults it is usually <3%.¹²

The use of certain antimicrobial classes is associated with an increased risk of CDI (Table 19.10), although other risk factors, such as use of proton pump inhibitors, presence of naso-gastric tubes, abdominal surgery or length of hospital stay also play a role. One possible control strategy of CDI is therefore restricting the use of these agents.

If CDI is suspected, the patient should be isolated and faecal samples tested for the presence of *C. difficile* toxin. Any contributing factors, such as proton pump inhibitors and antimicrobials should be removed, if possible.

Clinical severity of disease should be assessed and treatment strategies appropriate for the severity of the disease should be chosen. This may include oral metronidazole or vancomycin, but may also include intravenous immunoglobulins or colectomy in life-threatening cases.

Fidaxomicin is a recently licensed macrocyclic antibiotic that targets clostridium species specifically. The agent has recently been approved for restricted use in NHS Scotland, but guidance on its use in English NHS trusts is still outstanding.

As the concept of treating an infection caused by antimicrobials with another antimicrobial is somewhat illogical, non-antimicrobial methods of treating CDI are being investigated. A novel approach to the treatment of recurrent CDI that is becoming increasingly popular is the use of faecal transplantation to replace the abnormal gut flora with organisms that prevent overgrowth of *C. difficile*. This method of enhancing 'colonization resistance' has shown promising results in a number of studies.^{13, 14}

Local protocols for treatment and infection control procedures are available in most hospitals.

TABLE 19.10 Antibiotics and CDI

Antibiotic classes most frequently associated with CDI

- Clindamycin
- Quinolones
- Broad-spectrum penicillin – β -lactamase inhibitor combinations
- Cephalosporins

CORYNEBACTERIA

The *corynebacteria* and *listeria* are non-sporeforming Gram positive bacilli.

On Gram staining, both appear as pleomorphic Gram positive rods, often lying together in formations resembling Chinese lettering.

The different species of *corynebacteria* are indistinguishable on Gram stain, and in blood cultures they are frequently found as the result of contamination with skin commensals. These species may be involved in intravascular device associated infection.

Corynebacterium diphtheriae is the most important human pathogen. Diphtheria classically presents as a severe pharyngitis with pathognomonic formation of pseudomembranes. The organism can be grown on selective media containing tellurite and produces characteristic black colonies with a 'daisy head' edge.

There are four subspecies of *C. diphtheriae*, all of which are able to produce diphtheria toxin, the gene for which is integrated into bacterial genome by a lysogenic phage.

This toxin is made up of two protein subunits. Subunit B mediates entry of the toxin into the cell, where subunit A interrupts protein synthesis by inhibiting the elongation factor EF-2.

Mortality may arise from upper airway obstruction as a result of severe soft tissue swelling, but toxin-mediated myocarditis and polyneuritis are important contributing factors and anti-toxin should be administered to prevent death as well as significant neurological sequelae.

As the diphtheria toxoid vaccine is part of the routine childhood vaccination programme and has a good uptake (>94%), diphtheria is rare in the British population. The last case of respiratory diphtheria in Britain occurred in 1997, with only eight cases all in all since 1986. The patients in all cases had travelled to endemic areas (figures from Public Health England).¹⁵

Arcanobacterium haemolyticum is a Gram positive bacillus that produces haemolysis on blood agar. It is a

cause of bacterial pharyngitis associated with a maculopapular rash in young adults, which clinically is similar to pharyngitis caused by Group A streptococci.

Gram negative organisms

As mentioned earlier, [Figure 19.5](#) provides an overview of gram negative organisms commonly encountered in clinical practice.

The Gram negatives are distinguished from Gram positive organisms by a different cell wall structure.

In Gram negatives, the teichoic acid component that stains blue in Gram staining is much thinner and surrounded by an outer bi-layer membrane.

This membrane contains lipopolysaccharides that can act as superantigens and are responsible for triggering cytokine cascades that cause the systemic effects seen in Gram negative sepsis. This is sometimes referred to as the Gram negative endotoxin.

The periplasmic space between the outer membrane and the cell wall is where a number of Gram negative antibiotic resistance mechanisms are located (see also [Figure 19.1](#)).

GRAM NEGATIVE COCCI

Neisseria

Neisseria are the medically most important Gram negative cocci.

A number of non-pathogenic *Neisseria* spp. are commensals in the upper respiratory tract, but even the potentially highly pathogenic *N. meningitidis* is carried asymptotically by almost 24% of 19-year-olds; the carriage rates in young children and adults are generally lower than this.¹⁶

On Gram staining, neisseriae appear as small Gram negative diplococci. They will usually grow readily on a nutrient rich medium, such as chocolate blood agar, but selective media are available.

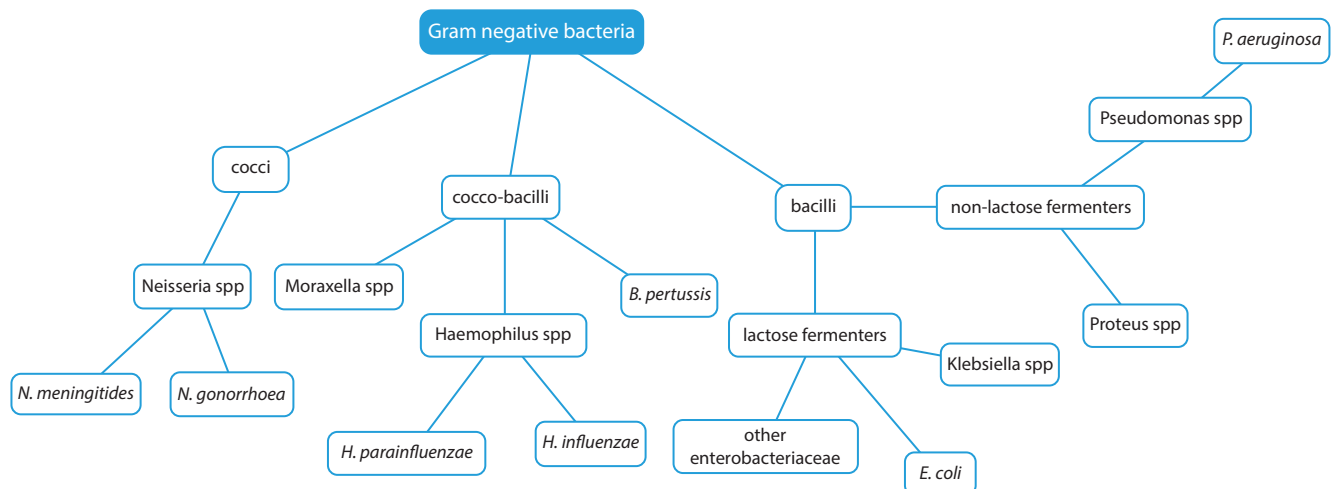

Figure 19.5 Overview of medically important Gram negative organisms.

Clinically *N. meningitis* can present with three distinct clinical syndromes: meningococcal meningitis, meningococcal septicaemia and meningococcal septic arthritis.

The first line treatment for suspected infection with *N. meningitis* is high dose ceftriaxone (i.e. 2g IV twice daily). In patients with anaphylaxis to penicillins or cephalosporins, therapy should be discussed urgently with an infection specialist.

The infection is a notifiable disease and referral to public health should be made in order to allow early contact tracing and, where indicated, offer post-exposure prophylaxis to household contacts and health-care workers.

Vaccines targeting specific surface lipopolysaccharides are available for all major serogroups of *N. meningitidis*, but at present only the vaccine against serogroup C forms part of the UK vaccination schedule.

Neisseria gonorrhoea is indistinguishable from *N. meningitidis* on both Gram staining and appearance in culture, but they differ in their capability to metabolize glucose and maltose, which is used in the laboratory to identify them biochemically.

N. gonorrhoea can be carried asymptotically in the upper airway as well as in the genito-urinary tract; infection may present as bacterial pharyngitis and it is not uncommon to isolate them from throat swabs.

Haemophilus influenzae

Haemophilus influenzae appears on microscopy as a Gram negative very short rod or cocco-bacillus. It has specific growth requirements in form of haemin and nicotinamide adenine dinucleotide and therefore grows more readily on a nutrient agar like chocolate blood agar.

Some strains are encapsulated, and six capsular serogroups (a–f) have been described.

Encapsulated strains, particularly strains of serogroup b, are associated with invasive disease. Asymptomatic carriage is common.

Infection can present as otitis, sinusitis or mastoiditis, acute bacterial meningitis and epiglottitis, but the most frequent presentation is as a lower respiratory tract infection.

Similarly to *S. pneumoniae*, *H. influenzae* may also be a causative agent in intra-cerebral abscess formation.

Moraxella catarrhalis is a Gram negative cocco-bacillus which is very similar to *Haemophilus* in that it forms part of the normal flora of the respiratory tract, but can play a role in otitis, sinusitis and infections of the lower respiratory tract, such as bronchitis and exacerbations of chronic obstructive pulmonary disease.

Some strains of *Moraxella* and *Haemophilus* produce a β -lactamase that renders them resistant to amoxicillin, but these strains will usually be sensitive to a penicillin with a β -lactamase inhibitor, such as amoxicillin with clavulanic acid and cephalosporins; other treatment options may include macrolides, quinolones or a tetracycline.

Bordetella pertussis

Bordetella pertussis, the causative agent of whooping cough, is a Gram negative organism of the upper respiratory tract that is exceedingly fastidious and conventional culture of this organism for diagnostic purposes has now been entirely abandoned in favour of PCR and serology.

Whooping cough is characterized by a bi-phasic clinical course. The early stage presents relatively non-specific with malaise and fever and is followed by a lengthy toxin-mediated phase of severe paroxysmal coughing, which may be accompanied by post-tussive emesis and is followed by a rapid intake of breath, the characteristic whooping.

In infants, the paroxysmal coughing can lead to significant hypoxia and be potentially fatal. Other risk groups include the elderly, immunosuppressed individuals and patients with chronic respiratory disease.

Whooping cough is notifiable and contacts, especially if small children are among them, should be offered post-exposure prophylaxis.

Cases of pertussis have been increasing in the past few years. The vaccine is included in the vaccination schedule, but it is unclear for how long the vaccination actually protects against the effects of pertussis toxin. Due to this a pertussis booster vaccination is offered to women in the third trimester of pregnancy, as immunity of the mother will minimize the risk of the infant becoming infected.

Gram negative bacilli

As appearances in Gram staining and often also in culture are very similar between different species of this group, identification is usually performed on the basis of biochemical properties.

One of these is dependence on the presence of oxygen; although most organisms are facultative anaerobes that are capable of anaerobic metabolism if required, dependence on oxygen or strictly anaerobic growth can be a useful pointer towards a putative identification of a Gram negative organism.

Another useful reaction is the ability to metabolize lactose, and on the basis of this they can be split into lactose fermenters and non-fermenters. A number of commonly used media for the culture of Gram negative organisms, such as the MacConkey agar, contain a colour indicator and if the organism ferments lactose the resulting change in pH will lead to a colour change (Figure 19.6), allowing for a categorization of the organism on the first day that growth is observed.

The third bench procedure that may aid in early identification of certain Gram negative bacilli is the test for the presence of cytochrome oxidase.

Further identification is usually undertaken by means of semi-automated methods.

Overall, there is a large number of Gram negative bacillus species, but of these only a few are commonly found in human disease.

Figure 19.6 Non-lactose-fermenting (NLF) and lactose-fermenting (LFC) enterobacteriaceae on MacConkey agar. Courtesy of Jasminde Karde and Margaret Woods, Department of Microbiology, Golden Jubilee National Hospital, Clydebank, UK.

ENTEROBACTERIACEAE

The enterobacteriaceae are a group of Gram negative bacilli that are part of the resident flora of the human gut. They are facultatively anaerobic and many of these organisms are common in clinical isolates, although only few of them are invariably pathogenic (Table 19.11).

Enterobacteriaceae usually possess one or more flagellae and are therefore mobile – an extreme example of these are *Proteus* spp., which are capable of swarming across an entire agar plate and overgrow other organisms that may be present in the sample.

Clinically, infections with enterobacteriaceae most commonly present as urinary tract or intra-abdominal infections and they play an important role in hospital-acquired infection. Most commonly, it will be the patient's own resident Gram negative flora that is involved in these infections.

Gram negative bacilli are frequent colonizers of the skin below waist level, chronic wounds and the mouth and respiratory tract, most frequently in individuals who are undergoing antimicrobial therapy and it can be difficult

to judge the relevance of these organisms without careful clinical assessment.

If thought to be clinically relevant, a number of antimicrobial agents are available for treatment, but the choice of agent will usually be based on antimicrobial susceptibilities, as resistance patterns and mechanisms are manifold, widespread and difficult to predict.

Gram negative bacilli that display resistance against broad spectrum penicillins and third-generation cephalosporins via production of extended spectrum β -lactamases as well as the current emergence of carbapenem-resistant Gram negatives are developments that are likely to evolve into a major healthcare challenge.

PSEUDOMONAS

Pseudomonas spp. are aerobic oxidase positive Gram negative bacilli. They are widespread in the environment, but commonly present as opportunistic pathogens in a clinical context.

The best known species is *Pseudomonas aeruginosa*, which is easily recognized in culture due to a characteristic fruity smell and green pigment production by some strains (Figure 16.7).

It is a common causative agent of acute otitis externa, but also a frequent isolate from the respiratory tract or chronic wounds.

In the healthcare setting it also plays an important role in infections of venous access lines, as well as catheter-related urinary tract infections and hospital-acquired pneumonia and can cause bacteraemia secondary to these.

Treatment of pseudomonas infection is complicated by the fact that *Pseudomonas* spp. are carriers of a number of antimicrobial resistance genes, which may restrict options for antimicrobial treatment significantly. Severe infection (e.g. bacteraemia) is often treated with dual antimicrobial therapy (e.g. with an anti-pseudomonal penicillin or cephalosporin together with an aminoglycoside), as resistance has been shown

Figure 19.7 A pigment-producing strain of *P. aeruginosa*. Courtesy of Jasminde Karde and Margaret Woods, Department of Microbiology, Golden Jubilee National Hospital, Clydebank, UK.

<i>Proteus</i> spp.	

to develop rapidly using a single agent; however, there is little evidence linking combination therapy with improved outcomes.¹⁷

Anaerobes

The anaerobes are a phylogenetically heterogeneous group of organisms that are united by two characteristics – they grow in culture under strict anaerobic conditions and are sensitive to metronidazole (Table 19.12).

Their strictly anaerobic lifestyle makes isolation of these organisms from clinical samples a challenge. It is very difficult to grow them from swabs and recovery from a volume of pus sent in a container or capped syringe with all air expelled is usually more successful. In order to maximize the chances of isolating anaerobes, selective media are incubated in specific anaerobic cabinets for an extended period of time.

Anaerobic organisms form the majority of the resident flora of the gut and are commonly found in the oral cavity and as colonizers in wounds.

Most commonly, anaerobes cause pathology in the context of polymicrobial infections and an anaerobic organism being responsible for significant morbidity and mortality on its own is rare (Table 19.13).

One of these rare exceptions is *Fusobacterium necrophorum*. The name, literally translated, means ‘the spindle-shaped bringer of death’. The organism is an anaerobic

TABLE 19.12 Anaerobic organisms

Gram negative rod, the shape of which is similar to a cigar or spindle.

The organism is classically the causative agent of Lemierre’s syndrome, although other *Fusobacterium* spp. are also able to produce the same presentation.

Lemierre’s syndrome usually affects young healthy individuals who initially develop bacterial pharyngitis with a peritonsillar abscess. In the anaerobic conditions of the abscess fusobacteria are able to multiply rapidly, invade the circulation and go on to cause severe systemic sepsis associated with septic embolic phenomena, classically in the form of lung abscesses arising from a septic thrombus of the internal jugular vein.

As the name suggests the condition is associated with a significant mortality rate.

Common to all anaerobic organisms is the susceptibility to metronidazole, although other antimicrobials such as clindamycin and rifampicin as well as β -lactam- β -lactamase-inhibitor combinations such as amoxicillin with clavulanic acid or piperacillin-tazobactam are also active against anaerobes.

Mycobacteria

The cell wall architecture of mycobacteria is characterized by the presence of mycolic acid, which is found in high concentrations in the waxy hydrophobic outer layer of the cell wall. Arabinogalactan connects this outer layer with an inner peptidoglycan layer. This makes the entire cell wall significantly thicker than that of either Gram negative or Gram positive organisms and conveys its typical staining properties of ‘acid and alcohol fastness’.

If subjected to Gram staining, mycobacteria will typically present as slender, Gram positive rods, but the stain is only taken up very poorly, resulting in an irregular or beaded appearance. If a sample is examined for mycobacteria, specific stains such as the Ziehl-Neelsen method or an auramine stain will be performed.

In the laboratory, mycobacteria are subject to specific restrictions in terms of processing and handling in order to minimize the risk of laboratory acquired infection.

If mycobacterial infection is clinically suspected, this should therefore be indicated on the sample request form.

Growth requirements for *Mycobacterium* spp. also differ significantly from most other bacterial organisms. The organisms divide only slowly, which means that incubation times of up to 6 weeks are not unusual. An exception is the atypical or fast-growing mycobacteria, but even those will still grow much less readily than other bacteria. Due to this, PCR methods play currently play an important role in the diagnosis of mycobacterial infection.

Speed of growth is one characteristic by which mycobacteria can be categorized, but nowadays more common is the distinction between tuberculous mycobacteria or *M. tuberculosis* complex, which all cause a clinical presentation of tuberculosis and the non-tuberculous mycobacteria, which are able to cause a pulmonary disease resembling tuberculosis, but also

TABLE 19.14 Examples of mycobacteria

Non-tuberculous mycobacteria	<i>M. tuberculosis</i> complex

<i>M. abscessus</i>	
<i>M. goodii</i>	
<i>M. ulcerans</i>	

cause cervical lymphadenitis in children, skin infections and may cause disseminated disease in immunosuppressed individuals (Table 19.14).

Mycobacterium leprae is characterized by extremely slow growth and is the causative agent of lepra, which is still endemic in areas of the developing world.

Three agents form the mainstay of anti-tuberculous therapy: rifampicin, ethambutol and isoniazid, and most anti-tuberculous regimens will include some or all of these agents. Other agents may include aminoglycosides, such as amikacin or kanamycin.

The aminoglycoside streptomycin was the first available agent for the treatment of tuberculosis, but it has somewhat fallen out of favour due to high resistance rates.

The treatment regimen should be determined on the basis of a susceptibility profile and treatment regimens should be discussed with an infection or respiratory specialist.

It is worthwhile noting that some commonly used antimicrobials like macrolides and quinolones have anti-tuberculous properties and therapy with these in a patient with suspected mycobacterial disease may prevent microbiological diagnosis.

Due to the slow-growing nature of the organism, anti-tuberculous therapy is usually lengthy, often between 6 months and up to a year and in order to minimize resistance development patient concordance with therapy can be monitored.

Spirochaetes

Spirochaetes have a characteristic spiral shape, which is supported by an axial filament that is fixed to either end of the organism, but located outside the cytoplasm. The organisms wrap around this filament, which leads to a tumbling, rotating motion. This can be observed directly in dark field microscopy.

They cannot be grown in routine culture and PCR and serology are the investigations of choice for diagnosis.

There are many non-pathogenic species, but a few cause disease in humans.

Treponema pallidum is the causative agent of syphilis, which is a sexually transmitted disease which, if untreated, follows a multi-phasic course of initial painless ulcers at the site of entry which may be genital, anal or oral (primary syphilis) followed by early systemic symptoms such as a rash involving palms and soles (secondary syphilis), a period of latency and later systemic manifestations, including tabes dorsalis, dementia, polyneuropathy and mesaortitis (tertiary syphilis).

Borellia burgdorferi is transmitted via tick bites and causes Lyme disease, which initially causes a characteristic skin rash, the erythema migrans, and may be followed by a number of systemic effects, such as arthritis, cardiac conduction abnormalities and neuropathy, which may present as facial nerve palsy.

Actinomycetes

Actinomyces spp. are a group of Gram positive bacilli that are strictly speaking facultative anaerobes, but generally grow best under anaerobic conditions.

They are part of the normal oral and gut flora.

On Gram film, individual rod-shaped organisms form a structure that looks like fungal hyphen, giving the organism its Greek name that translates as 'ray fungus'.

The organism is slow growing and usually requires specific culture media for optimum recovery.

Infection with actinomycetes usually presents as a deep soft tissue or intra-abdominal abscess and is usually the result of penetrating trauma into the oral cavity or viscus.

Pus drained from actinomycotic collections characteristically contains the organism in distinct granula, often called sulphur granules due to their colour.

Treatment of tissue actinomycosis is usually with penicillins; alternatives are clindamycin, tetracyclines or cephalosporins. Depending on the site of infection and its accessibility for drainage, treatment is continued for anything between 6 months and life-long.

KEY POINTS

- A large variety of bacterial organisms can be involved in clinical infection. Some of these form part of the human normal bacterial flora and it may be difficult to distinguish between colonizing and infecting agents.
- Most organisms display characteristic virulence factors, such as formation of biofilms or toxin production, which will influence a therapeutic approach to infection with a specific organism.
- Processing of clinical specimens in the laboratory involves several steps that require overnight incubation. The average time from receipt of a sample to formal identification and sensitivities in a sterile site sample is 48 hours.
- Bacterial culture results need to be interpreted in the context of the clinical assessment in order to identify significant results.

INTRODUCTION

Viruses are small acellular infectious agents that can only replicate within cells. They characteristically comprise of genetic material made of nucleic acids (DNA or RNA) encased in a protective capsule of proteins, the nucleoprotein or nucleocapsid (Figure 20.1). Some also contain lipid envelopes. Envelopes originate from the cells in which the virus particle was made (through a process called budding), and are essentially lipid bi-layer vesicles enclosing the virus particle. During budding, the cell's membrane proteins are replaced with viral proteins, which are important for the virus's entry into a new host cell. Although they vary in size and shape enormously (range 20 nm to 500 nm), at a mode of around 100 nm in diameter, they are approximately 10 times smaller than bacteria. Viruses are therefore not normally visible by light microscopy. Classifying viruses is done according to three parameters: type of nucleic acid; shape and size of capsid; and presence of a lipid envelope.

VIRAL PROTEINS

The virus genome codes for viral proteins, which usually fall into two categories: structural proteins, such as those

Figure 20.1 Diagram of influenza virus. H, haemagglutinin; M, matrix protein; N, neuraminidase; NP, nucleoprotein; RNA, ribonucleic acid.

comprising the capsid (including haemagglutinin, neuraminidase and matrix protein); and non-structural proteins such as viral enzymes (including integrase and reverse transcriptase), usually essential for viral replication.

VIRAL GENOMES

There are four main categories of viral genome: double-stranded DNA (dsDNA), single-stranded DNA (ssDNA), double-stranded RNA (dsRNA) and single-stranded RNA (ssRNA) viruses. The genomes of dsDNA viruses exist as a single DNA molecule, and usually contain a small amount of genetic information. On the other hand, the genome of dsRNA viruses is usually split into several fragments. ssRNA viruses are the most common type of virus. The RNA is termed either positive strand (if it can be used directly as a template for mRNA) or negative strand (if it must first be made into complementary RNA).

THE VIRUS LIFE CYCLE

There are as many life cycles as there are viruses, but there are some shared or common aspects (Figure 20.2). Firstly, viruses attach to the cells they will infect. The attachment is usually dependent on binding between proteins on the virus's surface and receptors on the cell membrane. This allows specificity of viruses for particular species and cell types: the virus can only infect cells that express the appropriate receptor on their surface. Following attachment, the virus enters the cell, usually through endocytosis. Once inside the cell, the viral capsid is removed in a process called uncoating, which involves proteases from either viral or cellular origin. Once the virus has uncoated and the genetic material is exposed, viral proteins are expressed

and replication of the genetic material occurs, using both viral and cellular proteins and enzymes. Finally, new virus particles are assembled and released through host cell lysis or budding for viruses with envelopes.

DETECTION OF VIRUSES IN CLINICAL SAMPLES

Diagnostic virology has now become part of mainstream medicine for several reasons. Firstly, novel antiviral therapies, which are expensive and have side effects, have generated a need to precisely identify virus infections in order to treat patients appropriately. Secondly, novel technologies allow precise and rapid identification of a wide range of viruses. Thirdly, viral identification plays a greater role in the clinical management of chronic diseases such as HIV and hepatitis C. Finally, specific viral diagnosis is important for public health to track and control potential epidemics. There are several methods used to identify viruses: viral culture, antigen detection, nucleic acid detection and serology.¹ Viral culture is the more traditional method, and is slow and expensive. It involves growing the virus in cultured cells, and looking for characteristic phenotypic changes. Although it is slowly being phased out by molecular methods, it is the only method capable of maintaining a viable isolate for further tests. Antigen detection involves the use of specific tagged antibodies (usually to a fluorescent molecule) to detect specific viral proteins in clinical samples. Antigen detection using techniques such as enzyme-linked immunosorbent assay (ELISA) is of particular use for viruses that grow very slowly in culture, but is not suitable for certain viruses with wide antigenic heterogeneity, such as rhinoviruses. Serology, the detection of virus specific antibodies, is limited to cases in which

Figure 20.2 Schematic of a virus life cycle.

differentiation between acute and convalescent infection is essential. Differentiation is established by analysing levels of IgM (acute disease) and IgG (convalescent infection). Many diagnostic laboratories are adopting polymerase chain reaction (PCR) to identify viruses and virus strains. PCR is a technique used to specifically detect nucleic acid sequences, and can potentially detect the presence of any virus for which at least part of the genomic sequence is known. PCRs are sensitive and specific. Furthermore, viral RNA can be measured, giving an indication of viral load as well as strain using quantitative real-time reverse transcription PCR. Multiplex PCRs allow for the detection of a number of different viruses within one test, and can even detect viruses and other pathogens within a single test. Viral diagnostic tests can be performed on respiratory, cutaneous or blood specimens, depending on virus location.

RESPIRATORY VIRUSES

Respiratory viruses are the most common cause of illness in humans, and cause around 30% of child deaths in the developing world.²

Rhinoviruses (HRV)

Rhinoviruses (Figure 20.3) are a group of ssRNA viruses, which cause approximately half of all upper respiratory tract infections, otherwise known as the common cold.³ The ssRNA genome of Rhinoviruses consists of a single gene, which is then cleaved to produce message for 11 proteins. Most rhinoviruses use the receptor ICAM-1 to enter cells and others use the low density lipoprotein receptor (LDLR). A new species of rhinoviruses was recently identified (HRV-C), whose mechanism of entry remains to

Figure 20.3 Rhinovirus. Courtesy of Dr. D. Bhella, MRC-University of Glasgow Virus Research Centre.

be identified. Rhinoviruses are transmitted through contact or aerosol, via the intra-nasal or conjunctival routes. Rhinoviruses generally do not cause much pathology in the upper respiratory tract, but do disrupt the epithelial cell barrier, allowing transmigration of bacteria and exposure of toll-like receptors. In addition, it is now understood that rhinoviruses can exacerbate asthma, chronic obstructive pulmonary disease (COPD) and cystic fibrosis.

Corona viruses (HCoV)

Corona viruses are enveloped positive strand ssRNA viruses. They cause around 15% of upper respiratory infections otherwise known as common colds. There are two serotypes of corona viruses that were identified in the 1960s: group I or 229E, and group II or OC43. A third strain, SARS-CoV was discovered in 2003, followed by a fourth strain, HCoV-NL63. There are no vaccines available and immunity following infection wanes after a year or two.

Adenoviruses (HAdV)

These dsDNA viruses (Figure 20.4) cause acute respiratory disease, epidemic keratoconjunctivitis, as well as pharyngitis and pharyngeal-conjunctival fever in infants.⁴ At the latest count, there were 67 different serotypes that are known to infect humans, and new serotypes are still being discovered. The large number of serotypes is due to frequent homologous recombination of viral genomes, and the detection and classification is greatly aided by improved methodologies such as rapid whole genome sequencing and bioinformatic analysis. In epithelial cells, HAdV infection causes the lysis of the cell when new viral particles are released. In lymphoid cells, fewer virus particles are released and the cell remains intact. HAdV have been linked to oncogenic transformation by two mechanisms: viral proteins such as E1A and E1B can transform human cells and the adenoviral DNA can integrate within the host cell DNA to cause oncogenic transformation.

Figure 20.4 Electron micrograph of adenovirus. Courtesy of Dr D. Bhella, MRC-University of Glasgow Virus Research Centre.

Influenza

Enveloped and containing negative sense ssRNA, influenza viruses (Figures 20.5 and 20.6) are responsible for both seasonal endemic infections and occasional pandemics.⁵ They cause respiratory disease with significant morbidity and mortality. Complications such as pneumonia, haemorrhagic bronchitis or laryngotracheitis (croup) can arise in patients with co-morbidities such as chronic pulmonary or cardiac disease, or diabetes mellitus. There are three subtypes of influenza virus: A, B and C. Types B and C are almost exclusive to humans while type A infects a very wide range of species. Influenza A viruses are further

Figure 20.5 Electron micrograph of influenza virus. Courtesy of Dr D. Bhella, MRC-University of Glasgow Virus Research Centre.

Figure 20.6 Tomogram slice of influenza-A virus. Courtesy of Dr D. Bhella, MRC-University of Glasgow Virus Research Centre.

divided according to the antigenic subtype of their surface proteins haemagglutinin (H) and neuroaminidase (N). There are 16 H variants and 9 N. Currently, H3N2 and H1N1 ('swine flu') are the dominant circulating types, and H5N1 is the 'avian flu' type. Vaccination and antiviral drugs are used for prophylaxis. However, influenza viruses display continuous antigenic drift (i.e. they continuously acquire mutations which allow them to escape established immunity) so the vaccines are not effective for long. For this reason, the World Health Organization continuously monitors influenza infections in order to predict which specific vaccine will be required. Furthermore, the RNA genome of influenza viruses is segmented, and can recombine between two viruses of different subtypes if co-infection occurs in the same patient or animal. This allows antigenic shift and is how new subtypes such as H5N1 arise.

Paramixoviridae

The paramixoviruses are a family of enveloped negative strand ssRNA viruses (Figure 20.7), responsible for a number of significant human diseases including those listed below.

RESPIRATORY SYNCYTIAL VIRUS (RSV)

RSV is the most common cause of respiratory tract infection in humans. In 1–2% of cases, complications such as bronchiolitis can occur, and are especially dangerous in infants and the elderly. Furthermore, it can exacerbate asthma and COPD. Despite ongoing research, no vaccine has yet been licensed for RSV, and the use of the neutralizing monoclonal antibodies palivizumab and motavizumab has at best, mild effects.⁶

Figure 20.7 Electron micrograph of a paramixoviridae. Courtesy of Dr D. Bhella, MRC-University of Glasgow Virus Research Centre.

PARAINFLUENZA (hPIV)

This group of viruses is the second most common cause of child hospitalization for respiratory illness after RSV. There are four subtypes, which cause diseases such as croup (laryngotracheobronchitis, hPIV-1 and -2), bronchiolitis and pneumonia (hPIV-3). hPIV-4 causes asymptomatic or mild disease. There are also rare associations with viral meningitis and Guillain-Barré syndrome.

MUMPS

Mumps (Parotitis) is highly infectious and spreads through saliva. The virus probably penetrates the body via the mouth and can be detected in the oral cavity 1–6 days prior to the appearance of swollen salivary glands (especially parotid glands), a symptom that typifies the disease.⁷ Other symptoms include fever and complications include oophoritis, orchitis, pancreatitis and viral meningitis. Transient hearing loss is a common symptom (approximately 1 in 20), but in extremely rare cases (1 in 20000) can become permanent. Although the illness can occur at any age, most cases present in children between the ages of 5 and 10. The disease is self-limiting and in most children the symptoms are generally not severe. There is no cure for mumps and therefore treatment is restricted to symptom relief. Clearance of the virus leads to lifelong immunity and immunization with the live virus MMR vaccine between the ages of 12 to 15 months provides a similar level of immunity and protection from subsequent infection.

MEASLES

Measles is extremely contagious, and causes coryza, conjunctivitis, fever, and a typical maculopapular rash that appears 1–3 days after the onset of other symptoms. The infective stage extends from around 2–4 days prior to the appearance of a rash to 2–5 days after. In the early phase of the disease the infection is primarily spread via contact with nasal or oral excretions, and in the later stages via contact with the rash itself. Measles infection is associated with a number of serious complications including encephalitis and pneumonia, leading to death in approximately 1 in 5000 cases.⁸ The group most at risk of developing such complications are infants less than 12 months old. In around 1 in 1000 cases, measles causes permanent bilateral deafness. Like mumps there is no cure for measles, and treatment is focused on ameliorating symptoms. However, the MMR vaccine given to children between the ages of 12 and 15 months elicits a highly effective and lifelong protection.

HERPES VIRUSES

Herpes viruses (HHVs) are a class of enveloped double-stranded DNA viruses that most commonly cause oral mucosal infections. They affect patients of all ages, and can cause significant pain and dysfunction.

Herpes simplex virus

Herpes simplex virus Type-1 (HSV-1) is the most common HSV affecting the mouth and is usually the cause of blisters in the skin and mucosal membrane called ‘cold sores’, although in rare cases, HSV-2 (which normally causes genital herpes) may be involved.⁹ Lesions heal with a characteristic scab. HSV chronically but latently infects cells of the nervous system, hiding in the cell bodies. HSVs are spread through contact with saliva. The initial infection is resolved by the innate immune system, while the adaptive immune system clears the remaining active infection. The latent infection cannot be treated at present, but general antivirals are used to treat active infections.

Epstein-Barr virus

Epstein-Barr virus (EBV) is also called human herpes virus 4 (HHV4), and is the cause of infectious mononucleosis or ‘glandular fever’. It is transmitted through contact with saliva. Viral entry into cells occurs through binding to CD21 (entry into B cells) and β 1 integrin (entry into epithelial cells). Similarly to HSV, after the primary infection, the infection enters a chronic latent phase that at the moment cannot be cured. As further detailed below, EBV is associated with several malignancies.

RETROVIRUSES

One large class of single-stranded RNA viruses are the Retroviridae, or retroviruses, which contain the enzyme reverse transcriptase, allowing them to synthesize double-stranded DNA from their RNA genome. One such virus is the human immunodeficiency virus (HIV), which is discussed in [Chapter 23](#).

RUBIVIRUS

Rubella, also known as German measles, is a positive sense ssRNA virus with a lipoprotein envelope. Viral replication occurs in cells of the respiratory system. It is a purely human virus, with no animal reservoir, so could theoretically be eliminated with global vaccination strategies. In developed countries, vaccination has reduced the incidence of rubella to non-endemic levels. If contracted during pregnancy, rubella can cause congenital rubella syndrome in the foetus, with profound and serious consequences including ocular and neurological abnormalities and deafness.⁸

HUMAN PAPILLOMA VIRUS

Human papilloma virus (HPV) is a family of DNA viruses. There are at least 70 subtypes of HPV so far identified. Many of these are thought to be asymptomatic; however, a subset of HPV subtypes is associated with human disease ([Table 20.1](#)).

TABLE 20.1 Conditions associated with particular HPV types

Condition	Usual HPV type	Less common HPV type
Oral papilloma	6, 7, 11, 16, 32	
Common warts	2, 7, 22	
Plantar wart	1, 2, 4, 63	
Anogenital warts	6, 11, 42, 44	
Heck's disease	13, 32	
Multiple papillomatosis	6, 11	67
Laryngeal papillomatosis	6, 11	16
Oropharyngeal carcinoma	16, 18	6, 11, 30
Inverted papilloma	6, 11	18
Genital cancers	16, 18, 31, 45	various

CONDITIONS WITH A VIRAL AETIOLOGY

Viruses are responsible for a wide range of pathologies involving the head and neck (see [Table 20.2](#) for a non-exhaustive list), and some of the most common ones are briefly described below.

Laryngeal papillomatosis

HPV6, 11 and more rarely HPV 16 are specifically associated with laryngeal papillomas. Treatment requires repeated laryngoscopy and bronchoscopy to facilitate surgical ablation of forming papillomas and avoid airway obstruction. Although malignant transformation can occur it is rare and typically associated with patients with additional risk factors such as smoking or long-term illness.

TABLE 20.2 Pathologies and associated viruses

Pathology	Virus(es)
Acute otitis media (AOM), and meningitis bullosa	Parainfluenza viruses, influenza viruses, rhinovirus, RSV, adenovirus
Asthma exacerbation	HRV, RSV, influenza, hPIV, adenovirus
Cold sores	HSV-1
Bronchiolitis	RSV, hPIV-3, influenza, adenovirus
COPD exacerbation	HRV, RSV, influenza, hPIV, adenovirus
Conjunctivitis	Adenovirus, HSV, VZV, HIV, poxvirus, picornavirus, measles
Typical maculopapular rash	Measles, rubella, parvovirus B19, HHV 6,7, EBV
Encephalitis	HSV-1,2, VZV, CMV, EBV, HHV6, adenovirus, influenza, measles, mumps, rubella, arboviruses
Cystic fibrosis exacerbation	HRV
Keratoconjunctivitis (epidemic)	Adenoviruses
Facial paralysis	Herpes zoster
Guillain-Barré syndrome	hPIV, EBV, HIV
Hearing Loss	Mumps, measles virus, VSV, cytomegalovirus, rubella virus, herpes zoster, parainfluenza viruses, influenza viruses
Infectious mononucleosis (glandular fever)	EBV
Labyrinth disease	HSV, varicella zoster, rubella, cytomegalovirus
Laryngeal papillomas	HPV-6, -11, -16
Laryngotracheitis (croup)	hPIV-1, hPIV-2, influenza viruses
Oophoritis	Mumps
Orchitis	Mumps
Parotitis	Mumps, HIV
Pharyngitis	Adenovirus, Coxsackie A, parainfluenza viruses, enterovirus-echo, HSV, EBV, VRS, influenza viruses, cytomegalovirus
Pneumonia	Influenza, hPIV-3, measles
Rhinitis	Adenovirus, coronavirus, parainfluenza viruses, rhinoviruses
Rhinosinusitis (predisposing to bacterial infection)	hPIV, influenza viruses, adenovirus, rhinoviruses
Stomatitis	EBV, HSV
Tonsillitis	Adenovirus, parainfluenza viruses, EBV, other viruses (42%)
Viral meningitis	Enteroviruses, hPIV, mumps, EBV, HSV, VZV, measles

Bell's palsy

Bell's palsy is an acute, idiopathic mononeuropathy affecting the facial nerve. The annual incidence is approximately 11–40/100 000 with a lifetime risk of 1 in 60. The course is usually benign with complete resolution in 71% of untreated cases.¹⁰ Although the aetiology remains unknown, one theory that has gained popularity is that the reactivation of latent varicella-zoster virus or herpes simplex causes inflammation and entrapment of the facial nerve in the narrow labyrinthine segment. This theory gained popularity after detection of the HSV-1 genome in endoneurial fluid in patients with Bell's palsy. However, a recent Cochrane review has shown antivirals against HSV are no more effective than placebo treatment in producing complete recovery.¹¹ This casts doubt on HSV being the causative agent for Bell's palsy. More recently, HPV-6 has been suggested as a possible causative agent after detection of significantly higher DNA copies in the saliva of Bell's palsy patients in comparison to healthy donors.¹²

Sensorineural hearing loss

Many viruses, including those that cause the common cold, have been implicated in sensorineural hearing loss (SNHL).¹³

In congenital hearing loss, cytomegalovirus (CMV) and rubella are the implicated viruses. CMV is the most common cause of non-hereditary congenital SNHL. In infants with congenital CMV infection, 33% of symptomatic and 21% of asymptomatic infants were found to have SNHL. The hearing loss progresses in 11% and fluctuates in 16% of cases.¹⁴ A histological study of inner ear lesions in congenitally CMV infected foetuses identified the structures within the inner ear infected with the virus. These structures were all involved in endolymph secretion and potassium homeostasis and the authors therefore postulated that the mechanism of damage to the inner ear may be related to potassium dysregulation, which causes secondary degeneration of the sensory structures.¹⁵

Idiopathic sudden SNHL is often attributed to viral aetiology. Potential viruses involved include measles, mumps, rubella, CMV, HSV, varicella zoster virus (VZV), EBV, HHV, adenoviruses and arenaviruses. The viral hypothesis postulates two potential direct mechanisms, the first being cochleitis or neuritis, in which the virus invades the fluid and soft tissues of the cochlea or the cochlear nerve, respectively. The second mechanism involves reactivation of a latent virus in inner ear tissues. A third, indirect, viral mechanism has been hypothesized, which implicates a systemic or distant viral infection that either elucidates an antibody response which cross-reacts with an antigen in the inner ear, or that triggers a circulating ligand that in turn produces a pathologic activation of the cellular stress pathways in the cochlea.¹⁶

Acute otitis media

Acute otitis media (AOM) is a polymicrobial disease that in many cases occurs following a viral upper respiratory

tract infection (URTI). One third of children with viral URTI develop AOM within four weeks of its onset.¹⁷ Viral URTI plays a pivotal role in the pathogenesis of AOM by causing nasopharyngeal inflammation, alteration of mucous properties, reduction of the normal mucociliary clearance of the epithelial cells in the nasopharynx, middle ear and Eustachian tube. This causes changes in bacterial adherence properties and Eustachian tube dysfunction.

In viral AOM, rhinovirus and RSV are most commonly detected and adenovirus, coronavirus and PIV are found less frequently.¹⁸ Furthermore, viral-bacterial interactions are thought to play a significant role in the pathogenesis of AOM.

VIRUSES AND MALIGNANCY

A virus that can cause cancer is called an oncovirus. In 2008, of the estimated 12.7 million new cases of cancer worldwide, 1.9 million were attributable to hepatitis B and C virus, human papilloma virus and *Helicobacter pylori* infections.¹⁹ With regard to primary head and neck malignancies, the International Agency for Research on Cancer has identified Epstein-Barr virus and human papilloma virus as causative oncoviruses for nasopharyngeal cancer and oropharyngeal cancer respectively.²⁰

Epstein-Barr virus

Epstein-Barr virus (EBV), the first identified human oncovirus, was isolated from Burkitt Lymphoma (BL) cells in 1964²¹ and its association with nasopharyngeal cancer was first recognized in 1966.²² It has been implicated in a number of malignant diseases including nasopharyngeal carcinoma, Burkitt's lymphoma (BL) and B-cell lymphoma.

BL is a B-cell tumour typically involving the mandibular area and occurs in children aged 4–12 years. Malaria is considered a cofactor as BL is endemic in certain areas of Africa where malaria is hyperendemic. EBV can be detected in 95% of BL tumours.²³ Cyclophosphamide is the treatment of choice.

Nasopharyngeal carcinoma has a high incidence in south China, Indonesia and Vietnam. As well as racial predisposition and genetic factors, environmental factors have also been identified, in particular the consumption of salted fish and other processed foods containing volatile nitrosamines. In addition, EBV is widely accepted as a cofactor in the development of nasopharyngeal carcinoma. Higher EBV antibody titres are observed in most nasopharyngeal patients. Latent EBV infection is identified in cancer cells of virtually all cases of nasopharyngeal cancer in endemic regions. The clonal EBV genome is consistently detected in invasive carcinomas and high-grade dysplastic lesions.²⁴

Hairy oral leukoplakia is considered a pre-malignant condition consisting of painless, white, raised lesions on the lateral aspect of the tongue. The condition occurs in

HIV infection and other causes of immunosuppression. Squamous epithelial cells have been demonstrated to contain large amounts of actively replicating EBV. Acyclovir inhibits EBV replication but only allows transient lesion regression.

Lymphomas occur more commonly in immunocompromised and HIV-infected individuals. In Hodgkin's and oral T-cell lymphoma, EBV proteins are expressed by tumour cells. Persistent EBV infection becomes uncontrolled in the immunosuppressed and there is an increase in viral replication and the numbers of virus-carrying B lymphocytes. Although this condition can remain 'silent', loss of immune control can lead to EBV-associated lymphomas.²⁵

Human papilloma virus

Human papilloma virus (HPV) is a double-stranded DNA papovavirus with a predilection for human epithelial cells. It is causally associated with benign and malignant diseases of the upper airway. Multiple studies and reviews have collected sufficient evidence to link infection with HPV-16 to the development of oropharyngeal cancer.^{26, 27} The association is strongest between HPV16 and tonsil cancer.²⁸ However, recent research has indicated that HPV positive head and neck squamous cell cancer is associated with improved prognosis over those which are HPV negative.²⁹

VACCINES

Vaccination has been highly effective in controlling measles, mumps, rubella and influenza viruses. They are however ineffective against viruses which have multiple serotypes, such as rhinovirus.

Vaccines can be produced in a number of ways.

Live attenuated vaccines, such as the measles, mumps and rubella vaccines, use a weakened version of the live virus. This can be created by passaging the virus through a series of cell cultures or animal embryos. In this way, the virus loses its ability to replicate in human cells, creating a virus that can be recognized by the immune system and elicits an immune response, but cannot replicate well enough to cause disease.

Inactivated viruses, such as the polio and hepatitis A vaccines, are created by inactivating the virus using heat or chemicals. This renders the virus unable to replicate yet allows recognition of the virus by the immune system.

Subunit vaccines, such as the HPV vaccine, contain only elements of the virus. The HPV vaccines are created by the isolation of a single viral protein from each strain. These particles contain no genetic material from the virus but prompt an immune response that confers future protection against HPV infection.

ANTIVIRALS

Antivirals are a large class of drugs used to treat or prevent viral infections. Antivirals do not 'kill' the virus, but

impede its replication or function. For this reason, specific antivirals are required for each virus type.

Matrix 2 ion channel blockers

The Matrix 2 ion channels (M2) are part of the influenza virus envelope, and play a crucial role in viral infection and replication. M2 blockers such as amantadine and rimantadine are effective for treatment of influenza A infections, but resistance is an increasing problem. For this reason, and as they are not well tolerated, these compounds are not recommended to treat influenza.³⁰

Interferon

Interferons (IFN) were the first cytokines that demonstrated efficacy in the treatment of viral infections. They are a group of naturally occurring cytokines with important immunomodulatory and antiviral activities. Clinically, they have uses in the treatment of certain malignancies and also as antiviral agents. IFNs exert their therapeutic action both by direct cellular effects, via action on cell surface receptors leading to activation of signalling pathways, and by indirect mechanisms involving induction of host anti-tumour responses.³¹ Interferon as a therapeutic agent is less effective *in vivo* than hoped. Unpleasant adverse effects such as 'flu-like' symptoms and haematological complications limit its use. However, alpha-interferon is used with success in chronic hepatitis B and C infection, often in conjunction with lamivudine and ribavirin, respectively.

Acyclovir

Acyclovir, a pro-drug, is phosphorylated by the thymidine kinase of the herpes virus. The active monophosphate inhibits herpes DNA replication. Acyclovir is used in the treatment of HSV and herpes zoster (HZV) infections and given as prolonged courses in those with recurrent HSV-1 and -2 infections. It is used as prophylaxis in bone marrow and organ transplant patients. High doses are given for varicella zoster virus (VZV) or HSV in the immunocompromised and HSV encephalitis.

Ganciclovir is a related compound with more activity against cytomegalovirus (CMV) than acyclovir. It is also more toxic and usually reserved to treat conditions such as CMV oesophagitis and retinitis in the immunocompromised.

Influenza neuraminidase inhibitors

Neuraminidase is a protein found on the surface of the influenza virion. Its function is to enable the release of progeny virions from the cell surface and prevent their self-aggregation. These antiviral agents prevent release and spread of progeny virions by blocking neuraminidase function.³² Zanamivir is an influenza A and B neuraminidase inhibitor administered by powder inhalation. A Cochrane review of the use of zanamivir

and oseltamivir in healthy adults found that both drugs shortened the duration of symptoms of influenza-like illness by less than a day and that oseltamivir did not affect the number of hospitalizations. Prophylaxis trials showed that oseltamivir and zanamivir reduced the risk of symptomatic influenza in individuals and households. Oseltamivir was associated with side-effects, but zanamivir showed no increased risk of reported adverse events in adults.³³ Current guidance is that oseltamivir and zanamivir should only be used prophylactically for 'at risk adults' who have not been effectively protected by vaccination³⁴ and that use of these drugs in the treatment of influenza should also only be used for 'at risk' patients

when national surveillance schemes indicate that influenza A or B is circulating.³⁰

Ribavirin

Ribavirin is a synthetic analogue of guanosine. *In vitro* it has good activity against a range of viruses including RSV, measles, influenza A and B, hepatitis A, B and C as well as HIV. However, *in vivo* it has dose-limiting toxic effects and few clinical indications. It is used in hepatitis C infection and is administered by aerosol inhalation in paediatric cases of severe RSV infection. Its efficacy is controversial with many studies failing to show significant benefit.³⁵

BEST CLINICAL PRACTICE

- ✓ Influenza immunization is recommended for at risk groups including those over 65, patients with chronic liver, cardiac, respiratory and renal disease, diabetes, immunosuppression and those in institutions.
- ✓ Influenza neuraminidase inhibitors are recommended only for 'at risk' patients.
- ✓ Although acyclovir is not always necessary in the immunocompetent patient, it is recommended in the immunocompromised, and at high dose in serious infection.
- ✓ In recurrent HSV infection, famciclovir or valacyclovir should be taken immediately upon the appearance of symptoms.
- ✓ There is no significant benefit in the use of anti-HSV antivirals in the treatment of Bell's palsy.

FUTURE RESEARCH

- **Virotherapy:** In recent years, research into the use of viruses for disease treatment has been re-energized by the ability to genetically engineer viruses. One category showing promise are oncolytic viruses, which kill cancer cells. For example, reovirus, a natural cancer cell-targeting virus that does not otherwise cause disease in humans is currently in Phase III trials for head and neck squamous carcinoma, in conjunction with chemotherapy. Viruses are also being engineered for their use in gene therapy, as a method of delivering therapeutic genes specifically to cancer cells. However, caution remains with integrating viruses, as inadvertent insertional mutagenesis and hence cancer development can result, as was seen in the trials for *IL2rg* gene therapy. To date, only one gene therapy treatment, Gendicine, is licensed for head and neck squamous cell cancers in China, but many clinical trials are ongoing internationally.
- Bacteriophages, a sub-group of viruses that infect bacteria are used to treat some bacterial infections. Future research may allow them to play a greater role in antibacterial treatment.
- **Novel antivirals:** Some specific novel small molecule compounds are showing promise as antivirals for influenza A and B by either interfering with the polymerase complex or with the RNA promoter. Other small molecules have been shown to interrupt protein interactions in a range of virus processes. It is possible that in the future, the emergence of specific small molecule antiviral therapeutics will improve treatment of viral diseases, but will require improved diagnostics due to their specificities for virus species and strains.
- **Vaccines:** Vaccine research is ongoing. Clinical trials and studies are underway to ascertain the impact of polyvalent HPV vaccines in the treatment of recurrent respiratory papillomatosis and in the prevention of head and neck cancers.

KEY POINTS

- Respiratory viruses are very common and cause significant morbidity and mortality.
- EBV and HPV are associated with a variety of malignant and pre-malignant conditions in the head and neck.
- Vaccination is highly effective in certain viral diseases. In others the characteristics of the virus have prevented effective vaccine development.
- Some antivirals, such as acyclovir, are highly effective while others have a limited role in controlling illness.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: fungal infections in ENT, fungal infections in otolaryngology, fungal sinusitis, fungal rhinosinusitis, invasive fungal sinusitis, acute invasive fungal sinusitis, chronic invasive fungal sinusitis, chronic invasive granulomatous fungal sinusitis, fungal ball, allergic fungal sinusitis, oropharyngeal candida, otomycosis and speech valves fungal infection.

INTRODUCTION

Many thousands of species of fungi have been identified and these organisms are extremely diverse in terms of morphology and habitat. Only a small proportion of these organisms, however, are medically important pathogens, and even fewer of these are commonly encountered in otolaryngology practice.

In this chapter, we aim to expand upon previous editions by providing an introduction into the basic science of fungal infections, and their laboratory identification, as well as providing a concise update on the subject of fungal infections in ENT. This is presented in a subsite specific manner, and is based upon a comprehensive review of the literature on the subject. The basic science material has been obtained from salient texts¹⁻³ along with online resources aimed at scientists and medical professionals, and governed by the national mycological associations of Britain, America and Australia.

FUNGAL TAXONOMY

Fungi are one of four major groups of microorganisms (bacteria, viruses, parasites and fungi). They are eukaryotic organisms that reproduce through spore formation,

and are distinct from both plants and animals. Based on the case or sac in which the spores are produced, fungi are classified into four divisions: Ascomycota (sac fungi), Basidiomycota (club fungi), Zygomycota (zygote forming fungi) and Deuteromycota (imperfect fungi).

Fungi exist in nature in one of two forms: as unicellular yeasts or as branching filamentous moulds. Some fungi are dimorphic – they change from one form to another depending on their environment. While yeasts cannot be seen with the naked eye, moulds can be seen as growths on ageing foods, or as mildew in damp bathrooms. Of the vast array of fungi in the environment, less than 200 species are associated with human disease and of these, only 20 to 25 species are common causes of infection.^{1, 2}

Fungi with importance in otolaryngology typically belong to the divisions Ascomycota and Deuteromycota, divisions to which *Aspergillus* species and *Candida* species belong respectively. Whilst Candidiasis and Aspergillosis account for the majority of fungal infections, Zygomycetes also contribute to a significant proportion.⁴ Pathogens in the Zygomycota phylum, including *Mucor*, *Apophysomyces*, *Rhizomucor*, *Rhizopus* and *Absidia*, more frequently cause infections in immunosuppressed patients with underlying conditions, such as diabetes and malignancy.⁵

FUNGAL TISSUE DIAGNOSIS

Specific tests are used to determine the causative agent of a fungal infection, and to guide the clinician towards appropriate treatment. For many superficial skin and yeast infections, a clinical examination of the patient and microscopic examination of the sample may be sufficient to determine that a fungal infection is present. Identification of the specific organism is not always necessary as several topical and oral antifungal treatment options are available for clinicians to prescribe empirically based on best practice guidelines and personal experience.

Fungi do not stain well with routine stains and special silver-impregnated fungal stains are required. The latter is not species specific. Other fungal tests including potassium hydroxide solution (KOH) prep test also detect fungi but are not species specific. This is a rapid test, which dissolves non-fungal elements in a sample. It is widely used on skin scrapings, tissue, body fluids and sputum. After the non-fungal elements of the sample are dissolved, yeast cells and fungal hyphae can be visualized directly on a microscope slide.

Similarly, the Calcofluor white stain (Figure 21.1) detects fungi rapidly in a non-specific manner from a similar range of samples to the KOH prep test. The stain binds to fungal elements in a sample and fluoresces under ultraviolet light allowing direct visualization on a microscope slide.

Fungal cultures are used to identify the specific fungi present in persistent fungal infections and in those that penetrate into deeper tissues or cause systemic infections. Fungi are typically slow-growing and must be isolated in specific fungal enrichment media that inhibit bacterial growth. Fungal culture can take several weeks depending upon the species isolated. Susceptibility testing performed on fungi isolated from a culture is used to determine which antifungal is best to use for treatment

When a fungal infection is persistent, involves deep tissues or there is systemic upset, more extensive testing may be required. As a minimum, susceptibility testing

Figure 21.1 Blastomycosis-Calcofluor white stain of yeast phase growth at 30°C (1000x magnification). Courtesy of http://www.mycology.adelaide.edu.au/gallery/dimorphic_fungi/

following fungal culture determines the most effective antifungal agents to use. This can take days to weeks after primary culture.

Serology for fungal antigens and antibodies may be used to determine if a patient has a specific fungal infection. They are more rapid than fungal cultures but only test for a specific fungal species, so are limited by the index of suspicion for a specific organism that the requesting clinician has. Fungal antibodies can also be present from a prior exposure to the organism so a single antibody test cannot always confirm the presence of a current infection in isolation. If antibody tests are requested to see if antibody titres are changing, results may take several weeks.

Molecular tests for nucleic acids are also available that detect genetic material of certain specific fungi. These are performed on samples of fungus isolated in culture and are not yet widely available (<https://labtestsonline.org>). The results of these tests may take days to weeks from the sample reaching the lab.

ASPERGILLUS SPECIES

The genus *Aspergillus* includes over 185 species. Around 20 species have so far been reported as causative agents of infections in humans. They are ubiquitous fungi found in the environment and are commonly isolated from soil and plant debris. The most commonly isolated species are *Aspergillus fumigatus* (Figure 21.2), *Aspergillus flavus* and *Aspergillus niger* (Figure 21.3). All three of these species are implicated in otomycosis, a superficial fungal infection of the ear canal, although in general *Aspergillus niger* is the most commonly isolated; this can be population dependent.⁶

Aspergillus species (*Aspergillus* spp.) are implicated in opportunistic infections, allergic states and toxicoses. Immunosuppression is the major factor predisposing to development of opportunistic infections. These can present as minor local infections or disseminated aspergillosis.

Almost any organ or system in the human body may be involved. In ENT practice, *Aspergillus* spp. most

Figure 21.2 *Aspergillus fumigatus* colony growth on Czapek dox agar showing atypical blue-green surface pigmentation. Courtesy of http://www.mycology.adelaide.edu.au/gallery/hyaline_moulds/

Figure 21.3 *Aspergillus niger* – microscopic morphology.

Courtesy of http://www.mycology.adelaide.edu.au/gallery/hyaline_moulds/

commonly infect the sinuses, which can rarely result in meningitis or cerebral aspergillosis, and the external ear canals, resulting in otomycosis. Construction in hospital environments poses a major risk for development of aspergillosis by unearthing spores from the environment. This is particularly risky in immunosuppressed, or neutropenic patients.

It is important to note, however, that since *Aspergillus* spp. are found in the natural environment, they are also common laboratory contaminants and therefore an awareness of the clinical features of their infections is paramount to allow for accurate clinical correlation of laboratory reports.

Within the Aspergilli, the major macroscopic features remarkable in species identification are the growth rate, colour of the colony, and thermotolerance. For the otolaryngologist, these finer details are something to be aware of, but will not be considered further in the context of this chapter.

CANDIDA SPECIES

Candida species (*Candida* spp.) are yeasts and the most common cause of opportunistic mycoses worldwide. *Candida* spp. are frequent colonizers of human skin and mucous membranes lining the mouth, vagina and gastrointestinal tract. As well as being a colonizer and opportunistic pathogen, it is found in the environment, on leaves, flowers, water and soil.

The genus *Candida* includes around 154 species, the majority of which are not frequently isolated in human infections. While *Candida albicans* is the most abundant and significant species, there has been a recent increase in infections due to non-*albicans* *Candida* spp. Patients who receive fluconazole prophylaxis, for example head and neck oncology patients, are at risk of infections with fluconazole-resistant *Candida krusei* and *Candida glabrata* strains. The diversity of pathogenic *Candida* spp. is expanding and the emergence of other species is a real possibility.

Figure 21.4 *Candida albicans* – microscopic morphology.

Courtesy of http://www.mycology.adelaide.edu.au/gallery/yeast-like_fungi/

Infections caused by *Candida* spp. are in general referred to as candidiasis. The clinical spectrum of candidiasis is extremely diverse. In otolaryngology, the most frequently encountered candida infections are of the oropharynx, larynx and external ear canal, although almost any organ or system in the body can be affected. Infection can be superficial and local or deep-seated and disseminated. Disseminated infections tend to arise via haematogenous spread from the primary infection site. *Candida albicans* (Figure 21.4) is the most pathogenic and most commonly encountered species. Its ability to adhere to host tissues, produce secretory aspartyl proteases and phospholipase enzymes, and transform from yeast to hyphal phase are the major determinants of its pathogenicity. Several host factors predispose to candidiasis including pregnancy, extremes of age, trauma, immunosuppression (including steroid use), endocrine disease and antibiotic use.

Candidiasis is mostly an endogenous infection, arising from overgrowth of the fungus inhabiting in the normal flora. However, it may occasionally be isolated from exogenous sources (such as catheters or prosthetic devices such as speech valves in laryngectomy patients) or by person-to-person transmission, such as oral candidiasis in neonates of mothers with vaginal candidiasis.

TRICHOPHYTON

Trichophyton is a dermatophyte that ordinarily inhabits soil. It is a leading cause of hair, skin and nail infections in humans and is most commonly encountered by the otolaryngologist as a causative agent of pinna dermatosis. There are several species of Trichophyton, most commonly being *Trichophyton mentagrophytes*, *Trichophyton rubrum* and *Trichophyton schoenleinii*. Trichophyton is a keratinophilic filamentous fungus with the ability to invade keratinized tissues. It produces enzymes such as proteinases, elastase,

and keratinases, which are the major virulence factors of these fungi.

CONIDIOBOLUS

The genus *Conidiobolus* contains several species. The most common ones are *Conidiobolus coronatus*, *Conidiobolus incongruus* and *Conidiobolus lamprauges*. *Conidiobolus* is a mould most commonly found in soil and decaying plant debris. It is mostly distributed in tropical areas and particularly in Central America, equatorial Africa and India (www.mycology.adelaide.edu.au). The most common clinical picture caused by *Conidiobolus* spp. is a subcutaneous infection involving nasal mucosa and maxillofacial tissues. This chronic inflammatory granulomatous disease is also referred to as entomophthoromycosis conidiobolae.⁷ It involves facial subcutaneous tissues and paranasal sinuses, leading to formation of firm, subcutaneous nodules or polyps. The infection may be acquired via inhalation of spores or a minor trauma such as an insect bite. The infected host is frequently an otherwise healthy individual working outdoors in tropical areas. However, the infection may also develop in patients with underlying pathologies, such as neutropenia or Burkitt's lymphoma.

On potato dextrose agar and following incubation at 25° *Conidiobolus* spp. produce rapidly growing colonies which are glabrous and waxy initially and become powdery after development of aerial hyphae. The colonies mature in about 5 days. (mycosesstudygroup.org)

In vitro data on the activity of antifungal agents against *Conidiobolus* isolates are very limited.

There is as yet no standard regimen for treatment of *Conidiobolus* infections. Potassium iodide, trimethoprim sulfamethoxazole, and azole derivatives have been used.

CRYPTOCOCCUS

Cryptococcus is an encapsulated yeast. Following its first identification in nature from peach juice samples, the major environmental sources of *Cryptococcus neoformans* have been shown to be either soil contaminated with pigeon droppings (*Cryptococcus neoformans* var. *neoformans*) or eucalyptus trees and decaying wood forming hollows in living trees. The genus *Cryptococcus* includes around 37 species. Among these, *Cryptococcus neoformans* is the only species that is pathogenic. It has four serotypes, A to D. *Cryptococcus neoformans* was generally accepted to include two varieties; var. *gattii* and var. *neoformans*.

The definitive identification of *neoformans* and *gattii* varieties is possible by biochemical tests, such as resistance to canavanine and EDTA.

Cryptococcus neoformans is the causative agent of cryptococcosis. Given the neurotropic nature of the fungus, the most common clinical form of cryptococcosis is meningoencephalitis. The course of the infection is usually subacute or chronic.

The polysaccharide capsule and phenol oxidase enzyme of *Cryptococcus neoformans*, as well as its ability to grow

at 37°C, are its major virulence factors. The infection commonly starts following inhalation of the yeasts.

Colonies of *Cryptococcus neoformans* are fast growing, although the growth rate is slower than *Candida* and usually takes 48 to 72 h. It grows well at 25°C as well as 37°C. Ability to grow at 37°C is one of the features that differentiates *Cryptococcus neoformans* from other *Cryptococcus* spp.

RHINOSPORIDIOSIS

Rhinosporidiosis is an infectious disease caused by an aquatic protozoan previously considered to be a fungus. The aetiologic agent of rhinosporidiosis, *Rhinosporidium seeberi*, is closely related to several protozoan fish pathogens. The infection affects nasal mucous membranes and ocular conjunctivae of humans and animals, producing slowly growing masses that degenerate into polyps. As this is no longer considered to be a fungal pathogen it will be considered no further in this chapter.

FUNGI IN ENT CLINICAL PRACTICE

Otomycosis

Otomycosis is a fungal infection of the external ear canal that can also affect mastoid cavities and in complicated cases, the middle ear. It is more common in hot, humid climates compared to temperate ones. Approximately 9% of cases of otitis externa are due to otomycosis.⁸ Other studies have reported a prevalence of up to 30% in patients presenting with inflammatory conditions of the ear.⁹ There is no preponderance of either gender, and it can affect any age, although it is rare in young children.

PREDISPOSING FACTORS

The most common causal fungal organisms are *Aspergillus niger*, *Candida albicans*, *Actinomyces*, *Trichophyton*, *Aspergillus fumigatus* and *Candida tropicalis*. Common predisposing factors include prolonged treatment with topical antibiotics, hearing aid use, regular swimming in contaminated water, trauma to the ear canal and immunosuppression.¹⁰

CLINICAL FEATURES

The symptoms of otomycosis are non-specific and include itching, otalgia, otorrhoea, aural fullness, hearing loss and tinnitus. Furthermore, although the classic sign of otomycosis is the presence of waving conidiophores, this is not universally present. Yeasts, such as *Candida* species, do not form the closely woven mass of hyphae that are formed by moulds, such as *Aspergillus* (Figure 21.5).⁸

More common is the finding of generalized inflammatory changes of the external canal (oedema, hyperaemia, granulomatous myringitis and aural discharge of variable colour).¹¹

COMPLICATIONS

Fungal malignant otitis externa is a skull base osteomyelitis and occurs when inadequately treated fungal infection spreads through small gaps in the cartilaginous floor of the external ear canal, and spreads medially to the skull base. From here, bony destruction continues, with cranial nerve palsies occurring, particularly affecting the facial nerve. Other lower cranial nerves including IX, X, XI and XII can also be affected. Malignant otitis externa should be suspected in a patient with severe otalgia, which interrupts sleep, and often occurs in immunocompromised patients. In a review of all reported cases of fungal malignant otitis externa, 84% of patients had conditions causing immunocompromise, including diabetes, AIDS and acute myeloid leukaemia.¹² Forty-four per cent had an associated cranial nerve palsy. Amphotericin B is traditionally used as a treatment for fungal malignant otitis externa, although more recently voriconazole has become more popular, due to its more favourable side effect profile.¹³

MANAGEMENT

The treatment for otomycosis includes elimination of predisposing factors, thorough aural cleaning and antifungal agents. Topical antifungals can be specific (clotrimazole, miconazole, econazole, nystatin, tolnaftate, potassium sorbate) or non-specific (acetic acid, alcohol, boric acid, m-cresyl acetate, and gentian).¹⁴

Overall, there are four main classes of antifungal treatments: azoles, polyenes, nucleoside analogues and echinocandins. Azoles are synthetic agents that block the synthesis of ergosterol, an essential component of fungal plasma membranes. Clotrimazole is one of the most widely used azoles in otomycosis and is highly effective, with efficacy rates of between 95% and 100%.¹⁵ Other azoles that are widely used include fluconazole, ketoconazole and miconazole. Polyenes, such as nystatin, are thought to interact with sterols in the fungal plasma membrane, causing pores to form within the membrane, thus causing

Figure 21.5 *Aspergillus niger* causing otitis externa.

altered permeability and fungal death.¹⁶ Although nystatin is not available as an otic preparation it can be prepared as a solution or suspension, or applied as a cream, ointment or powder. Amphotericin B, another polyene antifungal agent, is used in severe, life-threatening infections, such as fungal malignant otitis externa. Nucleoside analogues, such as flucytosine, interfere with fungal DNA, RNA and protein synthesis. Flucytosine has a reported efficacy of 90% and is available as an ointment.

Other agents less commonly used include Gentian Violet, boric acid and cyclopiroxolamine. Boric acid is a keratolytic non-specific agent, more commonly used in countries with less availability of specific antifungal agents.

Fungal disease of the paranasal sinuses

Fungi can affect the paranasal sinuses through inhalation of spores. Fungi are ubiquitous within the environment, but can rarely cause disease within the paranasal sinuses, often but not always in the presence of predisposing factors. The spectrum of disease is largely dependent on the immunological competence of the host.

Fungal disease affecting the sinuses can be defined as acute or chronic (lasting over 4 weeks) or as invasive or non-invasive. Invasive fungal disease is defined as the presence of fungal hyphae within mucosa, submucosa, bone, blood vessels and nerves of the paranasal sinuses. Non-invasive fungal disease implies colonization of the surface of epithelial tissues, rather than invasion. Currently, fungal rhinosinusitis is classified into three invasive (acute necrotizing, chronic invasive, and granulomatous invasive) and two non-invasive (fungal ball and allergic fungal) subgroups (Table 21.1).

Acute invasive fungal rhinosinusitis (AIFR)

AIFR is a rare but rapidly progressive disease process that can result in fatality within days. It is the most lethal form of fungal sinusitis with mortality rates of at least 50%.¹⁷ *Aspergillus* and *Zygomycetes* (particularly *Mucor* and *Rhizopus*) are the causative fungi in most cases. A high degree of clinical suspicion is required in order to correctly and promptly diagnose and manage this condition.

Following inhalation of spores, the fungi grow and invade neural and vascular structures, leading to vessel thrombosis and resultant mucosal necrosis. The fungi then extend beyond the affected sinus through a combination of bony destruction, perineural and perivascular spread.

PREDISPOSING FACTORS

Two main groups of patients are thought to be at risk of AIFR: diabetics, particularly with ketoacidosis, and patients who are immunocompromised (severe neutropenia, haematologic malignancy, systemic chemotherapy, steroid therapy, bone marrow transplantation, AIDS). Diabetic patients are particularly at risk from

TABLE 21.1 Definitions of fungal disease affecting the paranasal sinuses

	Non-invasive		Invasive		
	Fungal ball (mycetoma)	Allergic fungal sinusitis	Acute invasive fungal; sinusitis	Chronic invasive fungal sinusitis	Chronic granulomatous invasive fungal sinusitis
Pathogen	<i>Aspergillus</i> species; <i>Pseudallescheria boydii</i>	Primarily dematiaceous species: <i>Bipolaris</i> , <i>Alternaria</i> , <i>Curvularia</i> ; also <i>Aspergillus</i> species and multiple other moulds	Mucormycosis (Diabetics); <i>Aspergillus Fumigatus</i> (immunocompromised), <i>Candida</i> species, <i>Fusarium</i>	<i>Aspergillus flavum</i> , <i>A. fumigatus</i>	<i>Aspergillus flavum</i>
Immune status of host	Immunocompetent	Atopic	Immunocompromised	Immunocompetent or mildly immunocompromised	Immunocompetent
Geographical distribution	Humid area	Humid area	Non-specific	Non-specific	North Africa
Radiological findings	Hyperdense on CT, especially maxillary and sphenoid sinus	CT-heterogenous sinus opacification, bony remodelling +/- erosion MRI – signal void on T2 depending on metal concentration within mucin	CT-sinus opacification, bony erosion and tissue infiltration	CT-sinus opacification, bony erosion and tissue infiltration	CT-sinus opacification, bony erosion and tissue infiltration
Treatment	Surgical	Surgical + medical	Reversal of underlying Immunocompromise, surgical + antifungal therapy	Surgical + medical	Surgical + medical

Zygomycetes (*Rhizopus*, *Mucor*) as these organisms have an active ketone reductase system and thrive in high glucose acidotic conditions. *Aspergillus* species commonly affect immunosuppressed patients.¹⁸ Iron-overload is also thought to be a predisposing factor, particularly after treatment with deferoxamine, an iron chelator, for iron overload due to multiple blood transfusions. *Rhizopus* binds to deferoxamine and uses it to bind iron, which it requires for growth.¹⁹

CLINICAL FEATURES

The clinical hallmark of AIFR is febrile neutropenia and facial pain with or without nasal congestion and orbital signs.

Symptoms and signs occur rapidly, often within hours, depending on the pattern of invasion into nearby structures. Nasal features include discolouration of nasal mucosa, granulation, ulceration and crusting. Later, spread to the orbit and intra-cranially can result in proptosis, diplopia, visual loss and neurological deficit. Infection can extend to the cavernous sinus via the orbital apex, causing palsies of cranial nerves III, IV and VI resulting in ophthalmoplegia and orbital pain (ophthalmic division of trigeminal nerve). Orbital signs and symptoms are common presentations, occurring in around half of patients in a recent systematic review by Turner et al. examining survival outcomes in AIFR.²⁰ Thrombosis of the cavernous section of the carotid artery can extend to other

branches at the circle of Willis. As a result once disease has spread to the cavernous sinus, cerebral or brainstem infarction is almost inevitable. Intra-cranial extension presents as headaches, neurological deficit, seizures and coma. Around a fifth of patients in Turner's systematic review presented with altered mental status.

Interestingly, patients can present with advanced AIFR with orbital and cerebral complications with few signs or symptoms of rhinosinusitis and nasoendoscopy may be essentially normal.²¹ This reinforces the need to have a high degree of suspicion in patients with immunocompromise presenting with orbital or cerebral signs, with or without symptoms of sinus disease.

DIAGNOSIS

Changes in mucosal appearance and/or sensation (anaesthesia) are typical on endoscopic examination. In the early stages, the mucosa may appear pale. Necrosis resulting from angioinvasion results in black crusts and sloughing of the mucosal surface of the nose and septum; septal perforation may be present. Biopsies should be taken from multiple sites, particularly the middle turbinate and septum in order to confirm the diagnosis and the causal fungal organism. The gold standard of diagnosis is pathological examination of permanent sections, prepared in potassium hydroxide. This allows the identification of invasive features, and can often distinguish *Mucorales* from *Aspergillus* fungi. However, this process is time

consuming and may delay the diagnosis and institution of treatment. Frozen section is a technique that is useful in order to provide rapid evidence of invasion, and has been found to have a sensitivity of 84% and a specificity of 100% for the diagnosis of AIFR compared to gold standard permanent sections.²² Culture should also be undertaken in order to confirm the species of fungus responsible and sensitivity to antifungal agents, although culture has been found only to have a sensitivity of 54%.

Both CT and MRI are invaluable in the diagnosis of AIFR. CT allows detection of bony destruction while MRI is better at detecting mucosal, skin invasion, orbital or intra-cranial involvement. Non-contrast CT may show hypoattenuating mucosal thickening in the affected sinuses, bony erosion and/or thickening of periantral fat planes. MRI is superior at evaluating extra-sinus disease, such as intra-cerebral and intra-orbital spread. Early orbital changes include inflammatory changes in orbital fat and extra-ocular muscles and resulting proptosis. There may be subtle obliteration of periantral fat. Early changes in the cerebrum include leptomeningeal enhancement, which may preclude the development of frank abscesses or granulomas. There may be evidence of cerebral infarction or subarachnoid haemorrhage due to either thrombosis of the carotid artery and branches or mycotic aneurysm.²³

MANAGEMENT

The mainstay of treatment is reversing the underlying immunosuppression (e.g. ketoacidosis or neutropenia) aggressive surgical debridement and broad spectrum anti-fungal therapy. Hyperglycaemia should be reversed and blood glucose levels should be tightly controlled. Reversal of neutropenia, if possible, improves survival, and there may be a role for granulocyte-colony stimulating factor in these patients.^{18, 24}

Surgical treatment (endoscopic or open) aims to confirm the diagnosis and remove non-viable tissue. Debridement is carried out until clear, bleeding margins are observed. There is little evidence that radical resection, including orbital exenteration and radical maxillectomy, improves survival. In fact, in the systematic review carried out by Turner et al.,²⁰ patients who underwent endoscopic resection had significantly improved survival compared to those who underwent open surgery, although this may partly be due to the fact that patients undergoing open surgery had far more advanced disease. There is little consensus as to the role of orbital exenteration, although most agree that it should be reserved for those with a completely non-functioning eye.²⁵ A multidisciplinary approach utilizing ophthalmology, maxillofacial and neurosurgical expertise is paramount.

Broad-spectrum antifungal therapy should be started as soon as a diagnosis of AIFR is suspected. Fungal cultures are essential in determining sensitivity to anti-fungal agents. Amphotericin B is a polyene antifungal with activity against both *Mucorales* and *Aspergillus*. Amphotericin B deoxycholate is used as the mainstay of treatment prior to identification of the causal fungus, usually at doses of

1–1.5 mg/kg per day. However, the toxicity of amphotericin B has led to the development of safer lipid-formulations of the drugs such as amphotericin B lipid complex and liposomal amphotericin B. These formulations are less nephrotoxic and can be used at higher concentrations for longer. Liposomal amphotericin B is used at doses of 5–10 mg/kg per day, and although expensive is safer and may be more effective than amphotericin B deoxycholate, particularly in cancer patients with mucormycosis.²⁶

Once mucormycosis is ruled out, treatment may be changed to a less toxic azole that is more effective against *Aspergillus* but has less reliable activity against mucormycosis. A randomized unblinded trial showed that voriconazole led to improved survival and fewer side effects in patients with invasive aspergillosis compared to amphotericin B.²⁷ Voriconazole is used at an initial dose of 6 mg/kg iv for two doses, followed by 4 mg/kg iv every 12 hours. It is now recommended as first line treatment for invasive aspergillosis of the sinuses by the Infectious Disease Society of America. An alternative azole, posaconazole may be used as a step-down to oral treatment when clinical improvement is seen, to enable long-term treatment.

Hyperbaric oxygen therapy (HBOT) has been proposed as an adjunct to treatment of AIFR.²⁸ HBOT acts directly via increased production of oxygen-based free radicals and indirectly by reversing growth-promoting lactic acidosis and restoration of phagocytosis.²⁹ To date there is no clear evidence of the efficacy of HBOT in the treatment of AIFR.

PROGNOSIS

In the recent systematic review by Turner et al.,²⁰ diabetic patients were found to have better prognosis, despite often more aggressive disease, possibly due to the fact that their underlying condition was more easily reversed than other conditions. Patients who have intra-cranial involvement, or who do not receive surgery as part of their therapy, have a poor prognosis.

Chronic invasive fungal rhinosinusitis

Chronic invasive fungal rhinosinusitis (CIFR) has a similar clinical appearance to AIFS but a slower progressive course, occurring over months to years. It also tends to occur in immunocompetent individuals.

Aspergillus spp. (*flavus* or *fumigatus*) or *Mucor* spp. are the most common causative organisms.³⁰ In the initial stages of disease symptoms may be subtle and non-specific and include unilateral bloody nasal discharge, nasal obstruction, headache, cacosmia and purulent nasal discharge. Patients may present with advanced disease with proptosis, orbital apex syndrome and cranial nerve deficits reflecting invasion into the orbit. Destruction of the bony walls of the maxillary sinus causes palatal erosion and soft tissue swelling of the cheek. Disease invading into the cribriform plate and anterior cranial fossa may cause chronic headache, seizures and focal neurological deficit.

DIAGNOSIS

CT imaging may mimic the features of malignancy, which is the primary differential in most cases. CT shows a hyperattenuating mass in one or more of the sinuses with destruction of the sinus bony walls. MRI typically shows decreased signal intensity on both T1- and T2-weighted images.²³ Invasion into anterior cranial fossa may result in meningitis seen as meningeal enhancement on contrast enhanced MRI. Cavernous sinus thrombosis typically results in a swollen non-enhancing sinus with compression of the carotid artery on coronal post-contrast T1-weighted MRI.

Biopsies should be obtained to assess for mucosal invasion. Microscopically, there are few inflammatory cells (unlike AIFS) and CIFS lacks granulomas often witnessed in granulomatous invasive fungal sinusitis.

MANAGEMENT

The treatment of CIFS is similar to AIFS, that is, a combination of surgical and antifungal treatments. Surgical resection should be carried out until clear, bleeding margins are observed. Systemic and topical amphotericin B should be started until cultures exclude *Mucor* species. Amphotericin B has proven efficacy against invasive Aspergillosis, although its side effect profile may limit the length of treatment and the optimal dose.²⁷ Whilst newer lipid-formulations are safer they are also more expensive and can only be given in the intravenous route. Azole drugs such as voriconazole and itraconazole are promising alternatives as they are effective via the oral route and are therefore easier and cheaper to administer for longer term treatment but are less effective against *Mucor* spp. A prospective randomized unblinded study compared amphotericin B (conventional or liposomal) and itraconazole in the management of CIFS and found that both were equally efficacious.³¹

Chronic granulomatous invasive fungal sinusitis

Chronic granulomatous invasive fungal sinusitis is distinguished from CIFS by the geographical distribution of the disease, type of pathogen and microscopic findings. It is rarely seen in the West and is more common in North Africa, the Middle East and Asia. *Aspergillus flavus* is the most common causative fungi. It is defined by the presence of non-caseating granulomas with Langhan's type giant cells and fungal hyphae, although it may coexist with other types of fungal sinusitis.³² Similar to CIFS, it follows an indolent course and may be found in both immunocompetent and immunodeficient patients.

It is treated by surgery (resection of involved tissues to bleeding margins) followed by antifungals. Antifungals like voriconazole instead of amphotericin may be used as the disease is caused by *Aspergillus flavus*. Rupa et al.³² recommend post-operative treatment with either oral itraconazole or voriconazole for disease with limited extension and oral voriconazole for advanced disease extending to the brain. Amphotericin B was not recommended as first-line therapy for CGFS.

Allergic fungal rhinosinusitis

Allergic fungal rhinosinusitis (AFRS) is a non-invasive fungal disease, first reported by Safirstein³³ in 1976 in a patient with allergic bronchopulmonary aspergillosis (ABPA). This condition shares similar histopathologic features with ABPA. Unlike other forms of sinusitis, it has distinct clinical, histopathological and prognostic findings. Debate concerning the underlying pathogenesis and optimal treatment strategy is ongoing.

AFRS is more common in younger individuals (mean age 21–33 years) compared to CRS. It is also more frequent in warm, humid environments and lower socioeconomic status.³⁴ Atopic individuals tend to suffer from AFRS.

DIAGNOSTIC CRITERIA

Allergic fungal rhinosinusitis is often misdiagnosed, and there are many controversies surrounding its diagnosis and even its very existence. However, most experts use Bent and Kuhn criteria³⁵ for diagnosis (Table 21.2). These consist of both major and minor criteria, and all five major criteria must be met in order for a diagnosis to be made. The presence of minor criteria supports the diagnosis of AFRS.

De Shazo et al.³⁶ proposed a slightly revised set of criteria, reflecting the controversy surrounding the role of atopy in AFRS, and suggested the following: (1) sinusitis confirmed on CT scanning; (2) the presence of allergic mucin; (3) demonstration of fungal hyphae within the allergic mucin; (4) the absence of fungal invasion; and (5) the absence of diabetes or immunodeficiency states. In 2004 a panel of experts redefined AFRS as 'histological confirmation of eosinophilic mucin and the presence of type 1 hypersensitivity to fungi in CRS patients'.³⁷

PATHOGENESIS

The pathogenesis of AFRS is not completely understood and subject to controversy. The most common pathogens in AFRS are the dematiaceous species (*Curvularia*, *Bipolaris*, *Alternaria*). Due to the histopathological similarity of AFRS to ABPA, a common pathophysiological mechanism was attributed. In ABPA, both elevated IgE and IgG to either *Aspergillus fumigatus* or *A. flavus* are present. Both Type I (specific IgE antibody-antigen interaction) and Type III (IgG antibody-antigen complex) reactions have been postulated in the pathogenesis of ABPA. The immune pathogenesis of AFRS is supported

TABLE 21.2 Bent and Kuhn diagnostic criteria

Major	Minor criteria
Type I hypersensitivity (history, skin test or <i>in vitro</i> testing)	Asthma
Nasal polyposis	Unilateral disease
Characteristic CT findings	Radiological bone erosion
Eosinophilic mucin without invasion	Fungal cultures
Positive fungal stain	Serum eosinophilia
	Charcot-Leyden crystals

by Manning and Holman,³⁸ eight AFRS patients with culture-positive *Bipolaris* showed skin test positivity to *Bipolaris* as well as RAST IgE to *Bipolaris* and ELISA IgG antibodies for *Bipolaris*. In contrast, only 1 in 10 controls had a positive skin test for *Bipolaris*, as well as IgE and IgG antibodies to *Bipolaris*. On examination of mucosal specimens from AFRS patients, eosinophilic mediators predominated over neutrophil-derived mediators compared to control patients with unrecognized AFS.

In AFRS, a Type I (and possibly Type III hypersensitivity reaction) to inhaled airborne fungi is believed to result in tissue inflammation, oedema and production of an 'eosinophilic mucin'. This consists of eosinophilic inflammatory cells and Charcot-Leyden crystals (breakdown of cells by eosinophilic enzymes).

Interestingly, some patients with a clinical picture of AFRS did not display signs of systemic allergy. Collins et al³⁹ proposed a theory that AFRS is the result of a local Type I hypersensitivity rather than a systemic response. His study demonstrated fungal-specific IgE in sinus mucin in AFRS patients and may explain why the response was confined to the nose and paranasal sinuses without systemic involvement.

However, controversy exists about whether a Type 1 sensitivity reaction is central to the pathogenesis of AFRS. Ponikau et al.⁴⁰ prospectively studied 210 patients with CRS, with or without nasal polyps, and used rigorous methods to collect and culture fungus from nasal mucin. Cultures were positive for fungus in a surprising 96% of patients with CRS. Furthermore, all healthy control patients, with no history of sinonasal disease, had fungal-positive cultures, suggesting that fungi are ubiquitous within the sinuses and nasal passages. When using deShazo's criteria for a diagnosis of AFRS, 93% of CRS patients undergoing surgery (thereby providing samples for histological examination), had AFRS. Of patients diagnosed with AFRS, less than a third had elevated fungus specific IgE level by RAST. Ponikau's study has been criticized for a number of reasons. Furthermore, Ponikau states that 'allergic mucin' (required for a diagnosis of AFRS) was found in the vast majority of patients with CRS, whilst multiple studies have estimated the prevalence of allergic mucin to be much lower in patients requiring surgery for CRS.⁴¹ AFRS is usually associated with the production of copious amounts of allergic mucin, whereas the patients in Ponikau's study often only produced small pockets of mucin.

There is strong evidence that patients with 'simple' CRS show abnormal immunological responses to fungal elements within the nose and sinuses. Shin et al.⁴² demonstrated that patients with simple CRS showed exaggerated humoral and cellular responses to commonly found airborne fungi compared to healthy controls. However, it is important to recognize that whilst fungal allergy may play a role in the pathogenesis of simple CRS, AFRS is a distinct entity with very strict criteria for diagnosis, and more is needed for diagnosis over and above merely the existence of allergy to fungal elements in a patient with sinusitis.

CLINICAL FEATURES

Typically patients presenting with AFRS are young, immunocompetent individuals, with a history of atopy or asthma. They present often with unilateral, but sometimes bilateral, symptoms of nasal congestion, post-nasal drip, and a thick dark nasal discharge. There is often a history of recurrent symptoms following previous treatment or surgery and typically patients show an excellent response to oral corticosteroids, but not antibiotics. Patients may also present with signs and symptoms of bony erosion and involvement of the orbit, including proptosis and telecanthus.

On examination, there is usually gross nasal polyposis with thick, highly viscous mucin, classically described as the consistency of peanut butter. Green or black casts consisting of allergic mucin may be present. Microscopic examination of the fungal mucin with haematoxylin and eosin (H&E) staining typically shows the presence of Charcot-Leyden crystals and eosinophilic breakdown products, and often the eosinophils themselves form sheets. Fungi do not stain with H&E staining, but can be seen on special stains. Culture of the mucin may or may not be positive for fungus; however, this does not rule out AFRS as the yield of culture is typically fairly low. The fungi most commonly identified in the eosinophilic mucin include *Alternaria*, *Bipolaris*, *Cladosporium*, *Curvularia*, *Drechslera* and *Helminthosporium* from the dematiaceous family and *Aspergillus* species.⁴³

IMAGING

CT imaging typically shows characteristic pansinusitis, hyperattenuation of the intrasinus contents (representing thick allergic mucin) surrounded by lower attenuation hyperplastic mucosa. The 'double density' sign may be seen in affected sinuses (i.e. heterogeneous signal intensity due to the deposition of heavy metals within the mucin) (Figure 21.6). The affected sinus is often expanded and there may be erosion of the sinus walls (Figure 21.7). This erosion is not due to invasion by fungal elements, but due to local inflammation and the expansive nature of mucin, which differentiates it from invasive fungal sinusitis.⁴⁴ MRI, if interpreted in the absence of CT, can be misleading; on T2-weighted images, the high metal concentration within proteinaceous allergic fungal mucin may show up as a signal void, mimicking the appearance of a normally aerated sinus. On T1-weighted images the material is hypointense to isointense.²³ Both T1- and T2-weighted images shows peripheral enhancement (Figure 21.8).

MANAGEMENT

The mainstay of AFRS treatment remains surgery although adjunctive medical management is critical for optimal outcomes. The aim of functional endoscopic sinus surgery (FESS) is to remove all antigenic fungal elements, and to re-establish drainage of the affected sinuses. During the endoscopic procedure, all specimens including polyps and allergic mucin should be sent for microscopic examination

Figure 21.6 Coronal CT sinus showing classic 'double density' sign seen in AFRS.

Figure 21.7 Coronal CT sinus demonstrating erosion of lamina papyracea and skull base.

Figure 21.8 Axial MRI sinus showing near signal void in sphenoid sinus on T2-weighted (left) compared to T1-weighted images (right).

and staining for fungi, and all should be sent for culture. In particular, invasion of vasculature or mucosa should be excluded.

In 2014 Gan et al.⁴⁵ published an evidence-based approach for the post-operative medical management of AFRS. The review concluded that post-operative systemic and standard topical nasal steroids are recommended; oral antifungals, and immunotherapy are options in cases of refractory AFRS; and did not provide recommendations for topical antifungals and leukotriene modulators due to

lack of evidence. Recently, AFRS which is refractory to surgery and conventional medical treatment has been shown to be responsive to anti-IgE antibody, omalizumab.⁴⁶

Oral steroids

Gan et al.⁴⁵ recommend the use of oral steroids in the post-operative period, using grade B evidence from four studies (level 2b: 2 studies, level 4: 2 studies), and report a reduction in post-operative mucosal disease and inflammatory markers. The four studies included a total of 76 patients

fulfilling the Bent and Kuhn criteria for AFRS, although two were case series lacking comparison with control. In 2010, Rupa et al.⁴⁷ published a prospective, randomized, placebo-controlled trial of post-operative oral steroids in AFRS comparing the use of oral prednisolone (n = 12) and placebo (n = 12). They concluded that post-operative oral steroid in a tapering dose produces significant subjective and objective improvement of patients with AFRS.

Topical nasal steroids

Topical nasal steroids achieve effective drug concentration at the sinonasal mucosa with few systemic side effects. There is little evidence for the use of topical steroids post-operatively in AFRS. A randomized controlled trial examined the use of post-operative topical nasal steroids and nasal douching in patients with AFRS compared with nasal douching alone, and nasal douching plus itraconazole. This study showed no significant benefit at 6 months for topical nasal steroids, although there were limitations to the study.⁴⁸

Oral antifungals

The use of oral antifungals in AFRS should theoretically reduce fungal sinus load and therefore reduce the type 1 hypersensitivity reaction. However, there are numerous side effects associated with oral antifungals, and therefore they should be used with caution. Three level 4 studies (all case series) were included in Gan's review⁴⁵ and their use was restricted to patients with a poor post-operative response to oral or topical steroids. These studies show a reduction in symptoms, prevention of disease recurrence and reduced dependence on oral steroids (level C evidence). Itraconazole was used at a dose of 200 mg to 400 mg daily in divided doses for up to 6 months.

Topical antifungals

Topical antifungals may be used to reduce the risk of side effects associated with oral antifungals. However, to date there is no high quality evidence regarding the use of topical antifungals in AFRS.

Immunotherapy

There is level C evidence (two case-control studies and three prospective case series) that allergen immunotherapy shows improvement with reduced reliance of post-operative steroids, post-operative exacerbations and revision surgery.⁴⁵ Double-blind placebo controlled trials are lacking, and therefore conclusive evidence of efficacy is not yet available.

Bassichis et al.⁴⁹ studied a database of 82 patients and compared patients with AFRS who had been treated with post-operative immunotherapy against those who had not (36 versus 24 patients). They found a re-operation rate of 33% in those who did not receive immunotherapy compared to 11.1% in those who did. Folker et al.⁵⁰ published a case-control study comparing 11 patients who received IT for at least 12 months with those who did not and found improvements in mucosal endoscopic staging, quality of life and reliance on oral and systemic steroids. It is less clear if immunotherapy leads to significant reduction in recurrence of disease in the long term.⁵¹

To date, there remains no evidence of unusual side effects or immune complex formation in AFRS patients receiving immunotherapy.

Leukotriene modulators

To date there is no evidence that leukotriene modulators, such as montelukast, have a role in the treatment of AFRS. Only one case study has reported a benefit from using 10 mg oral montelukast in a patient with recalcitrant AFRS, with recurrent symptoms following three previous attempts at sinus surgery.⁵²

Fungal ball

A fungal ball consists of sequestered fungal hyphal elements within a sinus without invasive or granulomatous changes. It is distinct from saprophytic fungal infestation, which corresponds to fungal spores found on crusts and mucus in the nose. Fungal balls are typically found in immunocompetent individuals and may coexist with other forms of fungal sinusitis.

DEFINITION

DeShazo⁵³ developed a clear definition for the diagnosis of fungal ball of the paranasal sinuses. A dense mass of hyphae is found in the affected sinus, which separates easily from the sinus mucosa, and macroscopically resembles a clay-like or cheesy material. Microscopically there is no evidence of invasion of the mucosa, vessels or bone. There are typical radiological changes (see below) and non-specific inflammatory changes of the mucosa, with no predominance of eosinophils, no granuloma and no allergic mucin.

PREDISPOSING FACTORS

There is little evidence that the presence of pre-existing medical conditions predispose to fungal balls, and furthermore, no evidence that pre-existing sinus disease or anatomical abnormalities does so either. An association between previous dental treatment, particularly fillings, and fungal balls has been suggested with reports showing that between 56% and 84% of patients found to have fungal balls have had previous dental treatment.⁵⁴

PATHOGENESIS

Two theories as to the pathogenesis of fungal balls have been proposed. The first proposes that a large amount of inhaled fungal spores enter the sinuses through the natural ostium (the aerogenic pathway). The second suggests that fungal colonization of the sinuses occurs via an iatrogenic pathway when an oro-antral fistula is created during endodontic treatment with overfilling of the dental canal. Commonly used endodontic sealers may promote the growth of fungus, as demonstrated by experimental work, which showed that zinc oxide found in sealers promotes the growth of *Aspergillus*, whereas the second component, a liquid called eugenol, may inhibit its growth. Over time, however, the inhibitory effect of eugenol fades,

allowing the promotion of fungal growth many years after the initial dental treatment. This would explain why the maxillary sinus is the most commonly affected sinus, and why many patients with fungal balls have a history of previous endodontic treatment.

CLINICAL FEATURES

Fungal balls most often affect one sinus, most commonly the maxillary sinus (94%), followed by the sphenoid sinus. Symptoms are non-specific, and the patient may be completely asymptomatic, hence the reason why patients are often diagnosed late. Other symptoms include headache or facial pain, post-nasal drip and cacosmia. Fungal balls affecting the sphenoid sinus may present with retro-orbital pain at the vertex. Symptoms may be recurrent, coinciding with superimposed bacterial sinus infection, with relatively symptom-free periods between episodes.

Examination findings may be unremarkable, but careful examination with a flexible or rigid endoscope may reveal localized inflammatory changes at the natural ostium of the affected sinus, including the presence of small polyps or purulent mucopus (Figure 21.9).

Macroscopically the fungal ball consists of cheesy like material, which is green, yellow, brown or black. The underlying mucosa may be normal or hypertrophic. Microscopically at low power the ball is seen to consist of densely packed hyphae, and may have an onion-skin-like appearance, due to the alternating zones of dense and less-dense growth. The mucosa may show non-specific inflammation, but in particular there is an absence of invasion by fungal elements, or granulomatous reaction.

Aspergillus is the most commonly identified fungus in fungal balls, and can often be seen on haematoxylin-eosin

Figure 21.9 Endoscopic findings of AFRS showing nasal polyposis and thick mucinous secretions.

slides. However, all samples, including mucosa and fungal samples should be stained with silver impregnation stains in order to identify the presence of fungi. Whilst stains may be able to identify their presence, only culture will confirm the species of fungus. However, culture typically has a low yield of up to 50%.⁵⁴

IMAGING

CT scanning is the imaging of choice for suspected fungal balls. Five CT features are commonly found on CT imaging of fungal balls, including a heterogenous soft tissue density in a single unilateral sinus, absence of an air-fluid level, erosion of the inner wall of the sinus, sclerosis of the lateral sinus wall and the presence of calcification. In particular, the presence of erosion of the inner wall of the sinus and the presence of calcification have a positive predictive value in the diagnosis of fungal balls of 94.6% and 93.2% respectively.⁵⁵ The presence of calcification is thought to be due to the deposition of calcium salts within the fungal ball.

MRI scanning is not usually necessary, but may be used as an adjunct to CT imaging to differentiate mucosal swelling or mucous retention from a fungal ball. On T2-weighted MR imaging fungal balls are often hypointense compared to mucous or mucosal swelling, which is hyperintense.

MANAGEMENT

The treatment of fungal balls is surgical with no adjunctive medical treatment usually necessary. Functional endoscopic sinus surgery (FESS) is employed to create a wide opening of the affecting sinus ostium. All fungal material should be removed, and biopsies taken from the underlying mucosa to rule out invasion. Any dental filling material present in the sinus should also be removed. In immunocompetent patients there is no role for the use of systemic antifungal agents.

Oropharyngeal candidiasis

Fungal infection of the oral cavity and pharynx is most often caused by fungi belonging to the genus *Candida* (*Candidiasis*). There are three subtypes of oropharyngeal candidiasis (OPC) that are recognized: pseudomembranous, atrophic and hyperplastic candidiasis. Whilst candidiasis of the oral cavity is not uncommon, and is in most cases easily treated, in this section we consider oropharyngeal candidiasis in two populations: patients with HIV and head and neck cancer patients.

OROPHARYNGEAL CANDIDIASIS IN HIV PATIENTS

Candida albicans is found as part of the normal skin, genitourinary and gastrointestinal microflora, and may be isolated in up to 65% of healthy individuals. Prior to the development of antiretroviral therapy (ART) for treatment of HIV, OPC was seen in up to 90% of patients with

HIV, reflecting their underlying immunosuppression.⁵⁶ Since the introduction of ART, the incidence of OPC has declined, although it remains a problem for patients with limited access to ART, those with a poor response to ART and those with infections resistant to conventional antifungal treatment. In one study of 122 patients with advanced HIV, 81% were colonized by oral candida, and of these 33% had symptomatic infection.⁵⁶ *Candida albicans* was the most common candida species isolated in 54% of samples, with *C. dublinensis* and *C. glabrata* next most common. Rarer species of *Candida* may often be resistant to fluconazole and are important causes of recalcitrant oropharyngeal candidiasis.

HIV patients are at greater risk of OPC once their immunity drops to a certain level, normally taken to be an absolute CD4+ T-lymphocyte count of less than 200 cells/ μ L. Viral load is also found to be a contributing factor for the development of OPC, and the risk of OPC increases as HIV viral load surpasses 10,000 copies/mL.

Pseudomembranous candidiasis is the most common subtype of OPC in HIV patients. Painless, often asymptomatic plaques appear on the tongue, buccal mucosa and oropharynx, and can typically be wiped away leaving an erythematous base, which may bleed (Figure 21.10). Patients may complain of altered taste or pain if ulceration occurs. Distal spread to the larynx or oesophagus causes dysphonia, odynophagia and dysphagia. Erythematous OPC may also be seen in the HIV patient and clinically appears as flat, red lesions anywhere in the oral cavity, but often the dorsal tongue or palate. Hyperplastic candidiasis presents as firm, white plaques of varying sizes, which, in contrast to pseudomembranous OPC cannot be removed. These are important lesions to recognize as whilst they are rare in all populations, they have malignant potential.

Mild disease can be treated with topical nystatin suspensions, whilst more severe disease will require a 14-day course of fluconazole 200mg daily.⁵⁷ However, there is increasing recognition of *Candida* species that are resistant to fluconazole, estimated to cause up to 5% of OPC. A multicentre

randomized trial evaluating posaconazole as an alternative to fluconazole has shown posaconazole to be as effective and even better at sustaining clinical remission and is an alternative for fluconazole-resistant disease. Posaconazole suspension is given at a dosage of 400mg twice daily for 3 days, followed by 400mg daily for up to 28 days. Other alternatives include voriconazole, itraconazole or amphotericin B oral suspension. Refractory candidiasis may require parenteral treatment with amphotericin B or caspofungin.⁵⁷

OROPHARYNGEAL CANDIDIASIS IN HEAD AND NECK CANCER PATIENTS

Pseudomembranous and erythematous OPC are the most common variants of candidiasis in head and neck cancer patients.⁵⁸ The prevalence of OPC in patients receiving either radiotherapy or chemotherapy for head and neck cancer is approximately 38%.⁵⁸ *Candida albicans* is the most frequent species isolated, but other species are recognized including *C. tropicalis* and *C. glabrata*. The increased risk of OPC in these populations is likely related to salivary hypofunction. Amisfostine, an agent that acts to preserve salivary gland function, has been shown to reduce the risk of clinical OPC in patients receiving radiotherapy.⁵⁹ OPC in cancer patients is important to treat and recognize early as maintenance of oral intake and nutritional status is vital in patients receiving chemotherapy and radiotherapy. In addition, patients receiving such treatment are vulnerable to systemic dissemination of fungal infection via lesions associated with oral mucositis; this can be fatal. Non-*albicans* species are more likely to spread into the systemic circulation.

Treatment of OPC in head and neck patients is similar to the treatment of OPC in other populations; however, topical treatment may be uncomfortable in patients with significant mucositis. Oral fluconazole is the recommended first-line treatment for moderate or severe OPC. The use of fluconazole as a prophylactic measure should be used with caution, in view of the emergence of fluconazole resistant strains of OPC and should be restricted to frequent and disabling infection.

Laryngectomy patients with silicone trachea-oesophageal voice prostheses may develop the formation of *Candida* biofilms, which can invade the silicone, causing deterioration of the valve. Valves deteriorate fairly rapidly after placement and normally need replacing after between 3 and 5 months. The main reason for replacement is leakage of fluid into the trachea via an incompetent valve, which is thought to be related to biofilm formation. In 100 Provox2 voice prostheses that were analysed following removal due to leakage of fluid, the most common isolate from the biofilm was *Candida albicans* (53% of isolated fungi), followed by *C. krusei* and *C. tropicalis*.⁶⁰ Eighty three per cent of the valves were found to have biofilms of fungi and bacteria. A promising area has been the development of a nontoxic deoxyribonuclease that has been shown to be effective *in vitro* at dispersing biofilms from discarded voice prostheses contaminated with mixed biofilms.

KEY POINTS

- Fungi exist in nature as yeasts or branching moulds; of the thousands of fungi present naturally in the environment, only around 30 species are commonly associated with human disease.
- Fungal infection within the ear canal results in otomycosis, most commonly caused by *Aspergillus niger* and *Candida albicans*. Rarely, in immunocompromised hosts, fungal otomycosis can result in malignant otitis externa.
- Fungal infection affecting the sinuses can be divided into five main groups: acute invasive fungal sinusitis, chronic invasive fungal sinusitis, chronic granulomatous invasive fungal sinusitis, allergic fungal sinusitis and fungal ball.
- Oropharyngeal candidiasis can be a significant issue in patients with immunocompromise, particularly patients receiving treatment for HIV or head and neck cancer.

Antimicrobial resistance (AMR)	224	References	227

SEARCH STRATEGY

The information in this chapter is based on standard clinical microbiology practice in the UK; evidence level 4 (Expert opinion). Laboratory practices described are based on Public Health England's Standards for Microbiology Investigations (SMI). Data in this chapter may be updated by a PubMed search using the keywords: classification of antimicrobials; antimicrobial spectrum; susceptibility testing; antimicrobial resistance and principles of antimicrobial treatment.

INTRODUCTION

Historically, the prevention and treatment of infection had been one of the most pressing problems medicine was trying to solve. Following the introduction of anti-infective agents in the first half of the 20th century, it seemed as if infection had in all but the most severe cases become a manageable event, rather than a potentially life-threatening catastrophe.

The advances afforded by effective antimicrobial treatments in terms of both surgical and medical interventions have saved millions of lives.

However, shortly after introduction of antimicrobials into clinical practice, resistant organisms developed and began to spread.

When penicillin was first introduced in 1942, all strains of *S. aureus* were susceptible to it and its use during the Second World War contributed to a significant drop in infection associated mortality among wounded soldiers. Already by the mid-1940s, though, the first penicillin resistant strains had developed; they now dominate the circulating strains of *S. aureus* entirely.

Bacterial generation times are short (only 10 minutes for a division of *Escherichia coli*) and their inaccurate genetic replication mechanisms favour random point mutation. Any of these mutations has the potential to result in a new antimicrobial resistance mechanism.

Initially, the development of new antimicrobial compounds was rapid (Table 22.1) and able to keep at least apace with emerging resistances, but since the early 1990s there has been a decline in production of novel agents.

In short: this is a competition in which we're unlikely ever to retain the upper hand.

The threat posed by antimicrobial resistance is now widely recognized (Table 22.2). In March 2013 the Chief Medical Officer, Dame Sally Davies, highlighted the emergence of antimicrobial resistance as a major challenge in her annual report, stating:

The supply of new replacement antimicrobial agents has slowed dramatically and we face the prospect of a future where we have far fewer options in the treatment of infectious disease and infections that, previously easy to control, will become much more significant threats to health. Standard surgical procedures, such as hip replacements, could become riskier with widespread antimicrobial resistance, as would treatments that result in immunosuppression, such as chemotherapy or organ transplant, which rely on the ability to treat infections that occur in this very vulnerable group of patients.

TABLE 22.1 Historical overview of antimicrobial development

Year	Antimicrobial
1935	Protonsil - sulphonamide pro-drug
1942	Benzyl-penicillin
1944	Streptomycin – first aminoglycoside
1948	Chlortetracycline
1949	Chloramphenicol
1952	Erythromycin – first macrolide
1955	Vancomycin – first glycopeptides
1960	Metronidazole
1964	Cephalotin – first cephalosporin
1967	Rifampicin
1968	Clindamycin
1971	Gentamicin
1972	Amoxicillin
1980	Amoxicillin-clavulanic acid
1982	Ceftriaxone – 3rd generation cephalosporin
1987	Ciprofloxacin
1990	Clarithromycin
1992	Piperacillin-tazobactam
1996	Meropenem
2000	Linezolid
2011	Fidaxomycin

TABLE 22.2 Current and emerging problem resistances

- Methicillin resistant *S. aureus* (MRSA)
- Vancomycin resistant enterococci (VRE), also known as glycopeptide resistant enterococci (GRE)
- Penicillin-intermediate or resistant *S. pneumoniae*
- Extended spectrum β -lactamase (ESBL) producing enterobacteriaceae
- Carbapenemase-producing enterobacteriaceae

CLASSIFICATION OF ANTIMICROBIAL AGENTS

Antimicrobial agents can be classified according to several characteristics:

- chemical structure (e.g. β -lactams, quinolones)
- site of action (e.g. cell wall or ribosome)
- mode of action (i.e. bactericidal or bacteriostatic).

A summary of the properties of the most frequently used classes of antibacterial agents can be found in [Table 22.3](#). [Tables 22.4–22.7](#) list important antibacterial agents with their expected spectrum of activity. Please note that the information in these tables should be correlated with local resistance data, and cannot replace local empirical antimicrobial guidance.

SUSCEPTIBILITY TESTING

Once the identity of an organism is known, typical susceptibility patterns can be predicted for some organisms, for example penicillin susceptibility in strains of *S. pyogenes*.

These expected susceptibility patterns form the basis of empirical antibiotic choices.

The majority of resistance patterns are however highly variable and any isolate thought to be clinically significant will be tested formally against panels of antibiotics for their susceptibilities and resistances.

The panels in use may vary from laboratory to laboratory, depending on prevailing patterns of susceptibilities and local antimicrobial policies.

Several different methods for antimicrobial susceptibility testing exist.

Which method will be used may differ between certain organisms, but ultimately all methods demonstrate in vitro presence or inhibition of growth of the organism when exposed to a defined concentration of the tested antimicrobial.

The most accurate method for determining this is the broth dilution method ([Figure 22.1](#)), in which test tubes containing a broth medium are spiked with serial dilutions of the tested antimicrobial. A standardized inoculum of the organism of interest is then added and the tubes are observed for the presence of bacterial growth after a period of incubation. The first dilution with which no growth is observed represents the minimum inhibitory concentration (MIC) of the tested antibiotic.

While this process will yield very accurate information, it is time and labour intensive and routine use in a diagnostic lab is impractical; however, it forms the basis of most automated methods of susceptibility testing.

An alternative method that is in widespread use is antimicrobial disc diffusion testing ([Figure 22.2](#)).

In this, a specific testing medium is inoculated evenly with a standardized suspension of the test organism and a selection of paper discs containing defined amounts of antimicrobials is placed on the medium.

The antibiotic will diffuse from the disc into the medium, leading to a gradient of concentration with the highest concentration just around the disc.

A check for growth patterns takes place after a defined period of incubation and the zone of inhibited growth is measured. In order to be classified as susceptible, this zone must be equal or greater than a certain diameter, which varies between different organisms and different antimicrobials.

The interpretation of these results relies on extensive databases of susceptibility break points (i.e. zone diameters that are deemed to represent clinical susceptibility or resistance). Such databases are compiled by external agencies, such as the British Society for Antimicrobial Chemotherapy (BSAC) or the European Committee on Antimicrobial Susceptibility Testing (EUCAST).

A third method, known as the E-test, uses plastic strips that are coated with the tested antimicrobial forming a concentration gradient along the strip. This is placed on a testing medium inoculated with the test organism and

TABLE 22.3 Commonly used classes of antimicrobials

Chemical class	Site of action	Mode of action	Comments
β-lactams: • Penicillins • Cephalosporins	Cell wall	Bactericidal	<ul style="list-style-type: none"> • Short plasma half lives requiring frequent dosage intervals • Optimum action on actively dividing organisms • Cephalosporins have good penetration through the blood–brain barrier
Carbapenems	Cell wall	Bactericidal	<ul style="list-style-type: none"> • Very broad spectrum • Cautious use, ideally only if confirmed resistances • Once daily dosing possible with some agents • Good penetration through blood–brain barrier
Glycopeptides: • Vancomycin	Cell wall	Bactericidal	<ul style="list-style-type: none"> • Large molecules • Not absorbed from GI tract • Penetration into tissues variable • Potential nephrotoxicity • Require therapeutic drug monitoring
Aminoglycosides: • Gentamicin • Amikacin	Ribosome	Bactericidal	<ul style="list-style-type: none"> • Rapidly bactericidal • Nephrotoxic • Ototoxic • Require therapeutic drug monitoring
Macrolides	Ribosome	Bacteriostatic	<ul style="list-style-type: none"> • Good oral absorption • Gastro-intestinal side effects, but less pronounced with newer agents
Trimethoprim	Di-hydrofolate reductase	Bacteriostatic	<ul style="list-style-type: none"> • Contra-indicated in pregnancy, especially 1st trimester
Sulfamethoxazole	Di-hydropteroate synthetase	Bacteriostatic	<ul style="list-style-type: none"> • Given with trimethoprim as Cotrimoxazole • Inhibits earlier step in tetrahydrofolate synthesis • Contra-indicated in pregnancy, especially 1st trimester
Quinolones	DNA topoisomerase II, gyrase	Bacteriostatic	<ul style="list-style-type: none"> • Good oral bioavailability • Good tissue penetration
Lincosamides: • Clindamycin	Ribosome	Bacteriostatic	<ul style="list-style-type: none"> • Good tissue penetration
Oxazolidinones: • Linezolid	Ribosome	Bacteriostatic	<ul style="list-style-type: none"> • Excellent tissue penetration • Bone marrow toxicity
Nitroimidazoles: • Metronidazole	Directly damages DNA and proteins through formation of radicals	Bactericidal	<ul style="list-style-type: none"> • Exclusively anaerobic cover • Excellent tissue penetration

TABLE 22.4 Commonly used penicillins

Agent	Expected spectrum of activity
Penicillin V Benzyl-penicillin	Alpha-haemolytic streptococci <i>S. pneumoniae</i> <i>S. pyogenes</i>
Amoxicillin	Streptococci, enterococci Some Gram-negative cover
Flucloxacillin	Methicillin-sensitive <i>S. aureus</i>
Amoxicillin with clavulanic acid Piperacillin with tazobactam	Broad spectrum Gram-positive, Gram-negative and anaerobic cover, but not MRSA

TABLE 22.6 Commonly used macrolides

Commonly used macrolides	Expected spectrum of activity
Erythromycin Clarithromycin	<i>S. pyogenes</i> <i>S. pneumoniae</i> <i>S. aureus</i> , including some strains of MRSA

TABLE 22.5 Commonly used cephalosporins and carbapenems

Commonly used cephalosporins	Expected spectrum of activity
Cefuroxime (2nd generation) Cefotaxime (3rd generation) Ceftriaxone (3rd generation)	Broad spectrum Gram-positive and Gram-negative cover, but not MRSA
Commonly used carbapenems	
Meropenem Ertapenem	

TABLE 22.7 Commonly used quinolones

Commonly used quinolones	Expected spectrum of activity
Ciprofloxacin Levofloxacin Moxifloxacin	Broad spectrum Gram-negative cover <i>S. aureus</i> Levofloxacin and moxifloxacin have enhanced Gram-positive cover especially against <i>S. pneumoniae</i>

Figure 22.1 Determination of minimum inhibitory concentration by broth dilution method.

Figure 22.2 Disc diffusion method of susceptibility testing. Courtesy of Jasminder Karde and Margaret Woods, Department of Microbiology, Golden Jubilee National Hospital, Clydebank, UK.

Figure 22.3 Determination of MIC by E-test. The MIC is read where the inhibition zone intersects the test strip. Courtesy of Jasminder Karde and Margaret Woods, Department of Microbiology, Golden Jubilee National Hospital, Clydebank, UK.

again read after a period of incubation. An elliptical zone of inhibition is visible around the test strip, which intersects it at the measured MIC (Figure 22.3).

This test combines aspects of both the above methods – it yields information regarding the minimal inhibitory concentration, while retaining the ease of use of the disc diffusion method.

ANTIMICROBIAL RESISTANCE (AMR)

Broadly speaking, there are two principal types of antimicrobial resistance: intrinsic resistance and acquired resistance.

Intrinsic resistance

In 1984 the bodies of two members of an Arctic expedition led by the British explorer Captain Sir John Franklin in 1845 were exhumed on Beechey Island and autopsied. *Clostridium* spp. were isolated from their guts which were resistant to clindamycin and the second-generation cephalosporin cefoxitin, although they could not have been exposed to any modern antimicrobial.¹

This is an example of intrinsic resistance, which has its basis on traits common to all strains of an organism, such as characteristics of the cell wall or the metabolism, which render them impervious to the effects of an antimicrobial (Table 22.8).

TABLE 22.8 Examples of intrinsic resistance

Organism	Intrinsic antimicrobial resistances	Mechanism
Gram-negative organisms	Vancomycin	Agent unable to penetrate outer membrane of cell wall
Aerobic bacteria	Metronidazole	Aerobic metabolism unable to reduce the agent to its active form
Anaerobic bacteria	Aminoglycosides	Active uptake of agent dependent on oxidative metabolism

TABLE 22.9 Mechanisms of horizontal gene transfer

Mechanism	Genetic element transfer	Method of transfer
Transformation	Free genetic material from lysed organisms	Uptake of exogenous DNA from the environment
Conjugation	Mobile genetic elements, e.g. plasmids or transposons	Via direct cell-to-cell contact or through specific cell bridges (pili)
Transduction	Mobile genetic elements, e.g. plasmids or transposons	Introduction of foreign genetic material via viral (phage) vector

Acquired resistance

If a bacterial organism becomes resistant to an antimicrobial agent or class to which it was previously susceptible, it is said to have developed an acquired resistance.

This may be the result of a new mutation or the transfer of resistances from other organisms.

Chromosomal resistance is the result of a randomly occurring spontaneous mutation, resulting in resistance to an antimicrobial agent. If the host is exposed to the antimicrobial in question, organisms carrying the mutation will have a survival advantage and replace the susceptible isolates. The mutation will be passed on to the progeny of this organism with every cell division; this is referred to as vertical transfer and may lead to treatment failures, but the resistance is unlikely to spread to other strains or types of organisms.

The second, and more worrying, way of acquiring resistance is via mobile genetic elements, which can spread easily between different strains of the same organism, but also between different types of organisms.

This is called horizontal transfer and there are several ways this transfer can occur (Table 22.9).

MECHANISMS OF RESISTANCE

While there are many resistance genes, the effects of them fall broadly into three categories.

Alteration or removal of the antimicrobial's target

Resistance to flucloxacillin in *S. aureus* is the result of the alteration of the binding site of penicillin in the organism's cell wall components.

Usually, penicillin disrupts cell wall synthesis by attaching to a part of the peptidoglycan component known as the penicillin binding protein (PBP) and prevents cross linking of the components into a normal cell wall structure.

The *mecA* gene of methicillin-resistant strains of *S. aureus* (MRSA) encodes for an altered penicillin binding protein called PBP2a, which does not allow attachment of any β -lactam agent and therefore renders the organism resistant to this class of antibiotic.

Alteration of the drug leading to loss of activity

Many Gram-negative organisms produce enzymes called β -lactamases that are able to cleave the β -lactam ring of penicillins, rendering them resistant to their effects. They are usually located in the peri-plasmic space between the outer membrane and the peptidoglycan cell wall.

This enzyme can be inhibited, and several penicillin- β -lactamase inhibitor combination agents are available, such as amoxicillin with clavulanic acid or piperacillin with tazobactam.

If the enzyme is able to cleave not only the β -lactam ring of penicillins, but also that of third-generation cephalosporins, this enzyme would be classed as an extended spectrum β -lactamase (ESBL).

If the enzyme in question cleaves not only the β -lactam ring of penicillins and third-generation cephalosporins but also the carbapenem ring, it is classed as a carbapenemase.

Gram-negative organisms carrying various β -lactam resistance mechanisms are endemic in many parts of the world and frequently carry resistance mechanisms conferring resistance to additional classes of antimicrobials, rendering the organisms difficult to treat.

Alteration of the drug's access to its target

The easiest way of preventing a drug from acting on its target is by removing the drug before it even reaches the target.

Many bacteria have incorporated efflux pumps that share some molecular components with the flagellar apparatus into their cell walls. This comes at a price – while many of these efflux pumps are able to remove more than one type of antibiotic, the transport of the drug across the membrane is an active process that uses significant amounts of energy.

Resistance to tetracyclines in Gram-positives is the result of such an efflux pump.

Resistance to an agent may be mediated via different mechanisms in different organisms and different mechanisms conferring resistance to multiple antimicrobial classes may coexist in the same organism; listing all possible combinations of organisms and resistance mechanisms would be beyond the scope of this chapter.

CONTROLLING ANTIMICROBIAL RESISTANCE

The rise of resistant organisms has been recognized as a major healthcare challenge on a national and international level and the World Health Organization and the British Department of Health have both recently published guidance documents on AMR control.

The issue is a complex one, as antimicrobials in the form of antibacterial, antifungal, antiviral and anti-parasitic chemotherapy are used not only in a human healthcare setting, but also in veterinary medicine and agriculture.

In addition to this, resources, prescribing practice and surveillance programmes differ markedly between countries, making it difficult to develop an approach that is suitable for global application.

In the UK, the following key factors have been identified by the Department of Health:²

- Enhanced surveillance in order to identify existing and novel resistance patterns quickly
- Optimizing prescribing practice and antimicrobial stewardship, ensuring that antibiotics are only prescribed when needed and the correct agent is given for the correct amount of time
- Improving infection prevention and control
- Encouraging the development of new antibiotics, diagnostic strategies and novel therapies

PRINCIPLES OF ANTIMICROBIAL TREATMENT

Antimicrobials are amongst the most commonly prescribed medication in both primary and secondary care.

Approximately one-third of all inpatients at any given time are receiving some form of antimicrobial treatment.³

In order to ensure that unnecessary prescribing is minimized, it is good practice to adhere to some basic principles when considering antimicrobial treatment.

Identification of the source of infection

Ideally, antibiotics should only be prescribed when a clear clinical source has been identified. This relies heavily on careful clinical examination and consideration whether or not a bacterial infection is likely.

In suspected deep-seated infections, such as intracranial abscesses, imaging forms an integral part of the diagnostic process.

Appropriate sampling

Clinical samples from the suspected focus of infection should be collected before any antimicrobial therapy is commenced.

If the patient is septic (i.e. fulfils the criteria of systemic inflammatory response with a suspected infective focus), at least one set of blood cultures should be taken peripherally, and from any vascular access devices if present.

If a deep infection is present and the patient is stable, it may in some cases be possible to delay antimicrobial therapy until a diagnostic tap or drainage can be performed in order to maximize the chances of recovering the causative organism.

Source control

If the source of infection is identified as an abscess or collection, this should be drained wherever possible, as abscesses are not vascularized and penetration of antimicrobials into the cavity is very poor, even if given intravenously.

Recovery of organisms is more likely to be successful if a volume of pus in a sterile container is sent to the laboratory as opposed to a swab.

If the infection involves prosthetic material or a device, treatment success may depend on removal of the foreign material as this is obviously not perfused and may harbour bacteria in a sticky polysaccharide matrix known as a biofilm.

Choice of initial antimicrobial agent

Empirical antimicrobial therapy targets the most likely causative agents of a clinical syndrome, and local policies should be adhered to as they will take into account local resistance patterns.

Ideally, empirical broad-spectrum cover should be avoided as it will disrupt the normal protective gut flora and may also prevent a microbiological diagnosis. In a patient assumed to be bacteraemic, inclusion of a rapidly bactericidal agent in the regimen should be considered.

Appropriate dosing

Giving an appropriate dose of the correct antimicrobial maximizes the chance for cure of disease and may prevent development of resistance due to exposure to sub-therapeutic levels of antimicrobials.

A variety of reasons may prompt dose adjustments in antimicrobial treatment.

Patients with renal disease and low creatinine clearance require dose adjustments for many classes of antimicrobials.

The dosing of aminoglycosides and glycopeptides is usually adjusted to the patient's body weight and creatinine clearance. Local guidelines for dose calculation should be adhered to.

A special case is the dosing of antimicrobials in the morbidly obese, where standard dosing may not result in achievement of therapeutic serum or tissue levels.

These cases should be discussed with a pharmacist to ensure that appropriate doses are prescribed and serious side effects are avoided.

Route of administration

Many uncomplicated infections, especially in the primary care setting, will only require oral antimicrobial treatment. Indeed, depending on the source of infection, topical antimicrobials alone may be indicated, for example in the treatment of mild otitis externa.

However, if the infection is accompanied by signs of systemic upset and sepsis is suspected, the patient may well be bacteraemic and antimicrobial treatment should be given intravenously initially.

Bacteraemia should always be treated with an appropriate intravenous antimicrobial; the duration of intravenous

treatment may depend on the organism involved and the underlying source of infection.

In deep-seated infections or infections in poorly vascularized tissue, intravenous treatment is likely to continue for a prolonged course.

De-escalation and switch to oral administration of treatment

Once culture results are available, antimicrobial therapy should be adjusted according to the susceptibility of the organism in order to allow targeted treatment with a narrow spectrum agent.

If treatment has commenced via the intravenous route and clinical improvement is observed, the administration route should be reviewed after 48 hours by the latest and a switch to oral antimicrobials considered, provided blood cultures remained negative and oral treatment is appropriate for the source of infection.

Completing a course of treatment

Giving an antimicrobial for an appropriate amount of time maximizes the rate of cure of disease and reduces the risk of relapse and need for further courses of likely broader spectrum antimicrobials.

The duration of the course will differ between different foci and also partly depend on the organism involved. Generally speaking, deep-seated infections and infections in poorly vascularized tissue such as cartilage and bone will require extended courses of treatment with agents that are able to penetrate into these tissues to reach therapeutic levels.

KEY POINTS

- Antimicrobials may be classified by chemical class and mechanism of action.
- Organisms can display intrinsic resistance to certain agents.
- Acquired resistance may arise as a direct consequence of exposure to antimicrobial agents. There are a number of resistance mechanisms, some of which can spread within bacterial populations and between different bacterial species via mobile genetic elements.
- The control of antimicrobial resistance is a major public health challenge.
- Any decision to commence antimicrobial therapy should comply with best practice principles.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: acquired immunodeficiency syndrome, antiretroviral therapy, highly active, HIV, HIV infections, lymphadenopathy, otolaryngology, otorhinolaryngologic diseases, sarcoma and kaposi.

INTRODUCTION

Human immunodeficiency virus (HIV) has had a profound impact on global healthcare in the 30 years since its discovery. In 1981 healthy young men in America started to become gravely ill with atypical infections and tumours, previously only seen in the severely immunocompromised; the term acquired immuno-deficiency syndrome (AIDS) was coined. In 1983, HIV was isolated and identified as the causal agent. HIV is now a worldwide epidemic that affects individuals of every age, sex and socioeconomic group, with 34 million people infected.¹

Sub-Saharan Africa continues to bear the brunt of the epidemic, and accounted for 69% of all people living with HIV and 72% of new cases in 2011. Since 1998 more than 1 million people a year have died from HIV infection in Sub-Saharan Africa. South Africa alone has 5.6 million infected people, compared to 1 million in Western and Central Europe and 1.3 million in North America. The number of people infected with HIV continues to increase; however, the number of new cases per year and the number of deaths per year have been falling since the peak of the disease in 1997. Eastern Europe and Central Asia (particularly the Russian Federation and Ukraine) are bucking the trend for HIV control, with a 250% increase in HIV infection from 2001 to 2010. Changing health policies and new treatments are responsible for the relative decline

of the HIV epidemic. Public health campaigns have helped to change behaviour with an increase in condom use and a decrease in the number of sexual partners. Antiretroviral therapy for pregnant HIV-infected women has reduced mother-to-child spread. Targeting of high-risk groups such as sex workers (free condoms) and intravenous drug users (needle exchange programmes) has been effective. The effectiveness of these interventions is impeded by the number of people living with HIV who are unaware of their infected status; 84% of HIV-infected adults in Kenya were unaware of their infection² and in the UK the figure is 24%.³

Head and neck manifestations of the disease are prevalent and up to 100% of HIV patients will have some head and neck presentation of the disease during the course of their illness.

HUMAN IMMUNODEFICIENCY VIRUS

HIV is a retrovirus, of the lentivirus genus. There are two strains of the virus: HIV-1 and HIV-2. HIV-1 is the global epidemic strain, while HIV-2 is largely limited to West Africa and is less virulent. The HIV genetic material is a diploid, single-stranded ribonucleic acid (RNA) that uses the enzyme reverse transcriptase to

convert its single-stranded RNA into double-stranded deoxyribonucleic acid (DNA). The viral RNA encodes three virus specific genes: *pol*, *gag* and *env*. *Pol* encodes the enzymes for viral replication (polymerase, integrase and protease) while *gag* encodes the inner structural proteins. *Env* encodes the glycoproteins responsible for the viral envelope; this envelope contains two glycoproteins, gp41 and gp120, which form a complex essential for viral proliferation. gp120 binds to the glycoprotein receptor CD4 on the host-cell membrane. CD4 is found in highest concentrations on T helper lymphocytes and it is through these cells that HIV primarily proliferates. Once gp120 and CD4 are bound, the viral and host cell membranes fuse. This allows the viral contents to be injected into the host cell. Reverse transcriptase then catalyses the synthesis of viral DNA from RNA. The viral DNA then migrates into the host nucleus and is incorporated into the host cell genome through the action of integrase. This means that the viral genome is replicated along with the host cell DNA and passed onto progeny cells. Once activated, the provirus begins to synthesize new virus particles using host cell transcription machinery. Cells of the monocyte/macrophage lineage also express CD4 and thus can be infected by HIV and act as reservoirs.^{4,5}

HIV infection is characterized by three distinct phases: seroconversion, asymptomatic infection and AIDS. Seroconversion starts within 2 weeks of inoculation; viraemia occurs with widespread dissemination of the virus throughout the body. Reservoirs of infection are created in macrophages. The viral load is high and a sharp decline in the number of CD4+ cells occurs. The individual is very infectious at this stage. Eventually the immune system attains a degree of control and this leads to a reduction in the viral load and a recovery of the peripheral CD4 cell count but infection is not eradicated. Half of seroconverting patients experience symptoms, typically a 'flu-like' illness with fever malaise and generalized rash. The next phase of HIV infection lasts for several years, during which the patient is asymptomatic. During this latency period viral replication and CD4 lymphocyte destruction continues; however, the body's immune response keeps the viral load in check. Circulating CD4 counts are generally high during this period. Once the CD4 count starts to decrease, symptomatology may resume, beginning with fatigue and generalized lymphadenopathy. Further decreases in CD4 count produce more constitutional symptoms including fever, sweats, chills, weight loss, night sweats and diarrhoea. Eventually the CD4 cells reach a level where an effective immune response can no longer be mounted (less than 200 cells per microlitre). At this stage, the incidence of opportunistic infections and AIDS associated neoplasms greatly increases. T helper cells are important in the immune response against viruses and fungi, hence these infections are the most commonly encountered. Conditions such as *Pneumocystis carinii* pneumonia and Kaposi's sarcoma are diagnostic for AIDS. Untreated AIDS is universally fatal.

HIV TESTING

With prompt treatment, HIV morbidity and mortality can be minimized. One of the most important factors in poor prognosis is late presentation.⁶ Furthermore, undiagnosed individuals pose a significant risk of further transmission. Detection of HIV infection is therefore an essential pillar of HIV interventions. There are two main misconceptions regarding HIV testing: it requires extensive pre-test counselling and it will have an impact on future insurance policies for the patient. Where an HIV test is clinically indicated, extensive pre-test counselling is not required. Informed consent should be taken including discussion of the benefit of testing and how the results will be given. It is recommended that if a test is positive the clinician should have identified the appropriate local treatment providers and established a clear plan for onward referral prior to the consultation.⁷

Testing for HIV, by an otolaryngologist, should be carried out whenever HIV infection enters the differential diagnosis. In particular otolaryngologists should test patients with the following conditions: unexplained oral candidiasis, hairy leukoplakia of the tongue, atypical head and neck cancers, parotid cysts, cervical lymphadenopathy, chronic parotitis and pyrexia of unknown origin. High-risk groups should also be offered testing. In the UK all patients who attend antenatal, genito-urinary medicine clinics and drug dependency services are offered HIV testing. In the United States, the Preventative Services Task Force has recommended screening for all individuals aged between 15 and 65.⁸

THERAPY

Over the past 15 years significant progress has been made in the treatment of HIV-infected individuals. Highly active antiretroviral therapy (HAART) has transformed the prognosis for people living with HIV, turning the disease from a fatal affliction into a manageable chronic condition. HAART is a treatment consisting of various regimens of multiple pharmaceutical agents. Each drug in a HAART regimen inhibits a different part of the viral lifecycle. By inhibiting the virus at multiple stages effective viral suppression can be obtained. The commonly used drugs inhibit one of the three main viral enzymes for replication: reverse transcriptase, protease and integrase.

Two classes of drugs inhibit reverse transcriptase; nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs) and non-nucleoside reverse transcriptase inhibitors (NNRTIs). NRTIs are the oldest antiretroviral drugs and still have a central role in antiretroviral therapy. NRTIs are structurally similar to DNA nucleosides. Since reverse transcriptase lacks error correction, when it incorporates NRTIs into the proviral DNA, the replication process is terminated. NNRTIs inhibit reverse transcriptase by binding directly to its active site.

HIV protease catalyses the maturation of viral particles by cleaving polypeptides responsible for capsule

formation. Protease inhibitors (PIs) are highly robust antiretrovirals but their complex absorption kinetics require complex regimes and lack patient acceptability. However, the use of the PI ritonavir as a pharmacological booster has revolutionized their use by allowing once or twice daily regimes without difficult dietary restrictions.

Other classes of antiretrovirals include integrase inhibitors, entry inhibitors and fusion inhibitors but these are usually reserved for patients intolerant of first-line therapy or with resistant infection.

When used as monotherapy, antiretroviral resistance rapidly develops through the accumulation of mutations in viral genome caused by the relatively imprecise action of reverse transcriptase. This means that antiretroviral therapy must be delivered as combinations, usually of three drugs. The most common first-line regimes consist of two NRTIs (the backbone) with either a NNRTI or PI. With current HAART regimes, up to 95% of patients can achieve viral suppression with an undetectable viral load.

Not all people living with HIV need HAART. Current UK guidelines suggest healthy patients in the asymptomatic phase with a high CD4 count only require monitoring. Current British HIV Association guidelines suggest a CD4 threshold of 350 cells/ul. Development of serious HIV related infections or malignancies are other indications for initiation of HAART.

OTORHINOLARYNGOLOGICAL MANIFESTATIONS

The relative sparing of the humoral immune response in HIV-infected patients means that the incidence of most bacterial infections is similar to non-HIV-infected patients. Conditions such as bacterial otitis externa, bacterial sinusitis and tonsillitis have generally the same infective agents and treatments in HIV and non-HIV patients. This chapter will concentrate on the more challenging and unusual conditions that HIV patients encounter.

ACUTE HIV INFECTION

Patients recently infected with HIV can present to the otolaryngologist with the symptoms of their initial infection. Detection of infection at this stage is important both for the patients and from the perspective of public health. Patients with acute infection usually have a very high viral load and are therefore highly infectious. Early diagnosis gives an opportunity to intervene before further infections occur. Acute infection usually presents non-specifically; however, common symptoms include fever, pharyngitis, lymphadenopathy, oropharyngeal ulceration and rash. Heterophile antibody testing is usually negative but there are reports of positive tests in acute HIV.

UK testing guidelines recommend all patients with a mononucleosis-like illness should be offered an HIV test.

CERVICAL LYMPHADENOPATHY

The presence of peripheral lymphadenopathy is common in patients infected with HIV. In the era of HAART, AIDS-associated malignancies have become less common and it has become clear that patients with HIV are also at increased risk of non-AIDS malignancies including head and neck, lung and upper-gastrointestinal cancers with an overall odds-ratio of around 2–4.

Persistent generalized lymphadenopathy is a common feature of early symptomatic HIV infection, with cervical nodes the most commonly involved. Lymph nodes are usually small, symmetrical and non-tender. Biopsy is not required unless an alternative diagnosis is suspected and is usually prompted by continued enlargement or asymmetry. When biopsy is conducted, it reveals follicular hyperplasia and no treatment is required.

Other causes of lymphadenopathy common in patients with HIV include non-Hodgkin's lymphoma, Hodgkin's lymphoma, tuberculosis, syphilis, Kaposi's sarcoma (KS) and metastatic solid organ malignancies. Less common causes include infections such as mycobacterium avium complex, syphilis, dimorphic fungi and toxoplasmosis.

Castleman disease is a rare lymphoproliferative disorder. In most immunocompetent patients it is a localized disorder that rarely causes systemic symptoms. However, in HIV associated disease most patients present with constitutional symptoms associated with organ involvement (multicentric disease). The disorder is associated with human herpes virus-8 (HHV-8) infection, which is also the viral cause of KS.⁹ Patients with multicentric Castleman disease present with fever, weight loss and lymphadenopathy. Diagnosis is made with excision biopsy.

KAPOSI'S SARCOMA

Kaposi's sarcoma (KS) is a malignant spindle cell tumour. Initially it was a rare condition seen in elderly Mediterranean men (classical KS); however, it is now mostly associated with HIV infection. KS is an AIDS-defining condition and is the most common HIV-related tumour. KS is caused by the co-infection of HIV and HHV-8. Untreated HIV KS is an aggressive tumour; however, the advent of HAART has led to a decrease in the incidence and severity of KS.

KS presents with cutaneous or mucosal lesions, most commonly in the head and neck. Visceral organs and lymph nodes can also be involved. Cutaneous lesions are variable in nature; the colour varies from purple to dark brown, the size is from a few millimetres to several centimetres, there may be multiple lesions or a single lesion, and the lesions may be flat, raised or nodular. Oral mucosa lesions are classically raised and red and may ulcerate. Patients with suspected KS should have an HIV test and CD4 count; a biopsy will confirm the diagnosis.

HAART is the mainstay of KS treatment; as the immune system recovers the condition regresses. In advanced cases HAART may not be sufficient and local treatment is required. Localized radiotherapy to cutaneous or oral

lesions provides good control of the disease although HIV patients are more prone to radiation side effects.¹⁰ Surgical excision also provides local control; however, recurrence is common even with clear margins of excision. Other treatment modalities include topical retinoids, intra-lesional chemotherapy, laser coagulation and cryotherapy.

Bacillary angiomatosis is a condition that mimics KS and should be considered in the differential diagnosis. Bacillary angiomatosis is a bartonella infection in HIV patients that causes a vascular proliferation. The resulting lesions have an angiomatous appearance very similar to KS. Biopsy and microbiological studies will differentiate from KS. Bacillary angiomatosis resolves with antibiotics; erythromycin is the drug of choice.

OTOLOGIC

External ear

Malignant otitis externa (MOE) has a higher incidence in HIV patients. Osteomyelitis of the skull base causes facial nerve or cranial nerve dysfunction. Diagnosis can be confirmed using a computerized tomography (CT) scan of the temporal bone or a technetium 99m bone scan. The causative agent for malignant otitis externa is usually *Pseudomonas aeruginosa*, although in patients with very low CD4 count *Aspergillus* is common and can be very invasive.^{11, 12} In *Pseudomonas aeruginosa*, the treatment is 6–8 weeks of antibiotics. A combination of an antipseudomonal third-generation cephalosporin with either ciprofloxacin or aminoglycoside is appropriate.¹³ Invasive *Aspergillus* should be treated with intravenous antifungals such as amphotericin B. Surgical debridement may be necessary in more severe cases.

Pneumocystis jiroveci (previously known as *Pneumocystis carinii*) can infect the external auditory canal but may also involve the middle ear and mastoid bone. It may present as either a cyst or polyp, and the cyst if allowed to grow can occlude the external auditory canal or spread to the middle ear cleft and middle cranial fossa. The diagnosis is made by biopsy. Treatment with trimethoprim/sulphamethoxazole and/or dapsone¹⁴ usually results in resolution of infection.

Middle ear

The most common otologic entities seen in HIV-positive individuals are serous and recurrent otitis media. There are a variety of aetiologies that includes Eustachian tube dysfunction, nasopharyngeal neoplasms, adenoid hypertrophy and sinusitis/allergies. Nasopharyngeal neoplasms should be ruled out in HIV-infected individuals, particularly with unilateral otitis media. Myringotomy and tympanostomy tube placement can offer symptomatic relief easily and quickly. Treatment of associated sinusitis or allergies should be instituted. Adenoidectomy may be indicated when more conservative measures fail.

Mycobacterium tuberculosis (TB) is a common infective agent in HIV. *Mycobacterium tuberculosis* should be considered in patients with an otitis media unresponsive

to conventional therapy. The classical TB otitis media signs of multiple tympanic membrane perforations, granulations, painless otorrhoea and bone necrosis may not be evident in HIV patients. Tissue biopsies and microbiology cultures may be diagnostic; however, false negatives are common. Antituberculous chemotherapy should be continued for a minimum of 6 months. Surgery to remove sequestrum may speed up recovery; however, a conservative approach has also been shown to be effective.^{15, 16} Atypical mycobacteria such as *Mycobacterium avium* complex are also reported to cause otitis media in patients with HIV.¹⁷

Inner ear

Vestibular and cochlear symptoms are common in HIV-infected individuals. Sensorineural hearing loss is reported to be more common than in uninfected patients and to correlate with stage of disease.¹⁸ Sudden sensorineural hearing loss is also reported to be more than twice as common in this patient population.¹⁹ Identified causes of hearing loss include direct HIV central nervous system involvement, opportunistic infection, immune-reconstitution and drug induced ototoxicity.

Opportunistic infections associated with hearing loss include cytomegalovirus, herpes simplex virus, varicella zoster virus, *Cryptococcus neoformans* and syphilis. The role of antiretrovirals in sensorineural hearing loss is unclear; a cohort study suggested an association with NRTIs but this was not confirmed prospectively. Other drugs commonly used in patients with HIV associated with hearing loss include macrolides, aminoglycosides and isoniazid. There is some evidence that patients with HIV are more susceptible to aminoglycoside ototoxicity.

Otosyphilis is a rare but important cause of hearing loss in HIV. Patients with HIV can have an abbreviated course of syphilis with features of neurological involvement occurring early. Otosyphilis classically presents with hearing loss sparing the mid-range frequencies, tinnitus and vertigo mimicking Meniere's disease. Diagnosis is with serological testing. Treatment is with high dose procaine penicillin in combination with probenecid. The role of corticosteroids is controversial and evidence is limited but some experts recommend their addition.

Facial nerve palsy can occur in up to 7.2% of HIV patients and is referable to direct infection by the HIV, neoplasms, opportunistic infections, AIDS encephalopathy and toxoplasmosis. Bell's palsy is the most frequent diagnosis given for CN VII paralysis. It is postulated to be caused by HSV and is a diagnosis of exclusion. Complete recovery usually occurs within 3 weeks to 3 months.

Ramsay Hunt syndrome (herpes zoster oticus) usually occurs later in HIV infection and is more prevalent in AIDS patients. Symptoms include peripheral facial nerve palsy, herpetic vesicles along the seventh nerve dermatome and in the conchal bowl, and severe herpetic pain. Treatment is with high-dose acyclovir and high-dose steroids when not contraindicated.

Bilateral facial nerve palsies have been reported²⁰ and usually represent a systemic disease. Serology tests for

syphilis, cytomegalovirus, herpes simplex, herpes zoster and Epstein Barr virus should be carried out. MRI of the brain and CSF analysis will aid the diagnosis.

Patients with a low CD4 count may present with central nervous system disease with few or ambiguous clinical signs. There should be a low threshold for neuroimaging and lumbar puncture. Investigation and management should be undertaken in consultation with a physician with expertise in the management of HIV.

NOSE AND PARANASAL SINUSES

Thirty to sixty-eight per cent of HIV-positive patients will manifest some form of nasal and/or sinus symptom.²¹ Nasal obstruction secondary to a variety of aetiologies is a complaint that commonly causes these patients to see an otolaryngologist. Adenoidal hypertrophy can present as nasal obstruction, as can hypertrophy of any of the tissues in Waldeyer's ring. Any non-paediatric patient with adenoid hypertrophy should be tested for HIV.

Neoplasms such as KS or non-Hodgkin's lymphoma can also cause nasal obstruction. Both lesions can arise from the nasal cavity or nasopharynx. Kaposi's sarcoma can also arise from the nasal septum. Non-Hodgkin's lymphoma can also arise from the sinuses.

Sinusitis in HIV-positive individuals is similar to that in non-infected persons with *S. pneumoniae*, *M. catarrhalis* and *H. influenzae* the main infective agents. In HIV-positive persons with fever of unknown origin, the sinuses should always be investigated for possible infection. The bacteriology of chronic sinusitis differs from that of acute sinusitis. In patients with CD4 counts less than 200/mL, *S. aureus*, *P. aeruginosa* and anaerobes become more prominent, and antibiotic therapy should be broadened to include these organisms. As the CD4 count decreases below 50/mL, fungal infection of the sinuses can occur (Figure 23.1), with the majority of fungal infections caused

Figure 23.1 In advanced HIV disease, invasive fungal infection of the paranasal sinuses must be considered. As seen in this axial CT scan, subtle bony erosion with extension into the infratemporal fossa (arrow) indicates an invasive fungal process.

by *Aspergillus*. Other pathogens reported in the literature include CMV, *Microsporidia*, *Acanthamoeba castellanii* and *Legionella pneumophila*.

Evaluation of sinusitis in HIV involves bacteriology culture, nasal endoscopy and CT scanning. The mainstays of medical management of sinusitis are antibiotics and decongestants. First-line antibiotics include amoxicillin, co-amoxiclav, cephalosporins and co-trimoxazole. Topical nasal steroids may also be considered as an adjunctive therapy. There is also evidence suggesting a role for guaifensin therapy for these patients.²²

Surgery is advocated in patients with persistent symptoms despite medical therapy, or in any patient at any time with extra-sinus symptoms (mental status changes, cranial nerve dysfunction, intra-cranial extension, abscess, etc.). Endoscopic sinus surgery is safe and effective. The goal of surgery should be symptomatic relief, as well as optimizing nasal anatomy to facilitate drainage of the sinuses. However, as HIV disease progression continues and CD4 counts decrease, the physician can expect recurrent sinus infections that become more difficult to treat.

ORAL CAVITY

Oral cavity manifestations of HIV are extremely common and have been reported in up to 100% of AIDS patients. Oral manifestations are also common in patients with relatively high CD4 counts and are often the first manifestation of HIV in otherwise asymptomatic patients. Oral manifestations are also common in patients on HAART, despite the generally low incidence of manifestations of immunosuppression in this group.

Recurrent aphthous ulcers are common in immunocompromised patients and are generally larger than those in non-immunocompromised patients. On examination, the lesions are solitary or multiple, have an erythematous halo that is well circumscribed, and may have an exudate or pseudomembrane. The lesions are tender to palpation, and in giant aphthous ulcers can cause severe odynophagia and pain. In severe cases, the pain may accentuate the anorexia and dehydration common in advanced HIV. Treatment is primarily to provide symptomatic relief. Topical anaesthetics or steroids are often effective in less severe cases. Topical tetracycline or systemic clindamycin are effective agents when superimposed infection is present. An intralesional steroid injection with triamcinolone acetonide has been shown to have analgesic effects within 24–48 hours after injection, and has very few side effects.²³ Oral thalidomide has been shown in some studies to heal ulcers completely in 55% of patients and partially in 90% of patients, but is only recommended to be used for 2–4 weeks at a time secondary to increased HIV viral load. Thalidomide also has teratogenic effects limiting its use in women. Ulcers that do not respond to local treatment should be biopsied for pathological examination.

Oral candidiasis is a common infection in HIV patients. The most prevalent form is pseudomembranous candidiasis (thrush) and is characterized by a tender white plaque atop an erythematous and erosive mucosal surface. In the

chronic hypertrophic form, the plaques are heaped up and not easily removed with scraping. As with recurrent aphthous ulcers, the lesions can be extremely painful, leading to malnutrition, dehydration and wasting if not effectively treated. Oesophageal candidiasis can coexist with oropharyngeal lesions and patients should be questioned about oesophageal symptoms since oesophageal involvement will require systemic therapy. Treatment of mild disease consists of Nystatin mouthwash. Clotrimazole or amphotericin lozenges are also effective. Systemic therapy is indicated in patients with worsening immunocompromise or thrush unresponsive to topical agents. Fluconazole is the most commonly used agent – failure to respond can indicate resistance and samples for culture should be sent for sensitivity testing. A minority of cases require intravenous therapy with amphotericin or echinocandins.

Hairy leukoplakia is unique to HIV-positive individuals and typically arises on the lateral border of the tongue as a white, raised, corrugated or filiform lesion. It can also arise on the dorsal tongue, buccal and labial mucosa, floor of mouth or soft palate. It requires no treatment and is usually asymptomatic (Figure 23.2).

Figure 23.2 Hairy leukoplakia of the tongue.

Figure 23.3 While often presenting as solitary lesions, oral papillomas can be widespread covering much of the oral and oropharyngeal mucosa. This patient has multiple papillomas of the dorsal tongue, which predictably recurred following surgical management.

Oral herpes simplex commonly presents as herpes labialis (fever blisters, cold sores). The lesions frequently present as small bullae that form ulcerations after they rupture. These lesions are painful and are generally larger in HIV patients than in immunocompetent individuals. Treatment consists of oral acyclovir; long-term secondary prophylaxis may be required for frequent recurrence.

Gingivitis in HIV patients tends to be more severe than in non-infected patients. Bleeding from the gums can occur with minimal or no trauma. Periodontitis presents as loosening of periodontal attachments. It can progress to acute necrotizing ulcerative gingivitis, which is an ulcerative process along the gingival margin leading to destruction of the periodontal soft tissues. Treatment consists of antibiotics aimed at anaerobic organisms and topical irrigations with chlorhexidine gluconate. If available, a referral to a dentist or oral surgeon should be made early in the process.²⁴

Human papilloma virus can present as a verrucous, flat or spiky lesion in the oral cavity. It appears similar to venereal warts and usually appears in synchrony with anal or genital lesions. While often solitary lesions, these can occur as widespread involvement of the entire oral cavity and oropharyngeal mucosa (Figure 23.3). Treatment consists of surgical excision, but recurrence is likely.

Xerostomia secondary to chronic inflammation of the major and minor salivary glands is frequently seen in HIV patients. The treatment is for symptomatic relief and consists of oral irrigations, saline rinses, salivary substitutes and sialogogues.

KS is the most common HIV-related oral malignancy, with the majority arising on the palate. This tumour can also appear on the gingiva (Figure 23.4) or oropharynx.

Non-Hodgkin's lymphoma (NHL) may also arise in the oral cavity. In AIDS patients, NHL is usually a poor prognostic indicator of disease progression. Recurrences are common despite chemotherapy and radiation. The lesions may present as ulcerative lesions, but typically appear red and exophytic. They usually involve the gingiva and alveolar ridges and may arise from Waldeyer's ring.²⁵

Figure 23.4 The gingiva is a common site for presentation of Kaposi's sarcoma.

TABLE 23.1 Characteristics and treatment of the most common oral manifestations of HIV

Disease		Management	Comment
Gingival disease	Can develop gingival tissue loss, tooth loosening/loss, bone exposure	Best treatment is frequent dental cleanings, flossing, etc. Aggressive antibiotics and/or surgical management when advanced	Common in HIV. Requires close dental evaluations and frequent management
Oral thrush	Pseudomembranous candidiasis: <ul style="list-style-type: none"> • Typical plaque-like lesions • Atrophic form with erythematous lesions on palate, buccal mucosa, tongue • Angular cheilitis 	Topical agents such as clotrimazole. Systemic agents (e.g. fluconazole) for refractory cases in patients with advanced disease	Prolonged or frequent use of fluconazole increases risk of azole-resistance candidiasis
Oral aphthous ulcers	Lesions may be large. Biopsy confirms non-neoplastic, non-viral aetiology	Topical steroid therapy. Intra-lesional or systemic steroids. Thalidomide. Antiretroviral therapy	Are usually difficult to treat. Produce severe pain, odynophagia. Often cause substantial morbidity
Kaposi's sarcoma	Typically on hard, soft palate. Occasionally on gingival, buccal mucosa	Symptomatic relief. When functionally problematic, low-dose radiotherapy or intra-lesional vinblastine or systemic chemotherapy	
Radiation mucositis	Side effect of treatment for other oral lesions	Topical therapy (steroids, antifungals, etc.) Supportive care – nutrition, pain management, hydration	Can result even from low doses of radiation
Hairy leukoplakia	Usually occurs on side of tongue. Probably Epstein-Barr virus related	No treatment necessary if asymptomatic	Must be differentiated from other more serious oral disorders

Table 23.1 reviews the characteristics and treatment of many of the most common oral manifestations of HIV disease.

PHARYNX, LARYNX AND OESOPHAGUS

Many of the same processes that affect the oral cavity can also affect the larynx and pharynx. Many of these processes present with similar symptoms: odynophagia, dysphagia and in some cases, chest pain. Correctly identifying and treating these processes can not only provide symptomatic relief but also in many cases help in dealing with the wasting and malnutrition that can occur.

Candidiasis of the oesophagus and pharynx can cause severe dysphagia, odynophagia and weight loss. Laryngeal infection presents as hoarseness and in severe cases stridor and shortness of breath. Barium swallow will show an irregular cobblestone surface to the mucosa. Direct visualization can be obtained with panendoscopy and biopsy will exclude KS. Treatment is with systemic fluconazole.

Cytomegalovirus is the second most common infectious ulcerative condition of the upper aerodigestive tract. Of patients who fail empirical antifungal therapy, approximately one-third will have CMV ulcerations.^{26, 27} These ulcers tend to occur more commonly in the distal oesophagus with a raised indurated border and necrotic base. While occasionally occurring as solitary ulcers, CMV can also form multiple or diffuse ulcerations and lacking any defined pathognomonic appearance. Unfortunately, other than biopsy and culture, there are also no disease specific clinical characteristics that differentiate this from other forms of ulcerative oesophagitis. Once the diagnosis has been established, treatment can be instituted using intravenous ganciclovir or foscarnet.

Herpes simplex viral infection in the pharynx, larynx or oesophagus can present with similar symptoms as oesophageal and laryngeal candidiasis. Examination reveals discrete vesicles with mucosal ulceration. Biopsy and viral culture of lesions confirm diagnosis. The occurrence of HSV is usually associated with significant immune dysfunction, usually occurring only when the CD4 level is well below 100/mm²⁸ Treatment usually starts with intravenous acyclovir followed by oral agents.

Idiopathic oesophageal ulcer arises with the same frequency as CMV oesophagitis. Its aetiology is unclear and there is usually no associated specific infectious aetiology. These lesions also usually occur with severe immunocompromise. The endoscopic appearance is similar to CMV lesions, often with solitary, large ulcerations with raised indurated margins. Treatment has been effective using systemic steroids.²⁹ Successful treatment has also been described with thalidomide.³⁰

Kaposi's sarcoma can present primarily in the pharynx and/or larynx or extend to adjacent areas including the oral cavity. Oesophageal KS may present with dysphagia or odynophagia. Laryngeal lesions may present as shortness of breath, hoarseness or severe airway compromise.

SALIVARY GLANDS

Both major and minor salivary glands can be involved in disease processes in the HIV-infected individual. The most common complaint is xerostomia.

Lymphoepithelial cysts is a disease process that is almost diagnostic of HIV infection. Lymphoepithelial cysts present as progressive parotid swellings, which are usually multiple, bilateral and non-tender (**Figures 23.5** and **23.6**).

Facial nerve dysfunction should lead the physician to suspect a malignant neoplasm. Fine-needle aspiration

Figure 23.5 The most common etiology of an asymptomatic parotid mass in the HIV-infected patient is the lymphoepithelial cyst (arrow).

reveals fluid with lymphocytes and squamous epithelial cells. Computed tomography or ultrasound imaging will show multiple thin walled cysts in the parotid gland. With fine-needle aspiration biopsy (FNAB) and imaging, open biopsies or surgical excision for diagnosis is rarely indicated. The cysts usually resolve with HAART and surgery is only necessary for enlarged lesions that are a cosmetic challenge or where the diagnosis is equivocal. Needle aspiration of cyst contents is ineffective for long-term cure

Figure 23.6 This axial CT scan demonstrates the typical findings (arrow) of a benign parotid lymphoepithelial cyst.

as recurrence almost always happens.³¹ In patients not receiving HAART, sclerotherapy with alcohol or sodium morrhuate can be effective.^{32, 33}

KEY POINTS

- HIV infection continues to be a global health problem.
- Infection with the Human Immunodeficiency Virus leads to immunosuppression, opportunistic infections and Acquired Immunodeficiency Syndrome.
- Highly active anti-retroviral therapy (a combination of various anti-retroviral agents) is an effective treatment for HIV infection.
- Otolaryngologists should test for HIV infection whenever it enters the differential diagnosis.
- ENT manifestations of HIV infection are very common.
- Kaposi's sarcoma is a malignant tumour caused by the co-infection of HIV and Human Herpes Virus 8.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: transfusion, components, alternatives, blood sparing and adverse events.

INTRODUCTION

Surgical specialties are responsible for the transfusion of up to 40% of blood and blood components in the UK. It is therefore imperative for those in surgical practice to have a sound understanding of the principles of safe transfusion, the appropriate use of blood and measures for blood avoidance (**Box 24.1**).

The UK has been successful at improving the safety of blood and blood component transfusion over the last 25 years. The risk of death has dropped to under 3 in 1 000 000 per blood components issued, since the serious hazards of transfusion (SHOT) scheme started in 1996.

BOX 24.1 Principles of safe and appropriate transfusion

1. Do not just act on numbers. Not all anaemic patients need transfusing – consider the patient's symptoms, comorbidities and possible treatable underlying cause.
2. Transfuse based on clinical assessment and evidence-guided practice.
3. Involve the patient in the decision to transfuse (or not) and obtain consent.
4. Ensure the right blood is transfused to the right patient at the right time in the right place and for the right indication.

This reduction has been largely due to increased awareness of the hazards of transfusion, better screening of donors and improvements in the processing of blood and its components. A frequently encountered error in blood transfusion remains that of ABO incompatibility as a consequence of clerical error. Examples of this and other transfusion complications will be covered later in the chapter.

Blood is used in the management of anaemia, in surgical blood loss and in patients with acute massive haemorrhage. However, blood and its components are a scarce resource both within the UK and worldwide. Only 5% of eligible adults in the UK are blood donors, and this valuable resource needs to be used in a responsible and safe manner.

In relation to ENT surgery, a retrospective review of transfusion in patients undergoing sinus surgery in Germany found that only 0.46% of these patients actually needed a transfusion; this likely represents excellence in surgical techniques and patient management to avoid blood transfusion.¹ A study in the United States concluded that transfusion is no longer necessary during routine bimaxillary orthognathic surgery. Patients requiring double-jaw procedures are often the ENT patients most likely to require a blood transfusion.²

BLOOD DONATION

Extensive screening of altruistic, unpaid volunteers has been a major factor in the provision of safe blood in the UK. First-time donors in the UK have to be between the ages of 17 and 65 years, minimum weight of 50 kg, in good health and undergo a thorough health questionnaire and screening programme to exclude high-risk donors. There is no upper age limit for donors but after the age of 66 years, donors are required to undergo an annual review. Male donors can donate blood every 12 weeks up to a maximum of four donations in 12 months. Female donors can donate every 16 weeks up to three times a year. The minimum haemoglobin concentration (Hb) required for donation is 125 g/L for female and 135 g/l for male donors (for full eligibility criteria consult <https://www.blood.co.uk>).

Following thorough cleaning of the skin at the needle entry point, blood is collected into a sterile bag containing anticoagulant and preservative. It is labelled with the donor details and transported to a blood centre where it is processed. Whole blood is filtered and then separated into its blood components. Filtration eliminates leucocytes, which are associated with several complications of transfusion including febrile (non-haemolytic) transfusion reactions, human leukocyte antigen (HLA) alloimmunization and transmission of cytomegalovirus (CMV). Leucocyte depletion was introduced as a variant Creutzfeldt–Jakob disease (vCJD) risk reduction measure and the other effects were a useful by-product of this decision. From each unit of blood donated, red cells, platelets, fresh frozen plasma and cryoprecipitate can be obtained.

A sample from the donor on each occasion is tested for blood-borne viruses and syphilis (Table 24.1). Platelets undergo bacteriological testing requiring incubation for 36 hours to exclude any significant bacteria before release.

Due to concerns regarding the transmission of vCJD by blood transfusion, universal leucocyte-reduction of blood components was implemented in the UK in 1999. In addition, a number of restrictions on blood donors were put in place to reduce the risk of transmission. Individuals are restricted from donating if they have:

- previously received a blood transfusion after 1980
- received human pituitary-derived hormones, graft of human dura mater, cornea, sclera or other ocular tissue
- come from a family at risk of inherited prion disease

- been notified that they are at risk of vCJD due to exposure to infected individual via blood transfusion, transplanted tissue or surgical instruments
- been notified they are at risk because a recipient of their blood or tissue has developed a prion-related disease

Additionally, individuals born after 1996 who require plasma products are only transfused with non-UK plasma.

BLOOD GROUPS

There are more than 300 blood groups with around 23 being clinically significant. The most important are the ABO and RhD groups because of their association with haemolytic transfusion reactions and haemolytic disease of the newborn. However, some patients especially those who are multi-transfused may develop antibodies against other blood group antigens and thus it is important to look beyond the ABO and RhD in patients requiring transfusion.

ABO group

The ABO grouping of blood was first recognized in 1901 by Landsteiner. The ABO system is the most important because of the presence of naturally occurring anti-A and anti-B antibodies, which develop in the first months of life. The ABO system consists of three allelic genes – A, B and O – and each of these is responsible for production of antigens on the surface of red blood cells (Table 24.2). ABO incompatible transfusions are very serious because anti-A and anti-B are IgM antibodies causing intravascular haemolysis activation of coagulation and cytokines resulting in major morbidity and mortality. In the UK, blood group O is commonest, found in 47% of the population. Historically, blood group O individuals were considered to be universal donors and AB universal recipients. As a result, Group O, RhD negative blood is often used in emergency situations. Group O RhD negative blood is in short supply, consequently except in true emergencies it is desirable to establish the ABO and RhD group of emergency patients to ensure group specific blood is issued. Group AB is the rarest group in the UK and due to lack of donors they are often given group A or B blood.

TABLE 24.1 Screening for infectious agents

Routine screening of donor blood	Further screening may include (depending on travel history):
<ul style="list-style-type: none"> • Hepatitis B • Hepatitis C • Human immunodeficiency virus • Human T cell lymphotropic virus • Syphilis 	<ul style="list-style-type: none"> • Malaria • West Nile virus • Trypanosoma cruzi

TABLE 24.2 ABO groups

Blood group	Antigen	Antibody	UK frequency %
O	None	Anti A, Anti B	47
A	A	Anti B	42
B	B	Anti A	8
AB	AB	None	3

Rh antigens

The Rh system was discovered later by Landsteiner and Weiner in 1940. The RhD antigen is the most important, although others do also exist (Cc and Ee). The RhD gene may be either absent or present (i.e. RhD+ or RhD-); 85% of the UK population is RhD+. Rh antibodies are IgG antibodies causing extra-vascular haemolysis. They do not occur naturally but as a result of sensitization secondary to transfusion or pregnancy. The commonest significant event is that of a RhD- mother, developing an antibody as a result of carrying a RhD+ foetus. If not addressed, this can result in the fatal haemolytic disease of the newborn or hydrops fetalis. The UK programme of antenatal administration of anti-D for the prevention of RhD immunization in pregnancy and postpartum has reduced its incidence. However, it is imperative that all RhD- women of childbearing age only receive RhD- blood components.

BLOOD GROUPING AND CROSSMATCH PROCESS

Compatibility testing is carried out in accredited hospital blood transfusion laboratories by trained biomedical scientists. There is now increasing use of automated processes but there is still an important role for the clinical scientist.

As previously mentioned, the first step is determination of the ABO and RhD groups of the recipient: 'blood grouping'. This is rapid and can be done in less than 15 minutes. Once a patient is grouped an antibody screen is performed to identify any clinically significant red cell antibodies; this process takes up to 45 minutes in total. If the antibody screen is positive, the blood group specificity of the antibodies should be identified by testing the patient's plasma against panels of red cells with a wide range of known blood group antigens.

The full crossmatch takes up to 60 minutes and involves testing the patient's plasma against a sample of the donor red cells to be transfused. In many hospitals this serological crossmatch has been omitted as a negative antibody screen makes it highly unlikely that there will be any incompatibility with the donor units. A greater risk is that of a transfusion error involving the collection of the patient sample or a mix-up of samples in the laboratory. Laboratories can use their information system to check the records of the patient and authorize the release of the donor units (computer or electronic crossmatching/issue).

Electronic blood issue, as described above, can be extended to issue previously unallocated blood at blood fridges remote from the main laboratory ('remote blood issue'). This is possible using blood fridges electronically linked to the blood transfusion laboratory information system. The printing of compatibility labels for the blood and its collection are under electronic control using the same rules as electronic issue from the main laboratory. Issue of blood using this process reduces the time it takes to provide blood for patients needing it urgently, particularly at hospitals without a blood transfusion laboratory

because transport of blood from the central laboratory is not required.

In an emergency it is possible to provide group specific blood (same ABO and RhD groups as the patient) within a few minutes and follow this up with a full crossmatch. If time is short it is possible to administer group O blood, and for women of childbearing age this must also be RhD negative.

In elective surgical patients, blood grouping and antibody screening can be done weeks in advance of surgery. The British Committee for Standards in Haematology (BCSH) guidelines³ recommend a second sample be tested for confirmation of ABO group for all patients undergoing transfusion for the first time. With regards to the timing of pre-transfusion compatibility testing the following is recommended:

1. Samples should not be more than 3 days old in those who have been transfused or pregnant within last 3 months.
2. An extension to 7 days can be considered for those regularly transfused or pregnant women with no significant alloantibodies.

PLANNING FOR SURGERY

Many operations can take place without the need for transfusions. Blood transfusion laboratories can issue blood and blood components rapidly if there is unexpectedly large bleeding, and there is rarely a need to provide large numbers of units in advance.

It is important in elective surgical procedures to optimize the patient's Hb prior to surgery to minimize the need for transfusion. If there is evidence of anaemia this should be investigated and treated pre-operatively. Thirty per cent of patients found to be anaemic pre-operatively are iron deficient; this can be corrected with oral iron or, in patients who are intolerant to oral iron or those that have a short pre-operative period, intravenous iron can be used.

Maximum surgical blood ordering system (MSBOS)

In surgical procedures that have a high probability of requiring transfusion, an MSBOS should be agreed between the surgical team and transfusion laboratory. This must specify the number of units of each blood component that should be reserved routinely guided by evidenced based practice (Table 24.3). The recommended aim is to have a crossmatched to transfused ratio of <2:1 with regular review and audit of actual blood use.

TABLE 24.3 Examples of MSBOS

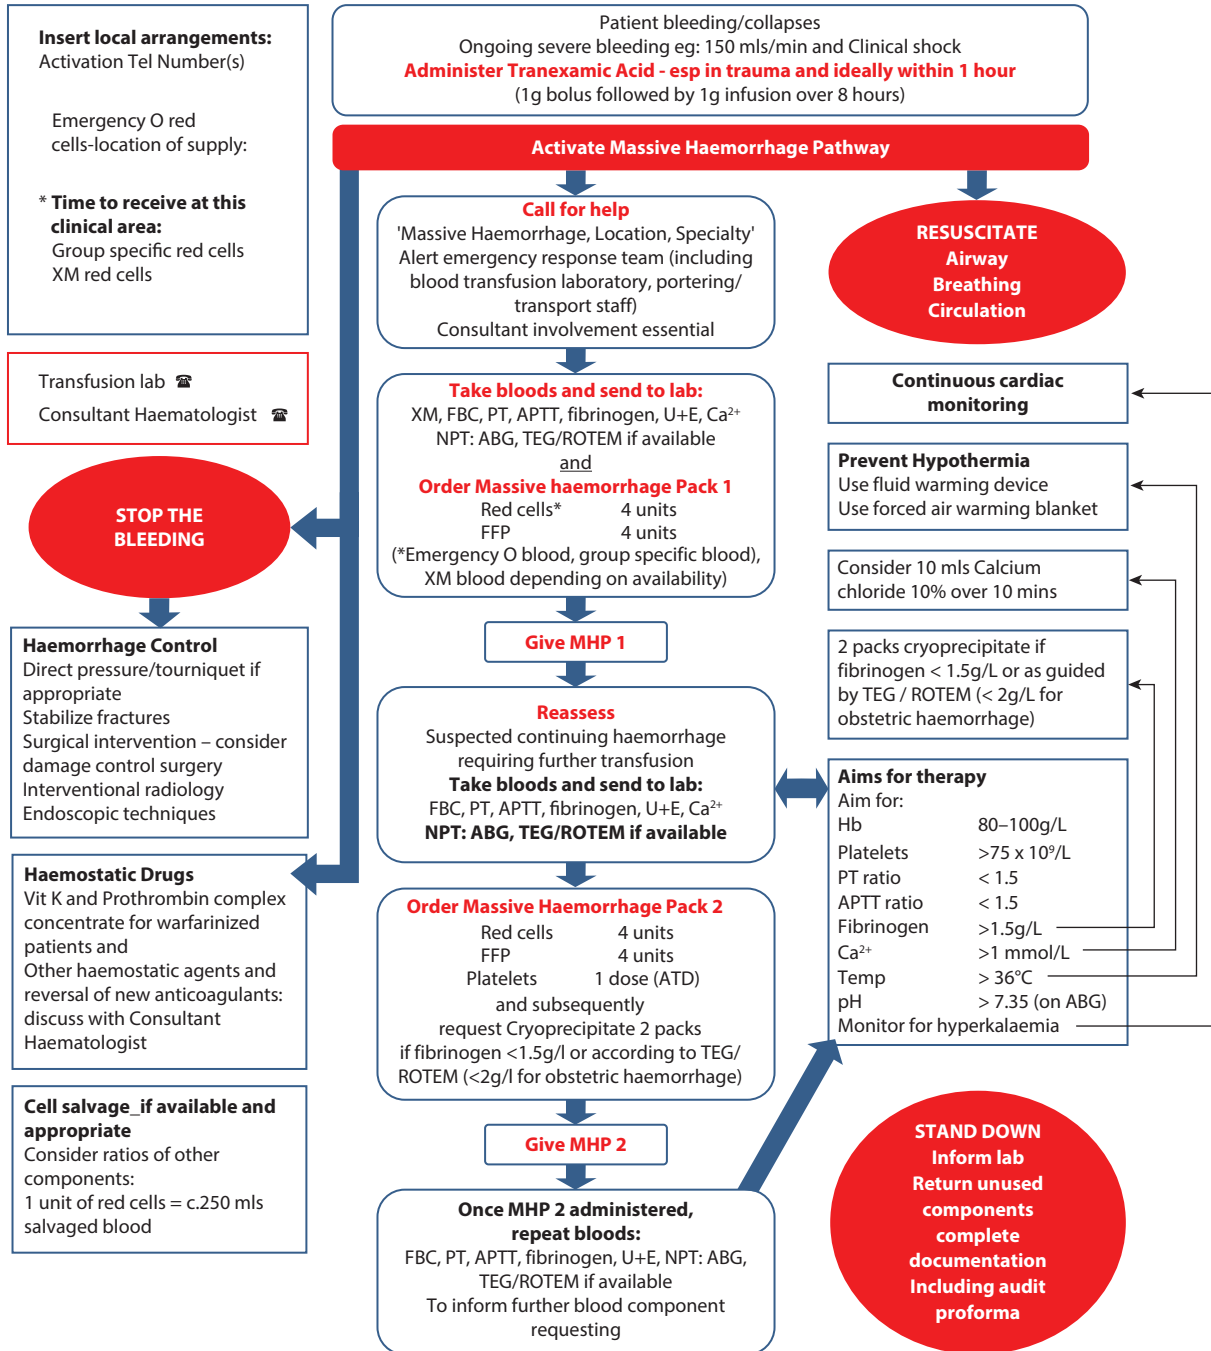

Surgical procedure	MSBOS
Tumour of palate	Group and Save only
Laryngectomy	2 units
Radical neck dissection	2 units
Commando	4 units

EMERGENCIES

Emergency requests for blood require clear communication between the clinical team and laboratory staff. If there is a massive haemorrhage (i.e. blood loss greater than 50% of patients' blood volume in 3 hours or more

than one total blood volume within 24 hours or greater than 150ml per minute associated with shock), the 'massive haemorrhage protocol' must be activated. Figure 24.1 gives an example of such a protocol. Early recognition and intervention to stop bleeding is vital for patient survival. It is important for the clinical team to liaise closely with the

blood transfusion laboratory and ensure the appropriate products are requested, issued and administered rapidly. Close monitoring of haemostasis is essential as a massive transfusion can result in platelet and coagulation factor depletion especially of fibrinogen, which will require replacement.

BLOOD COMPONENTS

Whole blood is composed of a number of components that are separated during blood processing in transfusion centres. Whole blood is not used in modern clinical practice and use of individual components makes for more efficient and safer therapy. **Figure 24.2** outlines the different components of blood and their preparation.

Red blood cells (RBC)

Red blood cells are responsible for the transport of oxygen. Transfusion of RBC is indicated in massive haemorrhage, symptomatic anaemia, after chemotherapy and in chronic haematological conditions. ABO and RhD compatibility are essential for safe transfusion as described above. RBC are stored at 2–6 °C for up to 35 days. Irradiated blood, which is required for immunocompromised individuals at risk of transfusion-associated graft versus host disease (TA-GVHD), has a shorter shelf life of 14 days. It is important for the clinical team to inform the transfusion laboratory of this requirement. TA-GVHD is explained in more detail later in this chapter.

There is no universal agreed trigger for the transfusion of RBC, and it is important to be aware of local guidelines. Patients must be assessed clinically for symptoms of anaemia or bleeding. Emphasis must be on clinical evaluation over correction based purely on numbers. A Cochrane review has recommended evaluated transfusion triggers and recommended target haemoglobin of 70 to 80 g/L and the transfusion of 1 unit followed by assessment of the patient's response. This current trend in practice favours restrictive rather than liberal transfusion; the groundbreaking TRICC study⁴ reported no significant difference in 30-day mortality in critically ill patients who were randomized to either a restrictive or liberal transfusion strategy. Additionally the group was able to demonstrate a benefit in outcomes in younger patients who received the restrictive transfusions.⁴ The recommendation that

followed from this trial changed critical care practice, as now unless contraindicated the recommended policy is not to transfuse until haemoglobin has fallen below 70 g/L aiming for a target haemoglobin of 70 to 90 g/L. This restrictive transfusion practice has received support from other randomized controlled trials in cardiac surgery and acute upper gastrointestinal haemorrhage and is now widely adopted throughout clinical practice. The only exceptions to this are patients with acute cardiac ischaemia and those on long-term transfusion programmes, for example thalassaemia and myelodysplastic syndrome, who may have a trigger haemoglobin of 80 g/L or greater to maintain a good quality of life (this should be discussed with the haematologist).

Platelets

Platelets are central to haemostasis. Platelet transfusions may be needed in patients with thrombocytopenia or platelet function disorders. Platelet concentrates are prepared either by centrifuging whole blood or from a single donor via plateletpheresis using a cell separator. Platelets are stored at 22 °C in an incubator that is constantly agitated for optimal platelet storage. Platelets have a shelf life of 7 days following the recent introduction of bacterial screening in the UK.

Platelets have ABO antigens on their surface and ideally should be ABO compatible. Although adverse reactions are rare, the survival time may be reduced if there is an ABO mismatch. As with RBC, only RhD negative platelets should be given to women of childbearing age. Irradiated platelets should be administered to those at risk of transfusion-associated graft-versus-host disease TA-GVHD. Platelets express HLA antigens and some patients with HLA antibodies fail to increase their platelet counts with platelets from random donors and require HLA-matched platelets. If HLA-matched platelets are required, early recognition is necessary as advance notice is required to identify compatible donors.

It is important to investigate the cause of thrombocytopenia to determine if it is autoimmune, secondary to bone marrow failure, drug-induced or secondary to platelet sequestration in the spleen or consumption, for example, in disseminated intra-vascular coagulation (DIC). In a haemodynamically stable patient with ear, nose or throat bleed with bleeding associated with thrombocytopenia or a platelet function disorder, it is important to consider

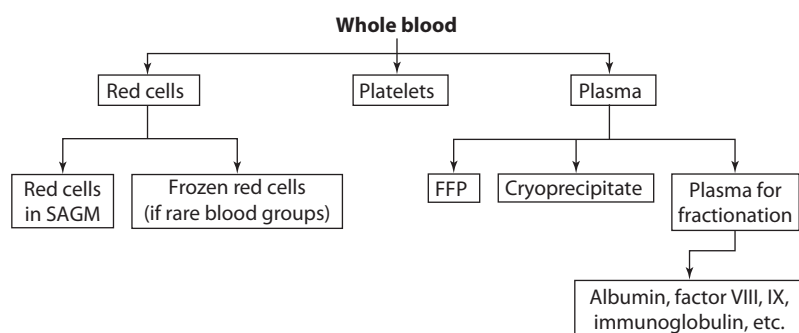

Figure 24.2 Blood components and products derived from whole blood.

TABLE 24.4 Examples of platelet thresholds

Procedure where platelet threshold is greater than 50	Procedures where platelet threshold is greater than 100
<ul style="list-style-type: none"> • Lumbar puncture • Gastroscopy and biopsy • Insertion of indwelling lines • Transbronchial biopsy • Liver biopsy • Laparotomy or similar procedures 	<ul style="list-style-type: none"> • Ocular region • Neurosurgery <p><i>Spinal anaesthesia requires platelet count >80</i></p>

measures such as tranexamic acid or surgical repair of bleed as well as a platelet transfusion.

The BCSH guidelines (2003)⁵ suggest the thresholds for platelets in surgical and medical procedures as outlined in [Table 24.4](#). However, transfusion of platelets must be assessed on an individual basis taking into consideration clinical factors and the presence or absence of other disorders of haemostasis. After a platelet transfusion it is important to assess whether it has been effective in stopping bleeding (if it was administered to a patient with thrombocytopenic bleeding) and perform a repeat sample 15–30 minutes later to determine its effect on the platelet count.

Platelets are relatively contraindicated in patients with thrombotic thrombocytopenic purpura and heparin-induced thrombocytopenia due to increased thrombotic risk. However, in bleeding patients with these conditions, it is advised to discuss the patients with a haematologist.

Fresh frozen plasma (FFP)

Fresh frozen plasma is derived from whole blood through centrifugation; it is rich in coagulation factors. FFP must be ABO compatible because of the presence of anti-A and anti-B in the plasma. FFP is indicated for the treatment of coagulation factor deficiency where a suitable factor concentrate is not available, coagulopathy associated with liver disease, massive haemorrhage and DIC. The usual dose is 12–15 ml/kg. FFP is no longer recommended for the reversal of warfarin. Reversal of warfarin and the newer anticoagulants will be covered later in the chapter. The response to FFP can be monitored by measuring the patient's prothrombin time and activated partial thromboplastin time.

FFP is frozen at -25°C to maintain the activity of the coagulation factors and can be stored for up to 36 months. When requested it must be thawed, which can take up to 30 minutes. Once thawed it can be stored at 4°C for 24 hours. In the UK, children born after 1 January 1996 should receive FFP from countries with a low risk of vCJD; the preparation provided in the UK is also treated with methylene blue, which inactivates bacteria and viruses.

Solvent detergent plasma, which is prepared from more than 1000 donation pools of plasma, undergoes pathogen inactivation including bacteria and viruses such as hepatitis B and C and HIV. Donations are sourced from countries at low risk of vCJD. As it is pooled, the concentration of coagulation factors is more standardized.

It is recommended for patients who have thrombotic thrombocytopenic purpura.

Cryoprecipitate

Cryoprecipitate is made from thawing FFP at 4°C . It is rich in fibrinogen, factor VIII and von Willebrand factor. It is used as source of fibrinogen, especially in massive haemorrhage where fibrinogen concentration is less than 1.5 g/l. The recommended dose is two pools of 5 units (1 unit per 5–10 kg body weight). Cryoprecipitate is stored at -25°C and has a shelf life of 36 months. Once thawed, it must be used within 4 hours.

TRANSFUSION REACTIONS

All transfusion-associated reactions and errors should be reported to the transfusion laboratory and/or hospital transfusion committee, who report them to the national haemovigilance scheme, serious hazards of transfusion (SHOT). SHOT produces an annual report with recommendations about transfusion safety, which is accessible online. In 2012, 62% of the errors reported to SHOT were secondary to preventable mistakes in the transfusion process, highlighting the scale of the problem ([Figure 24.3](#)).⁶ Blood sampling errors resulting in 'wrong blood in tube' continue to be a major preventable problem that can result in ABO-incompatible red cell transfusions with severe consequences.

Although not a drug, blood and its components should be treated as such. Blood products should be prescribed and administered by trained individuals. Patients should be transfused in areas where they can be directly monitored; observations should be performed and documented before transfusion, after 15 minutes to detect any immediate transfusion reaction, and at the end of transfusion. Transfusions should generally be avoided overnight unless they are urgently needed.

Acute transfusion reactions

These present within 24 hours of the transfusion and vary in severity. The diagnosis of an acute transfusion reaction can be challenging especially in the acutely unwell patient. As acute transfusion reactions can have profound morbidity, it is essential for the clinical staff to recognize them and respond promptly. [Box 24.2](#) summarizes a suggested approach to acute transfusion reactions:

SEVERE ACUTE TRANSFUSION REACTIONS

Immediate haemolytic transfusion reaction

Immediate haemolytic transfusion reactions are the most severe transfusion reactions caused by acute haemolysis secondary to destruction of donor red blood cells by IgM complement-fixing antibodies present in the recipient's serum, usually anti-A and/or anti-B. These antibodies can result in rapid intravascular destruction of donor red blood cells. It can also result in activation of coagulation and

Figure 24.3 Cumulative data from SHOT reports 1996–2012.

BOX 24.2 Approach to management of an acute transfusion reaction

1. Stop the transfusion.
2. Assess patient: Airway, Breathing and Circulation.
3. Maintain venous access with physiological saline.
4. Check the identification of the patient and compatibility of the blood component.
5. Inspect the component for clumps or discolorations (important in platelets).
6. Assess for evidence of blood loss.
7. Unless mild allergic or febrile reaction, perform full blood count, renal and liver screen, blood culture if temperature rise, direct Coombs test, repeat group and screen urine for haemoglobinuria.
8. Inform the transfusion laboratory.
9. Unless mild allergic or febrile reaction, return the blood components to the transfusion laboratory.
10. Report to SHOT.

release of cytokines and cause renal failure and disseminated intravascular coagulation. It is commonly caused by human clerical error and occurs in around 1 in 180 000 red cells transfused. Features include pain at infusion site, chest and back pain, hypotension and haemoglobinuria. Mortality can be as high as 10%.

Bacterial contamination

Although a rare complication of transfusion, it may be fatal. The patient becomes acutely unwell, pyrexial, hypotensive and may develop septic shock. The actions that should be taken when a bacterial contamination of blood is suspected include checking the appearance of the contents of the transfused component; there may be clots or purple discoloration of red cells, platelets may have clumps or green discoloration. Blood cultures should be taken immediately and the patient commenced on broad

spectrum antibiotics. The component should be returned to the transfusion laboratory for microbiological testing and the transfusion service should be informed so that other components from the same donor can be recalled.

Anaphylaxis

Severe anaphylaxis following transfusion is very rare but can be fatal. Symptoms may include wheeze, stridor and angioedema. Flushing and urticaria may occur in less severe reactions. Immediate resuscitation is imperative with administration of intramuscular adrenaline, intravenous chlorpheniramine and intravenous hydrocortisone. If further transfusions are needed, management should be discussed with the immunologist and haematologist.

Transfusion-related acute lung injury (TRALI)

TRALI typically occurs after transfusion of platelets or FFP. It has been the commonest cause of severe morbidity and mortality after transfusion. It is due to anti-leucocyte antibodies in the donor plasma reacting with the recipient's neutrophils, monocytes and pulmonary endothelium. Severe hypoxia may develop immediately or at the latest within 6 hours of the transfusion and be associated with hypotension and bilateral lung infiltrates. It is important to differentiate TRALI from acute respiratory distress syndrome and pulmonary oedema. Treatment is supportive with high flow oxygen and ventilator support if required.

Transfusion-associated circulatory overload (TACO)

This is a common adverse effect of transfusion in older patients and those with history of cardiac disease. It is often not diagnosed in a timely manner. It is defined as acute or worsening pulmonary oedema within 6 hours of transfusion.

Features include dyspnoea, tachycardia, hypertension and a positive fluid balance. Treatment involves stopping transfusion, administering oxygen and diuretics. TACO can be avoided by careful assessment of its risk factors and appropriate measures for its avoidance such as co-administration of diuretics and the use of single unit transfusions in small frail adults.

LESS SEVERE ACUTE TRANSFUSION REACTIONS

Febrile non-haemolytic transfusion reactions (FNHTR)

This is a very common transfusion-associated reaction. However, as it is associated with the recipient's anti-leucocytes antibodies, its incidence has reduced since the implementation of universal leucocyte-reduction of blood components in the UK. Features include pyrexia accompanied by rigours, nausea and muscle pain. Mild reactions, where temperature is greater than 38°C but less than 2°C above starting temperature can be managed by slowing the transfusion and/or giving anti-pyretic agents such as paracetamol. If the temperature rise is greater than 39°C or greater than a 2°C rise, the transfusion should be discontinued. When fever is associated with transfusion, immediate haemolytic transfusion reactions and bacterial contamination should be excluded.

Mild allergic reactions

Urticarial reactions to donor plasma proteins can be treated by slowing the transfusion rate and using antihistamines whilst the patient is monitored carefully. If repeated reactions occur and do not respond to antihistamines, washed red blood cell or platelet transfusions (washed in saline to remove plasma proteins) may be appropriate management for future transfusions.

DELAYED TRANSFUSION REACTIONS

Delayed haemolytic transfusion reaction (DHTR)

Delayed haemolytic transfusion reactions can occur in those who have had previous transfusions or have had a previous pregnancy and result from alloantibodies (e.g. Rh, Kell, and Duffy) that have fallen to low levels so they are undetectable in compatibility testing. Re-exposure to the antigen results in a secondary immune response with production of IgG antibodies and consequent extravascular haemolysis of the transfused red cells, usually a few days after the transfusion has taken place. Typical features include jaundice, haemoglobinuria, fever and fatigue. Investigations reveal a drop in haemoglobin, a positive direct Coombs test and rise in bilirubin. Renal failure may also be a feature. It is important to perform a repeat group and screen on the pre-transfusion and post-transfusion blood samples of the patient.

Post-transfusion purpura

In this condition, there is severe thrombocytopenia usually with a platelet count $<10 \times 10^9/l$ 7–12 days post-transfusion. There may be severe bleeding. It usually occurs

in previously pregnant and/or transfused females who are HPA-1a antigen negative and who develop high levels of anti-HPA-1a after the transfusion. It has become rare since leucocyte-reduction of blood components. The condition responds well to administration of high-dose intravenous immunoglobulin.

Transfusion-associated graft versus host disease (TA-GVHD)

This is a rare and usually fatal complication of blood transfusion caused by donor lymphocytes engrafting in the recipient and mounting an immune response against the transfusion recipient. Initial symptoms of TA-GVHD include fever, rash, diarrhoea, jaundice and bone marrow failure. It can occur up to 30 days post-transfusion.

Immunocompromised patients at risk of TA-GVHD include those with inherited immunodeficiency, HIV, recipients of certain chemotherapy agents such as fludarabine and post bone marrow transplant. It is important to identify at-risk patients and provide gamma irradiated blood components that prevent TA-GVHD.

REVERSAL OF ANTICOAGULATION

FFP is no longer first-line recommended management for the reversal of warfarin therapy. The BCSH guidelines (2012)⁷ recommend the use of Vitamin K (oral or IV in emergencies) and prothrombin complex concentrate (PCC). FFP should only be used if PCC is not available. PCC contains factors II, VII, IX and X. It is used for the reversal of warfarin in patients with a raised INR and significant bleeding. It has also been used in treating coagulopathy associated with liver disease. There is a small thrombotic risk associated with its use but this has to be weighed up in light of bleeding risk. It is given intravenously and the recommended dose is 25 to 50 units/kg based on the INR.

There is increasing use of the new oral anticoagulants such as the direct thrombin inhibitor Dabigatran and the anti Xa inhibitor Rivaroxaban, which are increasingly prescribed for the treatment of atrial fibrillation and deep vein thrombosis. There is no licensed antidote to these agents. However, if severe bleeding occurs, it is recommended to consider the use of PCC or recombinant factor VIIa and contacting the haematology team for further guidance.

ALTERNATIVES TO BLOOD TRANSFUSIONS

There have been many recent developments in the use of alternatives to blood and the avoidance of transfusion. The use of these alternative measures requires organization and a multidisciplinary approach to the patient, which is now often described as 'patient blood management'.

Pre-operative anaemia management

Surgical patients who are anaemic are more likely to require blood transfusion, have post-operative infection and a prolonged hospital stay, and so patients who have a low Hb should be identified prior to surgery. In collaboration with the pre-operative team these patients should be investigated and managed to optimize the Hb before surgery. It is important to identify if there is any iron or haematinic deficiency and also exclude any underlying causes such as an undiagnosed malignancy.

Where iron deficiency is identified, it should be treated with oral iron, but if it is not tolerated or there is no response after 4–6 weeks, or if surgery is urgent, then intravenous iron can be used. In patients who have anaemia on a background of chronic renal failure, malignant diseases or haematological conditions such as myelodysplasia, recombinant erythropoietin can be used with good effect to improve the Hb before surgery. Erythropoietin is not widely employed due to the considerable health economic costs associated with its use.

Any drugs known to increase risk of bleeding, such as aspirin and clopidogrel, should be withdrawn in advance of surgery; advice should be sought from the prescribing physician if necessary. Post-operatively, non-steroidal anti-inflammatory drugs should be avoided as they may contribute to bleeding.

Acute normovolaemic haemodilution

Blood is removed immediately prior to surgery, often post-anaesthesia, and returned post-operatively or if significant bleeding occurs. The patient's blood volume is maintained by the infusion by crystalloid or colloid fluids. There is little evidence for its effectiveness and thus this technique is rarely employed outside of cardiac surgery.

Cell salvage

Cell salvage can be used intra-operative or post-operatively.

INTRA-OPERATIVE CELL SALVAGE (ICS)

A number of devices are available and are widely in use. Blood lost during surgery is aspirated into a collection reservoir and filtered to remove any debris. Blood is treated with heparin and citrate to prevent clot formation. If adequate blood is collected and the patient meets

requirements for transfusion, the collected blood is centrifuged, washed and re-infused via a leucocyte-reduction filter in a closed and automated system within 4 hours. ICS is indicated in surgery where anticipated blood loss is greater than 20% of the patient's blood volume, greater than 1l in an adult (e.g. major orthopaedic, cardiac, vascular and cancer surgery).

POST-OPERATIVE CELL SALVAGE

This has very little role in ENT surgery. Blood is collected from wound drains and filtered or washed before it is re-infused via a closed automated system.

Tissue sealants

These are biological agents derived from human or animal clotting products such as thrombin, fibrinogen and calcium. They are applied directly to the bleeding point and fibrin clot formation occurs, impeding blood loss. Tissue sealants are commonly used in accident and emergency departments and minor injury clinics for minor cutaneous bleeds.

Tranexamic acid

Tranexamic acid is an antifibrinolytic drug that inhibits the conversion of plasminogen to plasmin and hence hinders fibrinolysis. It is inexpensive and can be given orally, topically or intravenously. It has a recognized role in the management of massive haemorrhage and reducing bleeding post-operatively. There is also a mouthwash preparation that can be helpful in managing minor oral cavity bleeds.

JEHOVAH'S WITNESSES

Jehovah's Witnesses have contributed considerably to the understanding of minimum blood requirements. JWs do not accept red cell transfusions, whether donor blood or their own pre-donated blood, although most patients will accept the use of cell-salvaged blood provided the blood is returned to them without a break in the circuit. When treating patients, it is important to take an individualized approach and discuss all options for blood avoidance. Most hospitals will have a Jehovah's Witness liaison committee that can be consulted.

KEY EVIDENCE

- The use of blood in surgery is in decline.
- There is increasing recognition that surgical patients can avoid transfusion through the application of patient blood management practices and more restrictive thresholds for transfusion.
- An organized approach to massive haemorrhage is key for improved survival.
- There is no role for FFP in the reversal of warfarin. Prothrombin complex concentrates should be used.

FUTURE RESEARCH

Patient blood management is integral to modern transfusion practice, with increasing evidence favouring restrictive blood transfusion. Ongoing trials are evaluating the expansion of restrictive transfusion to patient groups other than those undergoing critical care. Further research is needed to determine the optimal use of alternatives to transfusion.

KEY POINTS

- Before requesting a blood transfusion, assess the patient clinically, evaluate laboratory investigations and consider whether it is necessary.
- Patient identification is essential: ensure the right blood is transfused to the right patient at the right time in the right place.
- Early recognition of transfusion reactions is essential. Stop the transfusion, maintain intravenous access and assess the patient. Follow local protocols and inform the transfusion laboratory.
- Correction of pre-operative anaemia is fundamental in minimizing transfusion requirements.
- Surgical planning is key. A group and screen should be done a minimum of 24 hours pre-operatively. Where a large volume of blood is anticipated, agree with the transfusion laboratory how much blood should be provided.
- Early recognition of massive haemorrhage is imperative; activate local protocols and ensure a coordinated process takes place.
- There are many alternatives to blood transfusion that should be considered and discussed with patients.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: haemostasis, erythropoiesis, leukaemia, lymphoma, myeloma, sickle cell disease, otolaryngology, fungal rhinosinusitis and ototoxicity.

INTRODUCTION

Many patients with haematological malignancies will present initially to an ENT surgeon, for example with nodal disease of the head and neck. Patients with known haematological disease can also develop numerous problems of the ear, nose and throat as a result of either their disease or its treatment. Similarly many of the therapies used for primary ENT disorders can have important haematological effects.

The aim of this chapter is to provide clinically relevant information that enables practicing ENT surgeons and trainees to interpret basic haematological laboratory parameters, recognize the haematological disorders that present to their services and facilitate appropriate timely referral, manage the haematological complications of ENT disorders and interventions, understand potential ENT complications of haematological therapies and appreciate special considerations in the management of ENT conditions in patients with chronic haematological disorders.

OVERVIEW OF BASIC HAEMATOLOGY

Components of blood: their function and production

Blood is a liquid tissue whose cellular compartment consists of red cells (erythrocytes), white cells (leukocytes) and platelets. Erythrocytes, the most numerous blood cells,

are bi-concave discs that contain an abundance of haemoglobin, the protein responsible for oxygen transportation in vertebrates.¹ They have a lifespan of approximately 120 days after which they are removed by the spleen.² Leukocytes are a diverse group of cell types that are capable of migration into tissues where they have vital roles in the processes of immunity, inflammation and wound healing. Neutrophils are the most common white cell in adult peripheral blood and are a key component of innate immunity, providing defence against bacteria, which they are able to ingest and kill. Lymphocytes are the cellular effectors of the adaptive immune system and are capable of producing antibodies or recognizing and killing virally infected cells; some are long-lived, permitting anamnestic immune responses.³ Platelets are the cellular element of the haemostatic system but they also have functions in tissue repair and cytokine signalling. Their life span is 8–9 days.⁴ The liquid phase of blood is plasma, which contains a wide range of hormones, electrolytes and proteins; including albumin, immunoglobulins, fibrinogen, clotting factors and complement.

All of the cellular components of blood are derived from a common progenitor, the haematopoietic stem cell (HSC), which is capable of self-renewal as well as giving rise to a variety of progenitors and from there all cells of the blood (**Figure 25.1**).⁵ The presence of various combinations of haematopoietic growth factors, such as erythropoietin (EPO) and granulocyte-colony stimulating factor (G-CSF), will determine which progenitors successfully proliferate and differentiate, thus ensuring homeostatic

Figure 25.1 Schematic representation of haemopoiesis.

control over mature cell numbers.⁶ For example, in response to tissue hypoxia the kidney secretes EPO, which increases red cell production and restores oxygen delivery.⁷ Understanding the haematopoietic hierarchy helps to predict the behaviour of haematological malignancies (see below) and the effects of commercially available recombinant growth factors (G-CSF and EPO).

Haematopoiesis initially occurs in the yolk sac of the embryo, followed by the foetal liver and spleen. During the third trimester HSCs migrate to the bone marrow, which becomes the dominant site of haematopoiesis by term. Whilst the majority of the infant bone marrow is active, by adulthood only the axial skeleton and the proximal ends of the long bones are haematopoietic.⁸ However, if increased cell production is required then haematopoiesis can expand back down the long bones, resume activity in the liver and spleen and can even occur in soft tissue deposits outside these organs. This is seen in several haematological disorders such as thalassaemia major and myelofibrosis and it also explains the propensity for many haematological malignancies to involve the liver and spleen.⁹

Lymphatics and the mononuclear phagocyte system

The lymphatic system consists of a network of vessels that drain extracellular tissue fluid through a series of nodes and back to the venous circulation.³ This organization ensures that foreign material passes through lymph nodes where lymphocytes can compete for survival on the basis of their affinity for the antigen, allowing the selective expansion and activation of cells that are capable of producing an effective antibody. The architecture of lymph nodes reflects these complex processes and the pattern of

its disruption gives vital clues as to the nature of lymphoid malignancies (see below).¹⁰

Monocytes are produced by the bone marrow but migrate into tissues where they develop specialized functions, often involving the phagocytosis of debris. Examples include the Kupffer cells of the liver, lymph node dendritic cells, alveolar macrophages and the microglia of the central nervous system.¹¹ Collectively these cells are known as the mononuclear phagocyte system; the spleen is the largest component and has multiple functions, including the removal of senescent blood cells, recycling of iron and the phagocytosis of antibody coated bacteria.

Haematological malignancy: Principles of diagnosis and management

The cells of the bone marrow are actively dividing throughout life, predisposing them to the acquisition of genetic mutations. Lymphocytes also perform somatic recombination to produce their immunoglobulin, which involves breaking DNA and risks chromosomal translocation; with the result that translocations are commonly found in lymphoid tumours and frequently involve the immunoglobulin loci.¹² Haematological malignancies are the result of cells that have acquired defects in their apoptotic and/or proliferative pathways giving them a survival advantage that allows their uncontrolled expansion; leading to tissue disruption, organ damage and, ultimately, death. Whilst exposure to radiation and certain chemotherapeutic agents certainly increases the risk of myeloid malignancy, in practice this accounts for a small number of patients and the majority of cases of haematological malignancy are sporadic relating to the accumulation of somatic mutation. Notable exceptions include endemic Burkitt's lymphoma, believed to be caused by EBV infection in the

context of chronic malaria, and adult T-cell leukaemia/lymphoma, which is caused by the virus HTLV-1.¹³

Oncogenesis can occur at any stage in the haematopoietic hierarchy (Figure 25.1), resulting in a diverse spectrum of malignancies. Diagnosis is frequently dependant on the demonstration that a population of cells are 'clonal', meaning that they are all related to a common ancestor. Clonality can be confirmed by unique patterns of expression of cell surface antigens (immunophenotype), the presence of a shared genetic aberration (cytogenetics, molecular genetics) or by expression of the same immunoreceptor (immunoglobulin/TCR rearrangement studies).¹⁴ Whilst the concept that a malignant population consists of many identical cells remains clinically useful there has been increasing evidence in recent years that these cancers are genetically diverse disorders with multiple clones often populating the same patient.¹⁵ For example, acute myeloid leukaemia (AML) was shown to consist of 2–5 distinct clones in just over half of patients studied. It is likely that such studies significantly underestimate the number of clones present as current methods can only detect clones of a certain size (>5–10% of cells).¹⁶ The prognostic significance of the clonal structure remains unclear at this time.

Haematological malignancies will generally involve predominantly the blood and bone marrow (leukaemias) or the lymph nodes (lymphomas), but there is often considerable overlap. Many of these cancers are 'liquid', insofar as they are widely circulating at presentation and conventional notions of anatomical staging do not apply (e.g. acute leukaemia); others behave as solid tumours with orderly spread to contiguous lymphatic regions (e.g. Hodgkin's lymphoma). Bone marrow involvement frequently presents with pancytopenia causing fatigue, breathlessness, infection and bleeding. Whereas nodal disease presents with visible enlargement, the effects of local compression, or constitutional symptoms such as weight loss and night sweats.

The nature of the presenting symptoms will guide the diagnostic process; pancytopenia requires prompt assessment of the bone marrow by aspiration, trephine biopsy, flow cytometric evaluation and cytogenetic analysis. Nodal disease will require imaging to assess the extent of the disease followed by biopsy.

Treatment usually involves combination chemotherapy, the principles of which are similar to that of solid tumour regimes.¹⁷ Most haematological malignancies are radio-sensitive but the widespread nature of these conditions restricts the use of radiotherapy to the control of troublesome deposits or the treatment of localized lymphomas. Increasingly monoclonal antibodies and small molecule inhibitors are used to target and disrupt disease-specific processes. The most striking example is the tyrosine kinase inhibitor (TKI), imatinib, which has transformed the management of chronic myeloid leukaemia (CML) from an often-fatal disease to one that is held in remission by oral medication.¹⁸ In the era before TKIs CML would invariably transform into an acute leukaemia that was usually fatal. The only patients who survived were a proportion of those who were fit enough to undergo a stem cell transplant. With current therapies >90% of patients

remit and contemporary trials are exploring the possibility of stopping treatment in those who appear to be cured.

Whilst some haematological cancers can be cured with conventional therapy many have high rates of relapse and patients with responsive diseases who can tolerate the procedure are offered haematopoietic stem cell transplantation (HSCT). Allogeneic HSCT is an extreme form of immunotherapy that involves conditioning the recipient with immunosuppressive chemotherapy to allow engraftment of infused haematopoietic stem cells from a matched donor.¹⁹ The donor stem cells form a new immune system that is capable of engaging the recipient's neoplasm, but the price of this graft-versus-disease effect is graft-versus-host disease (GvHD). Acutely GvHD typically presents with diarrhoea, rash and liver dysfunction, whereas chronic GvHD is a truly protean disorder, with inflammation and scarring affecting any tissue.²⁰ GvHD is one of the major complications of HSCT, causing considerable morbidity and mortality and the management can be very challenging. To reduce the incidence of GvHD patients are given immunosuppressive therapy (typically Ciclosporin) for a period after transplantation, but in contrast to solid organ transplantation where lifelong immunosuppression is mandated, stem cell transplant recipients will typically stop these medications 3–9 months post-HSCT.

HAEMATOLOGICAL DISORDERS PRESENTING TO ENT

Head and neck lymphadenopathy

The most common presentation of a haematological malignancy to an ENT surgeon is that of a 'neck lump'; most lumps are cervical lymphadenopathy and a significant proportion of these will be lymphoma.²¹ It is important that lymphoma is considered early in the diagnostic process as an appropriately focused history and examination can save the patient time, stress and unnecessary investigations.

Symptoms of unexplained fever, drenching night sweats and weight loss (>10% in 6 months) are highly suspicious of lymphoma; in this context they are termed 'B-symptoms' and are also of prognostic significance, typically predicting an inferior outcome.²² However, these symptoms also occur in a range of infections and chronic inflammatory disorders, especially tuberculosis (TB); careful attention to any history of TB exposure should help to make this distinction. Generalized pruritus or alcohol-induced lymph node pain suggest Hodgkin's lymphoma (HL), which is the lymphoma most commonly associated with localized cervical disease, especially in younger patients, and usually has an excellent prognosis. Attention should also be paid to the time course of the symptoms as these give an indication of the pace of the disease and important clues as to the likely diagnosis. Indolent lymphomas can cause stable lymphadenopathy over many years, the nodes of HL often fluctuate in size with observation, whilst the most aggressive lymphomas can enlarge over the course of days and may require admission for urgent therapy.

Examination should be used to describe the neck lump and its relationship to surrounding structures, as well as establishing the extent of nodal involvement elsewhere; this must include examination of the liver and spleen, enlargement of the latter being highly suggestive of lymphoid malignancy. The oropharynx should be inspected for involvement of Waldeyer's ring, which is infiltrated in 5–10% of non-Hodgkin's lymphoma (NHL) but rarely in HL. The nodes of lymphoma are usually painless, often rubbery to palpate and can be mobile or fixed depending on whether the capsule has been infiltrated. In the absence of symptoms asymmetric palatine tonsils carry a low risk of malignancy. A review of 792 patients undergoing tonsillectomy identified 53 patients with asymptomatic asymmetric tonsils, all of whom had normal histology.²³ However, the presence of pain, dysphagia, ulceration, progressive enlargement or B-symptoms should prompt biopsy/removal. A more recent meta-analysis has suggested that whilst there is an association between tonsil asymmetry and lymphoma the risk is dramatically increased by the presence of other signs of malignancy.²⁴

Distended neck veins and facial oedema suggest superior vena cava obstruction (SVCO) by mediastinal disease, most commonly bronchogenic carcinoma but also HL or lymphoblastic lymphoma.²⁵ SVCO is a medical emergency that mandates urgent imaging and immediate referral to oncology/haematology, thoracic surgery and radiology.²⁶ In the case of lymphoid malignancy high dose dexamethasone can provide rapid relief. However, the tumour response to steroids can be so impressive that the diagnostic yield of subsequent biopsy is significantly reduced (see 'Airway obstruction' below). Careful consideration must therefore be given to the timing of biopsy and early involvement of oncology/haematology and thoracic surgery is vital in this regard.

A full blood count should be performed as pancytopenia suggests bone marrow infiltration and lymphocytosis raises the possibility of circulating disease. Chronic lymphocytic leukaemia (CLL – synonymous with small lymphocytic lymphoma) is the most common leukaemia in adults, has typical blood film appearances and can usually be diagnosed by performing flow cytometry on peripheral blood, without recourse to lymph node biopsy.²⁷ Renal and liver biochemistry should also be taken as derangement can suggest infiltration or compression and organ function is an important consideration when planning chemotherapy.

If malignancy is suspected then computed tomography (CT) of the chest, abdomen and pelvis should be performed to stage the disease. Early involvement of haematology or oncology at this point is helpful so that the most appropriate type and site of biopsy can be planned. The diagnosis of a specific lymphoma usually requires an extended immunohistochemical panel to be performed and an appreciation of the growth pattern within the node is often useful; as such whole node biopsies are preferred.¹⁰ Core biopsy can be useful when the tumour is inaccessible (e.g. retroperitoneal), but contains little information regarding architecture making the diagnosis of certain low-grade NHLs challenging.

Fine-needle aspiration (FNA) is commonly used in the initial investigation of neck lumps because it is quick, safe and diagnostic of many malignancies; but its role in lymphoma diagnosis has been controversial. Some lymphomas (especially HL) consist of small numbers of malignant cells within a reactive cellular background; in this situation FNA may yield only reactive cells and wrongly suggest an infective or inflammatory aetiology. This has led many organizations to advise against the use of FNA for suspected lymphoma, to avoid diagnostic delay or false negative results. However, increasing use of flow cytometry and immunocytochemistry has enabled many lymphomas to be accurately defined cytologically and the ability of this technique to provide fresh samples for DNA microarray analysis suggests that there may be an increasing role for FNA in the future.²⁸ Centres with sufficient expertise in these techniques are able to use FNA for preliminary diagnosis, although excision biopsy is often performed for confirmation and uncertainty can still arise with certain low grade B-cell malignancies, such as marginal zone lymphoma, where the markers themselves are not specific and an appreciation of tissue architecture is needed.²⁹ Overall we would still advocate proceeding directly to whole node biopsy when symptoms are highly suggestive of lymphoma, and using FNA only when there are several possible diagnoses and there is sufficient local expertise for cytology to be discriminatory.

Airway obstruction

On occasion lymphomas of the oropharynx, larynx or neck can cause intrinsic occlusion or extrinsic compression of the airway. In this context ENT surgeons can be asked to provide direct visualization with fibre-optic laryngoscopy and to advise regarding the security of the airway. Where a malignant condition is suspected then consideration must be given to both the immediate stabilization of the patient and the need for urgent diagnosis. Dexamethasone can be used to shrink tumours and rapidly relieve compressive symptoms, but the effect on certain lymphomas can be so dramatic that the diagnosis cannot be ascertained unless tissue is sampled prior to the administration of steroids. Clearly the priority in a situation of life-threatening airway compromise is to secure the airway, but where the presentation is less acute then priority must be given to urgently obtaining tissue for diagnosis, as this will allow definitive treatment to be started. Regular (daily) assessment will allow surgery that is both safe and likely to yield diagnostic tissue.³⁰

Extranodal and extramedullary disease

A quarter of NHL patients will present with extranodal disease, which commonly involves the CNS or GI tract, but can occur anywhere. Extranodal sites of head and neck lymphomas include salivary glands (marginal zone lymphoma – especially in patients with Sjögren's syndrome,³¹ sinuses (usually diffuse large B-cell lymphoma) and the nasal cavity (NK/T nasal type lymphoma). Bone marrow malignancies such as acute myeloid leukaemia

and myeloma are also capable of forming extramedullary deposits, referred to as chloromas and plasmacytomas respectively. The latter commonly involve the head and neck and frequently present diagnostic difficulties. Whilst most occur in the context of systemic myeloma a minority are solitary and potentially cured with radiotherapy.³²⁻³³ Deposits of extramedullary haematopoiesis can also occur at any site and often mimic the appearance of tumours; these should be considered when a paranasal lesion is found in a patient with chronic anaemia, especially a child with thalassaemia major or sickle cell disease.⁹

Hyperviscosity and leucostasis

Both myeloma and lymphoplasmacytoid lymphoma are capable of secreting large amounts of immunoglobulin; if the concentration of this paraprotein is sufficiently high it will thicken the blood and cause impairment of the micro-circulation, a condition known as hyperviscosity syndrome. Leucostasis refers to a similar situation that results from very high white cell counts (typically $>100 \times 10^9/L$), usually at initial presentation of acute myeloid leukaemia or CML. Impairment of blood flow causes a constellation of symptoms and signs that may include blurring or loss of vision, headache, hearing loss, vertigo, nystagmus, tinnitus, diplopia and ataxia. Untreated these conditions can progress to seizures, stroke, coma and death.²⁶ Plasmapheresis or leucopheresis can be used to rapidly remove the excess immunoglobulin or malignant cells (respectively), but the essence of successful management is the prompt instigation of disease directed therapy (e.g. chemotherapy). Although rare there have also been several case reports of sudden-onset bilateral deafness as the initial presenting feature of CML.³⁴

Bony disease

Multiple myeloma can affect any bone and cases of temporal bone involvement causing otitis media, hearing loss and mastoid effusions have been reported. Whilst this would be a rare presentation, myeloma is a common malignancy and should be considered whenever lytic bone lesions are identified.³⁵⁻³⁶

ENT COMPLICATIONS OF HAEMATOLOGICAL THERAPIES

Infections

Patients with haematological malignancies are often severely immunocompromised as a result of both their disease and the effects of treatment, making them susceptible to infection from a wide range of common organisms and opportunistic pathogens, including bacteria, viruses, fungi and protozoa. Whilst patients are often taking a variety of prophylactic antimicrobials these offer incomplete protection.

Certain congenital (constitutional) haematological disorders are associated with either neutropenia or disordered

neutrophil function and similarly increase the risk of bacterial or fungal infection. These disorders not infrequently present with discharging ears or lymphadenitis.³⁷

These infections can be of unexpected severity or duration and can occur at unusual sites; clinical signs can be subtle or misleading as the inflammatory response that usually produces symptoms is often attenuated or absent. Fungal rhinosinusitis can be fatal.³⁸

Bacterial infections are most frequent in patients with neutropenia (post-chemotherapy, acute leukaemia, aplastic anaemia etc.) or impaired neutrophil function (myelodysplasia). Otitis media and sinusitis are common acute infections that can become chronic and problematic for patients with persistent neutrophil defects.³⁹

Viral infections are common in patients rendered hypogammaglobulinaemic by CLL, HSCT or myeloma; they are usually upper respiratory tract infections or rhinosinusitis and tend to last longer than in an immunocompetent host, sometimes persisting for several weeks. More profoundly suppressed patients can experience reactivation of latent CMV, VZV or HSV 1+2; the latter is often associated with severe ulceration of the oropharynx and even abscess formation.⁴⁰

Fungal spores are ubiquitous in the environment and are continuously inhaled, often leading to colonization of the respiratory tract. Invasive infection is less common but occurs in the context of prolonged neutropenia or patients with GvHD, who have impaired immune reconstitution and are often taking multiple immunosuppressive agents.⁴¹⁻⁴² Acute fungal rhinosinusitis is an invasive infection with a high mortality usually caused by *aspergillus* species or pin moulds (mucorales).³⁸ The initial symptoms include fever, nasal congestion, facial pain and epistaxis; examination of the oral cavity and nasal passages may reveal mucosal thickening or areas of necrotic tissue. Invasion of the palate, orbit, cavernous sinus, cranial nerves and brain can occur within hours, days or weeks depending on the specific organism and the depth of immunosuppression.⁴³ Some patients have extension beyond the sinuses at presentation leading to visual disturbance, diplopia, facial numbness, altered cognition or seizures.

Rapid diagnosis is essential for survival so a high index of suspicion is required when immunocompromised patients develop sinus symptoms; early input from radiology, ENT and pathology is vital in this regard. Multiple sinuses are usually involved and can be recognized using CT by the presence of opacification, mucosal thickening and bony erosions; the maxillary and ethmoid sinuses are the most commonly affected.⁴⁴ If invasion of surrounding structures is suspected then magnetic resonance imaging (MRI) is needed to characterize intra-cranial involvement.⁴⁵ Whilst imaging is not diagnostic of fungal infection, it is important to define the extent of the disease and identify extension into the brain or orbit, so that surgical intervention can be planned. Early nasal endoscopy is crucial to look for necrosis, which can appear as sloughing or perforation of the nasal septum, or palatal eschars;⁴⁶ biopsy of the affected area should be performed and sent for both culture and histopathology. Diagnosis depends on

histological demonstration of fungal hyphae penetrating surrounding tissue and blood vessels, to distinguish invasive infection from colonization. Culture of the specimen permits identification of the fungus, which has important consequences for the choice of antifungal therapy.

When fungal infection is first suspected empirical therapy with intravenous amphotericin B should be commenced. The mucorales are resistant to voriconazole and this agent should only be considered if mucormycosis has been excluded.⁴⁷ Other species of fungus have varying sensitivities, highlighting the importance of early identification of the organism and discussion with microbiology. Where immunosuppression can be withdrawn then this should be considered, although in the context of haematological malignancy and HSCT it is often a case of buying time with antifungal therapy whilst immune reconstitution occurs. The surgical management of fungal rhinosinusitis can be challenging and is discussed in detail in [Chapter 96](#) (Fungal Rhinosinusitis).

Mucormycosis of the palate and middle ear have also been described in the context of haematological disease and HSCT, emphasizing the need to keep an open mind when assessing ENT problems in this population.^{47–49}

Ototoxicity

Cisplatin and carboplatin are platinum-containing chemotherapy agents that are used for the treatment of relapsed lymphomas and numerous non-haematological malignancies. They are potent neurotoxins that are capable of damaging the outer hair cells and the epithelium of the lateral wall of the cochlea. Cisplatin is the most ototoxic of this class, typically causing high-frequency sensorineural hearing loss with tinnitus in 15–20% of patients; audiometric changes can be demonstrated in many more, up to 75% in some studies.⁵⁰ Onset is variable with some patients suffering severe hearing loss after a single dose, whilst others develop symptoms several months after the last dose. The toxicity is dose dependant but there is considerable variation between individuals, suggesting significant polymorphism in the pathways responsible for the drugs metabolism. Risk is increased by the presence of renal failure and the concomitant use of other ototoxic therapies, especially radiotherapy (RT), which has a synergistic effect and also causes serous otitis media, potentially complicating assessment. Children are particularly susceptible, partly because of age but also the regimes that they receive are commonly high dose, combined with RT or contain two platinum based compounds. Avoiding ototoxicity is particularly important in children as it has profound consequences for speech and language development.⁵¹ Extended high-frequency audiometry is recommended to allow early detection of hearing loss before the frequencies required for hearing speech are affected.⁵² Distortion product otoacoustic emissions (DPOAEs) are also more sensitive than conventional audiometry and can be used in children under 5 years of age. Damage is typically irreversible and management should focus on prevention through early recognition and dose reduction or cessation where possible.⁵³ Sodium thiosulphate has been

trialed as a protective agent but the development of this and similar agents has been hampered by a lack of consensus regarding ototoxicity assessment criteria.

The ototoxicity of the aminoglycosides is well documented and gentamicin is commonly used in combination with extended spectrum penicillin for the treatment of neutropenic sepsis. Other ototoxic agents used in the management of haematological disorders include desferrioxamine (used to prevent iron overload in the chronically transfused), loop diuretics, vancomycin, amphotericin B, cytarabine, methotrexate and the vinca alkaloids.⁵⁴

Stridor during treatment of haematological malignancy

The ENT surgeon may be called to the haematology ward to see patients with respiratory compromise due to airway obstruction. Several causes should be considered:

- There may be mucosal inflammation of the mouth and pharynx secondary to intensive chemotherapy. This is known as mucositis and is related to the intensity of chemotherapy. It occurs in the weeks after such therapy and is self-limiting. There is evident inflammation of the mucosa with thick secretions that might contribute to airway compromise.⁵⁵
- Stridor secondary to vocal cord paralysis is rarely recorded secondary to vincristine chemotherapy, which is usually part of the treatment of childhood leukaemia.⁵⁶ The paralysis may be of long-standing duration.

LABORATORY HAEMATOLOGY AND THE ENT SURGEON

The full (complete) blood count

All basic laboratory haematology is fully automated. The full (or complete) blood count (FBC) will give the requesting clinician the following:⁵⁷

- The number of red cells (red cell count, RCC), their size (mean corpuscular volume, MCV) and the haemoglobin concentration within them (mean corpuscular haemoglobin, MCH or mean corpuscular haemoglobin concentration, MCHC).⁵⁸ It will also measure the haemoglobin concentration (Hb) within whole blood. The haemoglobin can be low and the red cell count high if those red cells don't contain much haemoglobin within them (as in certain haemoglobinopathies). Most analysers will also offer a reticulocyte count. Reticulocytes are simply young red cells recently made in the marrow and if the reticulocyte count is high then the marrow is making lots of red cells.
- The total white cell count; and usually a 5-part differential giving the number of neutrophils, monocytes, lymphocytes, eosinophils and basophils. The counters discriminate these cells on the basis of size and staining.
- The platelet count.

The analysers are good but abnormalities may be confirmed after examination of the blood smear. Samples that are clotted or diluted give erroneous results and should be repeated. Similarly samples that are not freshly analysed may give inaccurate results.

Cytopenia indicates reduction of a blood cell number and pancytopenia is a reduction in the blood of all cell types – red cells, white cells and platelets. Any cytopenia is either caused by diminished production of the cell in the marrow or by increased peripheral consumption. The causes of pancytopenia are given in [Box 25.1](#).

BOX 25.1 Causes of pancytopenia

- Decreased bone marrow function
- Aplasia
- Acute leukaemia, myelodysplasia, myeloma
- Infiltration with lymphoma, solid tumours, tuberculosis
- Megaloblastic anaemia
- Paroxysmal nocturnal haemoglobinuria
- Myelofibrosis
- Haemophagocytic syndrome
- Increased peripheral destruction
- Splenomegaly

Anaemia

The haemoglobin (Hb) is low on the analyser FBC. The practising ENT surgeon should be readily able to discriminate the likely causes for any anaemia from the clinical situation of the patient and the details of both the red cell parameters and the reticulocyte count:

- **Bleeding.** This might be obvious from the history of the patient. The red cells are usually normal in size and shape (unless the bleeding has been chronic and associated with iron deficiency) and there should be a raised reticulocyte count as the marrow compensates for the blood that has been lost with increased production. Note that reticulocytes are larger than normal cells and a reticulocytosis might be associated with a raised MCV and note also that the platelet count may be increased by bleeding.
- **Iron deficiency.** Iron is needed to make haemoglobin and when there is iron deficiency then the Hb will be low. The red cells will be small (low MCV) without much haemoglobin within them (low MCH and MCHC). The diagnosis can be confirmed by measuring the serum iron or the ferritin. Iron deficiency may be associated with a poor diet or with chronic blood loss. If the patient is female then take a history of menstrual bleeding and consider the gut as a source of bleeding – this might be asymptomatic and referral to the gastroenterology team might be indicated.
- **Haemolytic anaemia.** Haemolysis is shortened red cell survival so that they are surviving for fewer than their usual 120 days. The marrow should compensate for the shortened survival with a reticulocytosis (perhaps with a raised MCV). Red cell breakdown will result in unconjugated hyperbilirubinaemia. The cause might

be immune mediated with antibody on the red cell surface, which will manifest as a positive Coombs test (direct antiglobulin test, DAT).

- **Anaemia of chronic disease.** Sick patients will often be anaemic. This will include those with cancer and those with chronic infection or autoimmune disease. The anaemia is usually normochromic and normocytic (normal red cell parameters) or slightly microcytic.
- **Anaemia associated with haematological diseases.** Patients known to haematology services may have anaemia associated with their primary disease or its treatment.

Polycythaemia

This is a raised Hb with a raised red cell count. It may be secondary to hypoxia, which itself is most commonly associated with chronic cardiopulmonary disease and the arterial oxygen saturation is low. Such patients simply need more red cells to deliver oxygen to the tissues since each red cell delivers less since it picks up less in the lung. Sometimes polycythaemia might be part of a myeloproliferative condition where there is an endogenous and primary overproduction of red cells by the bone marrow.

Disorders of platelet number

An increase in the platelet count is known as thrombocytosis. Just as with polycythaemia it might be secondary or part of a myeloproliferative condition. Primary causes include bleeding and surgery. The count may also be raised in chronic inflammatory disease including infection.

Thrombocytopenia is a reduced platelet count. It may present with bleeding including bleeding from the nose and into the mouth. Causes that the surgeon should consider must include:

- Immune thrombocytopenic purpura (ITP). In this condition then there are autoantibodies directed at the platelet. The platelet count may be dramatically low (into single figures). In children it may resolve spontaneously. Steroids and other immunosuppressant drugs are used to improve the count, especially in adult patients.⁵⁹ Referral to haematology services is indicated.
- As part of a coagulopathy including disseminated intravascular coagulation (DIC). In DIC there is activation and consumption of clotting factors and platelets in association with severe illness such as severe bacterial infection or widespread metastatic malignancy. Where there is thrombocytopenia the coagulation profile should be checked and the hallmarks of DIC are prolongation of the prothrombin time (PT) and activated partial thromboplastin time (APTT) with reduction in fibrinogen and elevation of fibrin degradation products (expressed as FDP or D-Dimers).⁴
- Heparin can cause thrombocytopenia and there may be paradoxical thrombosis, which can be severe in heparin-induced thrombocytopenia (HIT). If HIT is suspected then an urgent referral to haematology is

indicated as there are specific investigations to detect the culpable antibodies and specific intervention will be initiated.

- Thrombocytopenia might be associated with primary haematological illness.

Disorders of neutrophil number

Neutrophil leucocytosis – an increase in the neutrophil count – is usually secondary to bacterial infection. It may be secondary to other inflammatory illness, to malignancy and it will frequently be raised post-operatively. Sometimes it may be part of a primary haematological process including myeloproliferative disease and leukaemia.

Neutropenia may also be associated with infection including viral infections and significant bacterial infection. As with ITP there may be immune mediated neutropenia. It may be associated with primary haematological disease and its treatment.

Abnormalities of lymphocyte appearance and number

The practising surgeon should recognize that lymphocytes deal with viruses and may be altered in number or appearance in viral infection or primary haematological disease. Certain conditions are worthy of specific mention:

- The lymphocyte may appear differently – often referred to as ‘atypical mononuclear cells’ or ‘atypical lymphocytes’ – in certain viral infections and particularly in the EBV infection known as infectious mononucleosis. In this illness there may be fever, lassitude, sore throat, with atypical lymphocytes seen on the blood smear.⁶⁰ Diagnosis is with EBV serology. Note that this illness may be indistinguishable from other virus infection such as CMV.
- There may be a lymphocytosis in other viral infections. It may be elevated in bacterial infection especially in children and classically with pertussis infection (whooping cough).
- The lymphocyte count may be chronically elevated in chronic lymphocytic leukaemia (CLL). There will often be associated lymph node enlargement as the malignant cells infiltrate nodes. The diagnosis can easily be made from peripheral blood investigations (starting with blood smear and then flow cytometry) and biopsy of an enlarged node might therefore be avoidable.

Monocytes, eosinophils and basophils

Monocytosis is seen in chronic infection and in primary haematological disease. Where it is part of a reactive picture there is usually an associated neutrophil leucocytosis.⁶⁰

Eosinophilia is seen in allergic conditions (asthma, eczema), in parasitic infections and in association with certain drugs. It is classically also seen in Hodgkin’s lymphoma and the association of lymphadenopathy with

eosinophilia should alert the clinician to this potential diagnosis.⁶¹

Basophils are infrequently found in the peripheral blood. They may be increased in chronic myeloid leukaemia where the total white cell count is usually typically greatly elevated.

SPECIAL CONSIDERATIONS IN CHRONIC HAEMATOLOGICAL DISEASES

Sickle cell disease

Sickle cell disease is a common haemoglobinopathy, which is encountered worldwide, although usually in patients of Afro-Caribbean, Middle Eastern or Asian ancestry. There is a single base pair substitution leading to a single amino acid change in the β -globin chain of the haemoglobin molecule.⁶² It can be considered as two diseases:

- There is a haemolytic anaemia with shortened red cell survival and anaemia with the generic features of haemolysis including reticulocytosis and jaundice.
- There is also a vaso-occlusive illness. The red cells occlude blood vessels during crises and either affect the oxygen delivery to that organ (stroke, painful crisis) or affect blood flow from that organ (sequestration crisis).

There are several points that the ENT surgeon should note.⁶³ All children with a possible diagnosis of sickle cell anaemia should be screened prior to surgery since there is an increased risk associated with anaesthesia. Safe surgery requires the meticulous avoidance of dehydration, hypoxia or hypothermia as these may trigger sickling.⁶⁴

In some countries including the UK there will have been implemented a national neonatal screening strategy. Otherwise it is easy to screen rapidly by testing for sickling in the lab (the sickledex test) and by looking at the blood film. Haemoglobin electrophoresis will detect haemoglobin S and distinguish it from normal adult haemoglobin A.

There is an increased risk of sensorineural deafness in children with sickle cell disease presumably as a consequence of the vasculopathy of sickle cell. Affected children have an increased incidence of obstructive sleep apnoea caused by adeno-tonsillar hypertrophy and surgical correction might reduce the risk of painful crises. Priapism of the nasal turbinates is a cause of nasal obstruction and partial turbinectomy might be indicated.⁶³

Bone marrow (stem cell) transplant

During stem cell transplant the recipient receives a stem cell donation from either a relative or an unrelated individual as part of their treatment of a primary haematological malignant or non-malignant disease. The stem cell donation follows a period of ‘conditioning’ high dose chemotherapy or radiotherapy that gets rid of both the patient’s

immune system so that the donation is not rejected and the patient's own bone marrow so that there is 'space' for the donated stem cells to engraft into.

The conditioning therapy will regularly and reliably generate mucositis (see 'Stridor during treatment of haematological malignancy' above). There will be the risk of infection including fungal infection that is discussed in 'Infections' above and in the management of which the ENT team will be not infrequently involved.

The transplant may involve immunological rejection of host tissue by the engrafted, regenerating donor immune system. This is the process of graft versus host disease (GvHD) and is the opposite of graft rejection. GvHD in the early months after transplant will involve attack on the skin (presenting as rash), the gut (presenting as diarrhoea) and the liver (presenting as jaundice). However there may be involvement of any organ in the months that follow. During this chronic GvHD phase there may be immunological destruction of the salivary gland and xerostomia.⁶⁵

Management is supportive and symptom-directed but also immunosuppressive.

Splenectomy

The spleen protects against infection with encapsulated organisms including *pneumococcus* and *haemophilus* species.³ Hyposplenism is rarely constitutional but usually follows surgical splenectomy, which may be done following trauma or as part of treatment of a haematological condition. The patient will usually receive protection against such infection with prophylactic antibiotics and with regular vaccination against *pneumococcus*, *meningococcus* and *haemophilus*. Malaria prophylaxis in endemic areas is also important. The FBC may be abnormal in the splenectomized individual with leucocytosis and thrombocytosis. The smear will show Howell-Jolly bodies in the red cells – these are nuclear fragments that the spleen will usually remove from the mature, circulating red cell.⁶⁰

KEY POINTS

- Haematological malignancies often present to the otolaryngologist as nodal disease in the neck.
- Patients with haematological malignancies may have severely compromised immune systems due both to the disease process and the treatment. This leads to increased risk of severe upper respiratory infections including rhinosinusitis, mastoiditis, supraglottitis and neck space infections.
- Invasive fungal rhinosinusitis can complicate haematological disorders.
- Lymphomas of the head and neck can progress rapidly in size, leading to airway obstruction.
- Severe mucositis of the aerodigestive tract can complicate the treatment of haematological malignancies.
- Vincristine is an uncommon but important cause of vocal cord palsy.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: haemostasis and thrombosis.

INTRODUCTION

It is common for surgeons to come across disorders of haemostasis. The three main scenarios are: i) peri-operative severe and potentially life-threatening bleeding; ii) pre-operative assessment that identifies or suggests a patient may be at increased risk of bleeding; and iii) post-operative thrombosis. The aim of this chapter is to provide the physiological and practical knowledge to manage these scenarios together with your haematology team.

In order to interpret laboratory tests and manage patients' safely it is important to have a working understanding of blood clotting. Blood clotting is somewhat confusing as clotting factors are numbered according to when they were discovered and this is not related to where they are in the clotting cascade. They are labelled in Roman numerals. Factors III, IV and VI are not referred to because, following their discovery, it became clear that they were already known substances (i.e. thromboplastin, calcium and factor Va).

While the traditional cascade model of clotting is not exactly what happens in the body it is still useful and important to understand in order to interpret laboratory tests and safely manage patients. In the body, blood clotting is a much more dynamic process also involving other blood cells and the blood vessel walls. It involves a fine

balance between excessive bleeding and clotting, either of which is pathological.

CLOTTING CASCADE

Blood clotting is the conversion of soluble fibrinogen (coagulation factor I), which is present as small monomers, to insoluble long chains of fibrin. Long strands of fibrin are insoluble; however, they are not strongly bound together until the long fibrin strands are cross-linked. This cross-linked fibrin is very strong and stable and the principal structure of the blood clot.

Thrombin is the only factor able to cause fibrinogen to generate fibrin, so thrombin generation is therefore essential for clot formation. Thrombin also controls many other parts of the blood clotting system including forming the cross-linked bonds through activation of factor XIII ([Figure 26.1](#)).

Common pathway

Prothrombin (factor II) is cleaved to form thrombin and itself can only be activated by activated factor X (Xa). This involves a complex reaction with factor V as a cofactor. Calcium and phospholipid are also required for this to occur.

Figure 26.1 The action of thrombin to form cross-linked fibrin.

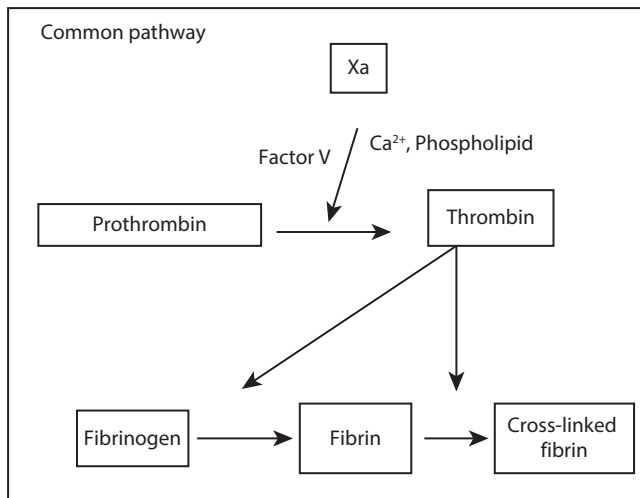

Figure 26.2 The common pathway of blood coagulation.

This section of the process is referred to as the common pathway (Figure 26.2). Descriptions of the clotting cascade are traditionally referred to as the common pathway, the intrinsic pathway and the extrinsic pathway. These will be discussed shortly.

Factor Xa can be formed in the laboratory in two different ways. In the prothrombin time (PT) test an **external** factor called ‘tissue factor’ is required; hence this is called the **extrinsic pathway**. In the partial thromboplastin time (PTT) – also known as activated partial thromboplastin time (APTT) or Kaolin cephalin clotting time (KCCT) – there is no additional biological factor so all the factors are already present in the plasma so it is called the **intrinsic pathway**.

Extrinsic pathway (Figure 26.3)

The PT is the time, in seconds, for a clot to form once tissue factor (made from rabbit’s brain) and calcium are added to the patient’s plasma. During this time factor VII is activated by tissue factor and calcium to become factor VIIa, which in turn directly activates factor X to become Xa, and so on through to the formation of fibrin (Figure 26.3).

Figure 26.3 The extrinsic and common pathway of blood coagulation.

Note that the PT includes all of the cascade from factor VII through to fibrin formation, but does *not* include cross-linked fibrin (so the PT is normal in factor XIII deficiency).

Intrinsic pathway

The PTT measures the time in seconds for a clot to form once calcium is added to the patient’s plasma after a pre-incubation with kaolin which acts as a catalyst (required within laboratory testing to allow the reaction to occur). This covers the time from the conversion of factor XII to XIIa, which then drives activation of factor XI to XIa. Factor XIa in turn activates IX to IXa, which leads to the activation of X to Xa. Factor VIII is a cofactor required for the action of IXa (Figure 26.4).

The physical structures of cofactors VIII and V (in the common pathway) are very similar to each other and they participate in similar ways in the reactions. The PTT measures the time for the process from Factor XII through to formation of fibrin, but again *not* to cross-linked fibrin so again this is also normal in factor XIII deficiency.

While the above pathways do not precisely represent what occurs in the body it is a useful working understanding of clotting in laboratory testing that can be used to identify deficiencies in specific factors. The above screening tests allow a measure of the presence and function of the patient’s factor levels. However, the differences that occur within the human body include thrombin, also providing positive feedback towards the formation of factors IX, X, XI and VII. Within the body factor VII also activates primarily factor IX, factor IX then activates factor VII in a positive feedback. These extra levels of positive feedback accelerate the process, and create a powerful amplification of the cascade. At each stage of the reaction the amplification is such that one molecule of a particular

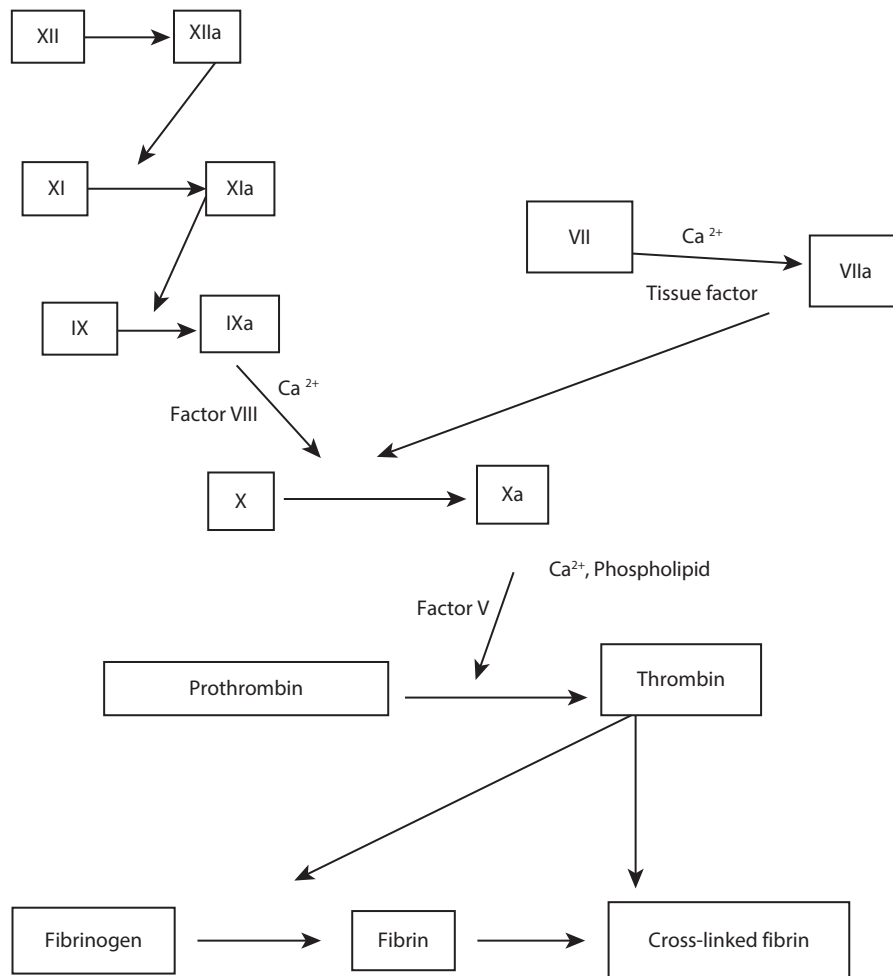

Figure 26.4 The intrinsic, extrinsic and common pathways of blood coagulation.

factor activates 100 molecules of the next factor in line. This allows rapid clot formation from a small initial stimulus. This speed is obviously essential when somebody is bleeding and differs from other much slower enzymatic reactions in the body.

Inhibitory systems

Inhibitory systems are in place to prevent clotting continuing extensively where it is not required. There are two main inhibitory systems; 1) antithrombin (previously referred to as antithrombin III) and 2) protein C with protein S.

Antithrombin's main action is, as the name suggests, inhibition of thrombin. Antithrombin also inhibits at multiple other levels within the cascade, the serine proteases, factors X, IX, XI and XIIa, which share some molecular features.

Factors V and VIII are structurally similar to each other but very different from the other factors. Not surprisingly, therefore, they have a different inhibition system, protein C and its cofactor protein S.

Deficiencies in any of these inhibitory proteins are a risk factor for the generation of clots in patients. An abnormality of the blood clotting system that predisposes to clots is called thrombophilia ('clot loving').

The role of platelets

Platelets are the smallest cell in the body and are fragments of cytoplasm formed from megakaryocytes in the bone marrow. Platelets contain 'packages' (granules) of various elements needed for coagulation, including clotting factors, ADP, serotonin, von Willebrand factor (vWF) and fibrinogen. They have two main receptors on their surface allowing them to stick to exposed collagen on a damaged blood vessel wall and allowing them to stick to each other directly and via vWF.

The steps in platelet function include:

- adherence – sticking to collagen exposed by damaged endothelium
- activation – secreting a range of chemicals to induce clot formation, vasoconstriction and start the healing process
- aggregation – sticking together (stimulated by ADP and thromboxane) (Figure 26.5).

ADHERENCE

This is the platelets sticking to exposed collagen underlying the damaged endothelium. There are two main

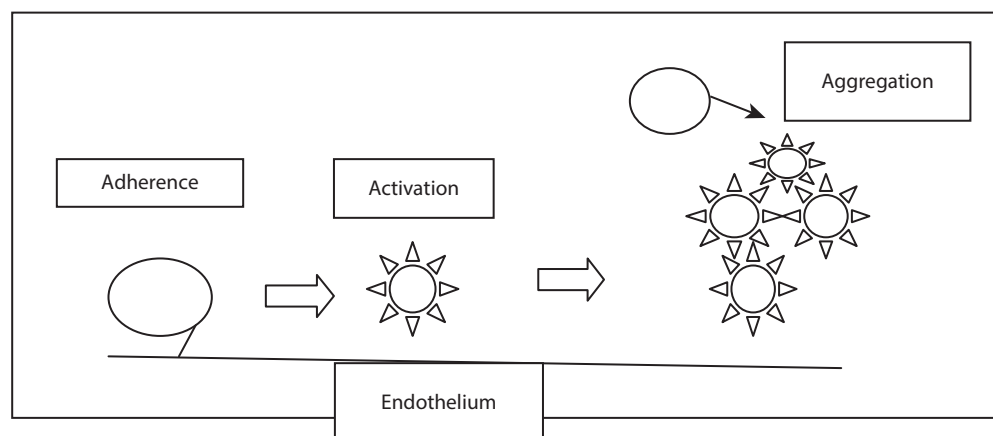

Figure 26.5 Platelet adherence, activation and aggregation.

membrane bound sticky molecular complexes that have this function:

1. Glycoprotein IIb/IIIa complex, which sticks to collagen directly. If this glycoprotein is missing it causes a severe bleeding disorder called Glanzmann's thrombasthenia.
2. Glycoprotein Ib/V/IX complex, which sticks to collagen indirectly via von Willebrand factor. If this glycoprotein is missing it causes a severe bleeding disorder called Bernard Soulier disease.

ACTIVATION

This is the process of locally secreting factors that promote blood clot formation, platelet aggregation, vasoconstriction and the start of tissue healing. One critical process is the 'arachidonic acid pathway'. Arachidonic acid is freed from cell membrane phospholipid molecules and converted to prostaglandin by cyclo-oxygenase (COX) enzymes. In turn the prostaglandin then forms thromboxane (via thromboxane synthetase present in platelets) and prostacyclin (via prostacyclin synthetase in endothelial cells). The thromboxane is a vasoconstrictor that stimulates further platelet aggregation and activation (aspirin irreversibly blocks this process, rendering the platelet function reduced for the rest of its 12-day life span), whereas prostacyclin has opposite effects, causing vasodilation and platelet inhibition.

Aggregation

This is when the activated platelets recruit other platelets to an enlarging 'platelet aggregate'. Much of this is by the release of ADP from dense granules and also through generation of thromboxane.

The role of von Willebrand factor

Von Willebrand factor (vWF) is in plasma and platelets. It is also released from the special storage granules in the endothelium called Weibel Palade bodies.

vWF has two main functions:

1. It makes platelets stick to each other and to damaged blood vessel walls. This can only occur when the vWF sticks to itself in ultra large high molecular weight multimers. These multimer molecules can be huge (from 500 to 20000 kDa)
2. It chaperones circulating factor VIII – this stabilizes factor VIII to prolong the half-life.

Interpreting laboratory results and diagnosing von Willebrand disease is not straightforward and is beyond the scope of this chapter. Difficulties arise firstly in that vWF is a highly labile protein that goes up with stress (which could include surgery) and also in pregnancy. In addition, the laboratory tests are difficult and results are not always robust, commonly giving falsely low levels.

The role of the vessel wall

The formation of a clot usually starts when there is damage to the endothelial wall. The endothelial wall in its healthy state is active in inhibiting platelet adhesion by the production of substances such as nitric oxide and prostacyclin. It therefore functions as a 'non-stick' surface. When collagen is exposed, allowing platelets to come into contact, they then become active. The two main anticoagulant systems discussed earlier (i.e. antithrombin and proteins C and S) are potentiated by normal endothelium. Antithrombin is bound on the endothelial cell surface by 'heparin like' glycosaminoglycans and is made much more powerful. Another molecule on the endothelial surface called thrombomodulin binds thrombin. Thrombin, instead of being the critical promoter of coagulation, then stops all procoagulant function and potentiates protein C. In effect thrombin becomes an anticoagulant in the presence of normal endothelium and limits the clot to the damaged surface (Figure 26.6).

When a platelet plug has formed, the larger blood vessels in particular need cross-linked fibrin to stabilize it. In smaller vessels this is not always a vital step and this partly explains the difference in bleeding manifestations in different disease states.

Figure 26.6 Natural anticoagulation via thrombomodulin, protein C and protein S pathway.

The flow of blood within the blood vessel can also affect the type of clot formed. Red clot, mostly erythrocyte (red cell) and fibrin, is formed where flow is reduced with no blood vessel damage (i.e. cases of DVT); they are generally treated best with anticoagulants. White clot is platelet and fibrin, forming where blood vessel damage has occurred and characteristically occurs in faster flow vessels/arteries (i.e. myocardial infarction), which is best treated with antiplatelets. Of course clots may be both white and red, especially where white clots are initially formed leading to alteration of flow and additional formation of red clot.

Blood clot breakdown (fibrinolysis)

As soon as a clot is formed the process of clot breakdown called fibrinolysis starts and is mediated via plasmin. Plasmin is generated from plasminogen, which is bound by fibrin. It is then converted to its active form by plasminogen activators. There are inhibitors to this process, which prevent the degradation occurring too quickly (e.g. plasminogen activator inhibitor PAI-1 and activated protein C) (Figure 26.7). All of the products of this breakdown are called fibrin degradation products. D-dimer is the specific product formed only by breakdown of cross-linked fibrin and can be used as an indicator of thrombus formation; however it will also be raised in other states of inflammation/infection.

Figure 26.7 Fibrinolysis.

INTERPRETATION OF COAGULATION SCREENING TESTS

(See Table 26.1)

International normalized ratio

Technically, an international normalized ratio (INR) should only be used for monitoring of warfarin as this is the setting validated for its use. In all other instances the PT should be requested. The INR is purely the PT ratio multiplied by a 'fiddle factor' specific to the laboratory to allow comparison between laboratories. Therefore there is no additional information in an INR compared with a PT.

With suspected Vitamin K deficiency (if time allows) the usual practice would be to treat with Vitamin K, either oral or IV, depending on concerns regarding gastrointestinal absorption (i.e. 10 mg for 3 to 5 days with a repeat test following this as a 'proof of suspicion') rather than checking Vitamin K levels.

Thromboelastography/rotational thromboelastography

In many settings there is now increasing use of thromboelastography (TEG) and rotational thromboelastography (ROTEM). This technology gives a quick guide as to the global coagulation functioning indicating the patient's current status. It produces a trace providing information of time to formation of clot, and its stability, enabling a more 'real time' guide to product use (Figure 26.8). It has particularly been employed in setting with major blood loss (i.e. trauma, vascular surgery).

The trace has a variety of measurements that help in interpreting (Figure 26.8):

- **R time** – time until clot first detected (prolonged if on anticoagulants or factor deficiency)
- **K time** – time to clot formation (time from initiation of clot to maximum amplitude/strength)
- **alpha angle** – helps guide if the patient is in a hypercoagulable state.

TABLE 26.1 Interpretation of abnormal laboratory tests

Test	Causes	Further laboratory investigations to consider
Prolonged PT only (with other tests normal). Can only be caused by factor VII deficiency, which in turn may be related to a variety of causes	<ul style="list-style-type: none"> • Vitamin K deficiency • Antagonists, e.g. warfarin • Dietary. Vitamin K in green vegetables • Early liver disease • Congenital deficiency (very rare) 	<ul style="list-style-type: none"> • LFTs • FVII assay • If dietary deficiency is considered, giving oral Vitamin K and repeating the PT is a simple way of excluding other serious causes.
Prolonged APTT only (deficiency of one or more of: factor VIII, IX, XI, XII)	<ul style="list-style-type: none"> • Heparin • Lupus anticoagulant or other inhibitor • Congenital deficiency (haemophilias) 	<ul style="list-style-type: none"> • Thrombin time • Reptilase time, which neutralizes heparin
Prolonged PT and APTT	<ul style="list-style-type: none"> • DIC (also may have low platelets and low fibrinogen) • Liver failure • Vitamin K deficiency • Warfarin • Factor X or V or II deficiency 	<ul style="list-style-type: none"> • LFT • Fibrinogen, factors V, X, II
Low fibrinogen	<ul style="list-style-type: none"> • DIC • Afibrinogenaemia/dysfibrinogenaemia 	<ul style="list-style-type: none"> • Fibrinogen assay (In routine coagulation testing the result is often a derived value rather than direct testing).
Low platelets	<ul style="list-style-type: none"> • Clumping/artefact • ITP • Bone marrow failure (many causes) • Drug cause • Infection/DIC 	<ul style="list-style-type: none"> • If a single low count that is unexpected, repeat sample • Blood film • Further investigation depends on the history
Normal tests but abnormal bleeding	<ul style="list-style-type: none"> • Consider surgical causes; it may be obvious but surgery is the commonest cause of bleeding post-operatively • LMWH • Abnormal platelet function • Von Willebrand disease • Factor XIII deficiency • Mild factor deficiency 	<ul style="list-style-type: none"> • Von Willebrand screen • Factor XIII assay • Platelet aggregation studies

**Figure 26.8** Thromboelastography.

The shape of the trace produced gives a lot of information on the coagulation and fibrinolysis and very typical traces can be seen in pathological states such as disseminated intravascular coagulation (DIC) when a patient is hypercoagulable with reduced R and K times and secondary fibrinolysis.

Specific factor assays

These are performed to quantify the levels of specific coagulation factors in a patient. They are needed for

initial diagnosis and then for guiding response treatment and further management. Using a plasma known to be deficient in a specific factor (which are now manufactured, although can be plasma from patients known to have haemophilia) and normal plasma, either the PT or PTT test can be performed, depending on which factor is to be assayed. By mixing the 100% normal plasma and 0% deficient plasma in different proportions to create a standard curve, the patient's plasma can then be tested and a specific factor level deduced from this curve. This is the basis of testing for all factor levels in the extrinsic and intrinsic pathways.

BLEEDING DISORDERS

It is vital to identify any underlying bleeding disorder prior to surgery. Patients with severe bleeding disorders can have life-threatening bleeding even with minor procedures. Patients with bleeding disorders should always be managed jointly with the haematology team.

Different bleeding disorders present with different bleeding symptoms, for example joint bleeds in haemophilia and mucocutaneous bleeding (i.e. bruising, bleeding from the nose, mouth and menorrhagia) with von Willebrand disease and platelet disorders. This is because the defect in the clotting system affects different aspects

of function. Bleeding disorders may be genetic/congenital or acquired. The history is crucial to guide further investigation and it is not always possible to fully interpret the laboratory investigations without the history.

It is useful to know that bleeding symptoms are common in the normal population. In a survey of normal controls, up to 25% of males and 46% of females with normal haemostasis are likely to have at least one bleeding manifestation (including menorrhagia, post-operative bleeding, bleeding post dental extraction).¹ Almost all of us will get a nose bleed at some point and 25% of younger children have recurrent nose bleeds. Most children experience fewer nose bleeds by the time they are teenagers. In some studies 65% of normal women in the control population would describe themselves as having menorrhagia. Bruising is normal with an active childhood lifestyle and if easy bruising is a symptom then objective questioning on the location, frequency, size and trauma associated with the bruising is essential. Bleeding scores have been developed to aid decisions on how significant the history is, but they are not necessarily in widespread use.

COAGULATION FACTOR DISORDERS

Haemophilia

One of the better known bleeding disorders is haemophilia. The genetic forms of this are grouped as haemophilia A (deficiency of factor VIII) or haemophilia B – Christmas disease (deficiency of factor IX). These are then classified as mild, moderate or severe depending on the patient's baseline factor level (mild is factor level <30%, moderate <5% and severe <1%). In most haemophilias the genetic defect 'runs true' within the family, therefore the severity of haemophilia also runs true within families.

Haemophilia A and B are X-linked genetic disorders and as such classically affect males. However, there are rare instances of female carriers presenting with increased bleeding tendency related to a low factor level (i.e. carriers of severe haemophilia). There are also instances of affected females with very low factor levels due to other complicated inheritance genetics (extreme X chromosome lyonization and mosaicism). Lastly it should be remembered that there are rare families who have two completely separate bleeding disorders, which can lead to some individuals having a much more severe bleeding phenotype than would be normally expected because they have inherited both. This means the patient's personal history and bleeding manifestations are of vital importance in treatment decision-making.

Severe and moderate haemophilias are usually diagnosed in childhood with many cases having been suspected antenatally when family history is known. Milder cases may present in adulthood. Spontaneous new mutations occur in approximately 20% of cases (therefore there is no family history). People with severe haemophilias have increased bruising but this does not usually cause a problem. The main issues for these patients are spontaneous joint and muscle bleeds and excessive bleeding following even minor procedures. All patients with a diagnosis of or

suspected haemophilia should have surgery managed in a centre with specialist haematology experience.

Patients with haemophilia A or B would be expected to have a significantly prolonged APTT on screening tests. Further assays can then be performed to ascertain specific factor levels.

Management of haemophilia

The management of patients ideally revolves around appropriate intravenous recombinant or plasma derived factor replacement. This can be 'on-demand' treatment for bleeds or 'prophylaxis' given regularly (usually 2–3 times weekly and often taken when sports or activities dictate). No oral factor replacement therapy is available as yet. Many patients who are newly diagnosed are now given primary prophylaxis and may not have experienced significant bleeds. Patients (particularly older ones) are generally very knowledgeable about symptoms of joint bleeds and most will self-treat at home, only attending hospital for review by the medical team if significant bleeding is experienced or if it is not settling. Acute bleeds require increased factor administration (i.e. often at least twice a day) with rest initially being advised followed by appropriate physiotherapy.

In developing countries expensive recombinant factor is often not available. Plasma derived factor is often cheaper but can carry the risk of blood-borne infection transmission. Simple measures of bleed management should always be considered in addition to factor replacement including RICE (rest, ice, compression and elevation) along with use of the relatively inexpensive tranexamic acid (an anti-fibrinolytic agent).

Management of any bleeding condition is a partnership between patient and multidisciplinary team. Perioperative management and dosing of factor replacement will usually be guided by exact levels and review of bleeding symptoms. The administered factor will be consumed more quickly in the face of bleeding and close monitoring of bloods may be required for a week or more post-operatively in the event of major surgery. Treatment options include bolus and continuous infusion of factor.

The management of haemophilia (and other bleeding disorders) may be complicated further by the development of inhibitors. This is an immune response with neutralizing antibodies against the factor treatment, which is viewed by the body as a foreign protein. The development of an inhibitor would be suspected in cases where there is an inadequate clinical response to treatment. Inhibitors are also usually monitored via laboratory testing as part of routine follow-up care. As the factor therapy is rendered ineffective, patients with inhibitors are very difficult to treat and can suffer life-threatening bleeding. Surgery should be avoided where possible until the inhibitor is controlled. Acute bleeds in these situations require administration of factor VIII inhibitor bypassing agent (FEIBA), which is a plasma derived concentration of a number of other factors or high dose recombinant factor VIIa (rFVIIa) to gain control. Patients with significant problems with inhibitors generally require treatment aimed at eradicating the inhibitor; however, this usually takes many months to be an effective strategy.

Acquired haemophilia

Acquired haemophilia is very rare but is important to mention as it can present to surgeons and has disastrous consequences if not identified. This usually occurs in older adults but can also occur in pregnancy. It is a type of auto-immune disease where patients develop (auto)antibodies to a coagulation factor (their own endogenous factor). This is most commonly FVIII or von Willebrand factor. It can present with no past history of bleeding manifestation. On presentation their bleeding, manifestations tend to be very different to those with congenital haemophilia and may consist of very extensive bruising and prolonged surgical bleeding. It does not usually lead to joint bleeds. From a laboratory point of view they will have a similar finding of markedly prolonged APTT, which would of course require further investigation. There will be a very low factor level. A 50:50 mix of patient plasma and normal plasma is a quick and easy test that all laboratories can perform even out of hours. The prolonged APTT does not correct as the inhibitor also destroys the factor in the normal plasma that is added (whereas it would normally correct in a congenital deficiency as enough factor is added with the 'normal plasma' and it is not destroyed by antibody). There may be an underlying condition driving the formation of the antibodies (i.e. malignancy, pregnancy). Patients with acquired haemophilia are complex and unbelievably expensive to manage and require two aspects of treatment: i) management of acute bleeding, which is similar to the management of a patient with congenital haemophilia who has an inhibitor; and ii) immunosuppression in an attempt to control the antibody, often with agents such as steroid, ciclosporin or Rituximab (a monoclonal antibody directed against CD20 cell marker that destroys mature B lymphocytes). Patients may spontaneously remit depending on whether an underlying driver can be treated but may have further episodes of relapse.

Von Willebrand disease

Von Willebrand disease is an inherited bleeding disorder. It can be seen with autosomal dominant or recessive inheritance. It is categorized into three types. The most common is type 1. This is usually a relatively mild partial quantitative deficiency, that is, a reduced amount of a normal von Willebrand factor (vWF). Type 2 is split into further groups but all involve abnormal vWF, usually with reduced function. Type 3 is near absence of vWF that leads to a severe bleeding phenotype very similar to severe haemophilia A.

It is often quoted that von Willebrand disease is very common at around 1% of the population.² This is false. The 'rumour' followed an Italian study that identified nine normal school children with low vWF levels out of 1000 tested. This in reality was just validating the reference range, which if set at 2 standard deviations from the mean will exclude 5% of the normal population (2.5% below and above). This paper is still repeatedly quoted today in literature but what is rarely quoted is the follow-up paper on the nine children, most of whom had surgery and none

of whom had any clinically relevant bleeding problems. In 2004–2005, UK international diagnostic guidelines were published that were much more restrictive.³ This is important as it will not be uncommon for someone to present with a historical diagnosis of von Willebrand disease and when you contact your haematologist to review they may retract the diagnosis.⁴ It is also recognized that as people get older their levels often improve, which may be another reason for altered management.⁵

Surgeons will frequently encounter patients with a personal or family member with a historical diagnosis. The international diagnostic guidelines have minor differences but essentially the diagnosis relies upon clinical significant bleeding symptoms and a vWF antigen (or activity level of vWF) of 40iu/dL or less on repeat occasions. A patient's blood group is also related to vWF levels, with group O patients having 30% lower levels than group A and B. This may well be the reason why blood group O patients are less likely to have thrombotic problems such as ischaemic stroke.

MANAGEMENT OF VON WILLEBRAND DISEASE

Management of vWD in most cases is by use of DDAVP (which leads to release of endogenous stores of vWF and factor VIII) or plasma derived product containing vWF and FVIII. There is as yet no recombinant product available. DDAVP is not effective in all cases so for routine surgery patients would normally have a trial of DDAVP prior to the procedure to assess response. Of course levels would still need to be checked prior to surgery even if a previous good response has been demonstrated. DDAVP leads to a rise in plasma level of FVIII and vWF, caused by increase release from Weibel Palade granules in endothelial cells. Once these storage granules release their contents there is a latency period before the treatment will be effective again. DDAVP should be avoided in patients with evidence of atherosclerosis. Fluid retention can be a problem post-administration, often leading to headaches, so patients should be fluid restricted following it. DDAVP also cannot be used in very young children who are prone to life-threatening sodium toxicity. It should be noted that different strengths of DDAVP are available depending on the indication so it is vital to ensure the correct formulation is used.

Other rare congenital factor deficiencies

Patients can present with deficiency of any coagulation factor. The next most common factor deficiency is factor XI. This is a very variable cohort of patients and the factor level does not necessarily correlate with bleeding manifestations. It can be treated with factor concentrate but levels should not be increased to above 70% as the risk of thrombosis becomes high. Tranexamic acid (an anti-fibrinolytic agent) should not be used at the same time as factor replacement in this group but could be an alternative strategy. As only small amounts of factor XI are required in mild factor XI deficiency adequate haemostasis can often be achieved with FFP.

Dys- or afibrinogenaemia may be a qualitative or quantitative defect of fibrinogen. It may manifest as abnormal bleeding following trauma or surgery. The severity depends on the exact defect. It is managed by replacement with fibrinogen concentrate; often twice weekly is sufficient.

Factor VII plays a vital role in initiating coagulation but only a small amount is required. However, a severe deficiency causes a similar bleeding phenotype to haemophilia with spontaneous bleeds occurring. Factor VII has the shortest half-life and therefore replacement during a bleed is required 3–4 times per 24 hours. There is a recombinant product available.

Factor II, V and X deficiency are all exceedingly rare. There are also cases of deficiencies seen in combination that can lead to diagnostic confusion.

Factor XIII is important in fibrin stabilization, so has a typical delayed bleeding after surgery. The classical presentation is in neonates with prolonged umbilical stump bleeding. It has a long half-life and in deficient patients treatment once a month with concentrate is adequate prophylaxis. Plasma derived concentrate has been used for many years but a recombinant factor XIII is available in some countries.

Factor XII deficiency leads to a prolonged PTT but it does not lead to clinical bleeding or symptoms, so is only relevant in relation to its effect on the laboratory parameter.

Disseminated intravascular coagulation (DIC)

Disseminated intravascular coagulation (DIC) can be a confusing condition with both bleeding and clotting problems being present. There is widespread over-activation of the coagulation system leading to significant, usually arterial, thrombosis. The extensive formation of tiny blood clots throughout the body can lead to consumption of coagulation factors. These deficiencies can then lead to bleeding. It is usually bleeding that causes the life-threatening problems (Table 26.2).

TABLE 26.2 The causes of disseminated intravascular coagulation (DIC)

Infection
Trauma: <ul style="list-style-type: none"> • bleeding post-surgery • shock/hypotension
Tissue necrosis (e.g. organ destruction, e.g. pancreatitis)
Malignancy-solid tumours, leukaemia
Obstetric-amniotic fluid embolism, placental abruption, pre-eclampsia
Vascular abnormalities – haemangioma and vascular aneurysm
Severe liver failure
Toxic and immunological insults-snake bites, drugs, ABO incompatible transfusion

The management revolves around ‘treating the underlying cause’ (Table 26.2) and supportive care (either by transfusion and other organ support, with or without anticoagulation dependent on the most problematic symptom). From a laboratory perspective it is usually diagnosed when an abnormal clotting screen is present with low platelets. The trend of blood counts should be monitored⁶ and would include a rising PT and APTT, reducing fibrinogen and platelets with a raised D-dimer. The decision to use FFP and/or cryoprecipitate depends on the relative PT, PTT and fibrinogen, and the clinical problem. Again it is wise to involve a haematologist if this condition is suspected to guide on what is likely to be the most effective product and to ensure that the laboratory is expecting and turning around samples and provision of blood products quickly.

PLATELET DISORDERS

Immune thrombocytopenic purpura

Immune thrombocytopenic purpura (ITP) is a relatively common cause of an isolated low platelet count. Platelets are usually produced normally but are destroyed by the immune system so it is an auto-immune phenomenon. In the paediatric setting it is usually a condition that spontaneously resolves often not requiring specific treatment. However in the adult setting, and occasionally in children, it can be a chronic condition. In either case patients generally do not respond well to platelet transfusion, only getting poor transient increments due to rapid destruction. Patients who have a low platelet count should be discussed with the haematology team whether they have a specific diagnosis already or not. When a patient newly presents, other causes of thrombocytopenia would need to be ruled out. A repeat full blood count (FBC) is always essential as clumping of platelets can give a falsely low result on automated counters. A blood film can confirm if it is a consistent result and look for other abnormalities. Advice on management would depend on the clinical presentation, mainly if the patient has haemorrhagic manifestations. The platelet count does not always correlate with the level of bleeding or bruising and in ITP patients often tolerate very low counts without symptoms.

If an immediate rise in platelet count is needed, advice is likely to include administration of intravenous immunoglobulin (IVIg) to gain a quick response, high dose steroid (IV or oral), which takes longer to act, and platelet transfusions.⁷ Despite a likely poor response, platelets are usually advisable in an emergency setting. IVIg is also often employed in an elective perioperative management plan. If a patient has previously been diagnosed they may well be on treatment which could include oral steroid or immunosuppression (i.e. azathioprine, ciclosporin, etc). Another treatment becoming more commonly used is Rituximab. Splenectomy can be very effective in some patients, but this leads to increased risk of sepsis, particularly from encapsulated organisms. Lastly the thrombopoietin (TPO) agonists are a newer treatment option with

oral and subcutaneous administration routes that stimulate increased platelet production.

Thrombocytosis

Very high platelet counts (>1000) can also lead to thrombosis or bleeding as the platelets are dysfunctional and also absorb increased amounts of von Willebrand factor, which then becomes depleted, contributing to the problems. The most common scenarios that cause this are myeloproliferative disorders, usually essential thrombocythaemia in older adults. The platelet count in this situation needs to be controlled because of both the bleeding risk and the risk of stroke or other thromboembolic events. Thrombocytosis in children is very rarely due to a primary blood disorder and is usually in response to infection or inflammation. This reactive picture is also seen in adults and in this situation no specific action is required other than monitoring.

Heparin-induced thrombocytopenia (HIT)

Many patients on prolonged heparin can develop a mild thrombocytopenias. This is not usually a clinical problem and heparin can often be continued. However, a rare drug reaction can be a severe thrombocytopenia that paradoxically also causes thrombosis as well as bleeding. This is a complication whereby a patient forms antibodies to heparin and the antibodies form immune complexes with heparin and PF4, which bind to platelet Fc receptors and lead to aggregation and thrombocytopenia. It may be suspected when a platelet count falls when on heparin (usually to between 20 and 50 or a drop of 50% compared with the baseline, with no other explanation) and when new thrombosis occurs. There are scoring systems to assess the likelihood, and testing for causative PF4 antibodies can be undertaken.⁸ Heparin should be stopped and treatment should be given with an alternative anticoagulant (i.e. danaparoid, argatroban, bivalirudin, Fondaparinux). The platelet count should increase over the next 2–5 days. Patients should not be re-exposed to heparin (or low molecular weight heparin) as recurrence is common.

Thrombotic thrombocytopenic purpura

Thrombotic thrombocytopenic purpura (TTP) is a rare life-threatening condition that requires urgent treatment when recognized. It is a haematological emergency. Patients present haematologically with low platelets and anaemia (due to haemolysis) with fragments of red cells (schistocytes) seen on blood film, a microangiopathic haemolysis. Patients can have clinical symptoms of fever and neurological features (confusion, seizures) along with renal failure. In TTP the low platelets are caused by thrombosis in small blood vessels. The fibrin strands act as a 'cheese wire' leading to the red cell fragments. The underlying pathology is a reduction in a protein called ADAMTS13, which is normally involved in controlling vWF. With reduced ADAMTS13 vWF builds up into even

bigger multimers than normal. The molecules can even get to the size of cells. Treatment is aimed at the underlying cause, reducing the abnormal vWF molecules and also replacing ADAMTS13. At the moment this is most effectively done by plasma exchange. Steroids and further immunosuppressive agents are also needed to gain control of the underlying drivers in the acquired form (there is a congenital variant of the condition with deficiency of ADAMTS13 and replacement by plasma infusion is sufficient treatment). When the platelet count rises thromboprophylaxis should be instigated as thrombosis is common in recovery.

Bone marrow failure syndromes

Myelodysplastic syndrome (MDS) is a collection of conditions where blood cell production in the bone marrow is abnormal and can affect one or all blood cell lines. Patients may therefore have features of anaemia, low platelets or low white cells. In most surgical situations patients will be managed with platelet transfusions if there is a bleeding risk. They may also need antibiotics to cover infection.

Other causes of bone marrow failure include conditions such as leukaemia and aplastic anaemia. Again the mainstay of bleeding management involves platelet transfusion. It may be appropriate to check a 'platelet increment', that is, repeat an FBC either 1 hour after the transfusion or 24 hours after. This may be particularly relevant if the patient has had previous transfusions and therefore a greater possibility of antibodies adversely affecting response to transfusion, or if a major procedure is planned to determine if further treatment is required.

Abnormalities of platelet function

Platelet function abnormalities generally present with post-surgical bleeding, mucocutaneous bleeding and/or menorrhagia. Platelet function abnormalities are most usually seen secondary to medication but there are very severe inherited disorders worth discussing here. Investigation of platelet function disorders will depend on a significant bleeding history usually with normal coagulation tests. A prolonged bleeding time is characteristic of platelet function disorders. A bleeding time is a very simple test where a cut of defined length, thickness and depth is made on the medial anterior aspect of the forearm and the time is measured in seconds until the bleeding stops. The bleeding time is rarely used as it is difficult to control and there is significant observer variability as well as the risk of scarring. Other platelet tests available include a screening test called the PFA-100 and more formal platelet aggregation studies. Platelet aggregation studies take a senior coagulation scientist a few hours and must be performed on fresh platelets. Therefore, this is an assay that must be booked with your laboratory in advance. In addition, intracellular platelet nucleotides can also be measured to aid diagnosis. Lastly, confirmation of some disorders may be sought by use of flow cytometry with monoclonal antibodies directed against absent receptors.

Platelet storage pool disorder is a term that covers abnormalities of the granules in the platelet cytoplasm. It includes deficiency of either alpha granules (grey platelet syndrome) or dense granules (MYH9 anomalies, Hermansky-Pudlak etc.) or both.

Platelet receptor anomalies include Glanzmann's thrombasthenia, where there is absent or abnormal glycoprotein IIb/IIIa (a receptor for fibrinogen and vWF), and Bernard Soulier disease with absent or abnormal glycoprotein Ib/V/IX complex (a receptor for vWF).

Management of bleeding problems in these structural platelet disorders will usually include platelet transfusions. However, these patients often need repeated platelet transfusions throughout their lives and frequently develop antibodies to the platelet antigen in the transfused platelets that they are missing. For this reason when planning minor procedures, where possible, the use of platelets is avoided. Other treatment options may include use of an antifibrinolytic such as tranexamic acid (mouthwash/PO or IV), avoiding antiplatelet agents and on occasion recombinant factor VIIa. Surgical technique should also be considered to minimize bleeding problems. To reduce the chance of developing antibodies any transfused platelets should be HLA matched irradiated and leucodepleted.

Medical problems

RENAL DISEASE

Renal disease and uraemia mostly affects platelet function, although anaemia also contributes to bleeding manifestations. The platelets, as the smallest constituent in blood, normally flow and travel along next to the endothelium so they are closest to the site where they will function. In anaemia they are not pushed out to the side as much, therefore increasing bleeding when injury occurs. Correcting the anaemia and the use of agents such as tranexamic acid or DDAVP are useful strategies to improve haemostasis in these patients when bleeding.

LIVER DISEASE

Liver disease has a potentially large impact on coagulation due to its role in the production of coagulation factors, particularly the Vitamin K-dependent ones (II, VII, IX, X and protein C and S) along with fibrinogen and the other coagulation factors. Portal hypertension can also lead to splenomegaly, which in turn can lead to a thrombocytopenia due to increased destruction of platelets.

THROMBOTIC DISORDERS

When a patient presents with thrombosis (the pathological formation of blood clot) an assessment should be undertaken as to the potential drivers behind clot formation. According to Virchow's Triad, three broad categories of factor contribute to thrombus formation: i) hypercoagulability (i.e. problems within the blood); ii) haemodynamic/blood flow changes; and lastly, iii) endothelial injury or dysfunction. Within this framework it is easier to see how certain states

contribute towards a hypercoagulability by one or more mechanism (i.e. surgery, inflammatory conditions, infection, pregnancy, dehydration, immobility). Most hospital inpatients are assessed on admission and a decision made regarding prophylaxis for venous thromboembolism (VTE), most commonly with low molecular weight heparin (LMWH).

Investigation of thrombosis may include a thrombophilia screen, although this is done much less frequently now, as usually the results do not change the management of the patient. However, where it would alter management it should be taken into account.⁹ Thrombophilia tests are best delayed until after the acute thrombus setting, ideally being done around 6 weeks after discontinuing anticoagulation treatment. Some patients will be tested because of their own history (e.g. VTE at a young age); however, some may be tested because of their relatives and family history. For the purposes of this chapter we will concentrate on the haematological abnormalities that lead to clots rather than the acquired non-haematological ones, of which there is a long list (i.e. dehydration, malignancy, advanced age, obesity, vascular malformation).

Table 26.3 gives an idea of comparable relative risks for various states in a large retrospective study.¹⁰ It is worth noting that a prospective study found much lower risks for both heterozygosity (3.7) and homozygosity (24) for factor V Leiden.¹¹

Thrombophilia screen

This includes:

- deficiency of natural anticoagulants (antithrombin; protein C; protein S)
- other genetic thrombophilias (factor V Leiden, an abnormal form of factor V protein which is resistant to protein C inactivation; prothrombin gene mutation (causing increased production of thrombin)).

Deficiencies in protein C, protein S and ATIII mostly occur as a genetically inherited phenomenon. Heterozygous inheritance (one abnormal gene copy) of factor V Leiden or prothrombin gene mutation leads to only a small increase

TABLE 26.3 Relative risk factors for thrombosis

Risk factor	Relative risk
Antithrombin deficiency (Heterozygous)	5
Factor V Leiden	8.1
Factor V Leiden homozygous	80
Hospitalization	11.1
Immobilization	8.9
Oral contraceptive	3.8
Pregnancy	4.2
Protein C deficiency	3.1
PT gene mutation	2.8
Puerperium	14.1
Surgery	5.9

in risk of thrombosis compared to the normal population and, depending on the clinical scenario, would not require any specific treatment. However, where there is homozygous expression, or co-inheritance with other defects the risk increases significantly and patients would often be on long-term anticoagulation, particularly if there is a personal history of blood clot ([Table 26.3](#)).

Patients with a deficiency of antithrombin, protein C or S generally have a more severe clotting phenotype and each case should be assessed on an individual basis with regards to anticoagulation.

Hyperhomocysteinaemia, which can be inherited or acquired, can also lead to increased propensity to clot, this raised level of homocysteine affects collagen and causes damage to the endothelial wall. It is managed by vitamin B6, B12 and folic acid (B9) supplementation as this reduces the concentration of homocysteine in the blood. This is not necessarily included as part of the basic screen.

Acquired causes of thrombosis

Antiphospholipid syndrome is an acquired condition and has strict criteria for diagnosis requiring both clinical (thrombotic events, unexplained miscarriage or premature labour) and laboratory findings (two out of; anticardiolipin antibodies, anti beta-2 glycoprotein or a lupus anticoagulant found persistently over a period of 3 months). Again with these patients anticoagulant decisions should be made upon consideration of their clinical history. It is important to mention that a lupus anticoagulant is a relatively common cause of a prolonged APTT and when found without other features mainly causes 'diagnostic issues' rather than clinical problems.

Rarities

There are also other haematological conditions such as paroxysmal nocturnal haemoglobinuria (PNH) and myeloproliferative disorders that can lead to an increased propensity to form clots. These should also be considered if investigating for thrombophilia, particularly where rare or unusual thrombus occurs (i.e. intra-abdominal) but they would commonly have an associated abnormality on the full blood count.

Treatment of venous thrombosis

When a patient presents with venous thrombosis, initial treatment is usually with low molecular weight heparin (LMWH) followed by warfarin or a direct oral anticoagulant (DOAC). Apixiban, Dabigatran, Edoxaban and Rivaroxaban are all licensed DOACs and are in increasing use. Decisions need to be taken regarding the length of treatment based on an assessment of risk factors, depending on whether it was provoked, the family history, whether hereditary thrombophilia is present, whether symptoms have resolved and if the risk factors present are modifiable or are going to resolve.

Post-operative deep vein thrombosis (DVT) without other suspected predisposition can usually be treated for

3 months, previously treatment for pulmonary embolus (PE) was given for 6 months, although there are more recent suggestions that 3 months may be adequate for PE if long-term anticoagulation is not indicated. When considering the risks of repeat events it is worth bearing in mind that it is most common to have the same type of event again, so if a patient has a PE they are more likely to have a further PE rather than DVT. There is evidence now to suggest that a raised d-dimer following the completion of treatment can be predictive of a repeat clot and this may be taken into account and a discussion between patient and medical team about the risks of recurrent clot versus the risks of side effects/bleeding on the anticoagulant is needed to decide if long-term anticoagulation should be continued. Decisions on anticoagulation need to be reviewed and the risk benefit balance needs to be reassessed if there is a change in the patients' situation.

Managing a patient on anticoagulation who needs surgery

Managing a patient on anticoagulation in an emergency requires consideration of how best to reverse it (if possible). For an elective procedure 'bridging' anticoagulation should be considered, depending on whether the patient is low or high risk for clotting (i.e. atrial fibrillation (AF) is low risk, compared with metallic heart valve or recent clot-high risk) and whether surgery is low or high risk for serious bleeding (tonsillectomy would be considered a high risk procedure in terms of bleeding, dental extraction of tooth low risk). If the patient is low risk and the surgery high risk, discontinuation of anticoagulation may be required. However if the patient is high risk and the surgery low risk it may be reasonable to continue as normal. In the middle of these extremes it may be necessary to switch onto an alternative, such as from warfarin to LMWH, which can be discontinued 24 hours before the procedure and restarted when haemostasis is secured post-operatively (24–48 hours). With NOACs generally, their half-life allows discontinuation 24–48 hours prior to an operation depending on renal function (although up to 5 days may be advisable in some cases). Where a clot has occurred recently (within 6 weeks to 3 months) an IVC (inferior vena cava) filter may be considered to add a level of protection from PE on the discontinuation of anticoagulation for theatre. Filters should be removed as soon as possible post-procedure otherwise they become permanent and have potential long-term complications. Again, discussion with the anticoagulation team or haematologist should be helpful in managing these situations

Medication affecting haemostasis

WARFARIN/COUMARINS

Warfarin is often described as a Vitamin K antagonist. It does not actually antagonize Vitamin K but it inhibits the enzyme that recycles Vitamin K (Vitamin K epoxide reductase) and therefore active Vitamin K will run out, which usually takes 2–3 days. The Vitamin K dependent

clotting factors are depleted (II, VII, IX and X), leading to increased bleeding tendency and the intended benefit of reducing clot formation. However, when it is first initiated patients are rendered prothrombotic because protein C and S are also dependent on Vitamin K and their levels can reduce before the other factors. When patients present with an acute clot it is advisable to overlap initial treatment with LMWH and warfarin until therapeutic. All coumarins have a narrow therapeutic window and, due to various polymorphisms, are metabolized with a lot of inter-individual variation. Warfarin needs to be monitored by the international normalized ratio (INR). The INR is a PT ratio of the patients compared to normal, to the power of an adjustment factor called the ISI that is specific for the laboratory. This gives a result that is comparable amongst laboratories internationally. The indications for coumarins include: treatment of VTE; prevention of VTE; anticoagulation for prosthetic heart valves; and reduction of stroke risk in AF. Patients may be on them for a period of a few months, or may be on lifelong treatment. The most common side effect is bleeding.

REVERSING A RAISED INR DUE TO WARFARIN

The availability of product needs to be taken into consideration if the patient is bleeding and also how quickly reversal is required. In reversing a patient's anticoagulation there should always be discussion with your haematologist. The need for reinstating anticoagulation also needs to be considered.

HEPARIN AND LOW MOLECULAR WEIGHT HEPARIN

Unfractionated heparin (UFH, administered by intravenous infusion) acts by binding to antithrombin and causing a conformational change. The antithrombin then inactivates thrombin, along with the other proteases, mostly factor Xa. Low molecular weight heparins (LMWH, administered by subcutaneous injection) are much smaller molecules so their mechanism of action is mediated more predominantly through anti-factor Xa action. The main indications for these drugs are acute VTE or coronary thrombotic event. Some patients remain on LMWH long term, particularly those with malignancy. Unfractionated heparin (UFH) is monitored by APTT ratio and LMWH by anti-factor Xa levels. Most patients do not require monitoring of LMWH (the exceptions where it is useful

include children, pregnancy, renal impairment, obesity and when in long-term use).

There is no specific reversal treatment, although protamine sulphate can have some neutralizing effect if given soon after administration, particularly when IV unfractionated heparin has been used. It is much less predictable in subcutaneous LMWH reversal and can act as a weak anticoagulant in its own right in high dose. Prior to surgery, UFH will be fully reversed if stopped 6 hours before with normal renal function; LMWH prophylaxis dose should be last given 12 hours before procedures and treatment doses 24 hours before.

OTHER PARENTERAL ANTICOAGULANTS

These are rarely used. Danaparoid is a heparinoid with mostly anti-Xa action and a little anti-IIa activity. It is renally excreted with no specific antidote. Fondaparinux is a pentasaccharide (synthetic) that acts indirectly through its anti-Xa activity. Again, it is renally excreted with no specific antidote. Bivalirudin is a direct thrombin inhibitor and has a short half-life but IV infusion is required for ongoing anticoagulation, so stopping it and general haemostatic measures are usually adequate.

DIRECT ORAL ANTICOAGULANT AGENTS (DOACS)

Dabigatran is an oral direct thrombin inhibitor. It has a half-life of 13 hours and is mostly excreted by the kidney. There is a specific antidote available called Idarucizumab for use in an emergency setting.

Rivaroxaban, Apixaban and Edoxaban are direct anti-Xa inhibitors. Both are 75% metabolized by the liver with 25% excreted unchanged by the kidney. They are both used as prophylaxis or treatment in VTE or used in stroke prevention in atrial fibrillation. Emergency management of bleeding consists of general haemostatic measures and use of prothrombin complex concentrate (PCC), activated PCC, also known as factor eight bypassing agent (FEIBA) or rFVIIa as there are no specific antidotes currently available,¹² although reversal agents have been developed and are likely to be available shortly

ANTIPLATELET AGENTS

Antiplatelet agents (i.e. aspirin, clopidogrel, dipyridamol, ticagrelor, abciximab, other NSAIDs, prasugel)

TABLE 26.4 Reversing a raised INR

Product/drug	Dose	Advantages	Disadvantages
Vitamin K	0.5–10mg	Cheap	Slow, takes over 7 hours for detectable effect and takes up to 24 hours for complete reversal
FFP	15mls/kg	Cheap	Plasma product, not very effective as doesn't replace some of the factors enough
Prothrombin complex concentrate (ideally 4 factor)	25–50 units/kg	Quick to act	Plasma product with more of factors II, IX and X
rVIIa	90mcg/kg	Quick to act	Expensive, prothrombotic; not viewed as first line treatment

generally have a short half-life although the length of effect depends on whether the effects are irreversible or not. There are no specific reversal agents. If they have irreversible binding (like aspirin) the action lasts as long as the life of the platelets, and in many cases they need to be discontinued 7–14 days before procedures where possible. The mechanism of action of most of the agents is as P2Y₁₂ antagonists or as GP IIb/IIIa inhibitors.

Aspirin acts by irreversibly inhibiting cyclo-oxygenase (COX) 1 and 2 (in contrast to some NSAIDs that reversibly act). Aspirin in low dose blocks the formation of thromboxane A₂ in platelets for the life of the platelet; however, there is little effect on prostacyclin (because endothelial cells have a nucleus to produce further enzyme to produce more prostacyclin). The balance of increasing prostacyclin and reducing thromboxane A₂ inhibits platelet aggregation. Platelet transfusion is the only way to reverse the effects of antiplatelet agents and only really helps if the drug has not been taken recently (otherwise the transfused platelets will also be affected).

FIBRINOLYTIC AGENTS

Fibrinolytic agents (i.e. streptokinase, tenecteplase, urokinas) all act by promoting plasmin indirectly and thus mediating clot breakdown. They are short acting and all potentially give a high bleeding risk. They are most commonly used in the acute management of stroke and myocardial infarction. In the event of serious bleeding, use of tranexamic acid and FFP or fibrinogen concentrates is indicated with other treatment guided by coagulation tests.

BLOOD PRODUCTS AND FACTOR REPLACEMENT IN BLEEDING DISORDERS

Included in this section is a brief summary of products.^{13, 14} Most of the coagulation factor therapies are either very expensive or extremely expensive. When available, recombinant factor concentrates are preferred as there is almost zero risk of infection transmission. In the 1980s, plasma derived coagulation factors caused tremendous (unintentional) suffering in a generation of patients with transmission of HIV/AIDS, and hepatitis B and C. Concerns over transmission of prion (specifically vCJD) have led to the UK government abandoning all UK sourced blood donors as sources for plasma factor concentrates. In an era of significantly improved safety of product and increased knowledge regarding use of prophylactic treatment the younger generations of patients have a good chance of not developing such disabling chronic joint problems that previous generations have suffered.

Platelets

Platelets are suspended in patient plasma, either apheresis units from one donor or pooled units from a few donors. Each unit is approximately 250ml and they are

stored at 22°C. They are therefore a higher risk for bacterial transfusion transmitted infection. Usually used as one adult dose, more may be required in order to gain an appropriate increment for surgery. They are useful in major haemorrhage, platelet dysfunction and bone marrow failure; but are generally not indicated in ITP or TTP, except with life-threatening bleeding. They are generally administered over 15–30 minutes.

Fresh frozen plasma

Plasma is the ‘liquid’ part of the blood, therefore it contains coagulation factors. It is indicated for bleeding where there are abnormal coagulation results. Fresh frozen plasma (FFP) is used to correct multiple coagulation factor defects and in major haemorrhage. It is also beneficial as replacement of congenital factor deficiency where a specific concentrate is not available.

Dosing is usually 15mls/kg (approximately 4 units in a 70kg adult). Each unit is given over around 15–30 minutes. They must be defrosted prior to being issued and made from human plasma.

Cryoprecipitate

Cryoprecipitate is made by the controlled thawing of FFP to produce a cryobulin concentrate, which is rich in fibrinogen, FVIII and von Willebrand factor. It is administered over 15–30 minutes and a dose of 2 pooled units would be expected to give a rise of 1g/L in fibrinogen. It is mainly used as a more concentrated form of fibrinogen compared to FFP (see also fibrinogen concentrate).

Prothrombin complex concentrate

Prothrombin complex concentrate (PCC) can be 3 or, ideally, 4 factors (II, VII, IX and X but also contains protein C and S). It is made from human plasma. Dosing is usually 25–50 units per kg. It is indicated for reversal of warfarin and can be used in liver disease, especially where volume overload is a problem or in bleeding with DOACs.

Recombinant factor

This is available following discovery of the genes used in production of factor (first used in FVIII). It is produced by recombinant DNA technology, whereby a cell line (usually animal-based) is modified to express the gene that produces the factor protein. Therefore no exposure to human plasma occurs and a high purity, safe product is formed. They have no risk of transmission of blood-borne virus or prion. Currently there are recombinant products for FVIII, FIX and rVIIa. Other factors are becoming available including Factor XIII.

Plasma derived factor concentrate

There are specific factor concentrates available for FVIII, IX, X, XIII and von Willebrand disease (containing

VIII and vWF). They are treated to reduce risks associated with administration of human plasma but still carry a possibility of infection transmission. They are rarely used where a recombinant factor is available and affordable.

Fibrinogen concentrate

Fibrinogen concentrate is currently licensed for congenital fibrinogen disorders, although some centres are using it in acquired states of low fibrinogen. It is made from donor plasma, but again has had viral inactivation treatment.

Intravenous immunoglobulin

This product is made from large pools of donor plasma. It is used in the treatment of autoimmune phenomena (i.e. ITP). In other settings it is also used as replacement therapy in hypogammaglobulinaemia and targeted against specific infection in the immunocompromised.

HOW TO GET THE BEST FROM YOUR LOCAL HAEMATOLOGIST

Most patients with a significant bleeding or thrombotic disorder should be managed in conjunction with the clinical and laboratory haematology team so that a perioperative treatment plan can be agreed upon. Discussion is needed to weigh up the risk factors for bleeding and thrombosis. It is important the patient is aware of the management plan, particularly as many are experts in their own condition.

This section gives some guidance on how to get the best advice.

Information to communicate to a haematologist about a bleeding patient

- The patient's personal history regarding bleeding (previous procedures and obstetric history; severity of bleeds, i.e. requiring transfusion; type of bleeds i.e. mucocutaneous).
- Whether the patient has ever had treatment for bleeding or thrombosis.
- Their family history, especially regarding siblings, parents, children, grandparents, aunts/uncles' bleeding and how their condition was managed.
- Medication the patient is currently on or has previously used, especially anything that could lead to bleeding and, if they have a diagnosis, what product they usually have (i.e. factor brand, as it is usual to try and continue with the same one).
- Do they have an alert/ information card with diagnosis details and baseline factor levels?
- Ensure FBC, PT, APTT and fibrinogen results are available. Where possible if an elective procedure is

planned results should be reviewed with time to carry out further investigations or the procedure should be delayed.

- What surgery is planned, with an idea of what bleeding would be expected in a haemostatically normal patient. Do not assume a haematologist will know a lot about procedures, particularly if new or complex.

For significant bleeding disorders it is usually advisable to carry out surgery at a centre of haemostasis expertise so the medical and laboratory advice is easily accessible. Usually, NSAIDs would be avoided, along with intramuscular injections. It is important to remember that patients on treatment may have a similar (or even higher) risk of thrombosis so VTE prophylaxis may still be indicated. In planning surgery patients may require admission even if the procedure is usually done as a day case for closer observation. Post-operatively they will require both clinical and laboratory assessment to guide further use of factor replacement.

Information to communicate to a haematologist about a clotting patient

- The patient's personal history regarding thrombosis including the type of clot, when it occurred and precipitants (i.e. hormones, perioperative, related to malignancy and treatment).
- Whether they have ever had treatment for bleeding or thrombosis.
- Their family history, especially regarding siblings, parents, children, grandparents, aunts/uncles' thrombosis and how it was managed.
- Medication they are currently on or have previously used, particularly anticoagulants and antiplatelets, and the indication.
- What surgery is planned. Do not assume a haematologist will know a lot about procedures, particularly if new or complex.

For advice on management of anticoagulation in an emergency (e.g. warfarin reversal in a patient who has attended A&E with significant bleeding) it is important to have information about why they are on the drug and how quickly reversal is required.

For warfarin, a weight is helpful so that dosing of PCC can be discussed. For LMWH, antiplatelets and DOACs it is important to know renal function and when the last dose was taken. Other comorbidities should be also taken into account to aid management.

The commonest cause of post-surgical bleeding is surgery

Post-surgical bleeding does not always equal a problem with the clotting system. Surgical causes and the need for a return to theatre should always be considered.

FUTURE RESEARCH

- More experience in direct oral anticoagulation agents (DOACs) and specifically in their reversal
- Further work on global coagulation testing and its applications
- Gene therapy as treatment and other novel therapies for haemophilia and other bleeding disorders

KEY POINTS

- Patients with bleeding disorders should be managed with close liaison between the haematology, laboratory and surgical teams.
- Pre-operative assessment should include bleeding history and medication. Where possible when screening coagulation tests are performed they should be reviewed with time for further investigation prior to procedures when needed.
- Bridging of anticoagulation therapy needs consideration for elective procedures.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: otitis externa, ear drops, antibiotics, betahistine, gentamicin, Menières, acyclovir and sodium fluoride.

INTRODUCTION

Medicines are commonly prescribed in the management of otological diseases. Whilst the efficacy of some treatments may be uncertain, it is important to understand how these drugs act, their indications, contraindications and side effects. This chapter discusses these factors in relation to a number of specific types of otological medications.

TOPICAL EAR PREPARATIONS

Ear drops are solutions or suspensions of medicaments in water, glycerol, diluted alcohol, propylene glycol or other suitable solvent for instillation into the ear. A solution comprises a solute (drug) dissolved in the solvent, whereas a suspension consists of an insoluble drug distributed in a liquid. Some preparations used in otology are also used as eye or nose drops. Since these drops are in multiple-application containers, the vehicle contains a bactericidal and fungicidal agent such as benzalkonium chloride (0.01%). Other adjuvants in ear and eye drops include buffers such as sodium metabisulphite and disodium edetate. The buffers are used to maintain the pH to minimize breakdown of the active constituents or to increase comfort for the patient. Both sodium metabisulphite and disodium edetate are effective at retarding oxidation reactions and the latter can enhance the bactericidal activity of benzalkonium chloride and chlorhexidine acetate. Information on excipients contained in drops is

found in the British National Formulary or its equivalent. This information is useful since some patients may be allergic to topical ear medication and this allergy may not be to the primary constituent but to the excipients.

Ear drops are dispensed in coloured fluted glass bottles with a plastic screw cap incorporating a glass dropper tube and rubber teat, or, more commonly, in plastic squeeze bottles fitted with a plastic cap incorporating a dropper device. Such containers are designed to prevent light degradation of the contents.

Some ear preparations are available as creams or ointments where the antimicrobial and/or anti-inflammatory substance is prepared in a suitable base such as liquid paraffin, wool fat and yellow soft paraffin. Both are semi-solid preparations but in a cream the base is absorbed into the skin, whereas in an ointment only the medication is absorbed from the greasy base. In general, ointments are useful in dry scaly conditions whereas creams can also be used in weeping skin conditions.

Again, warnings that the preparation contains lanolin (wool fat) are useful since some patients are allergic to lanolin.

Topical ear preparations for inflammatory and infective conditions

INDICATIONS

A number of topical ear preparations in the form of drops or ointments are available for the treatment of otitis

externa and discharging mastoid cavities. Many are also used in discharging ears with a perforated tympanic membrane or ears with a grommet *in situ*. In this latter situation this is an unlicensed indication for the use of many of these preparations. Manufacturers' data sheets continue to state that even plain steroid drops are contra-indicated in the presence of a perforation. In chronic suppurative otitis media, it has been shown that aural toilet and topical antibiotics, especially a quinolone, is effective in resolving otorrhoea and eradicating bacteria from the middle ear. This treatment used by specialists is now recognised in the BNF.¹ Topical antibiotic preparations are more effective than oral preparations and the addition of oral therapy to topical antibiotics confers no greater benefit than the latter used alone.²

SPECIFIC PREPARATIONS

Acetic acid 2% has antifungal and antibacterial properties and can be used to treat mild otitis externa. Aluminium acetate is an astringent that can be applied as drops or onto a gauze wick. An astringent is an agent that causes shrinkage or constriction and is usually applied topically. The hygroscopic effect reduces oedema in the inflamed ear canal, opening the meatus. Aluminium acetate has a tendency to form crystals in the ear. Regular aural toilet is required to remove both the crystals that form as well as the debris produced by the inflammatory process. This treatment can be safely used in pregnancy. Boric acid has been used in the past for its weak fungistatic and bacteriostatic activity and is used as a mild disinfectant in lotions, ointments and powders in concentrations of up to 5%. It is absorbed through damaged skin and may cause systemic toxicity. Acute and chronic toxicity can occur, presenting with gastrointestinal disturbance, rash, central nervous system and renal involvement that may result in death. Slow excretion of boric acid can lead to cumulative toxicity during repeated use.

Some preparations contain only a steroid and are used in eczematous otitis externa. The steroid reduces inflammatory swelling and helps control irritation. The steroid stimulates the synthesis of lipocortin in leukocytes. This protein inhibits phospholipase A₂ that reduces the formation of arachidonic acid, the precursor of many inflammatory mediators. Betamethasone sodium phosphate (Betnesol®) and prednisolone sodium phosphate (Predsol®) are steroids available as ear drops. These steroids are combined with anti-infective agents for use in the management of infected otitis externa. Other steroids found in combination with anti-infective drugs include dexamethasone (Otomize® – with neomycin and glacial acetic acid; Sofradex® – with framycetin sulphate and gramicidin), flumetasone pivalate (Locorten-Vioform® – with flumetasone pivalate and clioquinol), hydrocortisone acetate (Gentisone HC® – with gentamicin; Neo-Cortef® – with neomycin sulphate) and triamcinolone acetonide (Audicort® – with neomycin undecanoate and Tri-Adcortyl Otic® – with gramicidin, neomycin and nystatin). Clioquinol (found in Locorten-Vioform) is an

8-hydroxyquinolone with both antibacterial and antifungal properties and is useful when a mixed infection is suspected. Its use is contra-indicated in patients with iodine sensitivity. The other antibiotics included in ear preparations are framycetin sulphate, gentamicin and neomycin sulphate which are all aminoglycosides. They are bactericidal, inhibiting microbial protein synthesis and are effective against aerobic Gram-negative bacteria. Bacteria may acquire resistance via plasmids against one aminoglycoside but these bacteria rarely exhibit resistance to other aminoglycosides. This accounts for the benefit in changing the ear drops if the otitis externa fails to respond to one preparation.

Some of these preparations are available as ear sprays (Otomize), and there is some evidence that these cover the external meatus more effectively than traditional ear drops³ and are easier for the elderly to apply. However, in some clinical situations, drops are more likely to reach the infected and inflamed parts of the external ear, middle ear or mastoid cavity at which treatment is aimed. Prolonged use of antibiotic/steroid preparations may sensitize the skin and may lead to fungal infections.

Clotrimazole is an azole derivative with a broad-spectrum antifungal activity that acts by inhibiting ergosterol synthesis in the fungal cell membrane. At lower concentrations, clotrimazole merely inhibits fungal growth but at higher concentrations, fungi are killed by clotrimazole action causing direct membrane damage. Clotrimazole should be continued for at least 2 weeks after apparent resolution of the infection. Increasingly, ciprofloxacin eye drops are used as ear drops in the management of *Pseudomonas* spp. ear infections. This is an unlicensed use in the UK where licensed ciprofloxacin ear drops are unavailable. Ciprofloxacin drops have been used widely in the rest of Europe, North America and beyond.

CONTRAINDICATIONS

The use of preparations containing only a steroid is contra-indicated in untreated infections since the immunosuppressive effect of corticosteroids may exacerbate the infection. More controversial is the use of preparations with anti-infective agents in the presence of a perforated tympanic membrane because of the potential for ototoxicity.

SIDE EFFECTS

The most common side effects with these preparations are hypersensitivity reactions and local irritation, burning and itching.

The use of anti-infective ear drops in the presence of a tympanic membrane perforation

The product licences do not permit the use of anti-infective ear drops in ears with perforated tympanic membranes as a result of cochlear damage that occurred when such drops were instilled into guinea pig ears.^{4,5} These authors

recognize that the round window niche in humans is relatively deep and often protected by a pseudomembrane whilst in the guinea pig the round window is completely exposed. In patients with active chronic suppurative otitis media there is no evidence that the use of these ear drops causes sensorineural deafness.⁶⁻⁸

Topical ear preparations for removal of ear wax

Many cerumenolytics, including oils and aqueous preparations, are available to soften wax prior to syringing or to disintegrate or disperse the wax, to avoid the need for syringing altogether. Burton and Dorée⁹ undertook a systematic review and found nine clinical trials. All had a small number of participants, and most were of poor methodological quality. The review concluded that there is insufficient evidence to favour any one particular cerumenolytic. Water and sodium chloride 0.9% seem to be as effective as any proprietary agent. Sodium bicarbonate 5% ear drops, olive or almond oil ear drops are also safe and inexpensive although their effectiveness has not been evaluated in randomized controlled trials. These findings were supported by Clegg et al. in a more recent systematic review.¹⁰ If the wax is impacted, these drops can be used twice a day for a few days prior to syringing. Some proprietary preparations contain organic solvents (chlorbutanol, paradichlorobenzene) that may cause irritation to the meatal skin. The rationale for inclusion of these ingredients in the preparations is not clear and the vehicle alone is often effective.

SYSTEMIC ANTIBIOTICS

Indications

Systemic antibiotics are prescribed in the otological conditions of acute otitis media (AOM), cellulitis associated with furunculosis, otitis externa and perichondritis.

In AOM, the use of antibiotics is controversial. Venekamp et al.¹¹ found that antibiotic usage in AOM in children varied from 31% in the Netherlands to 98% in the USA and Australia. Their Cochrane review concluded that antibiotics provide a small benefit; however, since most cases resolve spontaneously, this benefit must be weighed against possible adverse reactions. Twenty children must be treated to prevent one child from having pain after 2 days. Antibiotic treatment did however produce a statistically significant reduction in tympanic membrane perforations and contralateral AOM episodes. Antibiotic treatment may play an important role in reducing the risk of mastoiditis in populations where it is more common. It is recommended that in children without systemic features, antibacterial treatment may be started after 72 hours if no improvement or earlier if systemically unwell or if at a high risk of serious complications (patients who are immunocompromised, the presence of mastoiditis or in children under 2 years with bilateral otitis media). If antibiotics are used, amoxicillin appears to be the first-line

treatment, with clarithromycin in those who are penicillin sensitive. Should treatment fail, second-line agents include co-amoxiclav and cephalosporins. Usually 5 days treatment is required but may be longer if severely ill.

Conservative management of acute mastoiditis (without subperiosteal abscess) has been adopted since a third of patients will settle in 24–48 hours with intravenous antibiotics.¹²⁻¹⁴

Flucloxacillin is the antibiotic of choice in treating cellulitis due to staphylococcus. Penicillin V is used in erysipelas due to streptococcus.

Ciprofloxacin is the drug of choice in malignant otitis externa and is also used in treating perichondritis due to *Pseudomonas aeruginosa*.

Mechanisms of actions

The penicillins have a bactericidal action, inhibiting cell wall synthesis by preventing the formation of peptidoglycan cross-bridges. The penicillinase-resistant penicillins, flucloxacillin, cloxacillin and methicillin, are semisynthetic penicillins, resistant to penicillinase by virtue of an isoxazolyl group on R₁. Many bacterial β -lactamases are inhibited by clavulanic acid, and a mixture of this inhibitor with amoxicillin (co-amoxiclav) is available. The cephalosporins are also bactericidal. They contain a β -lactam ring and their mechanism of action is similar to the penicillins.

The macrolides, for example erythromycin, act by inhibiting bacterial protein synthesis. It binds to the 50s bacterial ribosome subunit inhibiting translocation.

Metronidazole was initially used in protozoal infections but was found to be very effective against anaerobic bacteria. The drug is reduced to active metabolites that interfere with nucleic acid function. Ciprofloxacin is a fluoroquinolone and acts on both stationary and dividing bacteria by inhibiting DNA gyrase, an enzyme that compresses the bacterial DNA into supercoils. Cell death is thought to occur as a result of the unwinding of the supercoils.

Antibacterial spectrum

Table 27.1 demonstrates the antibacterial spectrum of the various antibiotics. The penicillinase-sensitive penicillins have a greater spectrum of activity than the β -lactamase resistant drugs, but the combination of clavulanic acid with amoxicillin enables protection of the β -lactam ring, allowing this essential part of the penicillin molecule to remain active.

Dosage

Specific dosage recommendations can be found in the British National Formulary.¹ Phenoxypenicillin, amoxicillin and flucloxacillin have better oral absorption than ampicillin but all should be taken at least 30 minutes before food since they are destroyed, to some extent, by gastric acid. The penicillins have good penetration to most tissues but poor entry to CSF (overcome by giving higher doses intravenously). Dosage modification is required in patients with severe renal failure.

TABLE 27.1 The antibacterial spectrum of antibiotics

Penicillins	Antibacterial spectrum
Benzylpenicillin and phenoxymethylpenicillin	Streptococcal, non β -lactamase producing staphylococcal, pneumococcal, clostridial infection, meningococcal, gonococcal, spirochaetes (syphilis), anthrax, actinomycosis
Ampicillin and amoxicillin	As above and <i>Strep. faecalis</i> , most <i>Haemophilus influenzae</i> and many coliforms
Methicillin, cloxacillin, flucloxacillin	Similar to penicillin but less active. Stable to staphylococcal β -lactamase
Carbenicillin and ticarcillin	Similar to amoxicillin and in addition activity to <i>Ps. aeruginosa</i> , most <i>Proteus</i> spp. and against bacteroides
Mezlocillin, azlocillin, piperacillin	Similar to ticarcillin and in addition to <i>Klebsiella</i> spp. and greater activity against pseudomonads
Mecillinam	Coliforms, little activity against Gram-positive bacteria
Cephalosporins	Antibacterial spectrum
First generation: cephaloridine, cephalothin, cephalexin, cefradine and cephazolin	Broad spectrum except against <i>Strep. faecalis</i> , <i>Ps. aeruginosa</i> , <i>H. influenzae</i> and <i>Bacteroides</i> spp. Staphylococcus is sensitive, except for MRSA
Second generation: cefaclor, cefuroxime, cefamandole, cefoxitin	Broad spectrum with stability against β -lactamases. Active against <i>H. influenzae</i> and <i>Bacteroides</i> spp. but less activity against staphylococcus
Third generation: cefotaxime, latamoxef, ceftazidime, cefsulodin, ceftriaxone, cefixime, cefpodoxime proxetil Fifth generation: ceftaroline fosamil	As for second generation but also active against <i>Ps. Aeruginosa</i> Similar to cefotaxime but also against Gram-positive bacteria including methicillin-resistant <i>Staphylococcus aureus</i> and multidrug-resistant <i>Streptococcus pneumoniae</i> .
Macrolides: erythromycin, azithromycin, clarithromycin	See penicillins but also active against <i>H. influenzae</i> , <i>Bord. Pertussis</i> , <i>Bacteroides</i> spp., <i>Campylobacter</i> spp. <i>Legionella pneumophila</i> , <i>Mycoplasma pneumoniae</i> and <i>Chlamydiae</i>
Sulphonamides and trimethoprim: co-trimoxazole	Broad, active against Gram-positive and Gram-negative bacteria except <i>Ps. aeruginosa</i>
Aminoglycosides: gentamicin, tobramycin, netilmicin, amikacin, kanamycin and neomycin Carbapenems: imipenem, meropenem, doripenem and ertapenem	Coliforms, <i>Ps. aeruginosa</i> and staphylococci; streptomycin; mycobacteria Broad spectrum of activity including many Gram-positive and Gram-negative bacteria and anaerobes. Good activity against <i>Pseudomonas aeruginosa</i> except ertapenem
Vancomycin	Staphylococci including MRSA, streptococci and clostridia
Tetracyclines: tetracycline, chlortetracycline, oxytetracycline, doxycycline, minocycline	Broad; Gram-positive and -negative bacteria, brucellae, <i>M. pneumoniae</i> , rickettsia, <i>Coxiella burneti</i> and <i>Chlamydiae</i> . Some resistance to <i>Strep. pyogenes</i> , pneumococci and <i>H. influenzae</i> . <i>Ps. aeruginosa</i> and <i>Proteus</i> spp. resistant
Metronidazole	Anaerobic bacteria and protozoa
Ciprofloxacin	Broad; Gram-negative bacteria including <i>Ps. aeruginosa</i> , staphylococci including MRSA, streptococci less sensitive
Monobactams: aztreonam	Narrow, active against aerobic Gram-negative bacteria (less sensitive to <i>Ps. aeruginosa</i>)

Ciprofloxacin can achieve high concentrations in bone and soft tissue, even after oral administration. A dosage of 1.5 g daily over a period of 6–12 weeks has been recommended in the treatment of malignant otitis externa.^{15, 16}

Contraindications

In all cases the prescribing of these drugs is contraindicated when the patient is known to be allergic to the ingredients or related compounds. Immediate hypersensitivity to penicillins occurs in 0.05% of patients, the severity of which ranges from urticaria or wheezing to a life-threatening anaphylactic response. Less than 5% of patients may develop a delayed hypersensitivity response to penicillins, usually a rash. Occasionally, haemolytic anaemia, leucopenia and interstitial nephritis may occur. There is a 10% hypersensitivity crossover with cephalosporins.

Precautions

The prolonged use of antibiotics may result in superinfection with unsusceptible organisms. There is no evidence that the penicillins, cephalosporins or erythromycin are hazardous in pregnancy but metronidazole should be avoided in high dosages and ciprofloxacin must be avoided in all trimesters of pregnancy. Antibiotics are secreted into breast milk and ciprofloxacin should be avoided in lactation. Other antibiotics, such as the penicillins and cephalosporins, are secreted into breast milk but may not be harmful to the infant. Antibiotics, such as the cephalosporins and ciprofloxacin, cleared by the kidneys may require dosage adjustments in patients with renal impairment. Similarly, antibiotics metabolized by the liver, for example erythromycin, may require dosage adjustments or to be avoided in patients with liver failure.

Interactions

Before prescribing a specific medication, the reader is advised to check for interactions in, for example, The British National Formulary.¹ Antibiotics may lead to oral contraceptive failure, probably because of diminished enterohepatic circulation. The anticoagulant effect of warfarin is affected by the penicillins, macrolides, metronidazole and quinolones.

Erythromycin interacts with some antihistamines and cisapride, resulting in cardiac arrhythmias. It also increases the plasma level of a number of drugs.

Metronidazole produces a disulfiram-like reaction with alcohol. Acetaldehyde accumulates in the body producing facial flushing, headaches, palpitations, nausea and vomiting.

Indigestion, iron or zinc therapies must not be taken within 2 hours of ciprofloxacin since absorption of this antibiotic is significantly affected.

Side effects

Most antibiotics may produce diarrhoea, rashes, blood disorders, nausea and vomiting. Ampicillin and amoxicillin have a unique adverse effect, comprising a rash, in up to 90% of patients with mononucleosis or chronic lymphocytic leukaemia. Reversible hearing loss has been reported with erythromycin. Angioneurotic oedema and anaphylaxis are, fortunately, relatively rare.

PREPARATIONS USED IN THE MANAGEMENT OF VERTIGO

Betahistine

Betahistine hydrochloride is commonly prescribed in the management of vertigo, usually when associated with Menière's disease or syndrome.

Betahistine is thought to reduce the endolymphatic pressure through improved microvascular circulation in the stria vascularis of the cochlear¹⁷ or by inhibiting activity of the vestibular nuclei.¹⁸

There is insufficient evidence from high quality randomized trials to say whether or not betahistine has any effect on Menières.¹⁹ It may reduce vertigo, and possibly tinnitus, but does not seem to influence the hearing loss.

Betahistine should be used with caution in patients with asthma, a history of peptic ulcer disease, in pregnancy and breastfeeding. It is contraindicated in patients with phaeochromocytoma. The side effects include gastrointestinal disturbance, headaches, rashes and pruritis; however, these are uncommon. Betahistine is prescribed initially at 16 mg three times a day; a maintenance daily dose of 24–48 mg has been recommended.

Dopamine antagonists

Prochlorperazine (Stemetil®) is a dopamine antagonist and acts centrally by blocking the chemoreceptor trigger

zone and thereby blocking the vomiting centre. The vomiting centre also has afferent input from the vestibular apparatus. This region has a high concentration of muscarinic receptors and histamine H₁-receptors.

Prochlorperazine belongs to group three of the phenothiazines. This means it has less sedative effects, fewer anti-muscarinic effects but more pronounced extra-pyramidal side effects when compared to the other phenothiazine groups.

Prochlorperazine is available as tablets, syrup, effervescent sachets, injection, suppositories and as a buccal preparation (Buccastem®). These last two preparations are useful because patients using prochlorperazine often vomit and fail to absorb the orally ingested form. The oral dosage varies from 5 mg three times a day increasing to 30 mg daily.

Antihistamines

The antihistamines are competitive antagonists of histamine at H₁-receptors, and their main action is on the vomiting centre rather than on the chemoreceptor trigger zone. They have weak anticholinergic effects and may occasionally produce a dry mouth and blurred vision. Drowsiness, occasional insomnia and euphoria are side effects that have been reported. These central effects are accentuated with alcohol. Cinnarazine (Stugeron®) and cyclizine (Valoid®) are less sedating than promethazine teoclate (Avomine®). Cinnarazine has been used in the prophylaxis and treatment of Menière's at a dosage of 30 mg three times a day. Cyclizine may be given in the acute attack orally or parentally at a dosage of 50 mg three times a day.

Gentamicin therapy in Menière's disease

Intra-tympanic gentamicin therapy was described by Beck and Schmidt²⁰ in 1978 and has been used both in Canada and the UK. Since its introduction, a variety of gentamicin dosage regimens and methods of administration have been developed and remain in clinical practice. These range from injection through the tympanic membrane, through a grommet or via intra-tympanic or round window catheters.

Other medical treatment for Menières disease

The use of salt restriction and diuretic therapy (hydrochlorothiazide, acetazolamide and co-triamterzide 50/25 (Dyazide®) are aimed at reducing the accumulation of endolymph. Although a study with Dyazide showed a reduction in vestibular symptoms, there was no effect on hearing loss or tinnitus. Acetazolamide may initially increase the hydrops and Brookes and Booth²¹ concluded that this drug has no place in treating Menière's disease. Steroids and immunological therapy have also been proposed by those who believe that a disorder of the immune system underlies Menière's disease or syndrome.

DRUGS USED IN SUDDEN SENSORINEURAL HEARING LOSS

Corticosteroids

Steroids are commonly used in patients with sudden sensorineural hearing loss (SSNHL), but evidence for their effectiveness is lacking. There are several alternative dosage regimes when a ‘short reducing course’ of steroids is required. One such consists of enteric-coated prednisolone, 60 mg on the first day, 50 mg on the second day, 40 mg daily for 3 days, 30 mg daily for 3 days and a further reduction so that therapy is discontinued after 3 weeks.

Antiviral agents

Aciclovir (acycloguanosine) is an antiviral agent active against herpesviruses and is prescribed in patients with Ramsay Hunt syndrome (herpes zoster oticus). It acts by inhibiting nucleic acid synthesis. Herpes simplex and varicella zoster contain a thymidine kinase that converts the aciclovir to a monophosphate that is then phosphorylated by the host cell enzymes of acycloguanosine triphosphate that inhibits viral DNA polymerase and viral DNA synthesis. Selectivity for infected cells is achieved since the DNA polymerase of herpesvirus has a much greater affinity for the activated drug than the cellular DNA polymerase.

Aciclovir may be administered orally at a dosage of 800 mg five times a day for 5 days. If treatment is commenced prior to 72 hours after the onset of the rash, aciclovir may shorten the rash duration and acute symptoms and reduce the incidence of post-herpetic neuralgia.²² Aciclovir should be used with caution in patients with renal impairment or who are pregnant or breastfeeding. Side effects include nausea, vomiting, gastrointestinal disturbances, rash, photosensitivity and, rarely, hepatitis, acute renal failure and neurological reactions. Two newer antiviral agents are famciclovir (a prodrug of penciclovir) and valaciclovir (an ester of aciclovir), which, depending on indication and co-morbidities, are administered up to three times a day (see British National Formulary¹ for further details).

SODIUM FLUORIDE TREATMENT IN OTOSCLEROSIS

Sodium fluoride has been used for 35 years in an attempt to slow down or arrest sensorineural hearing loss in patients with stapedial otosclerosis or after stapedectomy. It has also been used in patients with ‘pure’ cochlear otosclerosis.

Sodium fluoride is an enzyme inhibitor and reduces osteoclastic bone resorption. The clinical benefit of sodium fluoride is controversial. Causse et al.²³ found that in ‘otospongiosis-otosclerosis’, sodium fluoride influenced the underlying bony changes in the labyrinth so as to arrest or prevent the onset of hearing loss. In their prospective clinical double-blind, placebo-controlled study of 95 patients, Bretlau et al.²⁴ found that there was a statistically worse deterioration of hearing loss in the placebo group than in the active treated (40 mg sodium fluoride daily) group. Further work by Colletti²⁵ showed benefit in 50% of patients 5 years after a 2-year treatment with sodium fluoride (dosages up to 16 mg/day). Cruise et al. in a review of the literature 1966 to 2009 concluded that there is low evidence suggesting sodium fluoride may be of benefit to preserve hearing and reduce vestibular symptoms in patients with otosclerosis.²⁶ Treatment doses used vary greatly and the optimum treatment time has yet to be determined. Deka et al.²⁷ suggested the use of Florical at a dosage of two capsules three times a day in active cochlear otospongiosis. Their study showed that variation in absorption occurs with the use of different preparations and also amongst individuals.

The side effects of sodium fluoride need to be considered. In a prospective case-controlled study of ten patients with otosclerosis receiving sodium fluoride 30 mg/day and matched healthy volunteers, Das et al.²⁸ found a high incidence (70%) of dyspeptic symptoms in those taking sodium fluoride, as well as histological and electron microscopic abnormalities.

BEST CLINICAL PRACTICE

- ✓ Before prescribing, ensure that the patient is not known to be allergic to the medicine or adjuvants (such as the preservatives).
- ✓ Ensure medication does not interact with patient’s established medication or medical conditions.
- ✓ Prescribe medicines at the lowest dose for the shortest time that is effective.
- ✓ Review whether medication is still required.

FUTURE RESEARCH

- There is insufficient evidence to favour any one particular cerumenolytic and a randomized controlled trial may be useful to determine the most clinically and cost-effective preparations for this purpose.
- There is insufficient evidence from high-quality randomized trials to determine whether betahistine, diuretics, steroids and immune therapy have any effect in Menière’s disease.

KEY POINTS

- Topical ear preparations can be used for a limited period in discharging ears with a perforated tympanic membrane or a grommet *in situ*.
- The use of topical ear preparations containing a steroid only is contraindicated in untreated infections since the immunosuppressive action of the corticosteroid may exacerbate the infection.
- Flucloxacillin is the antibiotic of choice in cellulitis due to staphylococcus. Penicillin V is used in erysipelas due to streptococcus. Ciprofloxacin is the antibiotic of choice in malignant otitis externa.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: acute rhinosinusitis, chronic rhinosinusitis, nasal polyposis, fungal rhinosinusitis and medical treatment. The chapter has also relied on a review produced by the European Rhinological Society and the European Academy of Allergology and Clinical Immunology (EAACI) that was published as a supplement by *Rhinology* in March 2012, and their abbreviations are used in this chapter.

INTRODUCTION

This chapter covers the medical treatment, in particular the use of corticosteroids and antibiotics, in managing the various types of rhinosinusitis. A separate section is devoted to other medicines that are used in the management of rhinosinusitis. Finally, other medical treatments used in rhinology are discussed under related topics.

Rhinosinusitis is a significant health problem that reduces the quality of life for individuals and places a large financial burden on society. The evidence for the effectiveness of medical treatment of rhinosinusitis has been reviewed by the European Rhinological Society (ERS) and the European Academy of Allergology and Clinical Immunology (EAACI), and the authors of this chapter have relied on the ERS/EAACI review.¹

Rhinosinusitis is an inflammatory process involving the mucosa of the nose and one or more of the sinuses. Factors contributing to the inflammation include mucociliary impairment, bacterial infection, allergy, swelling of the mucosa for other reasons and mechanical obstruction. Inflammation around the osteomeatal complex is of particular importance and treatment is aimed at reducing the factors causing inflammation and ensuring adequate ventilation in this area. The classification of rhinosinusitis includes: acute rhinosinusitis (ARS) (viral or post-viral;

a few of these having acute bacterial rhinosinusitis (ABRS)), and then chronic rhinosinusitis with (CRSwNP) or without (CRSSNP) nasal polyps.¹

TREATMENT OF RHINOSINUSITIS WITH CORTICOSTEROIDS

Topical corticosteroids have improved the treatment of rhinosinusitis and asthma. Their efficacy may partly depend on their ability to reduce the viability and activation of eosinophils and to reduce the secretion of chemotactic cytokines by the nasal mucosa. This is mediated through activation of intracellular glucocorticoid receptors that are expressed in many tissues and cells. Other beneficial effects of steroids include: change of vascular permeability, reduction of mast cell degranulation and reduction of squamous metaplasia of allergic nasal polyps.

Acute rhinosinusitis (ARS)

In published studies, where either a placebo or a topical steroid has been added to antibiotic treatment for ARS, the results generally show that the patients who were treated with a topical corticosteroid improved more rapidly than

when the antibiotic was combined with a placebo. A representative study by Meltzer et al.² found Mometasone furoate 400 µg a day improved the symptom score more than placebo in patients with ARS also treated with amoxicillin clavulanate potassium for 21 days. Recently a double-blind, double-dummy, placebo-controlled trial found topical corticosteroid given twice daily as monotherapy to be more effective than amoxicillin twice daily in ARS³ and has been supported by others^{4,5} as well as a Cochrane review.⁶

Gehanno et al.⁷ looked at the effectiveness of systemic steroids in the treatment of ARS. Eight milligrams of methylprednisolone was given three times a day for 5 days as an adjunct to 10 days' treatment with amoxicillin clavulanate potassium in patients with ARS. The diagnostic criteria consisted of facial pain, purulent nasal discharge and purulent secretions from the middle meatus, together with opacities on CT scan. The conclusion was that there was no difference in the therapeutic outcome at day 14 between the steroid group and the placebo group, although 4 days after initiating treatment, the headache and facial pain was significantly less in the steroid group. A Cochrane review suggests systemic steroids may be a useful adjunctive therapy to oral antibiotics in the short-term relief of symptoms of ARS.⁸

There is very low evidence for a prophylactic effect of nasal corticosteroids in preventing recurrence of acute rhinosinusitis.¹

Chronic rhinosinusitis without nasal polyps (CRSsNP)

Most studies compare topical steroid versus placebo as an adjunctive treatment to antibiotics. Two large trials of 407 and 967 patients, respectively, found that mometasone furoate produced a significant improvement in symptom score over the placebo. In one study topical steroid did not help the symptom of post-nasal drip⁹ but it did in the second study.¹⁰ There was no statistical difference in the CT findings of the treatment group compared with placebo.

A systematic review of level 1 or randomized controlled trials (RCTs) failed to demonstrate a universal benefit of local intra-nasal corticosteroids in CRSsNP. The method of delivery and post-surgical improved access were significant but the type of corticosteroid was not.¹ Epistaxis, dry nose, nasal burning and nasal irritation may occur as side effects to topical corticosteroid use but these are usually mild, the benefit outweighing the risk. There is a lack of clinical data to support the use of systemic corticosteroids in patients with CRSsNP.

Chronic rhinosinusitis with nasal polyps (CRSwNP): Topical steroids

In patients with CRSwNP the studies have tended to consider the effectiveness of the treatment on the rhinitic symptoms and then, as a separate outcome measure, the effect of the treatment on the size of the polyps.

In a landmark paper published in 1979, Mygind et al.¹¹ showed that beclomethasone dipropionate (BDP) was more effective than placebo at reducing nasal symptoms in CRSwNP but no reduction in the size of the polyps occurred in 3 weeks.

A systematic review found 34 studies in which a topical steroid has been compared to placebo. Three compared two agents and three compared topical steroid against no intervention in patients with CRSwNP. Topical steroid is more effective than placebo in reducing symptoms, particularly nasal blockage. About half report improvement in sense of smell and reduction in polyp size. The response was greater in post-surgical patients; however, their improvement in symptoms and nasal flow was not statistically significant.¹

A comprehensive study compared fluticasone propionate 400 µg daily, with BDP 400 µg daily and with topical placebo over a 12-week period in a double-blind randomized parallel group that was conducted in a single centre study.¹² The symptom score was significantly improved in the fluticasone group and the nasal cavity volume improved in both active treatment groups when measured with acoustic rhinometry. The peak nasal and inspiratory flow also improved in both active groups but the improvement was quicker in the fluticasone propionate group. After 12 weeks there was no difference statistically in the symptoms between the two active groups.

In conclusion, therefore, there is good evidence that topical corticosteroids improve the symptoms associated with nasal polyps, in particular nasal blockage, nasal secretions and sneezing, and in some patients they are effective at improving the sense of smell. In the majority of patients, topical corticosteroids also appeared to reduce the size of the nasal polyps, provided they were used for several weeks.

Chronic rhinosinusitis with nasal polyps (CRSwNP): Systemic steroids

A Cochrane review updated in 2010 identified three level 1 studies supporting the use of systemic steroids in CRSwNP. In one study, oral prednisolone was given in doses of 60 mg daily to 25 patients with severe nasal polyposis for 4 days and, for each of the following 12 days, the dose was reduced by 5 mg daily. Antibiotics and antacids were also given. Seventy-two per cent of patients experienced a symptom improvement due to the involution of polyps and in 52% of patients an improvement was seen on the CT. Nasal obstruction reduced and sense of smell improved. This study supports the general clinical impression that systemic steroids are highly effective in treating patients' symptoms whilst taking the systemic steroid but the beneficial effects seem to be lost once the steroid is stopped.¹³ The chronic nature of CRSwNP has to be considered along with the short-lived benefits of systemic corticosteroids. Local corticosteroid treatment appears to be useful so long as it can be administered effectively.

The post-operative treatment of patients with chronic rhinosinusitis and nasal polyps (CRSwNP) with steroids

Six studies have found topical steroids do reduce the recurrence rate of nasal polyps after nasal polyp surgery. To quote from two of the representative studies, Karlsson and Rundcrantz¹⁴ treated 20 patients with BDP and 20 were followed with no treatment after polyp surgery. The follow-up period was for 30 months. After 6 months, there was a statistically significant difference between the groups in favour of BDP and its effect increased during the study period over the next 30 months.

Hartwig et al.¹⁵ used budesonide 6 months after polypectomy in a double-blind parallel group on 73 patients. In the budesonide group, 'polyp' scores were significantly lower than in the controls after 3 and 6 months. Interestingly, this difference was only significant for patients with recurrent nasal polyposis and not those who had had a polypectomy operation for the first time.

TREATMENT OF RHINOSINUSITIS WITH ANTIBIOTICS

The exact incidence of rhinosinusitis within populations is not known but it is a common condition for which antibiotics are frequently prescribed. According to the National Ambulatory Medical Care Survey in the USA, rhinosinusitis is the fifth most common diagnosis for which antibiotics are prescribed, accounting for 9% of all paediatric antibiotic prescriptions and 21% of all adult antibiotic prescriptions written in 2002.¹⁶

Recurrent acute rhinosinusitis

A recent Cochrane review compared antibiotics against placebo or between antibiotics of different classes in the management of acute maxillary sinusitis in adults.¹⁷ Fifty-nine studies met the appropriate criteria for inclusion in this review and included six placebo-controlled studies and 53 comparing different classes or dose regimens of antibiotics. Compared to placebo only a slight statistical difference in favour of antibiotics was found although the clinical significance was equivocal with cure or improvement being high in both the placebo (80%) and antibiotic group (90%).

A previous Cochrane review in which comparisons were made between the newer non-penicillins (cephalosporins, macrolides, minocycline) versus penicillins (amoxicillin and penicillin V), no significant differences were shown. The rates of cure or improvement appeared to be 84% for both antibiotic classes. Adverse effects were infrequent with no significant difference between the two groups of antibiotics. Sixteen trials (4818 patients) compared newer non-penicillin antibiotics (macrolide or cephalosporin) to amoxicillin/clavulanate with similar cure or improvement rates (72%) but less adverse effects occurred with cephalosporin antibiotics. Relapse rates within one

month of successful therapy did not differ between the groups.¹⁸ Six trials, of which three were double-blinded (1067 patients), compared a tetracycline (doxycycline, tetracycline, minocycline) to a heterogeneous group of antibiotics (folate, cephalosporin, macrolide, amoxicillin) and no relevant differences were found.

The Cochrane reviewers¹⁸ concluded that for recurrent ARS, confirmed radiologically, current evidence is limited but supports the use of penicillin or amoxicillin for 14–17 days. In the Cochrane review, local differences in susceptibility of microorganisms to antibiotics used were not acknowledged, although it is known that resistance patterns of predominant pathogens, such as *Streptococcus pneumoniae*, *Haemophilus influenzae* and *Moraxella catarrhalis*, vary considerably.¹⁹ The prevalence and degree of antibacterial resistance in common respiratory pathogens is also increasing worldwide, presumably because of the increase in antibiotic consumption. The choice of which antibiotic is used may depend on local resistance patterns and disease aetiology.

Antibiotic treatment for chronic rhinosinusitis

It is significantly more difficult to evaluate the efficacy of antibiotic treatment in chronic compared to intermittent ARS because of the difficulties of defining the clinical diagnosis of CRS in the literature. In many studies there is no radiological diagnosis and, therefore, data supporting the use of antibiotics in CRS are limited; however, a number of open studies using macrolides have shown a response rate of 60–80%.

In a double-blind prospective study by Legent et al.,²⁰ 251 adult patients with CRSsNP were treated with ciprofloxacin or amoxicillin/clavulanic acid for 9 days. Only 141 of the 251 patients had positive bacterial cultures from the middle meatus at the beginning of the study. At the end of the treatment period, the nasal discharge disappeared in 60% of the patients in the ciprofloxacin group and 56% of those in the amoxicillin/clavulanic acid group. The clinical cure and bacteriological eradication rates were 59% and 89% for ciprofloxacin versus 51% and 91% for amoxicillin/clavulanic acid, respectively. The differences were not significant. In 2002 Namyslowski reported the results of an open parallel randomized clinical trial of 206 adults with exacerbation of CRS had either amoxicillin/clavulanic acid or cefuroxime axetil. The clinical response was similar (95% and 88% respectively) as was the bacterial cure rate (65% and 68% respectively).²¹ Short-term treatment of CRSsNP may be considered in exacerbations with a positive culture. In patients with CRSwNP one RCT has shown that doxycycline for 3 weeks had a small effect on polyp size and post-nasal discharge but no effect on other symptoms compared to placebo.²²

There is some evidence that long-term treatment with low-dose macrolide antibiotics may be effective in treating patients with CRSsNP that has not been cured by surgery or corticosteroid treatment. In animal studies, macrolides have been shown to increase mucociliary transport and

reduce goblet cell secretion. There is evidence *in vitro*, as well as clinical experience, that macrolides reduce the virulence and tissue damage caused by chronic bacterial colonization without actually eradicating the bacteria, that is their action is immune-modulatory rather than anti-bacterial.

Clinical studies have shown that long-term treatment with macrolide antibiotics increases ciliary function.²³ In a prospective RCT, 90 patients with CRSwNP and CRSsNP were randomized to erythromycin for 3 months, or endoscopic sinus surgery, and followed up over a year. The outcome measures included a symptom score, the SNOT 22, the SF 36, nitrous oxide levels, acoustic rhinometry, saccharine clearance times and nasal endoscopy. Both the medical and surgical treatment of CRS significantly improved almost all the subjective and objective parameters with no significant difference between the two groups, or between CRSwNP and CRSsNP, except for the increase in total nasal volume, which was greater following surgery.²³ Further studies are necessary to determine the effect of long-term treatment with antibiotics in CRSwNP.

There are two placebo-controlled studies on the effectiveness of long-term antibiotic treatment. One using roxithromycin showed efficacy in patients with CRSsNP. The other study included CRSwNP as well and although more responded in the treatment group this was not significant. Data suggest patients with high IgE levels are less likely to respond to macrolide treatment than patients with normal IgE levels.²⁴ Studies comparing different antibiotics did not show any significant difference between ciprofloxacin versus amoxicillin/clavulanic acid. The few available prospective studies showed a positive effect on the patient's symptoms in 56–95% of patients.

Long-term low-dose macrolide treatment may be of use if surgery and/or steroids and saline irrigation have failed. Further placebo-controlled studies should be performed to establish the efficacy of macrolides if this treatment is to be accepted in the future. There is also an urgent need for randomized placebo-controlled studies to investigate the effectiveness of antibiotics in general for CRS.

There are three placebo-controlled trials with topical antibiotics in CRSsNP. None showed any additive effect compared to saline.^{25–27} There are no data on the effect of topical antibiotics in CRSwNP.

TREATMENT OF RHINOSINUSITIS WITH OTHER MEDICINES

Decongestants

After corticosteroids and antibiotics, the medications that are perceived to be most useful for treating rhinosinusitis are decongestants. The rationale behind the use of decongestants is to improve sinus ventilation and drainage. Radiological studies using CT and MRI scanning show that topical decongestants markedly reduce the size of the inferior and middle turbinates and improve osteomeatal complex patency but have no effect on ethmoidal and maxillary sinus mucosa.^{28, 29}

Experimental studies suggest that topical decongestants (xylometazoline and oxymetazoline) have a beneficial anti-inflammatory action that is caused by decreasing nitric oxide synthetase.³⁰ A controlled clinical trial showed improved mucociliary clearance *in vivo* after 2 weeks of oxymetazoline for ABRS when compared to fluticasone and hypertonic saline and saline. The clinical course of the disease between the three groups, however, was not significantly different.³¹ This, together with another study using decongestants in addition to a penicillin treatment in acute maxillary sinusitis, suggests that decongestion of the sinus ostia is not of primary importance during the healing of ARS.³²

Topical decongestants are also recommended for individuals who have problems clearing their ears while flying or diving. The decongestants are all alpha adrenergic agonists and act on the two types of alpha receptor, one of which controls the venous capacitance vessels of the nasal tissues, which are responsible for erectile function, and the other alpha receptors, which mediate contraction of arterioles that supply the mucosa.

Ephedrine nasal drops (0.5% and 1%) are weak sympathomimetics whilst oxymetazoline and xylometazoline are more potent causing intense vasoconstriction. The rebound effect that occurs after the vasoconstriction wears off is more with the potent decongestants and patients should be advised not to use topical decongestant for more than 10 days. In patients who become addicted to decongestant drops or sprays, there is a risk of developing rhinitis medicamentosa where the nasal mucosa becomes permanently damaged.

One preparation combines the steroid dexamethasone isonicotinate with the sympathomimetic tramazoline hydrochloride (Dexa-Rhinaspray Duo). The spray is promoted for the treatment of allergic rhinitis. The suggestion is that the decongestant allows better mucosal access for the steroid. Clinical experience suggests that this is a useful spray. The use of all sympathomimetic preparations is contraindicated in patients on monoamine oxidase inhibitors (MAOIs) and they should be used with caution in patients with hypertension, hyperthyroidism, cardiovascular disease, diabetes mellitus and closed angle glaucoma, and in infants of less than 3 months of age.

The use of decongestants for CRS has not been evaluated in any RCTs. There are no controlled trials to test the efficacy of decongestants for the treatment of nasal polyps.

Systemic decongestants appear to be less effective than local preparations but rebound nasal congestion on withdrawal of the drug does not arise. Pseudo-ephedrine is available over the counter in the UK, both in tablet form and as a linctus. Little evidence supports the use of systemic decongestants in the treatment of rhinosinusitis.

Mucolytics

The rationale for using mucolytics in the treatment of rhinosinusitis is to reduce the viscosity of the nasal secretions. There is minimal evidence to support the use of mucolytics in the treatment of rhinosinusitis. One RCT study

(report in Italian) suggests bromhexine is superior to placebo in acute rhinosinusitis.³³ In one paediatric study, an RCT did not prove bromhexine to be superior to saline inhalation for children with CRS.³⁴

Antihistamines

These can be used orally and as a nasal spray. Clinical experience suggests that they reduce rhinorrhoea, sneezing and itching, but have little effect on nasal obstruction. There is no evidence that antihistamines reduce or abolish the symptoms of the common cold. The non-sedating antihistamines acrivastine (Semprex), cetirizine hydrochloride (Zirtek), desloratadine (Neoclarityn) and fexofenadine hydrochloride (Telfast) cause less sedation and psychomotor impairment because they penetrate the blood–brain barrier to a lesser degree than the older type of antihistamines. Side effects of antihistamines include hypotension, hypersensitivity reactions, extrapyramidal effect, dizziness, blood disorders and liver dysfunction.

In the treatment of ARS, the beneficial effect of loratadine (the predecessor of desloratadine) for patients with allergic rhinitis was confirmed in a multicentre randomized double-blind placebo-controlled trial. Patients receiving loratadine as an adjunct to antibiotic treatment suffered significantly less sneezing and obstruction on daily visual analogue scale (VAS) scores.³⁵

In CRS there is little evidence that antihistamines are effective. However, they are often prescribed for patients with CRS, particularly in the USA. One randomized placebo-controlled trial on patients with residual or recurrent nasal polyps was identified using cetirizine 20 mg twice a day or placebo for 3 months. Inhaled steroids for asthma was allowed. The end point was poorly defined and no significant improvement in symptoms found using cetirizine over placebo.³⁶ The use of antihistamines may be useful in patients with CRSwNP with concomitant nasal allergies. No RCTs are identified for treatment of CRSsNP or CRSwNP with antihistamines without previous sinus surgery.

Sprays such as azelastine hydrochloride (Rhinolast) and levocabastine (Livostin) are topical antihistamines that are promoted for use in allergic rhinitis. Topical antihistamines are considered less effective than topical steroids and good evidence to support their use is lacking.

Sodium cromoglicate

Sodium cromoglicate is available as a 4% aqueous nasal spray (Rynacrom) and a 2% nasal spray (Vividrin), and it is also combined with xylometazoline (Rynacrom) and is promoted for prophylactic use in allergic rhinitis. Depending on the preparation, it needs to be taken either four or six times a day. Its mechanism of action is debatable; it was originally thought to act by preventing mediator release from mast cells. However, agents subsequently developed with this property do not demonstrate the same anti-asthmatic effects as cromoglicate. There is some evidence that cromoglicate depresses the exaggerated neuronal reflexes generated by irritant receptor stimulation.

Side effects are few and include local irritation and transient bronchospasm. It may have a role in the treatment of allergic rhinitis in children but the fact that it needs to be taken several times a day means that compliance is low.

Antifungal agents used in rhinology

Fungal infections may be superficial or systemic. Antifungal agents can be classified into polyenes, flucytosine, imidazoles and triazoles. The polyenes, amphotericin and nystatin interact with ergosterol in the fungal cell membrane. Pores are formed through which the fungal cell contents are lost. Selectivity is obtained since the human cell membrane contains mostly cholesterol rather than ergosterol.

Amphotericin has a wide spectrum of activity and is used parentally in severe systemic infections since oral absorption is poor. Side effects are common and include nausea and fevers. Renal impairment can occur but is reversible if detected early. Liposomal amphotericin is significantly less toxic but is more expensive. It is likely that it will become the agent of choice. Nystatin is used principally for *Candida albicans* infections of the skin and mucosal membranes.

Flucytosine is given orally or intravenously to treat systemic candidiasis or cryptococcal infections, often in combination with amphotericin to prevent resistance. Flucytosine is converted in fungal cells to flurouracil which inhibits DNA synthesis.

The imidazoles, miconazole, ketoconazole and clotrimazole, are mostly used to treat topical infections. They are broad-spectrum antifungals that prevent ergosterol synthesis. Ketoconazole is better absorbed by mouth than the other imidazoles but it has been associated with fatal hepatotoxicity.

The triazoles include fluconazole and itraconazole and both can be given orally and parentally. Itraconazole is active against *Aspergillus* but has been associated with hepatotoxicity.

There has been interest in the role of fungi as a possible cause for the various types of rhinosinusitis. Antimycotics have been used topically and systemically and as an adjunct to sinus surgery in the treatment of allergic fungal rhinosinusitis, invasive fungal rhinosinusitis and conventional recurrent ARS.

Surgery is considered the first-line treatment for allergic fungal rhinosinusitis,³⁷ and surgery and systemic antimycotics are used in the treatment of invasive fungal rhinosinusitis.³⁸ Although the use of antimycotics in the treatment of allergic fungal rhinosinusitis has not been tested in controlled trials, a high dose of post-operative itraconazole, combined with oral and topical steroids in a cohort of 139 patients with allergic fungal rhinosinusitis, reduced the need for revision surgery.³⁹ The antifungal prophylaxis in immunocompromised patients did not prevent the development of invasive zygomycosis but treatment with liposomal amphotericin B resulted in improved response and survival rates with early detection being as important as the surgical and antifungal treatments.⁴⁰

Researchers from the Mayo Clinic proposed that CRS may arise because of a local immune response to fungi that are present in nasal and sinus secretions.⁴¹ Given the correct equipment, fungi can be detected in nasal secretions in virtually all patients with CRSwNP, but also in a controlled disease-free population. There is no definitive proof that fungi are involved in the aetiology of the inflammatory response in some patients. One double-blind randomized placebo-controlled trial in 60 patients with CRSwNP, comparing topical treatment with amphotericin B with saline douching,⁴² found radiological and subjective scores were actually worse in the treatment group. One trial with nasal amphotericin B treatment significantly reduced symptoms at 2 but not 4 weeks and endoscopy scores and fungal culture rates did not significantly differ. This treatment is not recommended in CRSsNP.⁴³

MEDICATION THAT MAY IMPROVE THE IMMUNE RESPONSE

Since an altered immune response to bacterial infection or fungal infection may be responsible for some of the episodes of recurrent rhinosinusitis, there is interest in medications that may alter the immune response.

Bacterial lysate preparations

Bacterial lysate preparations (e.g. ribosomal fractions of *Klebsiella pneumoniae*, *Streptococcus pneumoniae*, *Streptococcus pyogenes* and *Haemophilus influenzae*) have been tested against placebo in three multicentre placebo-controlled trials and the evidence from these studies suggested that this type of therapy may reduce the need for antibiotics in the treatment of chronic rhinosinusitis.⁴⁴⁻⁴⁶ Based on the results of one RCT oral OM-85 BV treatment may be considered as an adjunct to standard medical treatment in adults with CRSsNP.¹

Treatment with more expensive agents that either stimulate or modulate the immune system (e.g. recombinant human granulocyte colony stimulating factor) have been tested in a randomized controlled trial in a group of patients with CRS that were refractory to other types of treatment. The studies showed there was no significant improvement with this expensive treatment.

A pilot study has looked at treatment with gamma interferon and it suggested that this treatment may be beneficial in treating resistant CRS; but the number of patients was small.⁴⁷

NASAL AND ANTRAL IRRIGATION WITH SALINE

Saline irrigation

A number of RCTs have tested nasal irrigation with isotonic or hypertonic saline in the treatment of ARS and CRS comparing modalities of application. There was limited evidence of benefit with nasal saline irrigation in

adults with ARS.⁴⁸ The evidence is that nasal washout with isotonic or hypertonic saline is beneficial in alleviating symptoms and improves endoscopic findings in patients with CRS. Irrigation with saline has also shown to significantly improve nasal mucociliary clearance, as measured by saccharine tests in healthy volunteers.⁴⁹

ANTILEUKOTRIENES

The role of leukotrienes in the pathogenesis of bronchial asthma has been well documented and increased levels of these mediators have been detected in patients with rhinosinusitis and nasal polyps. Antileukotrienes have been evaluated in the treatment of asthmatics, especially in those with the aspirin-induced asthma (ASA) triad.

When seasonal allergic rhinitis was considered, antileukotrienes were not found to be superior to placebo in reducing symptom scores in a randomized controlled trial.⁵⁰

For patients with CRSwNP, one study looked at antileukotriene treatment in 36 patients and found that when antileukotrienes were added to standard treatment regimes, there was a significant reduction in symptom score.⁵¹

Two other studies support the use of antileukotriene treatment as an adjunct to standard treatment in patients with nasal polyps, asthma and aspirin intolerance.^{52, 53}

Leukotriene antagonists can cause skin rash, mood changes, tremors or shaking and occasionally can worsen the symptoms of sinus symptoms and asthma. Currently data do not support the use of antileukotriene antagonist in CRSwNP.

Aspirin desensitization

This treatment has been used in patients with aspirin-exacerbated respiratory disease (AERD) having CRSwNP, bronchial asthma and hypersensitivity to Cox-1 inhibitors (including aspirin). It was observed that following exposure to aspirin, these patients became refractory to the effects of aspirin for 24 to 72 hours. Several case series suggest a weak clinical benefit from oral aspirin desensitization.^{54, 55} There is no randomized placebo-controlled trial on oral aspirin in AERD patients. In one trial, 14 patients who reacted to an aspirin provocation test were allocated to 100mg or 300mg aspirin daily for 1 year. It was found that all patients on 100mg aspirin had recurrence of nasal polyps but no polyps were found in patients on 300mg aspirin daily.⁵⁶

Nasal administration of lysine-aspirin may reduce the risk of severe hypersensitivity reactions as well as gastrointestinal side effects. In a randomized, double-blind placebo-controlled trial patients with AERD were given either 16mg lysine-aspirin or placebo every 48 hours for 6 months but no significant clinical benefit was found in the treatment group compared to the placebo group.⁵⁷

Based on current data, the benefit of oral or nasal aspirin desensitization in patients with AERD has yet to be determined.

AGENTS USED TO BLOCK THE PARASYMPATHETIC NERVOUS SYSTEM

Ipratropium bromide (Rinatec) is a muscarinic receptor antagonist blocking the parasympathetic nervous system. It should be effective in anyone with a wet dripping nose due to parasympathetic overactivity. In practice, it is effective for some elderly men with a dripping nose! Side effects include a dry mouth, epistaxis and dryness of the nose. A Cochrane review identified seven studies and concluded that ipratropium bromide is effective in reducing the rhinorrhoea with no effect on congestion experienced by those with the common cold.⁵⁸

VACCINATION

Although vaccination does not have a direct effect in the treatment of ARS, a study showed that in the 5-year period following the introduction of 7-valent pneumococcal vaccination when compared to the previous 5-year period, the cause of acute maxillary sinusitis by *Streptococci pneumoniae* decreased by 18% but *Haemophilus influenzae* increased by 8%.⁵⁹

RELATED TOPICS

Preparation of the nasal mucosa prior to surgery

Cocaine solution (5% or 10%) or cocaine paste (25%) has been used to prepare the nose prior to surgery for more than 100 years. The majority of rhinologists believe it to be the most effective way of ensuring good operating conditions providing sufficient time for the drug to work is allowed. The application of Moffat's solution by a spray (Figure 28.1) is one method of preparing the nose and it is sensible to do this immediately after the induction of anaesthesia.

Figure 28.1 The application of Moffat's solution by a spray.

Moffat's solution consists of 2 mL of 5% cocaine, 1 mL of 1:1000 adrenaline and a small amount of bicarbonate solution. In order to avoid systemic effects, the maximum dose recommended for application to the nasal mucosa in fit adults is 1.5 mg/kg. The solution is dyed pink reducing the risk of it being mistaken for other drugs in the anaesthetic room.

Vestibulitis

Non-infective vestibulitis may be treated by applying vaseline or a mild topical corticosteroid to the vestibule. In the presence of infection an antibiotic ointment active against *Staphylococcus aureus* is required. A combination of chlorhexidine and neomycin (Naseptin) or mupirocin (Bactroban nasal) are available. The latter is used as a second-line agent for the eradication of methicillin-resistant *Staphylococcus aureus* (MRSA). The ointment is applied three times a day for 5 days and a swab is taken 2 days later to determine whether MRSA has been successfully eradicated. Naseptin includes arachis (peanut) oil and should not be used in patients with peanut allergy. Naseptin is contraindicated in pregnancy.

Hereditary familial telangiectasia

The epistaxis associated with hereditary familial telangiectasia (HFT) is difficult to treat and a variety of medical and surgical treatments have been tried. Systemic and topical oestrogen provoke squamous metaplasia of the epithelium and in this way provide a protective coat over the blood vessels. Ethinyloestradiol may be used under supervision for the treatment of HFT in women. The side effects include nausea, fluid retention and thrombosis. It is not popular in men because of the gynaecomastia it induces.

Atrophic rhinitis

Steam inhalation, humidification and saline nasal douching are useful in atrophic rhinitis. A 25% glucose in glycerine solution restores moisture to the nasal mucosa: 25 g of glucose is dissolved in 75 g glycerine (gently warmed). Once bottled the drops have a 3-month life span. The drops can be used several times a day and provide some relief to this distressing condition.

METHODS OF ADMINISTERING TOPICAL NASAL PREPARATIONS

If two nasal sprays are to be administered to each nostril, one spray should be directed upwards and the other backwards whilst the patient does not breathe or breathes in gently.

The best position for administering nasal drops is head-down, as in Figure 28.2.

Fluticasone propionate nasules (400 µg) can be used to increase the topical dose of steroid. One nasule is shared between each nostril once daily; thus the dose given is precisely known.

Figure 28.2 The best position for administering steroid drops.

BEST CLINICAL PRACTICE

- ✓ Topical steroids improve the symptoms associated with nasal polyps and reduce the recurrence rate of nasal polyps after surgery.
- ✓ The best position for administering steroid drops is head-down (Figure 28.2).
- ✓ One way of introducing cocaine into the nose is by spraying Moffat's solution into the nose immediately after induction of anaesthesia, increasing the chances of obtaining a 'bloodless surgical field'.
- ✓ Before prescribing naseptin, ensure the patient is not allergic to peanuts and is not pregnant.

FUTURE RESEARCH

- Topical steroids reduce the recurrence rate of nasal polyps following surgery but there is yet to be an effective long-lasting medical polypectomy.
- The optimum length of treatment with topical steroids is yet to be established with the different clinical scenarios.
- A large prospective study is required to determine the role of antibiotics in preventing acute complications.
- The aetiology of polyps is yet to be identified.

KEY POINTS

- Rhinosinusitis is one of the most common healthcare problems. It diminishes patients' quality of life and consumes resources.
- Corticosteroids are useful topically in post-viral ARS, CRSsNP and CRSwNP (in both adults and children). Oral steroids are useful in adults with CRSwNP.
- Antibiotics with oral corticosteroids in adults and topical corticosteroids in children are effective treatments for acute bacterial rhinosinusitis.
- Oral antibiotic therapy (<4 weeks) may be useful in CRS during exacerbations.
- Topical decongestants are a useful adjunct to analgesia and antihistamines in viral ARS in adults.
- Antihistamines reduce rhinorrhoea, sneezing and itching but not nasal obstruction and may be useful in patients with CRSwNP in allergic patients.
- Saline irrigation of the nose is an effective treatment for rhinosinusitis.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: antiplatelet, anticoagulant, antibiotic prophylaxis, and head and neck surgery. This chapter relied on the medicines listed in the *British National Formulary*.¹

INTRODUCTION

The laryngologist and head and neck surgeon prescribes medicines for prophylactic purposes, for example antibiotics and anticoagulants, as well as for therapeutic use in the management of infections, immune conditions and voice/throat problems. An appreciation of the pharmacology, preparations available, side effects and contraindications is required for appropriate and safe prescribing. This chapter addresses these matters.

ANTIPLATELET DRUGS

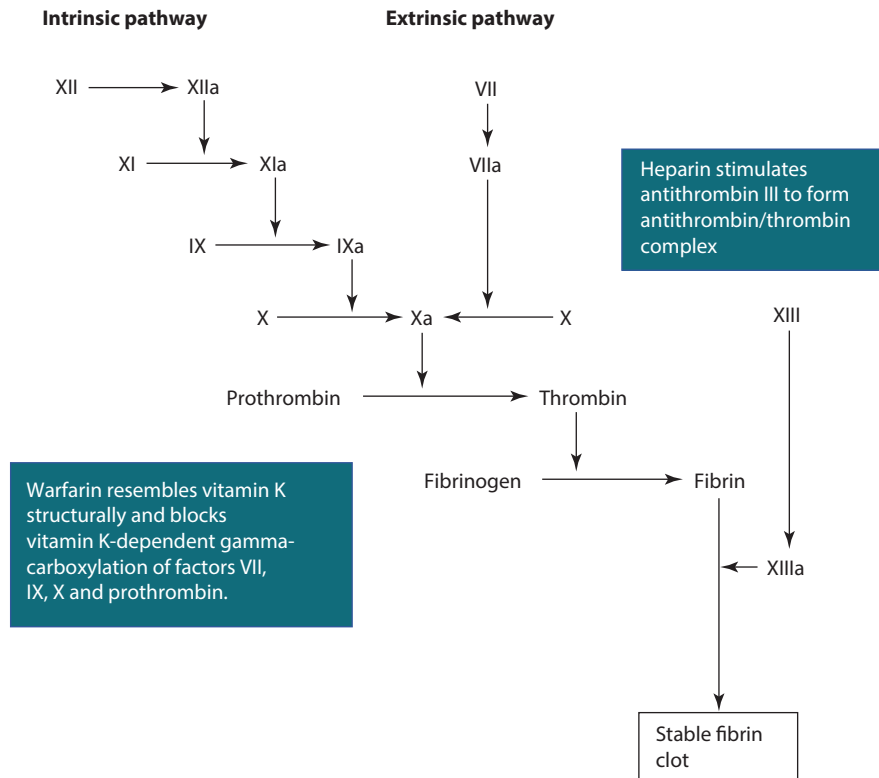

These reduce platelet aggregation and thereby thrombus formation in the arterial circulation where thrombi are primarily composed of platelets with little fibrin. Aspirin, clopidogrel and dipyridamole are often encountered in ENT patients with comorbidities to prevent atherosclerotic and thromboembolic events (see NICE guidelines²). The decision to stop these preparations prior to surgery is based on the balance of risk of bleeding versus the risk of thrombus formation. Sylvester and Coatesworth³ found that there is a significant morbidity and mortality

associated with early cessation of antiplatelet agents but evidence from cardiac surgery suggests that the operative blood loss is only marginally greater in patients on aspirin and clopidogrel. They, like others,⁴ suggest the management of these patients in the perioperative period should be made after multidisciplinary consultation.

ANTICOAGULANTS

The perioperative management of patients taking anticoagulants may be complex and should be considered on an individual patient basis, taking into account the increased risk of haemorrhagic complications in that procedure with the risk of thromboembolism if the anticoagulation therapy is stopped. Where necessary, involvement of the haematology/medical teams is advised.

The anticoagulant drugs heparin and warfarin are widely used in the prevention and treatment of venous thrombosis and embolism perioperatively. Anticoagulants should not be used where there is a history of haemorrhagic disorders, peptic ulcer disease, severe hypertension and severe liver disease. **Figure 29.1** illustrates the clotting pathway and the action of heparin and oral anticoagulants.

Heparin is a family of mucopolysaccharides with a molecular weight of 4000–30000. The molecules are attached to a protein backbone consisting entirely of serine and glycine residues. Heparin is found in mast cells, in plasma and in the endothelial cell layer of blood vessels. This highly acidic substance is extracted from beef lung or hog intestinal mucosa for therapeutic use. Heparin's main action is preventing fibrin formation by interacting with the protease inhibitor antithrombin III enhancing (by 1000-fold) the binding of antithrombin III with thrombin. In addition, the heparin–antithrombin III complex has inhibitory effects on factors IXa, Xa, XIa and XIIa.

Heparin is not absorbed from the gastrointestinal mucosa because of its charge and large molecular weight; therefore it must be given intravenously or by subcutaneous injection. Intramuscular injection is avoided to prevent haematoma formation. The onset of action of heparin is immediate and it has a half-life of 40–90 minutes. It is inactivated by heparinase in the liver and platelet factor IV released from activated platelets may also have a role.

When used for prophylaxis of deep vein thrombosis in surgery, 5000 units of heparin should be given 2 hours before surgery, then 8–12-hourly for 7 days or until the patient is ambulant. Monitoring is not required in this situation but when used to treat a thrombosis, a regime of 5000 units intravenously followed by 15–25 units/kg/hour intravenous infusion or 15 000 units 12-hourly necessitates monitoring of the thrombin time, which should be increased by a factor of 2 to 3.

Low molecular weight heparins (certoparin, dalteparin, enoxaparin, reviparin and tinzaparin) are also effective in the prophylaxis of venous thromboembolism and their

once daily subcutaneous administration is more convenient. These can also be used to treat deep vein thrombosis and monitoring is not required.

Platelet counts should be measured in patients receiving heparin since thrombocytopenia (an immune reaction) may occur but this does not usually happen until 6 to 10 days after the start of treatment. Should thrombocytopenia, or a 50% reduction of the platelet count occur, and further anticoagulation is required, patients should be given the heparinoid, danaparoid, or the hirudin, lepirudin.

Heparin inhibits aldosterone and may result in hyperkalaemia, especially in patients with diabetes mellitus, chronic renal failure, acidosis, raised plasma potassium or those taking potassium-sparing drugs.

The oral anticoagulants prevent the reduction of vitamin K that is required as an active cofactor of carboxylase in factors II, VII, IX and X. The effect on fibrin formation depends upon the balance between the decreased rate of carboxylation and the unaltered rate of degradation of factors already carboxylated. Warfarin has a half-life of 40 hours and a duration of action between 2 and 6 days. It takes at least 48–72 hours for the anticoagulant effect to develop fully and so heparin is also used initially when an immediate anticoagulant effect is required. Warfarin is the most commonly prescribed oral anticoagulant; nicoumalone and phenindione are rarely used. The drugs are metabolized by the mixed function oxidases in the liver.

Monitoring of the prothrombin time (usually reported as the international normalized ratio, INR) is required and dose adjustments made accordingly. Target INR values (usually between 2 and 4) are detailed in the

British National Formulary. The INR can be dramatically altered by coprescribing other medication and the reader is again directed to the British National Formulary¹ prior to coprescribing.

ANTIBIOTICS

Antibiotics are commonly prescribed prophylactically, even in so-called clean operations.^{5, 6} The use of antibiotics post-tonsillectomy has failed to show a reduction in the secondary haemorrhage rate but may reduce pain at day 5 post-operatively.^{7, 8} Where there is no violation of mucosa, no pre-operative inflammation and no drain, the incidence of wound infection in the head and neck is 2%. In surgery such as laryngectomy, prophylactic antibiotics with a broad spectrum are used to prevent wound infections. A pre-operative dose (given to allow a high tissue level at the time of surgery) and three post-operative doses of a cephalosporin and metronidazole are suitable. Violaris and Bridger, using a cephalosporin at 8 hours pre-operatively with the premedication and three doses 8-hourly post-operatively, reduced the development of pharyngocutaneous fistulae.⁹ Johansen et al.¹⁰ found prophylactic metronidazole resulted in a highly significant decrease in the frequency of post-operative fistulae.

Antibiotic prophylaxis is also necessary in patients with artificial heart valves or cardiac valve disease. Local policies may vary but amoxicillin 3g orally or 1g intramuscularly can be given 1 hour before surgery and 6 hours post-operatively.

The choice of antibiotic to treat an established infection is initially on a 'best guess' policy based on the probable pathogen until swab results and sensitivities become available.

PREPARATIONS USED TO IRRIGATE WOUNDS

Before closing a wound following tumour excision it has been recommended that it should first be washed out well. Stell and Maran¹¹ describe the use of Savlon, hydrogen peroxide and sterile water as suitable solutions since it appears that the mechanical process of washing rather than the lytic action on the cells is important. They recommend the use of at least 1L of solution. In a xenograft model of tumour-cell wound contamination, Allegretto et al.¹² found that irrigation with water, saline or gemcitabine delayed tumour development: the latter two improved rates of long-term disease control.

LOCAL ANAESTHETIC SPRAYS AND LOZENGES

These preparations are used to desensitize the mouth and pharynx prior to examination, investigation or treatment. Lidocaine (lignocaine) is effectively absorbed from mucous membranes and is available as a pump spray as a 10% solution (maximum dose is 20 sprays in pharynx, larynx

or trachea) and more commonly as a topical 4% solution (maximum dose is 7.5 mL). Benzocaine is a neutral, water-insoluble local anaesthetic of low potency and is only used for surface anaesthesia in non-inflamed tissue in the mouth and pharynx. It is available in lozenges and sprays, sometimes combined with antiseptics. Sensitization may occur and there is little evidence for the benefit in using these combined preparations. Patients should be advised not to eat or drink until the numbness has worn off. Lidocaine belongs to the amide class, benzocaine to the ester class of local anaesthetics. Both bind to a receptor on the sodium channel in the axon preventing the opening of the channels, thereby preventing depolarization of the nerve. In over dosage, cardiac toxicity can occur.

MOUTHWASHES

Mouthwashes are usually aqueous solutions in a concentrated form of substances with deodorant, antiseptic, local anaesthetic or astringent properties. Sometimes they should be diluted before use. They have a mechanical cleansing action. Hydrogen peroxide mouthwash is a 6% solution and 15 mL should be diluted in half a cup of warm water two to three times daily. It contains an oxidizing agent and is useful in the treatment of acute ulcerative gingivitis. It froths in contact with oral debris, thereby having a mechanical cleansing effect, hence its use in the management of secondary tonsillectomy haemorrhages. Chlorhexidine gluconate, used when tooth-brushing is not possible or in combating oral infection, inhibits plaque formation on teeth but has the side effect of causing reversible brown staining of the teeth. Since chlorhexidine gluconate can interact with some of the ingredients in toothpaste, a 30-minute interval is advised between using this mouthwash and toothpaste.¹

THROAT LOZENGES AND PASTILLES

Lozenges and pastilles are both used to deliver medications for local effect, either to soothe or treat infections. Lozenges consist of medicaments incorporated into a flavoured base that dissolves or disintegrates slowly in the mouth. They are prepared either by moulding and cutting or by compression. Colours, flavours and sweetening agents may be incorporated. Heavy compression is used to ensure slow disintegration in the mouth.

Pastilles consist of medicaments in a base containing gelatin and glycerol or a mixture of acacia and sucrose. Sodium benzoate and citric acid monohydrate may be used as a preservative and antioxidant, respectively. Flavourings such as lemon oil may be incorporated.

SOLUTIONS, SUSPENSIONS AND SYRUPS

Solutions are liquid preparations containing one or more soluble ingredients, usually dissolved in water. They may be used internally, externally or for instilling into body

cavities and may be sterile or unsterilized depending on the application. Solutions given orally usually result in rapid absorption. Problems with solubility, taste and stability may prevent this formulation being available for a particular drug.

Suspensions are formulations in which the drug does not dissolve in the solvent but is distributed within it. It usually provides a more rapid dispersion and dissolution of the drug when compared to tablets and capsules so long as the drug has a suitable particle size and does not settle or cake on storage. The primary particle size may grow due to the action of surfactants, emulsifiers and other adjuvants.

Syrups are concentrated aqueous solutions of sucrose or other sugars to which medicaments or flavourings are added. Glycerol, sorbitol and polyhydric alcohols may be added to reduce the rate of crystallization of sucrose and to increase the solubility of other ingredients. Growth of microorganisms is usually retarded by sucrose concentrations greater than 65% w/w.

TREATMENT OF DRY MOUTH

Artificial saliva can be useful to relieve dry mouth resulting from radiotherapy or diseases affecting the salivary glands. These preparations should be of neutral pH and contain electrolytes approximating to the composition of saliva. These preparations are available as oral sprays, lozenges and pastilles. Pilocarpine (Salagen) is a muscarinic and can stimulate any residual salivary gland function. Side effects relate to the muscarinic action and its use is contraindicated in those with significant respiratory and cardiovascular disease, angle-closure glaucoma, pregnancy and breastfeeding.

COUGH MEDICINES

These are divided into cough suppressants and the expectorant and demulcent cough preparations. After excluding an underlying cause of a cough, such as asthma and gastro-oesophageal reflux, cough suppressants may be used. It is thought that these drugs act by an ill-defined central action in the nervous system and may depress the 'cough centre' in the brain stem. The narcotic analgesics are effective as antitussives in subanalgesic doses. Codeine phosphate is useful for dry or painful coughs but it also inhibits the secretion and mucociliary clearance of sputum, is constipating and dependence can develop. Pholcodine (related to codeine) and dextromethorphan (a non-narcotic, nonanalgesic) have lesser side effects. Over the counter preparations include sedating antihistamines, such as diphenhydramine, and may work by causing drowsiness.

There is no evidence that expectorants (ammonium chloride, ipecacuanha and squill) are effective at promoting expulsion of bronchial secretions. Their action is more placebo. Demulcent cough preparations may relieve a dry irritating cough by virtue of the fact that they contain a

syrup or glycerol that has a soothing effect. Simple linctus (a sugar-free preparation is also available) is harmless and inexpensive.

MANAGEMENT OF STRIDOR

The treatment required depends upon the cause and severity of the stridor. Heliox is useful in an acute situation but antibiotics, adrenaline, steroids and antihistamines may be required, as may surgery.

Helium is a colourless, odourless, tasteless gas that when mixed, one volume of helium to two volumes of air, diffuses more rapidly than air itself. Breathing such a mixture requires less effort due to the lower density. An air-helium mixture or a mixture of 21 volumes of oxygen and 79 volumes of helium (Heliox) has been used in the management of stridor.

DRUG THERAPY IN ANGIONEUROTIC OEDEMA

Swelling of the face and lips, and occasionally of the larynx, occurs in angioneurotic oedema of allergic origin. Antihistamines and corticosteroids are prescribed and, if life-threatening, 1 mL/1 : 1000 adrenaline can be administered subcutaneously. The non-allergic type results from a serum deficiency of the C1 esterase inhibitor protein. An acute attack is treated with an intravenous injection of 1000 units of C1 esterase inhibitor protein (derived from human plasma). This can also be given prior to surgery for prophylaxis. Conestat alfa (contraindicated if allergic to rabbits) and icatibant are also licenced in treating acute attacks of hereditary angioedema in adults with C1 esterase inhibition.¹ Long-term prophylaxis is achieved with epsilon aminocaproic acid or its derivative tranexamic acid or with androgen methyltestosterone or its derivative danazol. These stimulate the production of C1 esterase inhibitor protein.

USE OF BOTULINUM TOXINS IN SPASMODIC DYSTOMIA

Botulinum is available as botulinum A toxin-haemagglutinin complex (Botox, Dysport) and botulinum B toxin (NeuroBloc). The dosage is specific to each individual preparation and therefore the product literature must be consulted prior to use. In laryngeal dystonia, localization of the involved muscles and confirmation of correct needle position can be achieved by electromyographic guidance. The effect of botulinum toxin is observed within a few days. Patients may initially have worsening of their voice, dysphagia with the potential for aspiration and occasionally airway compromise. Improvement is seen 2 weeks post-injections and the effects of treatment may last for 3 to 6 months.

Botulinum toxin is contraindicated in patients known to be hypersensitive to ingredients, bleeding disorders,

pregnancy and lactation, concurrent or potential aminoglycoside or spectinomycin administration (neuromuscular blockade is enhanced). It should not be used in patients with generalized muscle disorders such as myasthenia gravis. No information is available on its use in patients with renal or hepatic impairment. Adrenaline should be available in case anaphylaxis occurs.

COLLAGEN INJECTION OF PARALYZED VOCAL CORDS

As a result of Teflon injection being unavailable in the UK, collagen (Contigen) is now used to medialize paralyzed vocal cords. It is a purified bovine dermal glutaraldehyde cross-linked collagen and has been used in genuine stress incontinence. A skin test (0.1 mL collagen and lignocaine, injected intra-dermally into the volar surface of the forearm) should be carried out 4 weeks prior to the treatment. Many patients requiring this treatment have a short life expectancy and so a compromise with the skin test performed only a week prior to vocal cord injection is practised. A positive response is defined as erythema, induration, tenderness or swelling with or without purities, persisting for more than 6 hours or first appearing more than 24 hours after the injection.

The use of collagen injection is contraindicated in patients hypersensitive to the ingredients, with a positive skin test, in pregnancy and lactation and in patients with autoimmune disease or a history of multiple severe allergies.

DRUGS USED IN THYROID DISEASE INCLUDING THE MANAGEMENT OF HYPOCALCAEMIA

Thyroid hormones

The two preparations levothyroxine sodium/thyroxine sodium (Eltroxin) and liothyronine sodium (Tertroxin) are available for use in the management of hypothyroidism, diffuse non-toxic goitre, Hashimoto's thyroiditis and thyroid carcinoma. Levothyroxine sodium (thyroxine sodium) is used for maintenance therapy, usually as a single dose before breakfast. The initial dose is 50–100 µg daily increasing at 2- to 3-week intervals by 25–50 µg increments until normal metabolism is obtained. In the elderly, patients with cardiac insufficiency or severe hypothyroidism, the initial dose is 25 µg, increased by 25 µg every 4 weeks until normal metabolism is achieved. The usual maintenance dose is 100–200 µg, the higher dose is used to suppress T4 in thyroid carcinoma.

Liothyronine has a shorter half-life with a more rapid onset of action and shorter duration of action. Twenty micrograms of liothyronine is equivalent to 100 µg of thyroxine sodium. It can also be given intravenously. A pre-therapy ECG should be performed since hypothyroidism can produce changes resembling ischaemia. The starting dose is 10–20 µg every 8 hours. The usual maintenance

dose is 60 µg daily in three divided doses. Sometimes it is coadministered with carbimazole to treat thyrotoxicosis. It may be used in severe hypothyroid states when a rapid response is required and is used in patients awaiting radioactive iodine scan following thyroid surgery. The latter enables patients to remain euthyroid in this interval period and patients need to stop liothyronine only 2 days prior to the scan.

These thyroid hormones must be used with caution in patients with hypertension, diabetes mellitus and insipidus, cardiovascular disorders, angina, the elderly, lactation, pregnancy (especially the first trimester) and in adrenal insufficiency. Interactions include sucralfate, phenylbutazone, warfarin, carbamazepine, phenytoin, rifampicin, barbiturates and propranolol. The side effects of arrhythmias, insomnia, tremor, palpitations, sweating, weight loss, thyroid crisis, vomiting, diarrhoea and headache have been reported.

Drugs used in hyperthyroidism

Antithyroid drugs are used for hyperthyroidism either pre-operatively or for long-term management. Carbimazole (Neo-Mercazole) is the most commonly used in the UK; propyluracil is used in patients sensitive to carbimazole. Both are thionamides containing a thiocarbamide group (S=C–N) that is essential for their activity. Carbimazole is rapidly converted to methimazole *in vivo*. Methimazole is available in the USA. Thioamides prevent the synthesis of thyroid hormones by competitive inhibition of I⁻ to I² by peroxidase and also block the coupling of the iodotyrosine, especially in forming diiodothyronine. More controversial is the possibility that the thionamides have immunosuppressive properties. These drugs are administered orally and accumulate within the thyroid gland. Their delayed onset of action of 3 to 4 weeks results from the need of preformed hormones to be depleted first.

The main concern with thionamides is the development of neutropenia and agranulocytosis. Carbimazole has an incidence of causing agranulocytosis in 0.1% of patients; propylthiouracil has an incidence of four times this (explaining the preference for carbimazole in the UK).

The Committee on Safety of Medicines recommends that:

- patients should be asked to report symptoms and signs suggestive of infection, especially sore throat
- a white blood count should be performed if there is any clinical evidence of infection
- the drug should be stopped promptly if there is clinical or laboratory evidence of neutropenia.

Iodine is used as an adjunct to antithyroid drugs in the pre-operative management of thyrotoxicosis. An aqueous iodine oral solution (Lugol's solution) is given at a dose of 0.1–0.3 mL three times a day, taken well diluted with water or milk. Patients may develop flu-like symptoms, headache, rashes, insomnia, lacrimation, conjunctivitis, laryngitis and bronchitis. It must be used with caution in pregnancy and be avoided in lactation.

Drugs used in hypocalcaemia

Following thyroid or parathyroid surgery, patients may develop hypoparathyroidism either temporarily or permanently. Parathormone (PTH) is the most important regulator of the extracellular calcium concentration. Hypocalcaemic tetany is first managed by an initial intravenous injection of 10 mL 10% calcium gluconate followed by a continuous infusion of 40 mL daily or oral calcium with careful monitoring of the plasma calcium concentration. Bradycardia, arrhythmias and irritation after intravenous injection may occur as can gastrointestinal disturbances after oral administration. Failure to obtain and maintain a corrected calcium concentration within the normal range with calcium supplements alone necessitates the additional administration of a vitamin D preparation. **Figure 29.2** demonstrates the control of calcium plasma concentration by vitamin D. Vitamin D is a prohormone, metabolized to hormones that increase intestinal absorption of calcium, mobilize calcium from bone and inhibit renal excretion. The hypocalcaemia of hypoparathyroidism often requires doses of up to 2.5 mg (1 000 000 units) calciferol daily. Calcifediol is the main derivative of liver hydroxylation and this is further hydroxylated in the kidney to the potent calcitriol. The latter step is regulated by PTH. A synthetic derivative of vitamin D commonly prescribed in hypoparathyroidism is alfacalcidol.

TREATMENT OF REFLUX OESOPHAGITIS AND LARYNGOPHARYNGEAL REFLUX

Initial treatment depends on the severity of the symptoms and treatment response. Changes to lifestyle (avoid excess alcohol and fatty foods), weight reduction, stopping smoking and raising the head of the bed may be advised. Antacids and alginates alone may be used for mild symptoms. The alginates are said to form a raft on the surface of the stomach's contents to reduce reflux and protect the oesophageal mucosa. McGlashan et al. in a prospective randomized controlled trial demonstrated a significant improvement in symptom scores and clinical findings with liquid alginate suspension compared to the control group in patients with laryngopharyngeal reflux.¹³

Histamine H₂ receptor antagonists (cimetidine, famotidine, nizatidine and ranitidine) block the action of histamine on the parietal cells and reduce acid secretion. They should be used with caution in patients with liver or renal disease, in pregnancy and breastfeeding. Side effects include diarrhoea, altered liver function tests, rashes and, more rarely, hypersensitivity reactions, AV block and blood dyscrasias. Cimetidine has been reported to cause gynaecomastia and it binds to cytochrome P-450 reducing the hepatic metabolism of drugs such as warfarin.

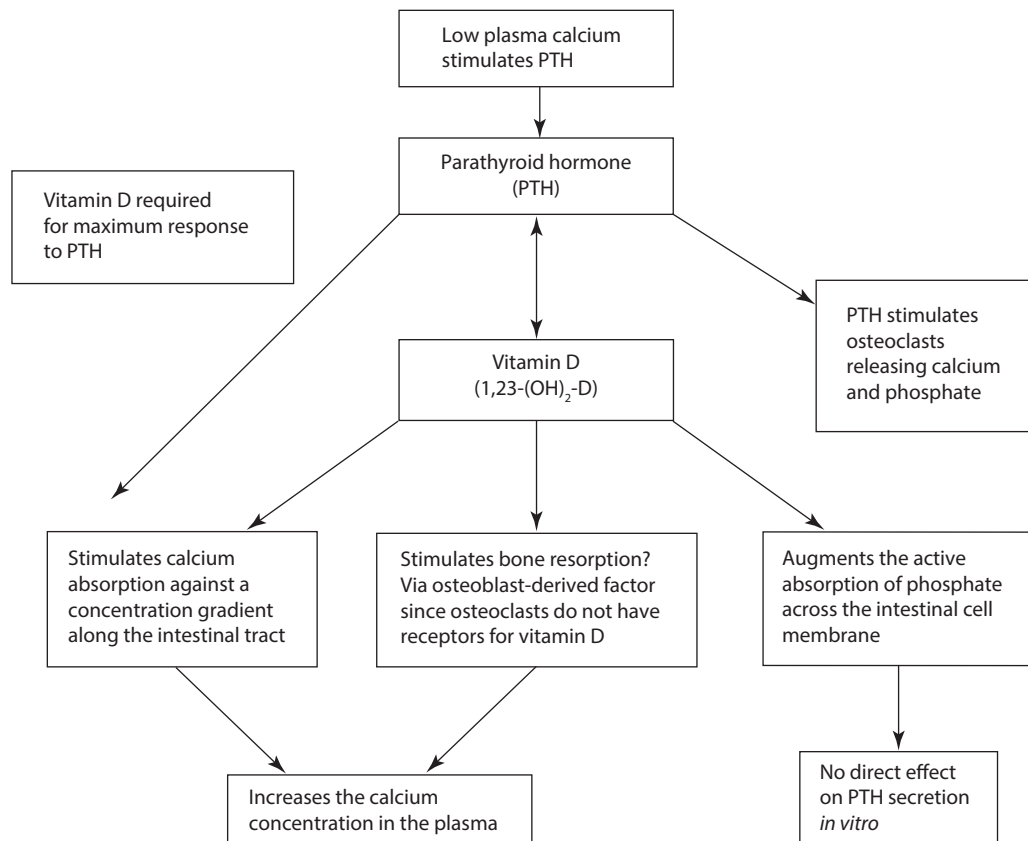

Figure 29.2 Calcium homeostasis and the role of Vitamin D.

The proton pump inhibitors (omeprazole, esomeprazole, lansoprazole, pantoprazole and rabeprazole sodium) react with sulphhydryl groups in the H⁺/K⁺ ATPase (proton pump) responsible for the transportation of H⁺ ions out of the parietal cells. Although their use is well established in the treatment of reflux oesophagitis, their use in laryngopharyngeal reflux is based on poor levels of evidence from uncontrolled studies. The few randomized controlled trials failed to show any benefit over placebo in this condition.¹⁴

CHEMOTHERAPEUTIC AGENTS

These drugs are used either alone or in combination with surgery and/or radiotherapy with the aim to cure or palliate a cancer. They inhibit the mechanisms of cell proliferation and rely upon malignant tumours having a greater proportion of cells undergoing division than in normal

proliferating cells, especially in the bone marrow, gastrointestinal mucosa and in hair follicles. Chemotherapeutic agents are classified with respect to their site of action, as demonstrated in **Figure 29.3**.

Alkylating agents (mustine, cyclophosphamide, chlorambucil, cisplatin and busulphan) cross-link the two strands of the double helix of DNA. The antibiotics actinomycin D, doxorubicin, mitomycin, mithramycin and bleomycin interact with the DNA preventing RNA production. DNA synthesis is prevented by a group of antimetabolites (methotrexate, fluorouracil, mercaptopurine and thioguanine) that prevent purine or pyrimidine synthesis. The vinca alkaloids (vincristine and vinblastine) bind to the microtubular proteins inhibiting mitosis. Glucocorticoids are included in regimes since they inhibit cell division by interfering with DNA synthesis.

Side effects such as nausea and vomiting, intestinal ulceration, diarrhoea, alopecia and bone marrow suppression are common but may become life-threatening.

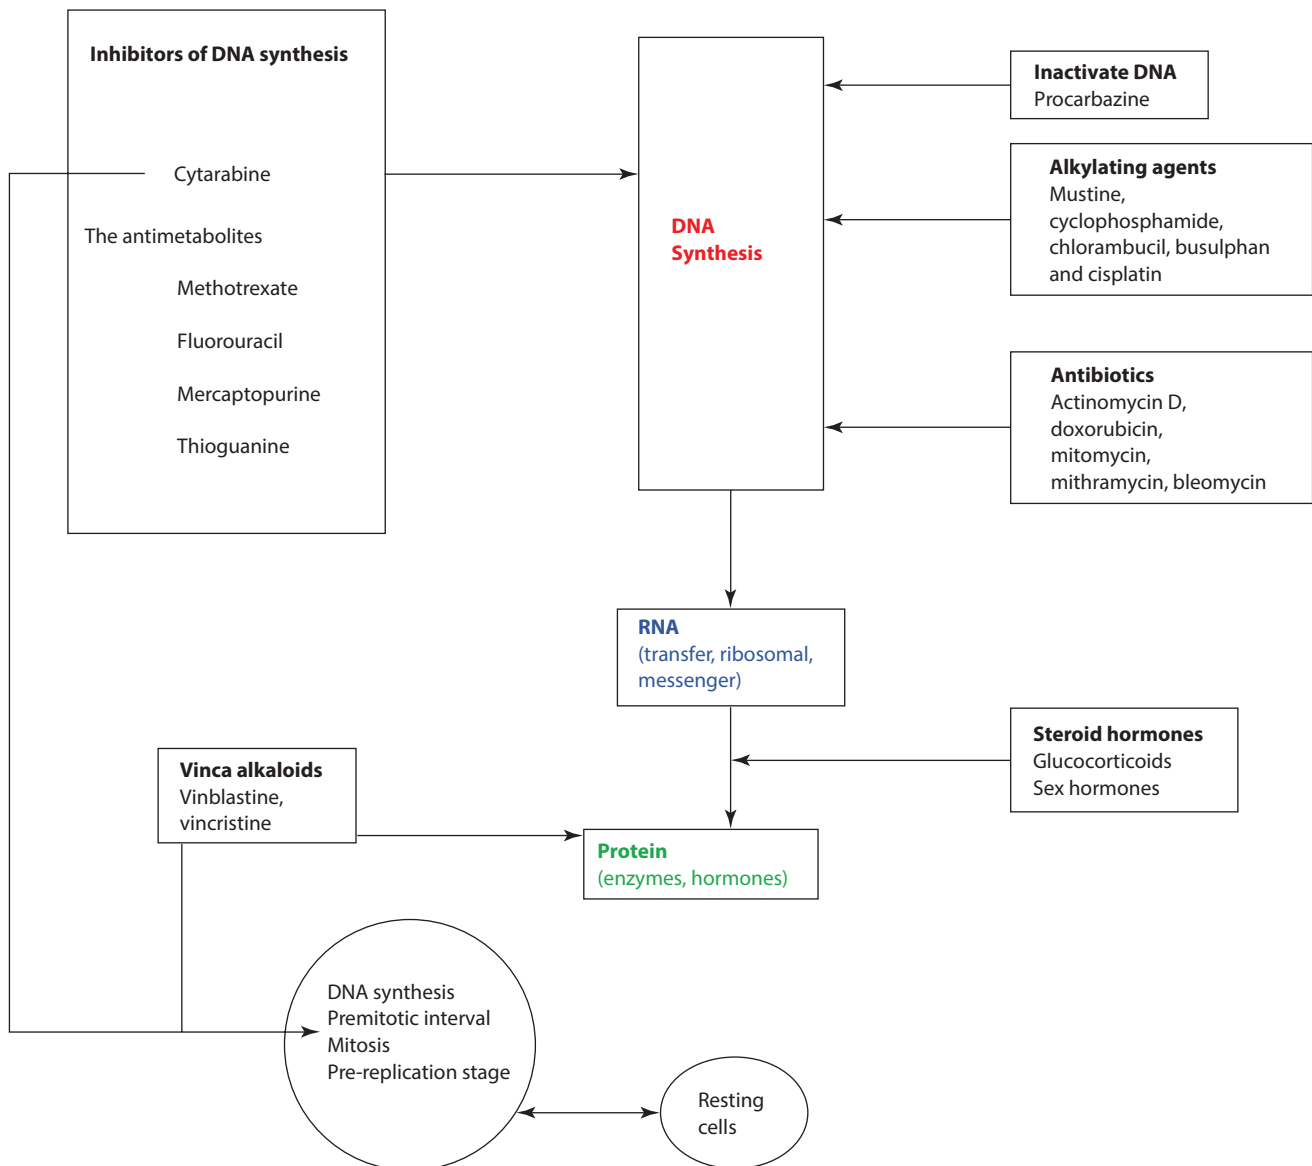

Figure 29.3 Site of action of chemotherapy.

MANAGEMENT OF FUNGATING WOUNDS

Charcoal dressings have been used to help combat malodorous fungating tumours. When this fails, topical metronidazole gel (Anabact or Metrotop) can be applied to

the cleaned wound once or twice a day and covered with a non-adherent dressing. The metronidazole has antimicrobial activity against the anaerobes likely to be responsible for the odour.

Alginate dressings may stop bleeding from fungating wounds and, if moistened prior to a dressing change, the risk of bleeding at this time can be reduced.

BEST CLINICAL PRACTICE

- ✓ The starting or stopping of antiplatelet drugs and anticoagulants should be in accordance with guidance from the haematologist and medical colleagues, taking into account other prescribed medications that may interact.
- ✓ Platelet counts should be monitored in patients on heparin to detect any thrombocytopenia.
- ✓ Cefuroxime and metronidazole should be given at induction and for at least three post-operative doses in head and neck procedures where the mucosa is breached.
- ✓ Heliox is easier to breathe than air and buys useful time in patients with stridor; however, it is important to take additional steps to treat the underlying cause and to secure the airway.
- ✓ First-line treatment of angioneurotic oedema consists of intravenous antihistamines and steroids with nebulized or subcutaneous adrenaline but C1 esterase inhibitor protein is the first-line treatment of hereditary angioedema.
- ✓ In order to avoid severe hypersensitivity reactions, pre-operative test injections of collagen are necessary where this is used to perform vocal cord medialization.

KEY POINTS

- Perioperative antibiotics have not been shown to reduce bleeding rates after tonsillectomy but may reduce pain.
- The use of perioperative cephalosporins and metronidazole reduce the rates of fistula formation in head and neck operations.
- Pilocarpine (used in the treatment of dry mouth) is contraindicated in patients with significant respiratory/cardiovascular disease, glaucoma, pregnancy or breastfeeding.
- Rarely, carbimazole can cause agranulocytosis.
- Botulinum is available as botulinum A toxin–haemagglutinin complex and botulinum B toxin. It is important to realize that the dosage is specific to each preparation.

Consideration of venous thromboembolism (VTE) prophylaxis	305	References	308

SEARCH STRATEGY

This included recent publications in scientific journals, from professional bodies and the UK Department of Health. Data may be updated using keywords such as consent, enhanced recovery, suitability for day surgery, pre-operative assessment, pain, anti-coagulation, pre-operative preparation and venous thromboembolism prevention.

PATIENT PATHWAY

The patient pathway describes the 'route' taken by a patient from initial referral to regaining health. A pathway includes processes and documentation, and should be amenable to audit and external review. Generally, the surgeon makes a broad judgement at the time of seeing the patient as to whether or not the patient is fit for surgery. The in-hospital segment of the pathway begins here and, within the confines of a busy clinic, the patient requiring surgery should be placed into one of five routes:

- day surgery
- inpatient, scheduled admission within a few weeks
- inpatient, elective surgery, fit patient
- planned inpatient but requiring prior medical/anaesthetic review
- immediate admission.

Suitability for day surgery

There are guidelines¹ about which patients are suitable for day surgery in a particular hospital. There are three main criteria for the selection of patients as being suitable for same day surgery: social, medical and surgical.

Social factors

- The patient must understand the planned procedure, post-operative care and have consented to day surgery.
- Following most procedures under general anaesthesia, a responsible adult should escort the patient home and provide support for the first 24 hours.
- The patient's domestic circumstances should be appropriate for post-operative care.

Medical factors

- Fitness for a procedure should relate to the patient's health as determined at pre-operative assessment and not be limited by arbitrary limits such as ASA status ([Table 30.1](#)), age or body mass index (BMI).
- Patients with stable chronic disease such as diabetes, asthma or epilepsy are often better managed as day cases because of minimal disruption to their daily routine.
- Obesity per se is not a contraindication to day surgery as even morbidly obese patients can be safely managed in expert hands, with appropriate resources. The incidence of complications during the operation or in the early recovery phase increases with increasing BMI. However, these problems would still occur with

TABLE 30.1 Physical status grading of American Society of Anesthesiologists

Grade	Physical status
Grade 1	Normal healthy patient without any clinically important comorbidity
Grade 2	Patient with a mild systemic disease
Grade 3	Patient with one (or more) severe systemic disease which does not present a constant threat to life
Grade 4	Patient with systemic disease processes which present a constant threat to life
Grade 5	Patient not expected to survive more than 24 hours

inpatient care and have usually resolved or been successfully treated by the time a day case patient would be discharged. In addition, obese patients benefit from the short-duration anaesthetic techniques and early mobilization associated with day surgery.

Surgical factors

- The procedure should not carry a significant risk of serious complications requiring immediate medical attention (e.g. haemorrhage, cardiovascular instability).

Pre-operative assessment is an essential part of peri-operative management in order to determine primarily if the patient is a suitable patient for day surgery. It is part of the UK governmental strategy to have 75% of all elective surgical cases carried out as day case surgery as it confers significant cost savings. The NHS Institute for Innovation and Improvement, Delivering for Health¹ suggests a fundamental shift in patient and NHS culture so that day surgery is regarded as the norm for elective surgery. Expansion of day surgery as an anaesthetic speciality in its own right and interest therein has grown vastly in recent times.

The following statements are from the consensus document¹ produced by expert members of a working party established by the Association of Anaesthetists of Great Britain and Ireland (AAGBI) and British Association of Day Surgery (BADS):

- Day surgery is a continually evolving speciality performed in a range of ways across different units.
- In recent years, the complexity of procedures has increased with a wider range of patients now considered suitable for day surgery.
- Effective pre-operative preparation and protocol-driven, nurse-led discharge are fundamental to safe and effective day and short stay surgery.
- Patients presenting with acute conditions requiring urgent surgery can be efficiently and effectively treated as day cases via a semi-elective pathway.
- Central neuraxial blockade and a range of regional anaesthetic techniques, including brachial plexus and paravertebral blocks, can be used effectively for day surgery.

- Each anaesthetist should develop techniques that permit the patient to undergo the surgical procedure with minimum stress and maximum comfort, and optimize his/her chance of early discharge.
- Every day surgery unit must have a clinical lead with specific interest in day surgery and whose remit includes the development of local policies, guidelines and clinical governance.
- Good quality advice leaflets, assessment forms and protocols are in use in many centres and are available to other units.
- Effective audit is an essential component of good care in all aspects of day and short stay surgery.
- Enhanced recovery is based on established day surgery principles and is aimed at improving the quality of recovery after inpatient surgery such that the patient is well enough to go home earlier and healthier.

PRE-OPERATIVE ASSESSMENT

Pre-operative assessment is often carried out by specialist nursing staff in the outpatient setting using pre-agreed screening forms. Significant issues detected are referred to an anaesthetist who can make recommendations for optimization or review the patient in a pre-admission clinic. The anaesthetic assessment includes review of:

- patient and family history of anaesthetic and/or surgical problems
- cardiorespiratory system including blood pressure measurement
- significant other medical conditions
- coagulation disorders (i.e. bleeding tendency or thromboembolic risk)
- assessment of difficulty with airway management or presence of airway aspiration risk
- likelihood of post-operative nausea and/or vomiting (PONV)
- difficulties with pain control
- medications, allergies, weight
- smoking, alcohol and illicit drug use
- home/family circumstances for post-operative discharge.

Cardiovascular disease

The pattern of presentation of cardiovascular disease and recommendations for assessment has changed markedly over the last 20 years with the advent of earlier detection and better management of these conditions.

In pre-operative assessment, the main considerations are as follows.

DETECTING PREVIOUSLY UNDIAGNOSED DISEASE BY MEANS OF CAREFUL HISTORY-TAKING AND RELEVANT INVESTIGATIONS

If a patient can manage two flights of stairs then this is a good indicator of cardiac ability and is generally used as an assessment of functional capacity. Investigations for a

patient with moderate or severe dyspnoea on mild exertion or at rest may include chest X-ray and echocardiography. As a screening test for left ventricular dysfunction a normal ECG corresponds with around a 95% chance of having a normal echocardiogram.² All patients should get blood pressure recorded. Uncontrolled hypertension should be controlled before elective surgery. ECG (electrocardiogram) is undertaken for selected patients (see preoperative investigations below). Note that dysrhythmias are uncommon but can be detected by examination or ECG.

ASSESSMENT OF EXISTING CARDIOVASCULAR DISEASE

Deteriorating pathology, exhibited by increasing symptoms (e.g. worsening angina) or decreasing exercise capacity, are indications for further investigation and management. Heart failure may present with limited exercise tolerance, dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea and ankle oedema. Echocardiography will demonstrate size of chambers, wall thickness, wall motion, valve function and allow an estimate of ejection fraction.

MANAGEMENT OF SPECIFIC CONCERNS

Antiplatelet therapy for coronary stenting

There is considerable variation regarding the use of aspirin in the perioperative period. In a recent study, it had no impact on myocardial infarction or pulmonary embolus but was associated with an increase in bleeding.³ There is still uncertainty regarding definitive treatment and large trials are necessary to determine optimal management.⁴ In patients with coronary arterial stents the situation is complex and advice should be sought from a cardiologist.

There is considerable variation in risk for transient ischaemic attack and stroke in atrial fibrillation ranging between 1% and 18% depending on risk factors.⁵

Discontinuation of aspirin or other thrombo-prophylactic therapy is calculated on the individual risk benefit ratio for the patient (i.e. the risk of bleeding vs the time of discontinuation of therapy). Aspirin is usually discontinued 5 to 7 days before an operation as it affects platelet function irreversibly. Patients who are on warfarin usually need inpatient management with discontinuation approximately 3 days prior to surgery and use of either low molecular weight heparin or an intravenous heparin infusion. Direct thrombin inhibitors such as dabigatran should be managed in a similar way as warfarin. These drugs are however of greater concern in emergency surgery as no reversal agent is currently available.

Cardiac medications

Cardiac medications may need to be considered perioperatively and the anaesthetist will usually advise on this.

Pacemakers

Pacemakers should be checked for correct functioning, preferably by a pacemaker clinic, and implantable defibrillators should be turned off immediately before surgery

and on again post-operatively. Patients with valvular disease, prosthetic valves or cardiomyopathy are at risk of bacterial endocarditis and should receive antibiotic prophylaxis at surgery.

Review by a cardiologist may sometimes be required pre-operatively to review patients with new onset, severe or increasing frequency angina. The cardiologist may arrange additional testing (e.g. exercise stress testing or coronary angiography) and optimize cardiac medication.

Risk indices⁶ have been developed over the years and, generally, coronary artery disease, heart failure, cerebrovascular disease, elevated creatinine, insulin-dependent diabetes and high-risk surgery have all been associated with increased perioperative cardiac morbidity. Age is another risk factor⁷ with the overall 30-day mortality associated with surgery and anaesthesia rising from 2.2% (age 60–69 years) to 8.4% (age >90 years).

Respiratory disease

Common conditions are chronic bronchitis, emphysema, chronic obstructive airways disease and asthma. Generally, a patient with known, mild, stable disease under review by the GP or respiratory department will not need special pre-operative assessment. Accurate assessment of disease severity is important. In the absence of clinical signs, chest X-ray is generally unhelpful. Asthmatic patients often know their normal peak flow measurement and this is a simple test to carry out. An assessment of functional exercise capacity, clinical examination and pulse oximetry are generally more helpful than pulmonary function tests. A respiratory physician and/or anaesthetic review should be sought for patients with severe respiratory disease. All patients should be advised to stop smoking.

Acute respiratory tract infection is an indication for postponement of elective surgery until resolution because of an increased risk of intra-operative bronchospasm and post-operative chest infection.

PRE-OPERATIVE INVESTIGATIONS

The National Institute for Clinical Excellence (NICE)⁸ produced recommendations for the use of routine preoperative tests for elective surgery which were updated in April 2016. Specific recommendations are made according to grade of surgery (minor, intermediate, major, complex), ASA status, presence of diabetes, obesity, cardiovascular, respiratory or renal comorbidities and consideration of existing medication (NG45). Pre-operative tests may be ordered on a selective basis for purposes of guiding or optimizing perioperative management, but should not be ordered routinely. The Association of Anaesthetists of Great Britain and Ireland⁹ states that ‘blanket routine preoperative investigations are inefficient, expensive and unnecessary’.

Written guidelines are, therefore, hospital or department-based and should be discussed during induction of new department members. Reasonable guidelines

for pre-operative tests in adult patients undergoing head and neck surgery are:

- dipstick urinalysis
- haemoglobin in all females, males aged over 40 years and any patient in whom blood grouping will be undertaken
- urea and electrolytes in all patients over 40 years or when indicated by disease process or medication
- clotting studies when indicated by history
- sickle cell testing in all patients of African or Afro-Caribbean origin
- pregnancy testing when pregnancy is possible
- blood grouping (group and save) in patients with a normal pre-operative haemoglobin and an anticipated blood loss of 10–15% blood volume (blood volume 70 mL/kg in adult), and all patients who have had a previous blood transfusion in case of the presence of antibodies
- blood grouping and cross-matching in all patients with an expected blood loss in excess of 15% blood volume (> 750 mL in the average adult) or at significant risk of sudden severe haemorrhage. The number of blood units requested for a particular surgical procedure should follow written guidelines drawn up in consultation with the hospital transfusion committee
- electrocardiography (ECG) in any patient with cardiovascular disease or in asymptomatic patients aged over 60 years.

Audiometry should be undertaken on all patients undergoing surgery on the middle ear, and vocal cord function visualized when surgery might damage the recurrent laryngeal nerve.

Failure of the initial broad screening will direct the patient into the wrong pathway and may lead to substantial delays or frustration and patient harm. It is the pathway of medical/anaesthetic review prior to surgery that is particularly testing since it involves initial detection of problem patients, sending them for review, initiating treatment as required and waiting for optimal response before admission for surgery. It is clear that perioperative mortality is reduced by pre-operative optimization, particularly of cardiac and respiratory disease.¹⁰

OBTAINING PATIENT CONSENT FOR PLANNED SURGERY

Currently, in the UK, the process of obtaining informed consent for planned surgery is carried out by a member of the surgical team and, ideally, by the surgeon who will be performing the operation. In taking consent, it is important that full information is provided to the patient including indications for the proposed treatment including its implications and significant as well as common risks. Some ENT departments (e.g. Cambridge University Hospital) have consent forms for specific surgeries (e.g. tonsillectomy, tympanoplasty), which detail surgical risks relevant to the specific operations.¹¹ The process of consent should

be seen as a stimulus for active discussion with patients about treatment options and decision-making following that discussion. ENT UK have produced 22 patient information leaflets which cover some common operations but also conditions.

Patients who have consented to surgery are considered to have implied consent to anaesthesia as specific written consent for anaesthesia is not required in the UK. However, as anaesthesia is associated with its own specific risks that are quite distinct and separate from those associated with the surgery, anaesthetists are advised to obtain specific consent for anaesthesia.¹² Ideally, each patient should receive a general leaflet about anaesthesia in the outpatient clinic.¹³ This allows the patient time to consider relevant anaesthetic issues. Discussion between the anaesthetist and patient should include:

- previous medical/surgical/anaesthetic history including problems (e.g. latex allergy, anaphylaxis, difficult or failed intubation, pulmonary aspiration, post-operative nausea or vomiting, awareness, suxamethonium apnoea, malignant hyperpyrexia or unexpected admission to a high dependency or intensive care unit)
- likely difficulties in provision of anaesthesia for the planned surgery (e.g. possibility of fiberoptic tracheal intubation/tracheostomy under local anaesthesia/alternative method of securing the airway)
- local anaesthesia options (either as an adjunct to analgesia or as an alternative to general anaesthesia)
- general conduct of general anaesthesia to include fasting advice, pre-medication, administration of intravenous fluids, blood transfusion, pain relief, control of nausea/vomiting, urinary catheterization, nasogastric tube insertion, placement of arterial and central venous lines
- immediate recovery period and post-operative destination (e.g. HDU/ITU/ward/day case discharge)
- complications related to anaesthesia (e.g. dental damage, cardiovascular complications).

Patient anxieties in relation to anaesthesia are predominantly around the issues of death, brain damage, intra-operative awareness, loss of control, memory loss, pain control, nausea or vomiting and needle insertion.¹⁴ Deaths caused by anaesthesia are very rare. A collection of 14 articles about specific risks associated with having an anaesthetic has been developed to be used with the patient information leaflets. The risk articles are available on the website www.rcoa.ac.uk/patientinfo

In the UK, the pre-operative anaesthetic visit often occurs only minutes before planned surgery. Ideally, all patients should be seen in an outpatient anaesthetic clinic before surgery. This gives time for proper pre-operative assessment, pre-operative preparation and discussion of anaesthetic options and this is what UK services should strive for as it allows for better patient satisfaction, same day admissions (therefore better use of resources) and a smaller likelihood of short notice cancellation due to poor patient preparation.

Patients should have adequate time to consider the indications and implications of any potential operation.¹⁵ The process of informed consent for surgery is a continuous process and rushing a patient to give consent has ethical as well as medico-legal consequences. The UK General Medical Council (GMC) code of Good Medical Practice was updated in 2008 and comprehensively covers consent issues.¹⁶ Ideally, consent for elective procedures should be taken well in advance of the proposed surgery (e.g. at a pre-assessment clinic). This gives the patient time to assimilate the information, discuss with family members if they wish and make appropriate choices. There have been successful cases of litigation when consent has been taken on the day of surgery.¹⁷

There is a specific consent form in the UK both for parents consenting for children and for those adults that are unable to consent (incapacity form). For those adults that lack capacity, the clinician has to record on this form how they have come to the conclusion that the patient lacks capacity to make this particular healthcare decision and why the proposed treatment would be in the patient's best interests.

Acute pain management plans

Acute pain management plans are made after discussion with the patient in the pre-operative period. Modifications to the WHO analgesic ladder¹⁸ may be useful when considering prescribing post-operative analgesia for patients. Some patients may already be on analgesics pre-operatively. Those patients who are on larger doses of opioids pre-operatively will require larger amounts of analgesia intra- and post-operatively to treat pain. Early liaison with the acute pain team should be made for patients in whom acute pain is anticipated to be difficult to manage.

Simple analgesics include paracetamol and ibuprofen/diclofenac. The vast majority of patients undergoing surgery will receive some intravenous opioid intra-operatively (e.g. fentanyl, alfentanil or morphine). Some patients may require continuing opioids (e.g. codeine or morphine) for a period post-operatively. Tramadol is another analgesic that may be considered.

Drugs should be given orally as far as possible. If they cannot be taken orally then other routes to be considered include sublingual, parenteral (including patient controlled analgesia (PCA)), rectal suppository, nasogastric/percutaneous endoscopic gastrostomy (PEG)/radiologically inserted gastrostomy (RIG) tube and transdermal patch. It is important to know doses, duration of action, contraindications and side effects of analgesics prescribed. The British National Formulary can be a useful guide if there are no local prescription procedures in place.

The correct dose of analgesic for the individual patient should be given at regular intervals to achieve adequate pain relief with minimal side effects and titrated according to pain intensity using regularly measured pain severity scores. It is important to ensure that the patient understands and is involved in their pain management.

As part of multi-modal analgesic delivery, surgeons can infiltrate wound sites with chirocaine (Levo-Bupivacaine)

0.5% (maximum dose 2 mg/kg) at the end of surgery. Elastomeric pumps that can deliver local anaesthetic infusions into wounds are also used particularly in free tissue transfer surgery. By providing a continuous infusion, the pumps have the potential to provide continuous analgesia, eliminating the peaks and troughs in analgesic effect that occur with intermittent local or systemic analgesics. Unlike simple incisional infiltration with local anaesthetics, evidence for the efficacy of local anaesthetic wound catheters is abundant.¹⁹ In a recent systematic review²⁰ it was concluded that continuous local anaesthetic wound infiltration resulted in a consistently reduced requirement for post-operative opioids, a subsequent reduction in post-operative nausea and vomiting, quicker return to normal bodily function and ambulation and a reduced length of hospital stay, especially in cardiothoracic and orthopaedic populations. Despite the cost of the equipment, the reduction in complications may lead to overall cost savings.

Local anaesthetic infiltration and infusions have recently been incorporated into enhanced recovery programmes.

CONSIDERATION OF VENOUS THROMBOEMBOLISM (VTE) PROPHYLAXIS

VTE is a recognized complication in hospital inpatients. It is associated with significant morbidity and mortality hence the importance in assessment and regular reassessment in patients with a view to the need for anticoagulation. Approximately 25 000 patients in England die each year from preventable hospital acquired VTE.²¹ The cost of treating non-fatal symptomatic VTE and associated long-term disability is around £640 million per year. It is not surprising therefore that efforts should be focused on prevention.

In the UK the DoH,²² the National Institute of Clinical Excellence (NICE)²³ and the Scottish Intercollegiate Guidelines Network (SIGN)²⁴ have stated that risk assessment and preventative measures for VTE are major patient safety interventions that must be made to save lives. Government policy states that every adult patient should undergo an individual risk assessment for VTE on admission to hospital and this should be a systematic and auditable process.²⁵

Therefore, medical and surgical patients who are expected to be in hospital for more than 24 hours are assessed for risk (of both VTE and bleeding) and risk stratified based on various factors including age, period of immobility, obesity and malignancy so that appropriate VTE preventative measures may be instituted (unless contraindicated or refused by the patient). Assessment outcomes must be documented. All patients (or carers) should receive written guidance and verbal information on VTE.

Methods of prophylaxis to be considered include general measures (mobilization, hydration), mechanical techniques (anti-embolic stockings, pneumatic compression boots) and pharmacological agents. Haematology opinion should be sought if hypercoagulable states are present

(e.g. protein C or S deficiency) or if patients are on long term anti-coagulation for other medical conditions.

Reassessment must be carried out every 24–48 hours and after any major clinical change. Appropriate discharge VTE prophylaxis should be prescribed.

CONSIDERATION OF SPECIAL REQUIREMENTS

Patients undergoing surgery in the head and neck region may lose, temporarily or permanently, sensation or motor activity in the distribution of the cranial nerves. Particularly important from a patient's perspective are the loss of communication arising from impairment of hearing, speech or vision, disabling sensation such as vertigo through vestibular dysfunction or alteration to normal activity such as eating, drinking or breathing. Patients who will be unable to speak post-operatively require a plan for communication, such as a bell to attract attention, prepared cards indicating common needs, pen and paper or the use of hand-signals. For those patients undergoing laryngectomy, the pre-operative period is the appropriate time to discuss voice reconstruction options and for the patient to meet the speech therapist and another patient who has undergone, and recovered from, similar surgery.

The disease process or nature of surgery may interfere with nutrition. Failure of adequate nutrition may lead to morbidity and mortality through infection, failure of wound healing and gross catabolism. Nutrition may be provided orally, through a nasogastric tube, via a percutaneous or open gastrostomy, via an open feeding jejunostomy or intravenously. The enteral route is superior in all regards to the intravenous route and should be used whenever possible. Poorly nourished patients require pre-operative supplementation and there is some evidence that a week of enteral (but not parenteral) nutrition improves outcome. A feeding gastrostomy or jejunostomy can be placed in a planned manner at the time of extensive surgery to cover post-operative feeding.

Patients in whom the small or large bowel is required for surgical reconstruction of the upper gastrointestinal (GI) tract may require bowel preparation with a low residue diet or intravenous fluids and laxatives.

PLANNING AND SCHEDULING OF THEATRE TIME AND POST-OPERATIVE CARE

The Confidential Enquiry into Postoperative Deaths (CEPOD) process identifies patients as being **elective** when the surgery can be planned for the convenience of the patient and surgeon, **scheduled** when admission will be prioritized within a few weeks of initial referral, **urgent** indicating an unplanned admission where resuscitation can be achieved before theatre and **emergency** in which surgery is required coexistent with resuscitation. A better scheme starts by indicating whether the patient is listed

or unlisted, since the classification of CEPOD urgent or emergency is not always understood or useful.

The operating theatre list should be presented to theatre reception in the manner required within that hospital. Generally, a theatre list should contain the patient's name, hospital number, date of birth or age and planned surgery. The side of surgery should be recorded as left or right. Some hospitals use the Office for Population Censuses and Surveys (OPCS) or Read codes. The first patients on a list are generally children in ascending age, or shorter operations before longer ones or patients with diseases such as diabetes. Patients with latex allergy must be scheduled first to allow correct preparation of the operating theatre. Similarly, the anaesthetist and senior charge nurse in theatre should be informed regarding patients who are either MRSA positive or have other infections as far in advance as possible. These patients should be placed last on the list wherever possible to allow the theatre to be cleaned adequately after the procedure. Scheduling problems should be resolved by discussion between the surgeon, anaesthetist and theatre sister. Some patients will require a planned extended stay in recovery, or admission to a high dependency unit (HDU) or intensive therapy unit (ITU). Generally, this will be for longer, major procedures, when ventilation is required post-operatively, when the airway is at risk or if extended patient monitoring is required for cardiorespiratory disease. Patients should know about the plans for the immediate recovery period (which may change) and may benefit from seeing the HDU/ITU pre-operatively or talking to a nurse from the unit.

PREPARATION ON THE DAY OF SURGERY

It should be possible to estimate a provisional time of surgery and preparation aims to make certain that the patient is ready when the theatre calls for the patient. Most units use a form with tick boxes to cover the areas of baseline blood pressure, heart rate, weight, allergies, false or capped teeth, patient's wrist band present, consent form signed, notes and X-rays present, investigations present, blood cross-matched, time of last oral intake and details of pre-medication. The side and site of surgery should be indicated with an indelible marker by the surgeon who reviews the patient on the day.

Oral intake on the day of surgery

Fasting guidelines are in existence for planned surgery to minimize the risk of regurgitation and aspiration pneumonitis at induction of anaesthesia.

Historically, surgical patients were fasted routinely from food and drink for unnecessarily prolonged periods sometimes exceeding 12 hours before anaesthesia. Recent studies have shown that reduced pre-operative fasting time without increasing risk of harm from adverse events²⁶ is beneficial in terms of patients' well-being to include increased patient comfort and hydration. Shortening the

fluid fast may also lead to less anxiety pre-operatively²⁷ and less nausea and vomiting post-operatively.²⁸ The volume of administered fluids does not appear to have an impact on patients' residual gastric volume and gastric pH when compared to a standard fasting regimen.²⁹

The Royal College of Nursing has produced fasting guidelines³⁰ for elective surgery. There is a '2–6' rule for adults, which advises that patients may have unlimited amounts of water and other clear fluid up to 2 hours before induction of anaesthesia and solids including milk containing drinks up to 6 hours before surgery. For children, there is a '2–4–6 rule' which recommends that water/clear fluids are advised up to 2 hours, breast milk at 4 hours and formula milk, cows' milk or solids 6 hours before induction of anaesthesia. As an advance to these guidelines the AAGBI guidance³¹ allows chewing gum as long as it is not swallowed, for up to 2 hours before induction of anaesthesia.

Regular medication taken orally should be continued pre-operatively unless there is anaesthetist/surgeon advice to the contrary. Diabetic medication needs to be specifically addressed by the anaesthetist. Up to 30ml water may be given orally to help patients take their medication. If an elective operation is delayed, consideration should be given to giving the patient a drink of water to prevent excessive thirst and dehydration.

ENHANCED RECOVERY AFTER SURGERY

Enhanced Recovery After Surgery (ERAS) is a multimodal perioperative care pathway designed to achieve early recovery for patients undergoing major surgery. ERAS reviews traditional practices and replaces them with evidence-based best practices if applicable. It encompasses all areas of the patient's journey throughout the surgical process.³² Use of the ERAS pathway has been shown to result in a significant reduction in both length of hospital stay and post-operative complications.³³

ERAS has mainly been studied in colorectal surgery,³⁴ vascular surgery,³⁵ thoracic surgery³⁶ and radical cystectomy.³⁷ The rationale behind these programs is to try to modify the physiological and psychological responses to major surgery.

The key principles of the ERAS protocol^{38–40} include:

- pre-operative patient counselling
- pre-operative nutrition, avoiding use of bowel preparation, carbohydrate loading* up to 2 hours pre-operatively, early commencement of feeding post-operatively
- goal directed fluid therapy and a standardized anaesthetic
- avoiding opioid analgesia
- early mobilization
- maintaining intra-operative normothermia.

There has been a recent publication with consensus recommendation⁴⁰ from the ERAS Society for Peri-operative Care in major Head and Neck surgery free flap reconstruction. In the OMFS Regional Centre in Glasgow, an Enhanced Recovery after Head and Neck Cancer Surgery (ERAHNCS) protocol for major free flap reconstructive surgery for OMFS/ENT oncology patients was introduced in 2013. The multimodule integrated care pathway focuses on multidisciplinary team involvement to achieve early recovery for patients undergoing head and neck oncology surgery.

There is a drive to introduce early enteral feeding to patients particularly as a component of part of the ERAS programme. Nutritional status is assessed (e.g. Malnutrition Universal Screening Tool (MUST) score in Greater Glasgow and Clyde) pre-operatively and regularly reassessed. There should be a critical care/ward policy in place for introduction of enteral feed for those who require it.

At the Glasgow Centre referred to above, carbohydrate-containing oral drinks are consumed the night before surgery and 2 hours before induction of anaesthesia. This has been shown to reduce hospital stay.⁴⁰ If the patient is unable to take oral intake or swallow then the drinks are administered via an enteral feeding tube. Currently, patients with delayed gastric emptying, galactosaemia and diabetes are excluded from the carbohydrate loading aspect of the ERAHNCS programme.

* The stress response to surgery results in a catabolic state and insulin resistance, which is a known risk factor for post-operative complications. Aggressive insulin therapy post-operatively has been shown to reduce morbidity and mortality. Similar results can be achieved when insulin resistance is attenuated and protein losses minimized by the use of pre-operative carbohydrate loading.

BEST CLINICAL PRACTICE

- ✓ The patient should be directed into the correct pathway as soon as surgery is contemplated, and sufficient oral and written information given to inform the patient and initiate the consent process.
- ✓ Attendance at a pre-admission clinic a few weeks before surgery allows a full history and examination to be taken, leading to the identification of any medical, anaesthetic or personal problems. This is particularly important when the interval between scheduling and admission for surgery is more than a few months.
- ✓ The requirement for specific pre-operative blood tests, investigations and blood cross-matching should be agreed by the whole team and produced in a written form which is available to doctors and nurses involved in pre-operative preparation.
- ✓ Pre-operative assessment of the problem patient by an anaesthetist, preferably the one who will be involved, is valuable and ideally should be arranged.
- ✓ Pre-operative tests taken at pre-admission should be reviewed before the admission for surgery so that abnormalities can either be treated in time or the patient rescheduled.

KEY POINTS

- Consider day surgery where possible.
- Assess the risk balance of operation/anaesthesia.
- Moderate or severe cardiorespiratory disease requires medical/anaesthetic review.
- Routine pre-operative tests are expensive and unnecessary.
- Valid, written consent is required for most surgery.
- Consider venous thromboembolism prevention.
- Consider the need for an HDU/ITU bed post-operatively.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: difficult intubation, difficult airway, obstructed airway.

DEFINITIONS

The difficult airway is the clinical situation in which a practitioner experiences difficulty with adequate maintenance and/or protection of the airway. The most commonly used adjunct airway devices that help maintain a patent airway are the face mask, with or without a guedel airway, the laryngeal mask, and the tracheal tube. These devices are designed to maintain the patency of an airway and hence reduce impedance to ventilation. A cuffed tracheal tube offers the airway the highest level of security from obstructions or contaminations as the other devices are 'supraglottic'. Tracheal tubes are often the adjunct of choice in head and neck surgeries.

Two broad categories of airway problems can be defined: difficult ventilation and difficult intubation. Difficult mask ventilation is defined by the American Society of Anesthesiologists (ASA)¹ as the 'inability to maintain the oxygen saturations above 90% by face-mask inflation with 100% inspired oxygen or to reverse signs of inadequate ventilation'. Oxygen stores in the body are exhausted within a few minutes and difficulty or failure to ventilate will rapidly result in morbidity or mortality from hypoxaemia. Maintenance of oxygenation but inability to ventilate effectively (we will discuss this later) may still be associated with significant morbidity and mortality related to hypercarbia.

Difficulty or failure to intubate is defined by the ASA as 'the inability to establish tracheal intubation within three

attempts at direct laryngoscopy or within ten minutes'. In the UK, the Difficult Airway Society (DAS) guidelines for failed intubation also recommend no more than three attempts at direct laryngoscopy before accepting that intubation by this method has failed.² Provided that face-mask ventilation is possible, failed tracheal intubation by itself should not result in hypoxaemia unless the failure of airway protection leads to gross airway soiling from gastric contents, blood, pus or debris. Failure to recognize that tracheal intubation has been unsuccessful is associated with morbidity and mortality. This may occur in cases of unrecognized oesophageal intubation or dislodgement of endotracheal tubes. Continuous capnography from induction to extubation of the patient in the perioperative period is now a basic recommended standard of practice.

Cormack and Lehane³ described the commonly used classification of the best view of laryngeal structures seen at direct laryngoscopy. Grade I is visualization of the entire laryngeal aperture, grade II is visualization of the posterior portion of the laryngeal aperture, grade III is visualization of the epiglottis only and grade IV is no view of any laryngeal structures. Difficulty with intubation of the trachea is more likely in laryngoscopy grades III/IV and in cases where multiple attempts at conventional direct laryngoscopy in these grades have failed to improve the direct view of the larynx.⁴ Classification of laryngeal view has also been described as a percentage of glottic opening or POGO scoring. This method is reported to have good inter- and intra-physician reliability when grading the

laryngeal view; however, there is limited evidence for this and in general it is the Cormack and Lehane system that is most commonly used.^{5,6} If there has been a requirement to use a specialized aid or device to aid direction of the endotracheal tube when intubating, this also would indicate that there has been a level of difficulty to intubate. Specialized devices such as tube stylets or gum elastic bougies are used to direct endotracheal tubes towards the glottis opening in cases of difficult laryngeal view. In addition different blades used with the direct laryngoscope, for example the Millar or Henderson straight blades, can be used to improve laryngeal view in 'poor grades' III and IV. The recognition of the need for additional adjuncts or devices has led to theatre suites ensuring specifically stocked carts or trolleys are available for use in cases of difficult or failed intubation. Difficult direct laryngoscopy is only one cause of difficulty with intubation. It may be easy to visualize the larynx but intubation is unsuccessful because the larynx, subglottis or trachea are abnormally narrowed or distorted.

PREVALENCE

Both difficult intubation and difficult ventilation are uncommon. The prevalence of Cormack and Lehane laryngoscopic grade III is 1.5% in the general population. Requiring more than three attempts at direct laryngoscopy occurs in approximately 0.4% of patients and the average anaesthetist will abandon intubation in approximately 1:2500 of general surgical patients. In 1200 consecutive ENT and general surgical patients the overall prevalence of difficult intubation (defined as requiring specialist equipment) was 4.2%.⁷ The highest prevalence was 12.3% in ENT cancer surgery, 3.5% in ENT non-cancer surgery and 2.0% in general surgical patients. This confirms the clinical impression that difficult intubation is more common in patients undergoing head and neck surgery, particularly in those patients following extensive surgery, flap reconstruction and post-operative radiotherapy or with an obstructed airway.

It is difficult to know the precise prevalence of difficult face-mask ventilation.⁸ Catastrophic failure leading to serious morbidity or mortality is generally quoted as 1:10000–1:100000. However, in any large series, a number of problem patients are identified pre-operatively and these patients may not receive a general anaesthetic. A North American study that involved 18500 patients of whom 18200 were intubated under general anaesthesia quoted that only 1.8% of patients required more than two attempts at direct laryngoscopy and no patient was impossible to mask ventilate.⁹ Approximately 300 patients underwent awake intubation and it is this group of patients that is likely to contain those who would have proved difficult to ventilate if anaesthetized. Another study of 1502 patients determined a prevalence of difficult mask ventilation of 5% but the definition used was that the anaesthetist considered the difficulty was clinically relevant and could have led to potential problems if mask ventilation had to be maintained for a longer period.⁸ More recent data from

the Fourth National Airway Project (NAP4) run by the Royal College of Anaesthetists (RCOA) of Great Britain and Ireland in 2012 reported an incidence of adverse airway events as 1 : 22000 and an incidence of death related to an airway event as 1 : 180000. More than 3 million anaesthetics were audited in this data collection.¹⁰

EVALUATION

The aim of perioperative airway management is to adequately maintain and protect the airway throughout this period. Adequate assessment and evaluation of each individual patient is paramount to make the most appropriate management strategy. Face-mask anaesthesia is impractical and provides no airway protection for head and neck surgery patients and so has limited application. The appropriate use of either a supraglottic airway or a tracheal tube is dependent on multiple factors such as patient comorbidity and pathology, the length of surgery and the level surgical access to the head and neck structures needed. The need for positive pressure ventilation during the procedure and minimizing the risk of airway soiling from blood, pus, cerebrospinal fluid or gastric contents are also of major importance.

The airway may be evaluated according to the scheme outlined in [Table 31.1](#).

History

The anaesthetic or hospital notes may indicate previously encountered difficulty with airway management. The patient may pass on verbal or written information from a previous anaesthetist that they are difficult, or difficulty may be inferred from a history of displaced front teeth, bruised lips, excessive sore throat or an unexpected stay in ITU. Past surgery or radiotherapy, or the current surgical condition, may be relevant if it affects the head, neck or mediastinum. A number of medical conditions, such as rheumatoid arthritis, obstructive sleep apnoea and acromegaly, have some association with difficult airway management. For example, the incidence of Cormack and Lehan grade III larynx, which is associated with difficult intubation, is reported as 10% in acromegalics. This is six to eight times higher than in the general population.¹¹ In this group there is also an association with difficulty with

TABLE 31.1 Scheme for evaluation of the airway

Evaluation

Examination	General Specific predictive tests
Investigations	MR imaging CT imaging Flow-volume loop Flexible nasendoscopy

bag valve mask ventilation due to the soft tissue hypertrophy of the tongue. Rheumatoid arthritis patients may have reduced neck mobility or have had surgery for fusion of cervical vertebrae and therefore the optimum position for intubation or the 'sniffing the morning air' cannot be achieved. There are a number of congenital conditions, such as Treacher-Collins and Pierre-Robin, in which airway management, particularly intubation, is often difficult. Anatomical hypoplasia of the mandible in these conditions is often associated with poor laryngeal view.

Figure 31.1 illustrates a patient with Hunter's syndrome, in which abnormal mucopolysaccharide is deposited in the tissues. Characteristically, he was difficult to intubate for a tonsillectomy to alleviate obstructive sleep apnoea and required an emergency tracheostomy in the recovery period. He is pictured in his late teens when his original standard tracheostomy tube had been replaced by one designed to circumvent lower tracheal and carinal deposits. This T-Y silastic stent passes from just below the vocal cords into each main bronchus (an inverted Y shape) with a limb passing out through the tracheostomy (the T component).

Examination

General examination is aimed at identifying individual physical findings that may be associated with difficult intubation:

- trauma, burn, swelling, infection, scarring, haematoma of the mouth, tongue, larynx, trachea or neck

- large tongue, receding jaw, high-arched palate, prominent upper incisors, short thick neck, large breasts, microstomia, fixed larynx, impalpable cricothyroid membrane, limited mouth opening, limited head/neck movements
- voice change, shortness of breath, stridor, inability to lie down.

A number of these factors, such as the appreciation of a short neck or receding jaw (**Figure 31.2**), are subjective. This does not diminish their importance since professional judgements may often be subjective.

A number of subjective tests are used as predictors of difficult intubation. The five tests most commonly used are gape, jaw slide, thyromental distance, Mallampati and atlanto-occipital movement.

GAPE

Patients with small mouths, large teeth, previous surgeries or obvious physical deformity, among other things, may have reduced mouth opening.

Gape is the measurement of maximal mouth opening and is usually expressed as inter-incisor distance in fingerbreadths (fb) or centimetres. Normal values are 3 fb or 5 cm. A mouth opening of 2 fb is limited and 1 fb is severely limited, making direct laryngoscopy very difficult. It is difficult to insert a laryngeal mask when the gape is less than 2 cm (**Figure 31.3**). Relatively long upper incisors may also contribute to difficulty.

Figure 31.1 Mucopolysaccharidosis (Hunter's syndrome).

Figure 31.2 Receding jaw.

Figure 31.3 Limited mouth opening due to dental abscess.

JAW SLIDE OR MANDIBULAR PROTUSION

Patients with a prominent overbite may be considered more likely to be an intubation challenge, as are patients who are unable to bring their mandibular incisors anterior to their maxillary incisors. The relationship between the maxillary and mandibular incisors during normal jaw closure and voluntary protrusion of the mandible have been graded in an attempt to predict significance to difficulty with intubation.

Functions are graded as follows:

- class A if the lower jaw can be protruded beyond the top teeth
- class B if the lower teeth can only reach the top teeth
- class C if the lower teeth will not reach the top teeth

The value of testing this function is that, in intubation by direct laryngoscopy, the lower jaw must slide forward. In some scoring systems, mouth opening and jaw slide are combined, the greatest difficulty indicated by a gape of <3.5 cm and class C jaw slide. Another method of testing mandibular protrusion is the upper lip bite test¹² in which the patient demonstrates how much of the upper lip may be covered by the lower incisors. Class 1 indicates 'biting' above the vermilion line, class 2 below the vermilion line and class 3 an inability to bite the upper lip.

THYROMENTAL DISTANCE

Patients who physically have short, fat, thick necks or reduced compliance of the submandibular space (e.g. radiotherapy, induration) may also be difficult to intubate. Many of these patients could have reduced thyromental distances.

Figure 31.4 A normal thyromental distance.

This measurement, described by Patil,¹³ is from the mentum to thyroid notch in full neck extension. The normal measurement is 6–7 cm or 3 fb (Figure 31.4). A short distance (2 fb) indicates a 'high' larynx and difficult direct laryngoscopy.

MALLAMPATI

Mallampati scoring is a commonly used scoring system for anaesthetists. While the scoring system may not be highly sensitive it is an easy bedside test that is generally regarded as useful in prediction of difficulty with intubation. Mallampati grading is commonly recorded on anaesthetic records.

Mallampati's contribution was a test to assess oropharyngeal space. The test asks a seated patient to open their mouth fully and extend the tongue maximally. The practitioner notes which posterior pharyngeal structures are visible. Mallampati described only three grades:

- class 1 indicates that the posterior pharyngeal wall, fauces and uvula are visible
- class 2 indicates that only a part of the fauces, posterior wall and uvula are visible
- class 3 indicates that the tongue meets the palate; the uvula is not visible.

Samsoon and Young¹⁴ arbitrarily introduced a subdivision of class 3 (tongue against soft palate) and class 4 (tongue meets hard palate).

ATLANTO-OCCIPITAL MOVEMENT

Optimal head and neck positioning for direct laryngoscopy requires cervical spine flexion and almost maximal extension of the head on the spine. A simple clinical test to look at atlanto-occipital movement is for the clinician to ask the patient to flex their neck maximally and then nod; the observer's hand placed posteriorly on the neck makes certain that the nodding motion is at the level of the cranium on the upper cervical vertebrae. Atlanto-occipital extension may be clinically graded as normal or reduced or measured and the normal value is 35°. Connective tissue conditions such as ankylosing spondylitis and

rheumatoid arthritis are associated with pronounced reduction in atlanto occipital movement. Instability of the cervical spine may render movement of the spine impossible due to the presence of a collar, traction or halo frame.

Investigations

Plain X-rays may demonstrate abnormalities, such as enlargement of the retropharyngeal space (Figure 31.5), a swollen epiglottis, tracheal deviation or narrowing, a radio-opaque foreign body or obstructive emphysema suggesting a ball-valve obstruction in the relevant bronchus. However, imaging of the whole airway by CT or MR scan is better and will show narrowing or distortion and allow planning of airway instrumentation. Flexible nasendoscopy under topical anaesthesia is extremely useful in delineating supra- or glottic pathology, and a longer flexible fibroscope can inspect the whole respiratory tract although generally this requires sedation.

Another useful test is the flow-volume loop. This expresses flow during expiration and inspiration as a function of lung volume. Airflow is measured during inhalation from residual volume to total lung capacity and exhalation back to residual volume. Extrathoracic obstruction causes limitation of inspiratory flow whilst intrathoracic obstruction causes limitation in expiratory flow.

Figure 31.5 Retropharyngeal abscess.

Limitation in expiratory flow is particularly noticeable because the highest flow-rates are usually present in peak expiration.

PREDICTION OF DIFFICULTY

The practitioner forms a professional judgement as to whether airway management plans need to be altered from that carried out normally based on information gathered from the history and examination of the patient, the nature of the pathological process and surgeries planned and investigations and imagine undertaken. Key predictors of difficulty as previously discussed would be a known history of failed intubation, presentation with breathing difficulty or stridor, absent mouth opening or previous head and neck reconstructive surgery. In pathological processes of the laryngopharynx supraglottic tumour is highly predictive of difficulty with intubation,¹⁵ as is the presence of tracheal compression, the presence of dyspnoea and cancerous pathology in patients with a goitre undergoing thyroid surgery.¹⁶

However, when there are no abnormalities in the anaesthetic, medical or surgical history, the presenting disease process does not affect the head, neck or mediastinum and the patient does not 'look' difficult, then it is not possible to predict difficulty accurately.

Most attention has been on predicting difficult direct laryngoscopy using various specific or predictive tests (described above), combination of tests and scoring systems. All are imperfect and the reason is partly the low prevalence of difficult intubation. Test sensitivity indicates the ability of the test to label a difficult patient as difficult, test specificity the ability to label a normal patient as normal and the positive predictive value (PPV) is the proportion of patients found to be difficult out of all patients predicted by that test to be difficult. Table 31.2 shows values of test sensitivity, specificity and PPV for the various tests. It can be seen that an individual test, such as Mallampati, has a low PPV indicating that most patients predicted to be difficult will, in fact, be normal.

It is likely that the upper lip bite test and the Mallampati are both poor predictors as single screening tests;¹⁷ however, the more tests that are abnormal in one patient, the increased likelihood that the patient will be difficult to intubate.

Another approach may be to produce a score from consideration of various predictive tests, with appropriate weighting. This may provide a system with higher

TABLE 31.2 Test sensitivity, specificity and positive predictive value from the literature and reference¹⁹

Test	Sensitivity %	Specificity %	PPV %
Thyromental	65–91	81–82	8–15
Mallampati	42–56	81–84	4–21
Wilson risk sum	42–55	86–92	6–9
Mouth opening	26–47	94–95	7–25
Neck movement	10–17	98	8–30

sensitivities and specificities; however, the subject of prediction of difficulty is fraught with difficulties arising from studies with small numbers of patients, definitions, curious mathematics and inappropriate conclusions.^{7, 18, 19} Some meta-analysis data of bedside screening tests for predicting difficult intubation in apparently normal patients propose that they have limited value.²⁰

Objective tests aim only to predict difficult direct laryngoscopy when the tongue has a normal compliance and the respiratory tract is normal. Viewing the larynx using direct laryngoscopy with a standard Macintosh blade is reliant on anterior elevation of the mandible and sweeping the tongue to the left while at the same time lifting the epiglottis to open the laryngopharyngeal space and view the glottis. Restriction of tongue movement due to poor tissue compliance may result because of multiple pathologies including tumour, infection, post-radiotherapy or scarring and oedema. Fixation or restricted movement of the tongue is known to cause difficulty.²¹ Unexpected difficulty with intubation occurs in cases such as a vallecular cyst and lingual tonsillar hypertrophy, which may be symptomless but will not be predicted, but also in cases with no physical pathology who have anatomically high and anterior larynx which are poor Cormack and Lehane views.^{3, 22, 23}

Airway evaluation is an essential part of pre-operative assessment. It may be rewarded by the detection of severe

or obvious problems that necessitate a strategy different to 'normal' management. When there are no obvious problems, evaluation is imperfect and safe airway management in all circumstances depends on the adoption of an airway strategy that is able to respond to unexpected difficulty with intubation or oxygenation.

STRATEGY

The recommendations of the ASA on management of the airway^{1, 4} promoted the five-step linear model of evaluation of the airway, preparation for difficulty, strategy at intubation, strategy at extubation and follow-up. The ASA difficult airway algorithm presents an overall scheme of planning airway management (Figure 31.6).²⁴

In September 2004 the Difficult Airway Society Guidelines were published in the United Kingdom. Similarly to the ASA guidelines, they were aimed at providing a standardized logical series of steps following a failed intubation in particular circumstances. The guidance was issued for unanticipated difficult intubation during routine induction of anaesthesia and following rapid sequence induction in the non-obstetric adult patient. They are widely accepted in the UK as a gold standard of care in airway management and they are based on a series of consecutive plans from A to D (Table 31.3).

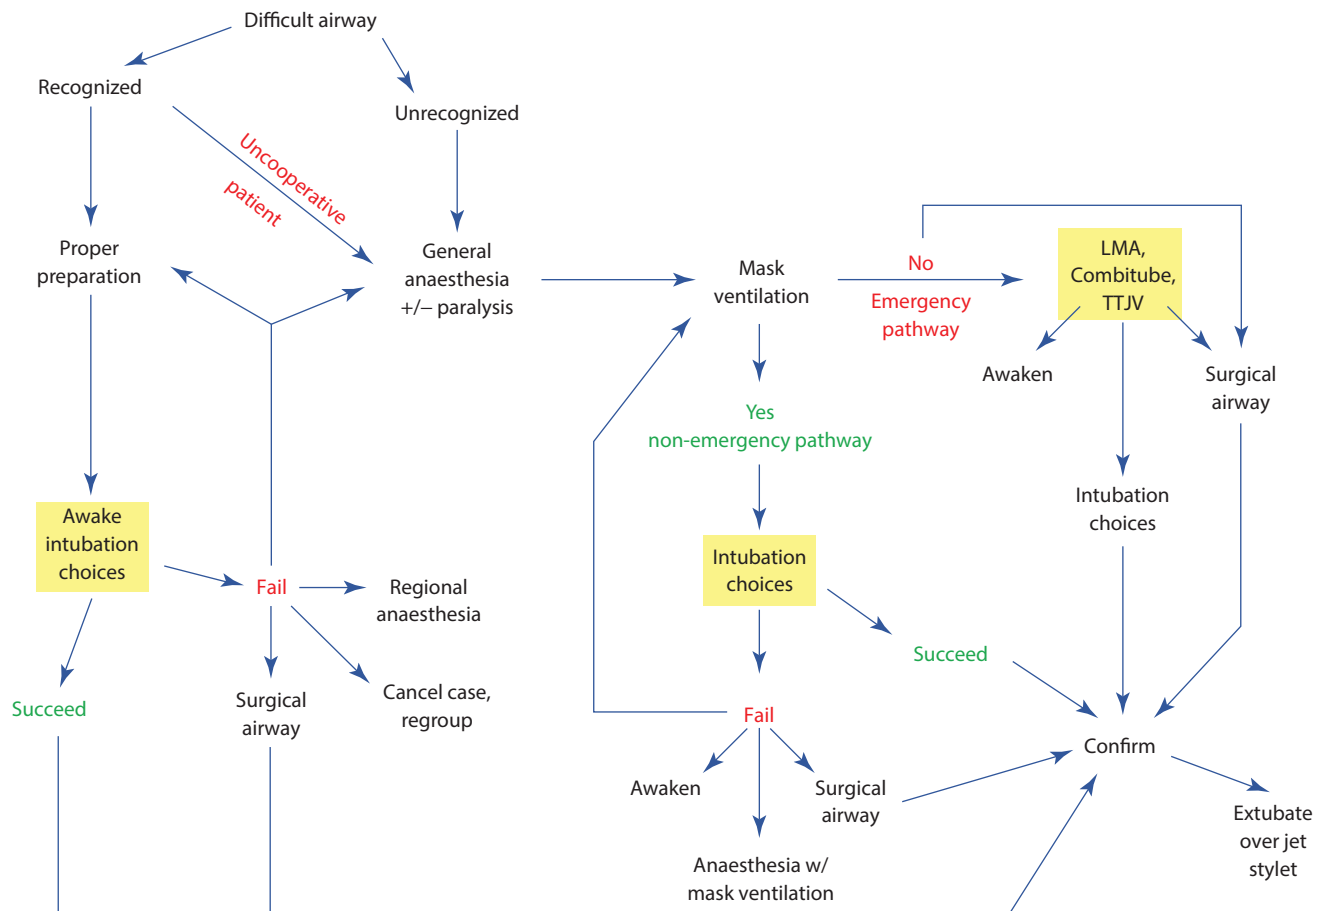

Figure 31.6 ASA difficult airway algorithm. Redrawn from ref. 20, with permission.

TABLE 31.3 Plans A–D in the failed intubation flowchart

Plan	Step following direct laryngoscopy, any issues arising and immediate call for help
A	Initial tracheal intubation plan; no more than four attempts at intubation while maintaining oxygenation with face mask
B	Secondary tracheal intubation plan following failure to intubate; supraglottic airway (LMA) not more than two insertions plus or minus fibre-optic/Aintree catheter guided assistance
C	Maintenance of oxygenation ventilation, postponement of surgery and awakening
D	Rescue techniques in the can't intubate can't ventilate scenario/proceed to needle or surgical cricothyrotomy

Forming a ‘management strategy’ rather than one isolated plan is the underlying principle of both societies’ guidelines. The practitioner is encouraged to plan in advance the steps they will take based upon the success or failure of the first-line plan or ‘plan A’ that they make following assessment of the patient. Following the publication by the RCoA of the NAP4 study data, it was concluded that this ‘strategy’ is fundamental to improving outcome from problems resulting from airway difficulties. This conclusion was consolidated by analysis of the reasons that problems arose during airway management. Such problems were shown to be potentiated by poor forward planning, preparation, training and communication. In 2011, the DAS published guidelines on extubation. This followed the recognition that although complications at intubation have been decreasing since the turn of the century, the incidence of complications at extubation has not improved.²⁵ Extubation scenarios will be discussed later.

Management strategies may not necessarily mean the initial plan A will employ the technique of direct laryngoscopy or the standard curved Macintosh blade to intubate the trachea; however, this is by far the commonest first-line approach. Recommendations when this approach fails are first to attempt to perform basic manoeuvres. Reposition the patient, maximize jaw thrust and neck extension, possibly in combination with backward upward pressure on the larynx by external manipulation to improve the view. During rapid sequence induction relaxation of cricoid force may be needed. Introduction of the tube may be aided by low-tech devices such as a tube stylet, bougie or Magills forceps.

The bougie is a useful ‘low-tech’ device (Figure 31.7) with proven success rates.²⁶ Its correct use during attempted direct laryngoscopy is by placement through the glottis, either blindly or by educated guess. Correct placement is confirmed by feeling the tracheal rings and hold-up at 25 cm when the bougie contacts the carina. This is followed by railroading the tracheal tube with the laryngoscope still *in situ*. There are traumatic complications to bougie use, epithelial damage or placement into the bronchus resulting in trauma. Caution should be exerted when railroading the tube not to further advance the bougie towards the smaller airways as the tracheal tube is passed over it.

**Figure 31.7** The gum-elastic bougie is an effective aid to intubation.

It is widely accepted that generally no more than three or four attempts should be made at direct laryngoscopy, including a change from a Macintosh blade to a straight or alternative blade, and there is some evidence to suggest morbidity with more than two attempts.²⁷ The correct decision is to acknowledge early a ‘failed intubation’ and abandon plan A. Defaulting to plan B, both failed ventilation and failed intubation are addressed by using alternative techniques to direct laryngoscopy with a standard Macintosh blade.²

ALTERNATIVE TECHNIQUES TO MACINTOSH LARYNGOSCOPY BLADES

Although the Macintosh curved design is the blade most commonly used by anaesthetists, there are a variety of blades that have proven their worth. Straight blades (for example, the Millar and Henderson blades) are used by a slightly different technique to the paraglossal approach with the Macintosh and they have been reported to provide superior views in some cases of lingual tonsillar hypertrophy.²⁸ It is a similar technique to the rigid laryngoscopy that is employed by head and neck surgeons. Another blade, originally invented by McCoy, employs a lever to increase markedly the angulation of the tip (Figure 31.8). A number of direct laryngoscopy blades have been introduced over the years incorporating prisms or mirrors to try and provide an indirect view of the larynx but these have not become mainstream devices.

Videolaryngoscopes

Rigid fibrescopes like the Upsherscope and Bullard, which incorporated fibre-optic viewing bundles into rigid curved blades, have been superseded by new generation videolaryngoscopes (Figure 31.9).²⁹ These devices, designed as aids to intubation, provide an indirect view of the larynx on a small LCD screen on a handheld device or a satellite screen and they have been shown to improve the view at laryngoscopy.^{30, 31} There is evidence suggesting that they have a shorter learning curve than direct laryngoscopy, may improve the learning of direct laryngoscopy and require less mouth opening.³² The LCD camera on these

Figure 31.8 McCoy blade with a hinged tip.

handheld devices was developed from CMSO (complementary metal oxide detectors) technology and provides high fidelity small screens similar to those on current phones such as the iPhone 4 and HTC. Videolaryngoscopes can be divided into two large categories: those with Macintosh style blades (direct and indirect view of the larynx is possible); and those with difficult airway blades (indirect view possible only).

Some videolaryngoscopic devices, such as the McGrath MAC and Stortz CMAC, have both types of blade attachment. Some devices have a guide channel for side mounting endotracheal tubes to help direct the tip through the laryngeal inlet, while others require the use of a stylet or bougie to mould the tube to the correct hockey stick shape or guide the tube through the inlet. Although scientific evidence suggests that videolaryngoscopes will consistently improve the view of the larynx there is little evidence to support one particular device over the other.³³ Currently videolaryngoscopes are in widespread use and are gaining in popularity. It can be assumed that successful use of the technique is dependent not only on adequate training but also on operator dexterity and skill, judgement and patient selection. The technique of videolaryngoscopy involves four stages: introduction of the device under direct vision into the mouth, followed by obtaining the best view indirectly by using the LCD screen, followed by introduction of the tracheal tube into the mouth or nose under direct vision. Ultimately the tube is advanced

(a)

(b)

while observing indirectly on the screen. Within a management strategy these devices would be used within one of the four attempts at intubation in plan A.

Flexible fibre-optic scopes

Tracheal intubation using the flexible fibrescope was first described in 1967 by Peter Murphy,³⁴ an anaesthetic senior registrar working at the National Hospital, Queen Square, London, and flexible intubating fibrescopes have

been commercially available for over 20 years. Several textbooks^{35, 36} are concerned solely with the technique. A standard adult intubating fibroscope has a length of 60cm and a nominal external diameter of 4mm. Its narrow diameter allows it to pass through the nose or mouth, its flexibility allows it to conform to the anatomy of the patient, the working channel can be used to instil local anaesthesia, oxygen or to pass wires in the antero- or retrograde direction to aid intubation, the technique is visual and can be used to confirm correct positioning of the tube in the trachea. It is fairly easy to use anaesthetic breathing system connectors or attachments that allow concurrent ventilation of the patient during intubation, or specially adapted airways to make oral intubation easier. It is not surprising that such an instrument has become the safest and most successful technique of intubation. A failed intubation rate of 0.045% is reported in one study and a success rate of 98.4% in another.^{37, 38} The complication rate is extremely low.

Fibre-endoscopic skills appear in the core competencies for trainee anaesthetists and include visual inspection of the respiratory tract for diagnostic purposes and placement of double lumen tracheal tubes. The problems associated with the intubating fibroscope are that it is a skilled technique requiring training and practice, the devices are expensive and require careful handling, and disinfection requires chemical agents. There has been particular concern over the inability of cold sterilizing agents to destroy prions. The recommendation from the Department of Health is that a register should be maintained such that all patients treated with an individual fibroscope can be traced easily. Fibre-optic intubation may be part of a practitioners initial plan A strategy or part of a plan B, possibly an asleep fibre-optic intubation or in conjunction with an intubating laryngeal mask airway or supraglottic airway device—Aintree catheter technique.

Intubating laryngeal mask airway

The intubating laryngeal mask was devised by Brain and introduced in 1999. The intubating laryngeal mask airway (ILMA) kit (Figure 31.10) differs from the classic laryngeal mask (LM) in several ways. The stem is a rigid highly curved metal tube with a handle, there is an epiglottic elevator bar, a ramp at the junction of the stem and bowl directs the tube appropriately and it is supplied with a special wire-spiral tracheal tube with novel bevel. Single use systems are now widely available. The described technique of intubation in the anaesthetized, paralyzed patient is for the mask to be placed and the patient ventilated through it. Mask placement appears to be easy provided the mouth opening is more than 2 cm. The tracheal tube is inserted through the stem and advanced slowly without force. As the tip of the tube emerges from the stem, it lifts the epiglottic elevator bar and the route is now clear for the tube to be advanced into the trachea. This blind intubation has a success rate of 95% or so if two to three manipulations of mask position and tube advancement are allowed. A fibre-optic modification is recommended that allows a visually guided technique and would seem to

Figure 31.10 Components of the intubating laryngeal mask airway.

be preferable. Published figures suggest a successful intubation rate of 96.5% with a blind technique and 100% when used with the fibroscope^{37, 38} although a small North American study³⁹ compared intubation by the ILMA in anaesthetized patients with awake fibre-optic intubation with suspected difficult intubation and found them both to be 100% successful.

Lighted stylets

The technique of transillumination of the neck to guide oro- or nasotracheal intubation was described first in 1959. A lighted stylet⁴⁰ uses the principle of transillumination and takes advantage of the anterior or superficial location of the trachea. A number of commercially available devices have been produced over the years and the most recent, the Trachlight, appears to be the most successful. The tracheal tube is loaded onto the stylet, which has a distal bulb, and the stylet is shaped into a hockey-stick. The lighted stylet is introduced into the oropharynx from the side and brought into the midline. The tip of the light wand is passed around the tongue and a bright, well-circumscribed circle of light seen externally at the level of the hyoid indicates that the tip lies in the vallecula. The tube is advanced into the trachea without resistance. In skilled hands it has been shown to be an effective and rapid technique although it has not gained widespread popularity in the UK. Concerns over heat damage to the mucosa from the lighted stylet Trachlight™ during prolonged attempts have led the manufacturers to design the bulb to flash on and off every 20 seconds.

LARYNGEAL MASK AIRWAYS

The Classic laryngeal mask (LM) has proven itself highly successful among supraglottic airway devices for maintenance of the airway. The classic laryngeal mask airway (LMA™) is the original design of the mask, which consisted of an elliptical high volume low pressure silicone cuff, a breathing tube and connector piece for connection to a breathing circuit or bag. Large study data put the incidence of failed placement as 1:600 patients. They were designed and marketed from the late 1980s for maintenance of the airway in planned, elective surgery

and within three years of launch had been used in over 2 million anaesthetics. There are now many different companies marketing their own disposable version of the device. LMA use has the advantages, when compared with tracheal intubation, of easier placement, no requirement for muscle relaxation and is tolerated *in situ* by the awakening patient. The major disadvantages are that it does not offer the same level of airway protection as a cuffed tracheal tube against gross gastric regurgitation and it does not traverse the larynx, so is no protection against airway occlusion by glottic or infraglottic pathology. LMA design has evolved in recent years with second-generation laryngeal masks (proseal LMA, LMA supreme) having the proposed benefit of a better pharyngeal seals allowing for more efficient controlled ventilation.

They also aim to provide an oesophageal seal or protection reducing the likelihood of aspiration of gastric contents and some (for example the LMA Supreme™ Teleflex®) have integral bite blocks. They have the advantage of having a drainage channel that, when positioned correctly, lies over the oesophageal opening and can be used to assist placement of the mask or pass a gastric tube. The NAP4 study executive summary now recommends the use of a second generation LMA in cases where there is a small but increased concern about regurgitation in preference to first-generation LMAs. There is also a recommendation that all hospitals should have second-generation LMA with an integral bite block available for use. LMAs in general have proved themselves to be a very useful device in difficult airway management and appear in several places in airway algorithms (Box 31.1).

BOX 31.1 Role of the classic LM in difficult airway management

- As the desired airway device
- Instead of a tracheal tube
- Rescue device in failed ventilation
- Conduit during emergence
- Conduit for fibre-endoscopy of the airway
- Conduit for intubation:
 - blind
 - bougie
 - fibre-optic-guided bougie
 - fibre-optic
 - Aintree catheter

Intubation via the LM

In normal use, the LM should be seated in close proximity to the vocal cords and it is not surprising that it can provide a route for passage of a tracheal tube. There are five methods for this (Box 31.1). A size 6.0mm will pass through the stem/connector of a size three or four Classic LMA™ and a size 7.0mm tube will pass through the size five Classic LMA™. This may not be the case for different brand disposable LMAs and should be checked in advance by any practitioner who would use the technique of intubating through these devices as part of a management strategy. Blind placement, in which the tube is lubricated and advanced blindly, has a success rate of only 50–90%

and passing a bougie through the LM first has an even lower success rate. Techniques under vision have appreciably higher success rates and flexible fibre-optic techniques are particularly useful. It is now not recommended that blind placement of the tube is attempted where fibre-optic equipment is available.

Fibre-optic-assisted techniques are useful because they are visually guided (Figure 31.11). The core technique is to insert the LM, load a 6.0mm tube onto the fibrescope, pass the fibrescope into the trachea through the stem of the LM and slide the well-lubricated tube into the trachea. It is also possible to ventilate an anaesthetized patient through the LM whilst intubation is in progress. This introduces the concept of the laryngeal mask as a dedicated airway,⁴¹ a device used for maintenance of the airway whilst other airway interventions (e.g. intubation) are in progress. Development of this concept led to the design of the Aintree catheter,⁴² a hollow bougie that may be placed over the fibrescope and inserted through the LM into the trachea (Figure 31.12). Effectively, the technique places a hollow bougie under vision into the airway, over which a tracheal tube is railroaded.

Figure 31.11 The laryngeal mask is a good conduit for fibre-optic intubation.

Figure 31.12 Aintree catheter – a hollow bougie inserted over a fibrescope.

FAILED VENTILATION AND EMERGENCY CRICOTHYROTOMY

Failed ventilation refers to the situation where a patient has been anaesthetized and muscle relaxants administered but it is not possible to provide positive pressure ventilation by use of the face mask and oral airway. A prepared sequence of steps (for example, DAS guidelines steps plan A–C) should commence to provide rescue oxygenation as quickly as possible. Bag/mask ventilation in which two hands are used to try to maintain airway patency and another hand squeezes the anaesthetic reservoir bag should be followed by insertion of an LMA. This may prove life-saving and must always be considered. If oxygenation cannot be achieved by face mask or LM, it may be worthwhile attempting intubation by direct laryngoscopy. This must be a brief attempt only and must not delay oxygenation by the next step.

In a can't intubate and can't ventilate scenario (CICV), and if it is known that the patient has normal airway anatomy or no airway pathology, it may be a consideration to follow the 'awaken patient' limb of the algorithm. If a non-depolarizing muscle relaxant has been given Sugammadex, a modern reversal agent should be administered and anaesthesia discontinued. Sugammadex is a synthetic modified gamma-cyclodextrin. It is the only selective binding agent that provides rapid reversal of the neuromuscular blockers rocuronium and vecuronium. It should be given in a dose of 16 mg/kg for reversal of neuromuscular blockade within approximately 7 minutes of administration of vecuronium or rocuronium. Careful consideration may be given to reversal of benzodiazepines or opiates to increase the speed of emergence.

Airway deaths, unfortunately, often involve prolonged fruitless attempts to intubate when oxygenation is the immediate necessity. Prolonged attempts to intubate patients who initially may have been low risk and appropriate to attempt waking up may lead to a situation where this cannot be performed due to airway trauma or unconsciousness as a result of hypoxia and hypercarbia. The CICV accounts for 25% of all anaesthetic deaths.

When the anaesthetized patient cannot be oxygenated by face mask or LM, and tracheal intubation is not possible, the practitioner should proceed with emergency oxygenation attempts directly into the respiratory tract below the level of the vocal cords. When attempting emergency front-of-neck access, routing via the cricothyroid membrane (CTM) has a number of desirable properties:

- superficial
- easy landmarks to locate
- present in most patients
- rarely calcifies
- relatively avascular
- wide enough to accept 6.0 mm tube
- inferior to vocal cords
- cricoid ring holds airway open
- posterior lamina protects back wall.

There are three types of cricothyrotomy as detailed in the following sections.⁴³

Needle or small bore cannula cricothyrotomy

A narrow-calibre rigid needle or flexible cannula is inserted through the CTM in a caudad direction. In adults, an appropriate size is 14 G with an internal diameter of 2 mm (Figure 31.13). Anatomically bevelled kink resistant cannulas specifically designed for cricothyroid puncture are commercially available. The old-fashioned technique of using a venous cannula has become obsolete. The resistance to flow through such a small calibre needle is high and this has implications for inspiration and expiration. In inspiration, adequate gas flows cannot be obtained by the pressures generated within a standard anaesthetic breathing system and exhalation of 500 mL takes >30 seconds. Inspiratory gas flows of 500 mL/s require oxygen at a pressure of 2–4 bar supplied by a jet injector (Figure 31.14). Traditionally the Sanders injector has been described for jet injection via a cricothyroidotomy cannula. It attaches to the 4 bar (400 kPa, 4 atmospheres) oxygen pipeline and has a hand-operated lever to control gas flow during inspiration and historically has been the common injector available in head and neck surgery for jet injection during rigid bronchoscopy. More recently the

Figure 31.13 Ravussin style cricothyrotomy cannula.

Figure 31.14 Sanders injector.

Figure 31.15 Ventrain device.

Manujet (VBM Medizintechnik GmbH, Sulz, Germany) has been widely used. It has the advantage of an adjustable pressure gauge to tailor inspiratory pressures between 0.5 and 4 bars. Other disposable devices for jet injection are available, such as the ENK flow modulator (Cook) and the Ventrain device (Dolphys medical; **Figure 31.15**), which can actively assist expiration. It is recommended that the pressure that should be used need be only the minimum required to raise the chest wall for inspiration (individual considerations would have to be accounted for if the patient had poor chest wall or lung compliance).

Exhalation occurs through the upper airway and particular attention must be taken to ensure that this happens, otherwise airway pressures rise and pulmonary barotrauma develops, as do haemodynamic consequences. A needle cricothyrotomy is a temporary measure; it will provide for oxygenation and so will give some time. However, it does not allow for adequate gas exchange and fatal hypercarbia can ensue. Consideration must be given to creation of a tracheostomy or competent airway allowing for adequate ventilation in relevant circumstances. It is possible for ventilation via needle cricothyrotomy to be used in the planned elective or urgent case. **Figure 31.16** shows a patient whose partial denture had fallen into the pharynx in such a position that the larynx was obscured. The cricothyrotomy needle was placed in the awake patient and its correct position in the trachea confirmed by aspiration of free air and attachment of the capnograph to show an appropriate trace. Following intravenous anaesthesia and muscle relaxation, the Sanders technique of intermittent application of high-pressure oxygen provided adequate oxygenation and ventilation. Exhalation through the upper airway was unobstructed.

Large cannula cricothyrotomy

A purpose-built cannula with an internal diameter of >4mm allows adequate inspiratory gas flows with the pressures generated by the standard breathing system and exhalation of 500mL takes approximately 5–6 seconds. This is an advantage because there is no requirement for high-pressure oxygen. It is easy to attach the capnograph

Figure 31.16 Planned use of transtracheal jet ventilation.

Figure 31.17 Combined Melker cricothyrotomy set.

to the circuit for confirmation of correct positioning within the trachea, and to suction the respiratory tract. Exhalation occurs through the cannula, even in the presence of complete upper airway obstruction. The cannula may be a cannula-over-needle or a Seldinger-type dilatational device. Cannula-over-needle devices place an uncuffed tube whereas the Melker Seldinger device allows positioning of a 6.0mm cuffed tube (**Figure 31.17**). There are advantages in placing a cuffed tube in allowing controlled positive pressure ventilation and protecting the airway.

Surgical cricothyrotomy

The technique is to make a 3cm midline incision in the skin followed by a horizontal stab incision in the inferior part of the cricothyroid membrane. The incision is spread horizontally and vertically and a 6mm tube is inserted. The complication rate was 40% in one series of 38 emergency surgical cricothyrotomies. Misplacement and bleeding requiring ligation of vessels were the most common problem. A more rapid four-step technique has been described⁴⁴ in which a single horizontal incision is made

through the skin and cricothyroid membrane together. In a cadaver study, emergency physicians compared the standard and rapid technique. The rapid technique was faster than the standard 43 versus 134 seconds, but the complication rate was higher. The horizontal incision through the skin may cause more haemorrhage. A cricothyrotomy tube should not be left in place for more than a few days and conversion to tracheostomy prevents the complications of dysphonia and subglottic stenosis.

OBSTRUCTED AIRWAY

The obstructed airway⁴⁵ is one in which the primary symptoms or signs are due to narrowing or distortion of the airway. There are two broad clinical presentations. In acute obstruction (Figure 31.18), a previously normal person develops problems over a matter of minutes or hours. The aetiology is usually one of inhaled foreign body or abnormal fluid accumulation, such as blood, pus or oedema. Typical clinical scenarios are infections in the head and neck, post-operative haematoma, and airway swelling secondary to anaphylaxis or angiotensin-converting enzyme inhibitors. The rapidity of onset produces prominent signs of difficulty with breathing and the patients may present in extremis. Imaging of the airway by X-ray, CT or MR scan is desirable but often inappropriate because the

Figure 31.18 Patient with Ludwig's angina.

patient may be unable to adopt the necessary position to complete the procedure and the radiology suite is not an appropriate location for a patient with a deteriorating airway. The management of acute obstruction includes 100% oxygen by face mask and continuous positive airway pressure (CPAP), adrenaline (epinephrine) if oedema is prominent, steroids intravenously and a trial of administration of heliox. This is known as CASH management, with the rapid institution of these measures in a stridulous patient aimed at buying time until pus is drained and tracheal intubation, emergency cricothyrotomy or tracheostomy is performed and the airway secure. Heliox is a combination of oxygen 21% and helium 79% and is three times less dense than air because of the low atomic weight of helium (4) compared with nitrogen (14). In airway obstruction, turbulent gas flow is inversely proportional to the square root of density and the use of heliox improves gas flow in turbulent conditions and also promotes laminar flow (Figure 31.19). It is suggested also that carbon dioxide molecules diffuse four to five times faster through heliox than an equivalent oxygen–nitrogen mixture and this may enhance carbon dioxide excretion in the airway.

In chronic obstruction, the airway pathology has developed over a period of weeks or months and is usually due to growth of tissue or to scarring. The slow onset allows development of enlarged intercostal muscle mass and patients can tolerate a very significantly narrowed airway without symptoms. Generally, a patient will not be dyspnoeic at rest until the airway is narrowed to <5 mm diameter, although they are likely to be short of breath on exercise. The slower time course of obstruction allows complete imaging of the airway and controlled intervention. Appropriate imaging in the stable, chronic condition is through flexible nasendoscopy and CT or MR imaging of the entire airway. Flow-volume loops may be helpful in detecting that a patient's problem is large airway narrowing and not truly pulmonary, or assessing the degree of tracheal narrowing before planning surgery.

Evaluation of the obstructed airway seeks to define the degree of obstruction, likely site, rapidity of onset and likely time course of deterioration by history, examination and special investigations. The history from the relative or patient usually indicates whether this is acute, chronic

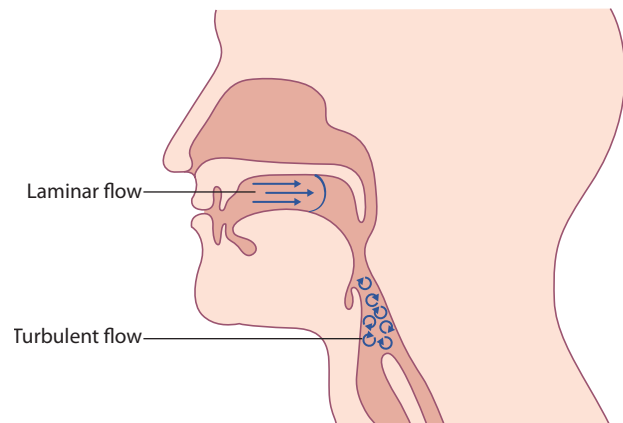

Figure 31.19 Laminar to turbulent flow.

or acute-on-chronic. Specific symptoms/signs in airway obstruction are degree of difficulty with breathing, stridor (noisy breathing) and phase of respiration of any stridor. Stridor indicates that the airway is narrowed to <50% of normal diameter, but this degree of airway narrowing is not always accompanied by stridor. Expiratory stridor indicates an infraglottic problem and inspiratory stridor a supra or glottic aetiology. There may be a positional aspect to the difficulty with breathing and patients may be more comfortable in the sitting or lateral position. Voice change and difficulty with swallowing may indicate the site or extent of disease, and pyrexia or sepsis indicates an infective component. Unilateral reduction in breath sounds indicate specific bronchial obstruction. With progressive obstruction, signs of ineffective ventilation and poor gas exchange are present. These include agitation, anxiety, confusion, restlessness and depressed level of consciousness. Increased work of breathing is indicated by a high respiratory rate, use of accessory muscles of respiration, flaring nostrils, sweating and tachycardia. Oximetry is not a good monitor of work of breathing and normal oxygen saturation does not indicate that all is well. In severe acute obstruction with untrained respiratory muscles, exhaustion occurs relatively quickly with a resulting decrease in effective minute ventilation, hypoxaemia, bradycardia and death.

Management strategy in the obstructed airway

Deaths resulting from an airway that is obstructed due to a pathological process are usually due to the underlying disease process. However, cases with these pathologies where the airway has been difficult to maintain in the theatre or recover unit have led to deaths.⁴⁶ In the NAP4 study 70% of adverse events reported in patients having head and neck surgeries were in patients with an obstructed airway. This includes patients with stridor but also those without. Patients with friable necrotic tumours may be made much worse by attempts at intubation causing swelling, oedema and bleeding and progressive difficulty in face-mask ventilation and this was reflected in the case studies that were reported. In addition, gas induction with the maintenance of spontaneous respiration in patients with obstruction is difficult, the airway liable to deterioration as anaesthesia deepens and airway tone is lost. Those patients with painful faces or necks associated with obstruction are liable to laryngospasm when the chin is lifted and pressure is placed on painful tissues by a face mask. This is explored in more depth later.

Patients should be seen by a senior surgeon and anaesthetist who consider carefully the plan for securing the airway and a backup strategy. Imaging of the airway should be obtained, if possible, to allow delineation of whether the airway is narrowed at supraglottic, glottic or infraglottic level. There should be coherence between the individual plans A–D. For example if a long-acting muscle relaxant is used in plan A, plan B cannot rely on a patient ‘waking-up’. If a surgical tracheostomy is the back-up plan,

anaesthesia should start in the operating theatre with the equipment, surgeon and theatre team immediately ready – it is foolish to start anaesthesia in the anaesthetic room and scramble into theatre when plan A fails. There has been much discussion in the anaesthetic literature about provision of anaesthesia in the presence of the abnormal airway but general agreement that classification according to the site of obstruction is helpful. Currently, the terms used by anaesthetists are not as precise as the ones used by surgeons to localize tumours.

‘SUPRAGLOTTIC’ OBSTRUCTION

In ‘supraglottic’ obstruction the obstruction is above or superior to the glottis and the glottic aperture is of normal dimensions. An example would be a base of tongue tumour (Figure 31.20), although clearly this is not truly a supraglottic structure in disease terminology. Direct laryngoscopy is likely to prove difficult and may cause bleeding if the blade contacts the tumour. It may also prove difficult to ventilate by face mask following induction of general anaesthesia. In this circumstance it is helpful to retain spontaneous respiration and to use an alternative means of intubation. Awake fibre-optic intubation (Figure 31.21) by the nasal or oral route has much to recommend it.⁴⁷ It is used successfully in adult patients with deep neck infections including classical Ludwig’s angina.⁴⁸

Awake intubation is a misnomer because it is very difficult to intubate a truly awake patient. The more correct term is tracheal intubation under topical anaesthesia with conscious sedation. It has a very good record of safety in airway management because the patient maintains his or her own airway and continues with spontaneous respiration until the airway is secure. It is possible for the patient to adopt a change in position, such as sitting up, and to aid intubation by protruding their tongue, vocalizing or taking deep breaths. There are a number of intubation techniques in an awake patient, such as oral direct laryngoscopy, blind intubation through the nose, through the classic or intubating laryngeal masks or a retrograde wire technique, although none of these are commonly practised.

Awake fibre-optic intubation (AFOI) appears to be the best technique, combining awake intubation with a

Figure 31.20 Magnetic resonance image of tongue base tumour.

Figure 31.21 Awake fibre-optic intubation.

visually guided method of both inspecting and intubating the airway, applying local anaesthesia to the airway and confirming correct positioning of the tube within the trachea. Fibre-optic intubation is generally easier in the awake rather than anaesthetized, paralysed patient because airway patency is maintained, the airway opens and closes with respiration and the flow of gas indicates the route to the larynx.

There are a number of specific practical steps and attention to detail is required. Premedication may be employed if there is no airway embarrassment, but should be avoided if there are symptoms or signs of airway obstruction. An antisialogogue is important and absence of secretions allows earlier and more profound topical anaesthesia, and easier fibre-endoscopy. Pre-operative intramuscular atropine 0.6 mg, hyoscine 0.4 mg or glycopyrrolate 0.4 mg are suitable. Although it is common to administer glycopyrrolate 0.2–0.4 mg intravenously as soon as the patient arrives in the operating room, the antisialogogue effect when used this way is limited and patients may develop tachycardia.

Sedation aims to provide a comfortable patient who maintains spontaneous respiration, airway patency and verbal contact.

Remifentanyl is an ultra-short-acting opioid that is commonly used nowadays by target-controlled infusion (TCI) or in micrograms per kilogram per minute for conscious sedation. It has a profound effect on airway reflexes and the cough response that is desirable during AFOI. It is often used as the sole sedative technique for AFOI.⁴⁹

Small incremental doses of a benzodiazepine and opioid may administered, taking care not to produce over sedation. Typical total doses are midazolam 1–5 mg and fentanyl 25–100 µg. Both drugs have a peak onset of 5 minutes and a specific antagonist (flumazenil and naloxone, respectively).

Benzodiazepines cause relaxation of genioglossus and destabilization of the airway and opioids are associated with central respiratory depression so neither drug is benign. However, appropriate doses produce a compliant patient who is not unduly upset by airway topicalization or instrumentation, and is usually amnesic.

Propofol, an anaesthetic agent, provides sedation at subhypnotic concentrations and is used by some anaesthetists for conscious sedation by target-controlled infusion. TCI devices are sophisticated syringe pumps that incorporate a pharmacokinetic model of the relevant drug. The operator enters the age and weight of the patient and the desired blood level. The TCI pump calculates and delivers the appropriate bolus dose to reach the required blood level and the subsequent infusion required to maintain it. Appropriate starting blood levels for propofol are 0.5–1.0 µg/mL.

There are a variety of ways of topicalizing the airway with lignocaine, most practitioners having their ‘own way’ of administering the local to the mucosa. There is no evidence reporting one technique being better than the other; however, it is important to keep in mind that local anaesthetic effect will be reduced if tissues are acidotic and that local anaesthetic toxicity is a small risk when using larger doses that are then followed by infiltration of tissues as part of a surgical procedure. The majority of lignocaine administered by topicalization will be swallowed and metabolized by first pass metabolism and so will contribute little to plasma concentrations. However, that fraction that reaches the larynx trachea and bronchial tree will raise blood levels.

If the nasal route is chosen for intubation, a topical vasoconstrictor should be applied. This may be xylo-metazoline or phenylephrine spray, ephedrine 0.5% drops or cocaine (3 mL 5%), which produces both vasoconstriction and topical anaesthesia. The use of cocaine as a vasoconstrictor for AFOI has reduced in popularity in the last 10 years.

Topical anaesthesia with lignocaine may be provided by:

- nebulization
- translaryngeal administration
- specific nerve blocks
- transendoscopic administration.

Nebulization sounds attractive but use of the technology that provides particles for alveolar deposition of drug (e.g. salbutamol nebulizer) may lead to disappointing results, partly because the particles are too small but also because a large amount of the drug escapes to the atmosphere. High drug concentrations may be effective and nebulized lignocaine 10% in a dose of 6 mg/kg has been described as effective.

A useful variant is the production of a larger droplet size produced during inspiration. This manual spray-and-inhale technique historically employed a 22 g Venflon attached to a constant oxygen flow rate of 1–2 L/min. Specific mucosal atomizer devices are now widely available for this purpose. Small increments of lignocaine 4%

are injected and coordinated with inspiration. One spray-and-inhale regime is to use 3 mL lignocaine 4% with ephedrine 15 mg to the nose, wait 3 minutes and apply the second 3 mL lignocaine 4%, asking the patient to inspire deeply and slowly through the nose. The droplets are inhaled and deposited onto the larynx and trachea. After a 3-minute wait, a further 3 mL lignocaine 4% is nebulized during slow forced inspiration. Maximum lignocaine dosage should be 9 mg/kg.

Translaryngeal administration has a long history of safe use.⁵⁰ A 22 G cannula or needle is passed through the cricothyroid membrane or trachea and 3–4 mL lignocaine 4% is injected preferably at end-expiration. The injection provokes a short period of intense coughing, which distributes the drug to the glottis and above. The experimental addition of methylene blue to the local anaesthetic shows staining of the superior aspect of the vocal cords in 95% of patients.

Appropriate specific nerve blocks are of the superior laryngeal and glossopharyngeal nerves and are uncommonly used for AFOI. The internal branch of the superior laryngeal nerve supplies sensation to the under surface of the epiglottis and the superior surface of the vocal cords. It may be blocked on each side as it traverses the thyrohyoid membrane. Extension of the head and neck aids identification of the hyoid and thyroid cartilages. A 22 G needle is placed inferiorly to the greater horn of the hyoid, passed into the membrane and 2 mL lignocaine 2% is injected. The glossopharyngeal nerve supplies sensation to the posterior third of the tongue, superior part of the epiglottis, lateral pharyngeal wall and inferior surface of the soft palate. The nerve may be blocked behind the anterior pillar of the tonsillar fossa. With full mouth opening the tongue is grasped and pulled to the contralateral side. A 20 G spinal needle is inserted to a depth of 5 mm into the base of the anterior tonsillar pillar at the level of the reflection onto the tongue, and 2 mL lignocaine 2% injected. Bilateral glossopharyngeal nerve blocks will abolish the gag reflex and allow greater manipulation in the oropharynx or direct laryngoscopy, perhaps when placing a large double lumen tube. These specific nerve blocks are not performed routinely.

Transendoscopic administration of lignocaine 4% through the working channel of the intubating fibroscope is an extremely effective means of applying local anaesthetic to the airway under vision. This spray-as-you-go technique is highly favoured and non-invasive. The intubating fibrosopes have connectors for injection but an easier alternative is to place an epidural catheter, cut to produce one terminal hole, substantially into the working channel (**Figure 31.22**). Aliquots of lignocaine 4% to a maximum dose of 9 mg/kg are administered.

It is helpful for the fibroscope to be attached to a CCTV system, particularly for training. An appropriate size tracheal tube is loaded onto the fibroscope and the scope is introduced under vision into the mouth or more patent nostril. The fibroscope is advanced without touching the mucosa until the vocal cords are seen. Additional local anaesthetic may be applied before the fibroscope is advanced to the carina. The tube is advanced or railroaded

Figure 31.22 Injection of lignocaine through an epidural catheter inserted into working channel of fibroscope.

over the fibroscope. This may be difficult because the bevel impinges on the larynx. Use of a small diameter tube and rotation of the tube minimize this problem.

Awake fibre-optic intubation may be difficult when the airway anatomy is abnormal and when there is blood or secretions in the airway. An illustrative case scenario indicates some of the pitfalls in management. An adult patient underwent removal of a fishbone impacted in the lower pharynx/upper oesophagus. Three days later the patient was pyrexial, with a sore throat, unable to swallow and with limited mouth opening. A lateral X-ray of the neck showed a retropharyngeal abscess. The patient was seen by two anaesthetic trainees, who did not inform the consultant on call. They decided on an awake fibre-optic intubation but administered too much sedation. In a deteriorating situation with a semi-rousable patient they attempted nasal fibre-optic orotracheal intubation (FOI) with the patient supine. They were unsuccessful and were moved aside by the consultant surgeon who managed to intubate the patient fibre-optically with the patient sitting, leaning forward on the edge of the operating table. Mistakes made here include failure to appreciate the seriousness of the condition and to inform a consultant, failure to realize that awake nasal FOI in the supine position would be difficult in the presence of retropharyngeal swelling and failure to realize that airway patency would be compromised by any sedation.

PERIGLOTTIC/GLOTTIC OBSTRUCTION

In these situations it may be difficult to visualize the vocal cords by direct laryngoscopy and the glottic aperture may be significantly narrowed or distorted. Much lively discussion is evident over the correct anaesthetic technique. When awake fibre-optic intubation is used, it allows visualization of the airway but becomes less useful in the patient with stridor due to glottic narrowing. The fibroscope has little rigidity to 'push' through a narrow hole and attempts to do this may precipitate bleeding and oedema. If the scope is passed through a small hole, the airway is completely obstructed for a short time and patients feel uncomfortable at this stage. Panic and ongoing obstruction with this 'corking the bottle' effect

can lead to airway catastrophe. There have been a few reports^{51, 52} of destabilization of the airway by applying anaesthetic agent to the airway and this is a reminder of the need to work at all times in the correct environment for immediate activation of the pre-formulated back-up plan. Awake fibre-optic intubation is, therefore, a technique that should always be considered but may not be suitable. It is not appropriate when adequate operator skill is not present, in children and uncooperative adults and in the opinion of some anaesthetists when stridor is present.

Mason and Fielder⁵³ argue that the correct anaesthetic technique in the presence of stridor due to periglottic/glottic pathology is inhalational induction of general anaesthesia. This permits a gradual onset of anaesthesia and maintains spontaneous respiration, even at a depth of anaesthesia appropriate for direct laryngoscopy and intubation. The maintenance of spontaneous respiration is viewed as highly desirable with supraglottic airway obstruction. A typical case scenario would be a child with epiglottitis and, in a survey of college tutors in the UK, 98% of anaesthetists would choose this form of anaesthesia. The face mask is applied to the patient who is in the most comfortable position (sitting if necessary) and 100% oxygen administered for a few minutes. The volatile agent is administered in increasing concentrations until a surgical level of anaesthesia is obtained. The agent commonly used initially is either halothane or sevoflurane and both drugs are non-irritant so do not provoke coughing. The speed of onset of anaesthesia is inversely proportional to the blood-gas solubility and is therefore faster with sevoflurane (0.6) than halothane (2.4). However, it is more difficult to establish sufficient depth of anaesthesia to instrument the airway with sevoflurane and it has a more rapid offset than halothane. Halothane may be associated with increased cardiac rhythm irritability and is now difficult to obtain in the UK. It is usual, therefore, to start with sevoflurane and consider a change over to isoflurane which does permit adequate levels of anaesthesia.

It is not an easy anaesthetic to administer in the presence of stridor and requires a sanguine anaesthetist. There may be periods of increasing obstruction due to glottic irritability or change in position. Generally, there should be no change in the position of the anaesthetist's hands or the face mask and no attempt in light planes of anaesthesia to provide positive pressure ventilation. Insertion of an oral airway is risky but there may be benefit in a nasopharyngeal airway, although it is perhaps useful to have applied a vasoconstrictor to the nasal mucosa first. Glottic irritability is confined to light planes of anaesthesia and should resolve, although induction may take much longer than normal because of the reduced alveolar ventilation. When an adequate depth of anaesthesia is reached, which may take 20 minutes, direct laryngoscopy is undertaken. The view may be quite abnormal and it may be necessary to press on the chest and observe the egress of bubbles to detect the glottis. A small tube will be needed and the use of a bougie should be considered. If intubation is not possible, the face mask is reapplied and a tracheostomy undertaken. Plan B must be formulated

and ready so that anaesthesia is induced in the operating theatre with the surgeon scrubbed and ready to undertake tracheostomy.

It is apparent that the safety of any approach is the combination of plans and the close cooperative working of the surgeon, anaesthetist and theatre team. In the common scenario of a known obstructing glottic tumour that requires initial histology and debulking, it is possible to construct a primary plan of (in the operating theatre) preoxygenation, followed by intravenous induction and rapid muscle relaxation. Direct laryngoscopy using a bougie and size 5.0 mm microlaryngeal tube is attempted. If it is unsuccessful, the surgeon is in the best situation to undertake tracheostomy – the patient is as well oxygenated as possible, unconscious and remains still. This technique is logical and popular but appears 'heretical' since it abolishes spontaneous respiration. However, it illustrates that safety lies in the combination of plans rather than any particular plan A. It also demonstrates that the site of obstruction requires plans that are specific for that level of obstruction and the safety that arises from the close working of experienced surgeon and anaesthetist.

There is an increasing evidence-base to the practice of planned prior placement of a transtracheal ventilation catheter under local anaesthesia and using this as a route for oxygenation and ventilation during intubation attempts under general anaesthesia.⁵⁴

TRACHEOSTOMY UNDER LOCAL ANAESTHESIA

This should be considered in any patient with an obstructed airway. It is particularly appropriate as the primary plan when the disease process is a large friable mass or abscess in the supraglottis or glottis and intubation attempts may destabilize or compromise the airway. There are differences between countries and between surgeon-anaesthetist pairs as to when the patient undergoes traditional intubation in the awake or anaesthetized state or awake tracheostomy. Elements within the decision-making are the availability of a skilled fibre-endoscopist, the ability of the patient to cooperate with the procedure and adopt a suitable position, the pretracheal anatomy and the likely time for resolution of the disease process. It may be a very difficult procedure in patients with short stocky necks, a previous tracheostomy or post-radiotherapy with respiratory distress. Considerations may be complicated by front-of-neck pathology or the patient's inability to lie flat.

Tracheostomy under local anaesthesia is undertaken in the operating theatre with the patient breathing oxygen or heliox, monitored by non-invasive blood pressure, ECG and pulse oximetry with intravenous access. CASH management can be continued throughout the procedure in the semi-sitting position with a roll under the shoulders and neck extension is ideal. Generally, reassurance is given to the patient but intravenous sedation is not required and should be used cautiously. Restlessness during the procedure may be due to hypoxia, hypercarbia or an inability to breathe in that position. Sedation may destabilize the airway leading to sudden hypoxia and

loss of consciousness. Consideration may be given to conscious sedation with remifentanyl with the primary aim of obtunding the airway reflexes and improving the distress of the patient; however, caution is highly advisable. The anaesthetist must be prepared for the back-up plan if the patient deteriorates. Placement of a cricothyrotomy needle at the outset may be useful when it is known that the pathology is supraglottic. The cricothyrotomy needle does not interfere with a surgical tracheostomy and can be used to provide oxygenation. If the patient becomes so restless that the surgeon is unable to operate, consideration should be given to providing general anaesthesia and oxygenation through the needle.

Another option in the distressed patient is to provide sedation/anaesthesia by addition of a volatile anaesthetic agent, such as sevoflurane, to the breathing system with 100% oxygen. At best, the airway proves to be adequate enough to allow a surgical plane of anaesthesia to be reached and the tracheostomy is undertaken in a relatively unhurried fashion on 100% oxygen/sevoflurane by face mask. At worst, the airway deteriorates with the onset of sedation/anaesthesia but the patient stops moving and a rapid emergency tracheostomy can be undertaken. In a rapid tracheostomy, the surgeon enters the airway with one or two incisions and a small cuffed microlaryngeal or armoured tube size 5.0–6.0 mm is inserted. Once the patient has been stabilized, a more measured exploration of the neck and fashioning of a formal tracheostomy may be undertaken.

It is important to verify that the tube is within the trachea before ventilation starts, otherwise gas may be forced into the mediastinal tissues. Signs of correct placement when undertaking a tracheostomy under local anaesthesia (with the patient breathing spontaneously) are firstly regular respiratory movement of the reservoir bag of the anaesthetic breathing system connected to the tracheostomy tube, and the presence of six successive breath-related carbon dioxide traces on the capnograph. If no carbon dioxide is detected in the breathing system, inflation of the cuff of the tracheal tube or tracheostomy and connection of the capnograph to the breathing system should be checked first. If both are correct, failure to detect carbon dioxide indicates that the tube is not in the airway. When an emergency tracheostomy is undertaken in an apnoeic patient, the confirmatory signs of anaesthetic bag movement and capnography can be obtained only by applying a number of positive pressure breaths. If the tube is not within the trachea, these positive pressure breaths into the mediastinum may prove deleterious. An alternative confirmatory device in these circumstances, although not widely used, is the oesophageal detector device. The principle is simple and takes advantage of the structural differences between the oesophagus and trachea. In the original version described by Wee in 1988,⁵⁵ an empty 60 mL syringe is attached to the 15 mm connector of the inserted tracheal tube and aspiration attempted. Aspiration of air is not possible if the tube is in the oesophagus because the mucosa is 'sucked' over the end of the tube, whereas the more rigid cartilaginous

structure of the trachea allows free aspiration of air. The syringe can be replaced by a self-inflating bulb with a volume of approximately 75 mL and in this version the bulb is squeezed flat before being attached to the inserted tube. If the bulb re-inflates immediately, the tube is in the trachea and if the bulb does not re-inflate the tube is in a false passage or the oesophagus.

SUBGLOTTIC AND MIDTRACHEAL OBSTRUCTION

Imaging is particularly useful in delineating the length of narrowing, the diameter of the airway at its narrowest and that sufficient distance is present inferiorly to the obstruction to permit the cuff of a tracheal tube to be positioned above the carina. The obstruction may arise from external pressure, such as a retrosternal goitre or other mediastinal mass, from a mass arising from the trachea, from an inflammatory condition such as Wegener's granulomatosis, from previous surgery or from damage due to prolonged intubation. The type of narrowing may range from a short subglottic stenosis due to previous prolonged intubation to a narrowing of several centimetres in the midtrachea due to tumour. In the presence of stridor, the principles of management vary according to whether it can be bypassed by tracheostomy. This will be true for subglottic disease but the Confidential Enquiry into Patient Outcome and Death (CEPOD) assessors noted that in two patients it had been difficult to bypass a mid/low tracheal lesion with a standard length tracheostomy tube. Awake fibre-optic intubation has a role in management of trachea narrowing, allowing inspection of the airway and confirmation that the tip of the tracheal tube has passed beyond the obstruction. Rigid bronchoscopy is an extremely effective means of managing these patients.

LOW TRACHEAL OBSTRUCTION

Narrowing of the lower trachea or carina presents great difficulty. The anaesthetic literature contains case reports of failed airway maintenance leading to death.⁵⁶ This characteristically occurs after induction of general anaesthesia or muscle relaxation when, presumably due to loss of muscle tone, airway patency is lost. Tracheal intubation may not provide an adequate airway because the obstruction is beyond the tip of the tube. Occasionally, the presence of carinal obstruction is not known and anaesthetic induction, intubation or indeed extubation may result in unexpected disaster. When imaging has provided good pre-operative localization of obstruction, a number of options may be used. Rigid bronchoscopy is invaluable and will often provide a route for ventilation ([Figure 31.23](#)). The rigid bronchoscope may also act as a guide to therapy, such as lasering of a tumour or introduction of a tracheobronchial stent. Surgical resection of carinal lesions requires specialist anaesthetic techniques including jet ventilation and undertaking surgery during cardiopulmonary bypass.

Figure 31.23 Rigid bronchoscopy used for ventilation and conduit for tracheal stent.

JET VENTILATION

Jet ventilation as an in-theatre technique is associated with allowing access in Head and Neck/ ENT surgery and also as an airway rescue technique. It has also been described as a technique for facilitating thoracic radiology procedures and rigid bronchoscopy, and was first described as such over 40 years ago.^{57–59} This chapter does not consider its use as a mode of ventilation on critical care.

It is best considered by its nature (high- or low-frequency) and by its position (supraglottic, subglottic or transtracheal). Delivery of each of these has advantages and disadvantages. High-frequency jet ventilation is defined as a respiratory rate of between 1 and 10 Hz and requires the use of a specific device. Low-frequency jet ventilation can be delivered by a Manujet (VBM) at a lower rate (Figure 31.24). More complex modes of jet ventilation are described. Superimposed High-Frequency Jet Ventilation combines HFJV with LFJV and has been shown to be effective in patients and offers potential benefits in terms of end-expiratory volumes.^{60, 61}

Mechanism: The most common mistake made about jet ventilation is in its mechanism of action. It does not work by the Venturi effect; it works by friction. There are actually six postulated mechanisms as to how it might function:

1. Convective or Bulk flow.
2. Laminar flow in the small airways.
3. Pendelluft.
4. Cardiogenic mixing.
5. Molecular Diffusion.
6. Taylor type dispersion.

Describing jet ventilation

Jet ventilation can be defined in terms of the Driving Pressure (up to 4 bar), the pressure generated by the ventilator, the frequency (or cycles per second) of jet ventilation (between 60 and 600 Hz) and the pause pressure. Pause pressure is sensed in the last 10 milliseconds of the expiratory pause. If the pause pressure alarm value is

Figure 31.24 A low-frequency jet ventilation system. Simple to use, however lacking the safeguards of a more complex high-frequency jet ventilator.

exceeded then cycling is stopped preventing breath stacking. This is well described by Wiedemann and Mannle.⁶²

Various articles have looked at the complications of jet ventilation. Hu et al reported a series of 839 cases using the Hunsaker tube.⁶³ They reported a complication rate of 5.8%, although 47 of the 58 complications were cited as hypoxia (Spo₂ < 90%) or hypercarbia (CO₂ > 60 mmHg). There were 2 cases of barotrauma and 4 cases of airway obstruction. They cited risk factors for complication as being a higher BMI, ASA class 3 or 4, history of heart disease, history of previous laryngeal surgery, longer case duration, and use of a laser. Patel and Rubin have reported 2 series; 142 cases who were grade I laryngoscopy with a complication rate of 0.7% (Rubin JS 2005) and a difficult airway series looking at 89 cases where they reported no anaesthetic or surgical complications, but noted that higher BMI patients required an increased driving pressure.^{64, 65} Jaquet et al. reported a series of 734 jetted patients with 24 minor complications and 4 major ones.⁶⁶ Transtracheal jet ventilation was associated with a significantly higher complication rate than transglottal jet ventilation. Serious complications occurred when jetting took place in the presence of airway outflow obstruction. They concluded that the use of a transtracheal jet ventilation catheter was the major independent risk factor. Bougain et al. provide different evidence of transtracheal

jet ventilation.⁶⁷ In their series of 643 episodes of transtracheal high-frequency jet ventilation they reported a 1% pneumothorax rate (57% required drainage) and an 8.4% rate of surgical emphysema. They concluded that transtracheal ventilation from an automatic ventilator with a cut-off alarm was safe for experienced users.⁶⁷ In their survey in 2008 Cook and Alexander noted that complications over a 5 year period were evenly spread between subglottic, supraglottic and transtracheal techniques although deaths all occurred in departments using low-frequency jet ventilation (no pressure alarms).⁶⁸ The three centres performing more than 100 cases of transtracheal jet ventilation did not report any serious complications.

The future

In 1990, Smith suggested that high frequency ventilation was here to stay.⁶⁹ However, in recent years, there have been innovations that may offer an alternative technique. The ventrain was designed by Enk, as an alarm-free manually operated device that permits transtracheal ventilation.⁷⁰ Driven by a conventional wall oxygen flowmeter it can generate a driving pressure for inspiration of 2.3 bar (pressure). However, crucially it can also generate a suction pressure to facilitate expiration (EVA-expiratory ventilation assistance) and avoid air trapping. Unfortunately, clinical trials of the device are limited at present. Unlike other forms of jet ventilation the Ventrain works by the Bernoulli principle.

High-flow oxygen therapy may also be an alternative to jet ventilation; however this technique is yet to be evaluated in patients under general anaesthesia.⁷¹

EXTUBATION AND RECOVERY

At the end of surgery a decision is made as to where and when the airway device should be removed. There is little problem with removal of a laryngeal mask. This is usually tolerated well by a patient until they are awake. Tracheal intubation is common in head and neck surgery due to the constraints of providing clear operative fields for the surgeon and maintaining a secure airway to the distal trachea. Extubation requires as much thought, and gives rise to as much difficulty, as intubation. Transient difficulties with oxygen saturations are common due to coughing, breath-holding and laryngospasm, particularly in children. Extubation problems may arise in those patients who were difficult to intubate and those who were not difficult to intubate but in whom surgery has affected the airway. Of the NAP4 reports, 28% of airway complications were reported at emergence or during recovery from anaesthesia and in all cases airway obstruction was the problem.

Default strategy at extubation when no difficulty is expected is for the anaesthetist to remove any pharyngeal packs, suction the pharynx under direct vision, administer 100% oxygen, antagonize residual neuromuscular blockade and consider whether to remove the tube in the anaesthetized or awake state. After extubation, 100% oxygen is administered by face mask and the patient observed by the

anaesthetist until it is clear that the patient is safe to go to the post-anaesthetic care unit (Recovery).

In the patient with a normal airway who was difficult to intubate, it is prudent to make certain that oxygen stores are maximal and to extubate in the awake state. Lung oxygen stores can be considered maximal when the end-tidal (i.e. alveolar) oxygen is 91%. This may take at least 5 minutes of breathing 100% oxygen or longer if nitrous oxide has been used. Awake extubation refers to removal of the tracheal tube when the person has opened their eyes and is able to obey commands. An additional option is to assess the leak around the tube before removal. This may be carried out by applying positive pressure to the tube, deflating the cuff and listening for egress of gas around the tube, or alternatively occluding the tube in spontaneous respiration and making certain that inspiration can occur around the tube. Failure of a leak test indicates that the tube is a very tight fit within the airway and an inadequate air passage may be left after extubation.

In the patient with an abnormal airway, either present pre-operatively or due to surgery, consideration should be given to keeping the tracheal tube in situ for 24–48 hours until any airway oedema subsides. The patient should be nursed in a high-dependency unit with an appropriate level of sedation to avoid inadvertent removal of the tube. In some circumstances it is appropriate to perform a tracheostomy to provide a secure airway in the first few post-operative days.

Extubation of the high-risk airway requires a strategy. Anticipation of complications may be possible, for example long complicated head down surgeries may be accompanied by laryngeal oedema. Awake extubation after maximal oxygenation in the presence of an anaesthetist in a well-equipped environment may be a good plan A, but what happens if it fails? The situation rapidly becomes critical with a struggling, hypoxic patient possibly with blood in the oropharynx. One possibility is to extubate over a thin bougie and to leave the bougie in the airway for a period until it is certain that the patient is coping satisfactorily. The bougie acts as a guide if reintubation is required and, if it is hollow, may be used for emergency oxygenation.

Problems may arise in the Recovery unit or post-operatively on the ward. Of most concern is post-operative bleeding following carotid endarterectomy or removal of a parapharyngeal mass. The physical presence of a mass of blood may compress the airway itself but also induces mucosal oedema, perhaps by impairment of lymphatic drainage. The deterioration of the airway may be very dramatic and necessitate emergency cricothyrotomy or tracheostomy as part of resuscitation. In a dire situation it is always worth fitting an LM. It is helpful to open the wound and evacuate the blood clot and this may provide temporary improvement. The patient is returned to theatre for surgical exploration. Intubation should take place with the patient breathing spontaneously, if possible. This may be by awake intubation or with inhalational anaesthesia. Blood in the pharynx may impair the view and the first response

Figure 31.25 Post-extubation emergency tracheostomy.

is to try suctioning. An LM may cover the larynx and provide some respite before being used as a conduit for intubation. Emergency tracheostomy may be required. In the patient in [Figure 31.25](#), drainage of a peritonsillar abscess had been undertaken with intubation by awake fibre-optic intubation. The patient had been extubated and returned to Recovery. Approximately 45 minutes later, the patient developed severe breathing difficulties and was returned immediately to the operating theatre. Awake intubation was not possible due to soiling of the airway, the patient was too restless to adopt a position suitable for formal tracheostomy and, in a deteriorating situation, the surgeon managed to carry out a rapid emergency tracheostomy.

The Difficult Airway Society have recently seen published extubation guidelines in an effort to reduce complications at extubation.²³

FOLLOW-UP

Following difficulties with airway management, a certain scheme should be followed. An account of the problem and management should be written in the anaesthetic record and in the hospital notes. The patient needs to be reviewed clinically to detect and treat any morbidity, an explanation is required for the patient with details of the problem encountered and management, and a written account should be sent to the patient with a copy to their general practitioner.⁷² If the problem with airway management is

likely to be recurrent with subsequent anaesthetics, consideration should be given to the patient registering with Medic Alert and wearing a bracelet or to registering the patient with the difficult airway database supported by the Difficult Airway Society.

Immediate morbidity or mortality from difficult airway management arise from the effects of severe hypoxia, hypercarbia or cardiovascular responses, from failure to adequately protect the airway leading to aspiration and from physical trauma to the airway during attempts at intubation or resuscitation. Airway damage may occur even when airway management has not been notably difficult. Valuable information can be obtained from detailed analysis of the medical information contained in insurance reports, once claims for negligence have been settled or closed. In an analysis of such closed claims in North America,⁷³ 6% of 4460 claims were for airway injury. The most frequent sites of injury were the larynx (33%), pharynx (19%) and oesophagus (18%). Approximately 20% of laryngeal injuries were associated with difficult intubation and included granuloma formation, arytenoid dislocation and hoarseness. Injuries to the pharynx and oesophagus had a much stronger association with difficult airway management. Half of all pharyngeal injuries and 68% of pharyngeal perforations were associated with difficult intubation.

There were five deaths in the pharyngeal injury claims and all involved perforation and the development of mediastinitis. The oesophageal injuries involved a significantly greater proportion of females and patients older than 60 years than the other sites and oesophageal perforation involved difficult intubation in 67% of claims. Oesophageal injuries were the most severe and were associated with a poor outcome with 19% mortality. Pharyngo-oesophageal perforation is a serious condition (overall mortality 25%) and risk factors include difficult intubation, emergency intubation and intubation by inexperienced personnel. Perforation may also be caused by passage of a nasogastric tube. The triad of surgical emphysema, chest pain and pyrexia should be sought and treatment with antibiotics, limitation of oral intake and surgical review initiated as soon as possible. In the closed claims study, surgical emphysema was only evident in 56% of patients and the diagnosis was sometimes delayed. It is suggested that treatment within 24 hours improves outcome.

BEST CLINICAL PRACTICE

- ✓ All patients should undergo airway evaluation as part of pre-operative assessment.
- ✓ Strategy must cover unexpected failed intubation and failed ventilation.
- ✓ The LM is a versatile airway device and should always be available.
- ✓ Decisions about management of the obstructed airway are made by senior anaesthetists and surgeons.
- ✓ Awake fibre-optic intubation and tracheostomy under local anaesthesia should be considered in the obstructed airway.
- ✓ Maintenance of spontaneous respiration is recommended when general anaesthesia is employed in the presence of upper airway obstruction.
- ✓ Consider placement of a transtracheal ventilation catheter prior to inducing general anaesthesia in the difficult upper airway.
- ✓ Always confirm correct placement of the tube in the trachea.
- ✓ A strategy is required for extubation.
- ✓ Follow-up is important to detect and treat morbidity caused by airway management.

FUTURE RESEARCH

- ▶ Unified surgical and anaesthetic terms describing the location of disease pathology in the airway.
- ▶ Randomized comparative studies of anaesthetic techniques in management of the obstructed airway.
- ▶ National collection of serious adverse incidents resulting from airway management in head and neck disease.
- ▶ National audit of attempts at emergency cricothyrotomy.
- ▶ Annual publication of circumstances of death within 28 days of surgery for the obstructed airway.

KEY POINTS

- The difficult airway is an important feature in head and neck surgery.
- Difficult intubation and difficult mask ventilation are different entities.
- Evaluation of the airway is imperfect and may fail to predict difficulty.
- Airway obstruction may be acute or chronic.
- Imaging of the airway is essential, when possible, to delineate the level of obstruction.
- Airway strategy means a primary plan A and back-up plan B.
- The anaesthetic room is an inappropriate location for plan A if plan B is a surgical tracheostomy.
- Pharyngo-oesophageal perforation due to intubation attempts has a high mortality and needs early detection and treatment.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search using the keywords: anaesthesia, ear, nose, throat and maxillofacial, and combinations of the words. Reference lists of retrieved papers were searched manually as were reference lists of standard text (listed in the reference list at the end of the chapter).

As is the case with anaesthesia in general the evidence levels are largely from observational, non-experimental, non-controlled studies or expert opinion (i.e. levels 3 and 4), or in the case of clinical evidence from low-quality case-controlled/cohort studies or clinical series and expert opinion (i.e. grades C and D). This arises purely due to the paucity of randomized controlled trials or meta-analyses of the common questions covered in this chapter.

PRINCIPLES OF GENERAL ANAESTHESIA

Derived from the Greek ‘an aesthesis’ meaning ‘without sensation’, anaesthesia is a relatively modern speciality. In 1846, Dr William Morton publicly demonstrated the use of ether to facilitate successful ENT surgery (the removal of a neck tumour). By the early twentieth century, the importance of pain relief and reduction of the stress response in reducing mortality had been recognized. Anaesthesia has continued to evolve not only to enable surgery but also to provide organ support, patient stabilization and long-term pain relief. Based on perioperative mortality statistics, anaesthetic care is often cited as a model for its improvements with regard to patient safety.¹ High quality, low morbidity anaesthesia is tailored to individual patients and their concurrent illnesses and begins with meticulous pre-operative assessment. The role of the anaesthetist as perioperative physician continues to develop.

To facilitate surgery, modern practice seeks to deliver the ‘triad’ of anaesthesia:

1. Hypnosis – loss of consciousness, implicit and explicit memory
2. Akinesia – prevention of movement
3. Analgesia – obtundation of subconscious response to pain, stress and trauma.

At first a single agent such as ether or chloroform was used to achieve these aims but at perilously high doses. In contrast, modern anaesthesia tackles the triad of anaesthesia using a combination of drugs or agents to satisfy each of the aims separately. This has become known as ‘balanced anaesthesia’.

In balanced anaesthesia, the ‘anaesthetic vapour’ (isoflurane, sevoflurane or desflurane) is used to depress cognitive function and provide the element of ‘hypnosis’. This is achieved at relatively low concentrations far below

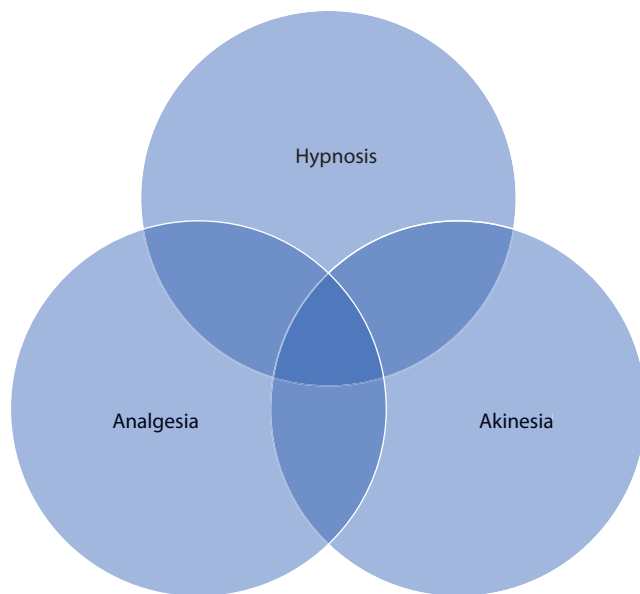

Figure 32.1 Triad of anaesthesia.

those required to achieve akinesia and analgesia and far below concentrations associated with respiratory depression and cardiovascular collapse.

Analgesia is provided by specific drugs such as the opioid fentanyl or the opiate morphine, or by supplemental use of regional or local anaesthetic blocks.

The combination of hypnotic and analgesic drugs may also be sufficient to provide akinesia and abolish movement in response to stimulus yet the patient may still breathe spontaneously. However, it may be desirable to abolish all movement and to relax the tone in all skeletal muscle, for example to facilitate endotracheal intubation or to provide good conditions for laser surgery. This can be achieved by specific drugs such as rocuronium or atracurium, which block the neuromuscular junction and paralyse skeletal muscle. When the element of akinesia is provided in this way, it is possible to reduce the doses of hypnotic and analgesic drugs yet further. So by judicious use of hypnotics, analgesics and muscle relaxants, a state of balanced anaesthesia can be achieved in which the dose of anaesthetic agent is a fraction of that which would be required if it were used as a sole agent (Figure 32.1).

PREMEDICATION

Premedication was originally introduced in the nineteenth century to reduce the amount of chloroform required and thereby speed the onset of surgical anaesthesia. Morphine and its derivatives were often combined with an anticholinergic antisialagogue such as atropine and this reduced patient anxiety and facilitated anaesthesia. Although now uncommon, the combination of an antisialagogue with or without an opiate can still find use prior to an anticipated fibre-optic or difficult intubation.

With the advent of quicker acting anaesthetics and the move to day surgery and same-day admission, sedative premedicant drugs have fallen out of favour. In very

anxious patients, an anxiolytic may still be indicated and oral short-acting benzodiazepines such as temazepam are most commonly used in such circumstances. These need to be given approximately one hour prior to surgery.

Other premedication drugs are still commonly administered to improve patient safety and facilitate anaesthesia. For example, pulmonary aspiration of gastric contents can cause a severe pneumonitis. In at-risk patients such as those with diabetes, renal impairment, obesity or gastro-oesophageal reflux disease (GORD), H₂ blockers (ranitidine), proton pump inhibitors (omeprazole), gastric alkalinizers (sodium citrate) or prokinetic agents (metoclopramide) may be used.

Paracetamol and non-steroidal anti-inflammatory agents can also be administered orally prior to surgery. These are well absorbed from the stomach and oral administration is cost-effective. Evidence that this is better in preventing pain in the early post-operative period than a similar analgesic treatment initiated after surgery, so called pre-emptive analgesia, is weak. Although widely used, care must be taken with non-steroidal anti-inflammatory drugs (NSAIDs), particularly in the elderly and in patients with dyspeptic symptoms or renal impairment. Altered platelet function and coagulation is an additional consideration in some types of surgery.

KEY POINTS

- Sedative premedication is seldom used in modern anaesthetic practice, especially as day-case surgery is increasing.
- Antiemetic and antacid prophylaxis should be given pre-operatively to high-risk patients.
- Pre-operative oral administration of simple analgesics is cost-effective but NSAIDs must be prescribed with caution in some patient groups.

ANAESTHETIC AGENTS

Intravenous agents

Intravenous (i.v.) anaesthetic agents are most commonly used to induce anaesthesia although they can also be used for maintenance. Their rapid onset of action relates to their high lipid solubility, which allows them to diffuse rapidly into the lipid-rich brain. The brain has a high blood flow and so the drug is delivered quickly to its site of action. After a single induction dose, plasma levels rise and then fall rapidly. This is not due to metabolism, but rather redistribution to other lipid-rich tissues with lower blood flows. Metabolic clearance mostly occurs after hepatic metabolism but this accounts for a much slower 'background' elimination of drug and in most clinical situations plays no part in emergence from anaesthesia.

For many years, the thiobarbiturate thiopentone dominated this class of drugs. However, by far the most commonly used i.v. induction agent in the Western world is propofol, which is a derivative of phenol. This white emulsion mixture has a rapid onset and offset as a consequence of its short context-sensitive half time so patients wake up quickly. The quality of recovery is good with a

low incidence of post-operative nausea and vomiting and a quick return to street fitness. Further benefits include bronchodilation, safety in porphyria and in malignant hyperpyrexia patients, and a lack of active metabolites.

Like most anaesthetic agents, thiopentone and propofol are associated with a fall in blood pressure mediated by a number of mechanisms, including a reduction in central sympathetic vasomotor tone and cardiac contractility. These features are particularly marked in the elderly and patients who are dehydrated or hypovolaemic.

Propofol, unlike thiopentone, can also be used to maintain anaesthesia. This relates to its favourable pharmacokinetics. With a large volume of distribution (Vd), recovery occurs quickly even after prolonged infusions due to drug redistribution. Again the quality of recovery is good with a low incidence of post-operative nausea and vomiting.

Algorithms using population-based pharmacokinetic models (Marsh or Schneider) allow the delivery of propofol by target-controlled infusion and this makes administration safe and predictable.

Propofol is often used in combination with remifentanyl, an ultra short-acting synthetic opioid, as part of a total intravenous anaesthesia (TIVA) technique. Remifentanyl is metabolized by non-specific plasma esterases and with a context sensitive half-time of 3 minutes and elimination half-time of 6 minutes, it has minimal active metabolites. Used by infusion including target control with the Minto pharmacokinetic model, remifentanyl has a short, predictable duration of action with no accumulating effect. Deep intra-operative analgesia can be achieved quickly and yet reversed rapidly. This can contribute to improved intra-operative cardiovascular stability and may also be used to negate the need for neuromuscular blocking drugs, useful when nerve monitoring is required. At the end of surgery, faster recovery and less respiratory depression are achieved in comparison with other opioids but the short duration of action means that alternative post-operative analgesia is required.² Remifentanyl can also be used to provide sedation during awake fibre-optic intubation. By suppressing airway reflexes, it facilitates excellent intubating conditions (Figure 32.2).³

KEY POINTS

- Intravenous induction agents owe their rapid onset and offset of action to rapid diffusion across the blood–brain barrier due to their high lipid solubility.
- Hepatic clearance is moderately slow, and does not play a significant part in the return of consciousness after a bolus dose of intravenous agent.
- Propofol by target-controlled infusion can be used to maintain anaesthesia.
- Remifentanyl is a short-acting synthetic opioid often administered intravenously along with propofol as part of a total intravenous anaesthesia technique.

Inhalational agents

Inhalational or ‘volatile’ agents may be used for induction and/or maintenance of anaesthesia, although they are more commonly used for maintenance alone. The historical

Figure 32.2 Target controlled infusion pumps for propofol and remifentanyl. Pharmacokinetic algorithms calculate drug delivery taking into account patient age, weight and, for remifentanyl, height.

archetype is ‘ether’ (actually diethyl ether), now replaced with less flammable and toxic modern agents such as isoflurane, desflurane (halogenated methyl-ethyl ethers) and sevoflurane (isopropyl ether). Like the intravenous agents, the volatile agents are lipid soluble; the higher the lipid solubility, the higher the potency. Modern agents are extremely lipid soluble and so their potency is sufficiently high to require only an inspired concentration of a few percent to induce anaesthesia. The depth of anaesthesia is determined by the partial pressure (i.e. the effective concentration) of the volatile agent in the brain. Since the brain is in equilibrium with the arterial blood, and the latter is in equilibrium with the alveolar gas, then the depth of anaesthesia should be determined by the partial pressure (or concentration) of volatile agent in the alveoli. Given that the concentration of the anaesthetic vapour in the alveoli (i.e. in the expired breath) can be measured easily, the anaesthetic depth can therefore be estimated reliably. In contrast, there is no means of doing this for intravenous agents.

Volatile agents can also be used to induce anaesthesia, and some do so more quickly than others. The rate of onset (and offset) of a volatile agent is determined by its blood solubility. It has already been stated that the depth of anaesthesia is determined by the partial pressure of the agent in the alveoli/blood/brain. In the blood, only molecules that are not in solution contribute to the partial pressure. For more soluble agents such as halothane, the rate of rise of alveolar partial pressure is comparatively slow because some of the agent is able to enter the blood in solution rather than remaining in the alveolus to contribute to the rise in partial pressure. In contrast, modern agents such as sevoflurane and desflurane have a high lipid solubility and so low blood solubility. This results in a rapid rate of rise in partial pressure in the alveolus and in the blood and brain in turn and so induction is quick. Likewise, when volatile administration is discontinued, elimination is rapid and recovery quick with an early return of airway reflexes.

Sevoflurane is preferred to desflurane for inhalational induction because of its lack of airway irritation. Desflurane has a rapid rate of recovery in prolonged cases and has an important place in some ENT procedures of long duration.

KEY POINTS

- Older agents (ether, halothane) have high solubility in blood and therefore a slow onset and offset of action.
- Modern agents (sevoflurane, desflurane) have low solubility in blood and therefore rapid onset and offset of action.
- Because vapour concentrations can be measured in the expired breath, adequate depth of anaesthesia can be determined with confidence.

DEVICES USED IN AIRWAY MANAGEMENT

The sections above outline the drugs that can be used to induce and maintain anaesthesia. This section examines the devices used in airway management during anaesthesia. One of the hallmarks of anaesthesia for ENT surgery is the concept of the ‘shared airway’. The surgeon operates in the same anatomical region as the anaesthetic devices used to maintain the airway. Therefore, the detailed properties of the airway device selected and precise conduct of anaesthesia are particularly important to ENT surgery as compared with many other types of surgery.

The simple face mask

The upper airway is composed of a wide array of soft tissues, muscles and bony structures that modulate its patency. Induction of anaesthesia invariably causes a degree of collapse and the oropharynx behaves as a Starling resistor with airflow critically dependent on pharyngeal tone and transmural pressure.

Pharyngeal collapse is governed by a complex interplay of mechanical and neuromuscular factors but reduction in the tone of the pharyngeal dilator muscles and genioglossus is key. These muscles are innervated by the efferent outflow of the ‘respiratory centre’, and tone varies cyclically in much the same way as does the diaphragm under the command of the phrenic nerve. Drugs that depress the respiratory centre and have a tendency to produce a ‘central’ apnoea, also by this mechanism have a tendency to produce an ‘obstructive’ apnoea. Central and obstructive apnoeas are therefore inextricably linked and cannot adequately be categorized as separate entities.⁴

If neuromuscular blocking drugs are used, then spontaneous ventilation is abolished completely. All these factors require the use of devices that both give anatomical support to the upper airway and facilitate ventilation. Perhaps the simplest means of achieving these aims is a face mask that, when connected to a suitable supply of oxygen and anaesthetic gas, may be used to support the airway manually or (if spontaneous ventilation is absent) allow hand-ventilation of the patient’s lungs. Problems with the

face-mask technique include poor surgical access to the face, head or airway; it requires that one or both of the anaesthetist’s hands are occupied in airway maintenance; and active ventilation of the patient’s lungs can often be inefficient as not all the tidal volume administered enters the patient’s lungs, some being lost as a ‘leak’.

Supraglottic airway devices

A range of supraglottic airway devices (SADs) have been developed which reduce some of these problems. First introduced into clinical practice as the classic LMA (cLMA), these are tubes with a distal component, often inflatable, to ‘hold’ the airway in place. They lie in the oropharynx, above the level of the glottis. SADs allow spontaneous breathing and, similar to the face-mask techniques, facilitate active ventilation. However, since SADs lie above the glottic opening and so do not seal it, there is a risk that positive pressure ventilation of the lungs may not always be possible with leakage of ventilating gas into the oesophagus and stomach. If gastric fluid should then regurgitate, SADs will not completely protect the airway from lung soiling. Second generation SADs such as the ProSeal, LMA Supreme and i-gel, seek to improve on the classic laryngeal mask airway to improve efficacy (airway seal) and safety (gastric access and protection from aspiration). These are modified with an oesophageal drain tube and structures to improve the seal with positive pressure ventilation. They have significant use in modern airway management and resuscitation; however, their value in ENT is more restricted when a ‘shared’ airway is required (Figure 32.3).⁵

Tracheal tubes

Tracheal tubes maintain airway patency and protect against aspiration of gastric contents. In adult anaesthesia

Figure 32.3 SADs (a) standard disposable; (b) i-gel (intersurgical) – a second generation mask with non-inflatable cuff, improved seal pressure over cLMA, and gastric vent; (c) ProSeal – has additional posterior cuff and deeper mask. Drain tube acts as vent if regurgitation occurs; (d) flexible wire reinforced SAD allows tube to be moved out of surgical field without cuff displacement and is resistant to compression.

cuffed tracheal tubes are most commonly used and these are sited so that the tip lies in the trachea above the carina. To minimize the risk of late onset tracheal stenosis, high volume low-pressure cuffs are preferred and these are inflated with air (saline or methylene blue in laser surgery). The cuff improves the efficiency of ventilation by minimizing leaks and helps maintain the tube in the centre of the trachea. In addition, the airway is protected from soiling by blood coming from above in mouth, nose or laryngopharyngeal surgery and from regurgitated gastric contents.

Since tracheal tubes form a sealed conduit into the trachea, they are primarily used when the patient is paralysed and requires positive pressure ventilation (there is no risk of blowing air into the stomach). It is indeed possible to allow the patient to breathe spontaneously through a tracheal tube, but since the glottis and trachea are richly innervated, deep anaesthesia is required to prevent the patient from reflex coughing. The dose required to achieve this may lead to dose-related side effects (as described below). Whereas most SAD devices can be used effectively after relatively short periods of training, the techniques used by the anaesthetist to insert a tracheal tube are more specialized and are described in more detail in [Chapter 31](#), 'Recognition and management of the difficult airway'.

Tracheal tubes may be passed either orally or nasally and choice of route can depend upon the type of surgery performed. For example, a nasotracheal tube better facilitates surgical access for oral surgery, but is clearly a hindrance during operations of the nose.

The shape, size and material used in manufacture are important in relation to the intended use. Preformed endotracheal tubes (ETTs), such as the Ring, Adair, Elwyn (RAE) tube, direct anaesthetic circuits away from the surgical field to improve access whilst wire-reinforced ETTs also prevent obstruction from kinking. Microlaryngoscopy ETTs are small diameter, large cuff tubes of long length (e.g. 31 cm long, 4–6 mm internal diameter) designed

to optimize the surgical view on direct laryngoscopy ([Figure 32.4](#)).

In thyroid and parathyroid surgery the Nerve Integrity Monitor (NIM) electromyography (EMG) ETT can be used to identify and monitor the recurrent laryngeal and vagus nerves. With two integrated bipolar stainless steel electrodes on each side of the low-pressure cuffed silicone tube, it is placed in close contact with the vocal cords to allow monitoring of the EMG activity of the intrinsic laryngeal musculature. Electrode contact with the true vocal cords is important to ensure adequate response. Nerve stimulation is carried out using a sterile monopolar or bipolar probe. Both electrodes and nerve stimulators require grounding electrodes, usually placed on the sternum or shoulder. These are then attached to the NIM monitor, which produces an audible and visual electromyographic signal whenever the recurrent laryngeal nerve or vagus nerve is stimulated ([Figure 32.5](#)).⁶

Endotracheal tubes designed for airway laser surgery are constructed to minimize the potential damage to surrounding tissues from heat and toxins. These are further discussed below.

Regardless of which airway device is selected, it is vital that there is constant communication between surgeon and anaesthetist regarding the other's needs during surgery. The airway device must not hinder the surgical process because of its size or shape; it must be properly secured in place to prevent dislodgement during head movement by the surgeon and the direction of the airway device shaft must be appropriate to the operation. Use of surgical gags and props may compress the airway device, so the anaesthetist must be vigilant about the patency of the airway. Even with the presence of a cuffed tube, throat packs are commonly used to protect the airway from blood soiling in nasal surgery and careful removal of these prior to extubation must be ensured. Airway obstruction may occur not only during induction of anaesthesia, but also after extubation and in some circumstances it is important that the surgeon is present at extubation.

Jet ventilation techniques and tubeless surgery

Jet ventilation was first described in 1967 by Douglas Sanders as a technique to allow patient ventilation during rigid bronchoscopy. It improves access to the airway, particularly in laryngeal surgery, and avoids the need for an endotracheal tube. Low (LFJV) and high frequency jet ventilation (HFJV) systems are available. Both systems work on the premise that high pressure jets of gas are delivered intermittently either manually or automatically. This generates a tidal volume supplemented by the entrainment of gases at the jet nozzle. Expiration is a passive process. No volatile agents can be administered by jet and total intravenous anaesthesia is required.

In LFJV, gas exchange is achieved by direct alveolar ventilation or bulk flow. Most commonly, a hand-triggered manual jet ventilator (e.g. Sanders injector /Manujet III) is used and the lungs insufflated at a frequency of 8–10 breaths per minute to allow adequate expiration. The gas source (usually oxygen piped at 4 bar) is passed through pressure reducing valves, which can be further adjusted via a regulator to a pressure that produces the desired chest-wall movement and maintains oxygenation. It is important for the injector cannula to be aligned with the airway to improve ventilation and prevent gastric distension, particularly when placed in the supraglottic position. Ventilation may be difficult in patients with poor lung or chest wall compliance (Figure 32.6). End-tidal CO₂ (ETCO₂) is not usually monitored except when a Hunsaker tube is used.

In high frequency jet ventilation, tidal volumes smaller than anatomical dead space are delivered at supraphysiological frequencies of 1–10 Hz. Gas exchange takes place by Pendelluft, Taylor dispersion and cardiogenic mixing.

HFJ ventilators such as the Mistral or Monsoon jet ventilator (Acutronic Medical Systems) humidify and warm gas jets to minimize heat loss and reduce the likelihood of complications arising from the airway drying out. Peak airway pressures are limited by an automatic

cut-out device and are lower than with LFJV but barotrauma remains a risk. Surgical conditions are very good with minimal movement of the surgical field (Figure 32.7).

Jet ventilation can be applied above or below the vocal cords or in emergencies via the cricothyroid membrane. The supraglottic approach allows a completely tubeless surgical field although there is greater vocal cord movement than with other techniques and a risk of blowing debris including tumour into the distal airway. It is not possible to monitor end-tidal CO₂ (ETCO₂) or airway pressures and there is a risk of gas trapping and barotrauma. The inspired oxygen concentration is unknown as significant entrainment occurs. The airway is maintained during the procedure by the surgeon and the quality of ventilation can be impaired by misalignment of the jet with the airway during attempts to access the operative site. Good communication between surgeon and anaesthetist is thus required to ensure adequate ventilation.

In comparison, the subglottic approach requires a narrow catheter or tube such as a Hunsaker and this may limit surgical access posteriorly. However, vocal cord movement is minimal. Furthermore, ETCO₂ can be monitored and with minimal entrainment of air, inspired oxygen delivery is more consistent (Figure 32.8).⁷ Transtracheal jet ventilation can be used as a rescue technique.

KEY POINTS

- Anaesthesia and loss of consciousness result in reduced tone in the pharyngeal dilators and posterior displacement of the tongue.
- The oropharynx behaves as a Starling resistor: airflow is critically dependent on pharyngeal tone and transmural pressure.
- A variety of devices and techniques can be used to maintain the airway during anaesthesia and include the simple face mask, supraglottic airway device and tracheal tube, as well as jet ventilation.
- Jet ventilation is useful in airway surgery to improve the surgical field but TIVA is required and high driving pressures increase the risk of barotrauma.

Figure 32.8 Laser safe Hunsaker tube provides self-centring, subglottic ventilation with both manual and automated jet ventilation. The jet ventilator is attached via the luer lock and there is a gas sampling lumen.

FACTORS INFLUENCING CHOICE OF DEVICE IN AIRWAY MANAGEMENT

The selection of airway device in individual patients is influenced by several considerations. In general terms, these can be divided into patient factors and surgical requirements.

Patient factors influencing choice of airway device

Of the many patient factors determining choice between an SAD or endotracheal tube, preventing aspiration, maintaining airway patency and facilitating ventilation are the most important.

GASTRO-OESOPHAGEAL REFLUX

Hiatus hernia, symptomatic reflux, pregnancy, abdominal sepsis or injury and recent ingestion of solids or particulate liquids all predispose to regurgitation of gastric contents. Endotracheal intubation minimizes the risk of subsequent aspiration and lung soiling. In high-risk cases, rapid sequence induction with cricothyroid pressure is employed to reduce the time between loss of protective airway reflexes and lung protection by inflation of the tracheal cuff.

OBESITY

Obese patients do not always find it easy to breathe when lying supine, even when awake. This results from both a reduction in lung volume and a restrictive defect. When anaesthetized, this difficulty is exacerbated and tracheal intubation is often necessary to facilitate positive pressure ventilation.

OBSTRUCTIVE SLEEP APNOEA

Closely correlated with morbid obesity, although other ENT related abnormalities of the nose, pharynx and larynx can also be the cause, obstructive sleep apnoea (OSA) is characterized by repetitive intermittent pharyngeal airway collapse during sleep. This results in obstruction of the airway, apnoea and desaturation. Anaesthesia exacerbates OSA and an airway secured with an endotracheal tube is preferred. Potential difficulties with intubation require identification pre-operatively and formulation of an appropriate management plan. Risk extends into the post-operative period following extubation.

PATIENTS WITH KNOWN OR ANTICIPATED DIFFICULT AIRWAY

In cases of known or anticipated difficult intubation where general anaesthesia is the sole option, it can be argued that it is prudent to intubate the trachea electively and so achieve a definitive 'secured airway' before surgery begins. While it is also acceptable to use a SAD device (and sometimes necessary should tracheal intubation fail), the risk remains that, should urgent tracheal intubation be necessary during the course of surgery, this might be difficult or impossible to achieve in a short space of time.

Surgical factors influencing choice of airway device

A number of surgical requirements reasonably influence the choice of airway device.

FACTORS RELATED TO THE 'SHARED AIRWAY'

As a result of the large distal cuff, most SAD devices do not permit a good view of structures distal to the oropharynx. Thus, for almost all periglottic, laryngeal and subglottic operations in which an unobstructed view of the relevant anatomy is required, a tracheal tube is preferred. A tracheal tube is also less likely to be dislodged by excessive movements of the head and neck.

SAD devices may, however, be used for operations related to the tonsils, anterior tongue, nose, teeth and ears without obstructing the surgical field. There may be reduced incidence of coughing and gagging at emergence but care must be taken to ensure the oropharynx is clear of blood to prevent soiling of the airway.

LASER SURGERY

Standard (polyvinyl chloride) tracheal tubes can ignite if struck by a laser beam and manufacturers discourage the use of unprotected PVC tracheal tubes in such airway operations. Wrapping conventional tubes with metallic tape or other materials to shield the flammable material from laser contact has also been described and this reduces the risk of combustion.

More effective protection is provided by specialized laser resistant endotracheal tubes. A number have been developed and these are manufactured from a variety of materials including metals, ceramics and Teflon. Double cuffs

Figure 32.9 Metal spiral armoured laser tube. Note the twin cuffs, which are inflated with saline or methylene blue.

reduce the leak risk resulting from cuff damage and so minimize the fire risk resulting from an oxygen leak. None are completely laser-proof and may combust in certain circumstances (Figure 32.9).

The flexible wire reinforced laryngeal mask airway has also been shown to have some laser-resistance but is not used routinely. Anaesthesia for laser surgery is further discussed below.

REQUIREMENT FOR NEUROMUSCULAR BLOCKADE

Neuromuscular blockade is a reliable way of preventing patient movement, coughing and swallowing and this is particularly important for certain operations such as skull base, laryngopharyngeal, and laser surgery. With paralysis, positive pressure mechanical ventilation is required and an endotracheal tube is most commonly used to facilitate this. Rocuronium, a short acting non-depolarizing aminosteroid neuromuscular blocker, has the advantage that it can be reversed quickly and reliably with sugammadex, a cyclodextrin that encapsulates and binds the active drug. Profound muscle relaxation can thus be used for short procedures including panendoscopy.

POST-OPERATIVE PLAN

After some major operations of the head and neck the risk of post-operative swelling and subsequent obstruction is best mitigated by admission to an intensive care unit with an endotracheal tube *in situ*. Post-operative ventilation might also be necessary in the presence of certain medical conditions such as poor lung function.

KEY POINTS

- In ENT, shared airway surgery is common; a variety of airway devices exist and appropriate selection is particularly important.
- Choice of airway device is influenced by a variety of medical and surgical factors.
- Communication between surgeon and anaesthetist is vital.

Conduct of anaesthesia: Principles guiding induction of anaesthesia

Anaesthesia is planned taking into consideration the requirements of the surgical procedure and the comorbidities of the patient that may impact on safety. Both intravenous and inhalational induction can result in haemodynamic instability, loss of airway tone, apnoea and desaturation. Risk can be reduced with preoxygenation and appropriate monitoring.

Preoxygenation

Before induction of anaesthesia, it is common to preoxygenate by administering 100% oxygen via a tight fitting face mask for two to three minutes. Perhaps counter-intuitively, breathing 100% oxygen in this way may not increase the oxygen content of the blood. This is because for most patients, the arterial blood is almost fully saturated with oxygen even when breathing room air, so breathing oxygen cannot really improve on this. Rather, the purpose of this manoeuvre is to wash out the nitrogen-rich air within the lungs and thereby increase the mass of oxygen within the alveolar compartment. A reservoir of oxygen is created that serves to delay the rate of desaturation during a subsequent apnoea. As an alternative, four successive vital capacity breaths of 100% oxygen over 30 seconds can provide effective preoxygenation.

Intravenous induction

The commonest method of induction of anaesthesia is by intravenous administration of one of the drugs listed above but most commonly propofol. Surgical anaesthesia is rapidly induced in one 'arm-brain circulation time' and Guedel's stage 2 anaesthesia, first described using ether and associated with coughing, vomiting, struggling and laryngospasm, is avoided.

The dose of intravenous agent is guided by patient weight but should be titrated slowly according to the observed effect. Injudicious dosing can result in cardiovascular compromise and loss of spontaneous ventilation.

If there is any doubt that ventilation can be maintained post-induction, then the safety of the technique should be questioned and alternative management plans considered. The details and nature of these doubts (i.e. the ability to predict a patient who is difficult to intubate or ventilate) are discussed in Chapter 31, 'Recognition and management of the difficult airway'.

Prior to neuromuscular blockade it is not uncommon to 'check' the ability to ventilate by face mask. This precaution is predicated in the belief that if for some reason the trachea cannot be intubated, then ventilation can at least be achieved and oxygenation preserved. This practice is not universal and in the 'can't intubate, can't ventilate' group of patients neuromuscular blockade with short acting muscle relaxants such as suxamethonium or rocuronium has been advocated as a rescue route to improve mask ventilation.⁸

The Fourth National Airway Project (NAP4) recognizes the importance of a rescue plan in all patients but highlights the importance in head and neck patients, in whom 40% of the serious airway complications occurred.⁹

Rapid sequence induction

Rapid sequence induction seeks to protect the airway from soiling by minimizing the time between loss of protective reflexes and inflation of the ETT cuff. It is particularly indicated in emergency surgery where a patient may have a full stomach or in hiatus hernia with active reflux. It may also be considered where there is airway or gastrointestinal haemorrhage.

Following preoxygenation, a bolus of intravenous induction agent is administered and quickly followed with a neuromuscular blocker. Either suxamethonium or rocuronium (1 mg/kg) are used. No attempt is made to confirm that the lungs can be ventilated by face mask prior to administration of neuromuscular blocker.

As soon as consciousness is lost, the anaesthetic assistant applies 'cricoid pressure' to the larynx. A force of 40 N (4 kg weight) applied to the cricoid cartilage using the finger and thumb compresses the oesophagus posteriorly against the C6 cervical vertebral body and so prevents passive spillage of gastric contents. Laryngoscopy and intubation are now undertaken in the usual manner.

Inhalation induction

Inhalational induction is now relatively uncommon but still remains relevant in ENT practice, particularly in the management of the difficult airway. One advantage of the technique is that spontaneous ventilation is maintained. If the upper airway collapses as anaesthesia deepens and breathing becomes obstructed, then no further anaesthetic vapour can enter the lungs. The anaesthetic is redistributed during apnoea and the patient begins to wake up, thereby restoring upper airway tone and breathing. For this reason, inhalational induction has been advocated as a safe option for patients with perilaryngeal tumours and stridor. In contrast to intravenous induction, therefore, inhalational induction may be used even when there are doubts about the ability to intubate the trachea or maintain ventilation.

Inhalational induction may also be the technique of choice in patients with little cardiovascular reserve and relatively stable conditions can be provided in patients at risk from hypotension, hypertension and tachycardia.

However, there are some practical disadvantages. First, because induction is slow, there is a danger that the stage of excitability is prolonged. Second, should collapse of the upper airway occur during inhalational induction then not only anaesthetic vapour but also oxygen is prevented from reaching the lungs. Thus, inhalational induction may not be as safe or controlled as may be claimed.

In clinical practice, sevoflurane has now largely supplanted halothane for inhalational induction, its rapid onset and offset being accompanied by a pleasant smell and minimal airway irritation.

Induction after securing the airway

Certain conditions require techniques that achieve tracheal intubation with the patient awake or sedated, anaesthetic induction occurring only after the airway is secured. These methods are discussed further in [Chapter 31](#), 'Recognition and management of the difficult airway'. Planned awake tracheostomy under local anaesthesia is an additional option.

MONITORING IN ANAESTHESIA

Derived from the Latin *monere*, to warn, monitoring is used to describe measurements whose prime purpose is to 'warn' of imminent (possibly injurious) events, and allow action to be taken to avoid them, or moderate their effect. The Association of Anaesthetists of Great Britain and Ireland publishes guidelines for minimum monitoring standards, and these are reviewed from time to time ([Figure 32.10](#)). Both at induction and throughout the operation, the most important 'monitor' is undoubtedly the anaesthetist who can synthesize information derived from clinical observation and specialized devices and take appropriate action.

BASIC INTRA-OPERATIVE MONITORING

ECG

Continuous ECG recording is universally used, its purpose being to detect the development of dysrhythmias and myocardial ischaemia.

The lead II configuration best displays rhythm disturbances (atrial fibrillation, heart block, asystole, ventricular tachycardia, ventricular fibrillation) while the CM5 placement best detects myocardial ischaemia (ST depression, T wave inversion).

The ECG gives no information about pump function and circulation.

Figure 32.10 Minimal standards of monitoring; ECG, pulse oximetry, ETCO₂, NIBP.

Pulse oximetry

Pulse oximetry provides safe, non-invasive monitoring of arterial oxygen saturation. Based on spectrophotometry and the different light absorption characteristics of oxygenated and deoxygenated blood, these devices shine two different wavelengths of red light through an extremity (usually a finger) and measure the absorbance of transmitted light. A number of substances absorb or scatter this light, including arterial haemoglobin, venous haemoglobin, skin, bone and nail-bed. However, in addition to the background absorbance, there is a component that varies throughout the cardiac cycle, and this pulsatile absorbance is due to the added volume of arterial blood that enters during or shortly after systole. If this pulsatile signal is subtracted from the background, the resulting absorbance signal is wholly accounted for by the composition of arterial blood. The proportions of oxygenated and deoxygenated haemoglobin can then be identified and SpO₂ calculated.

The pulsatile waveform displayed on the oximeter screen also gives a beat-to-beat indication of circulation, the electronic equivalent of keeping one's finger on the pulse.

Most accurate above 90% saturation, reliability decreases at lower saturations below 70%. Accuracy is also affected by poor peripheral perfusion, electrical interference, and the use of dyes such as methylene blue.

Oxygenation rather than ventilation is measured. Hence patients breathing supplemental oxygen may still be well saturated, despite being virtually apnoeic and at risk of imminent respiratory arrest. In high-risk patients at risk of respiratory depression or obstruction post-operatively, pulse oximetry must not be relied upon to monitor the adequacy of ventilation.

Automatic non-invasive blood pressure

Automatic non-invasive blood pressure (NIBP) monitoring uses the principle of oscillometry applied to an inflatable cuff around the arm. These devices record blood pressure intermittently and have gained widespread acceptance because they are safe and easy to use but they do have limitations.

While the mean blood pressure measurement is reasonably accurate, the systolic and particularly the diastolic values are less so and low pressures tend to be overestimated and high pressures underestimated. Readings may be inaccurate or difficult to record in the presence of an irregular cardiac cycle resulting from a rhythm disturbance such as atrial fibrillation, or in patients who are shocked or peripherally shut down.

As blood pressure measurement is not continuous, detection of sudden changes including cardiovascular collapse may be delayed.

Invasive monitoring of blood pressure

Blood pressure can be measured invasively through a cannula sited in a suitable artery, usually the radial. This allows beat-to-beat measurement and the detection of

rapid changes in real time. The morphology of the arterial 'waveform' including the rate of upstroke, pulse pressure and the presence of 'pulsus paradoxus' provides useful information on circulatory and vasotonic status. Blood gas sampling via the arterial cannula is also facilitated. Unlike non-invasive blood pressure measurement, invasive monitoring is reliable and accurate in both high and low pressure states. Disadvantages are few, but include the fact that siting such cannulae can be difficult, and the disposables are relatively expensive. There is a very small risk of unrecognized disconnection and bleeding, drug injection error, thrombosis, distal ischaemia and infection.

Oxygen analysis

It is axiomatic that oxygen is vital for safe anaesthesia. Since it is odourless and colourless, the use of an oxygen analyzer with audible alarm is vital to monitor the composition of gases leaving the anaesthetic machine and entering the patient airway. Gas is continuously sampled from the airway and a rapid gas analyzer displays the concentration of inspired and expired oxygen breath-by-breath. Most analyzers are also capable of monitoring other gases including CO₂ and anaesthetic vapours.

Inspired and expired CO₂

Inspiration of CO₂ raises PaCO₂ and severe hypercapnia may be life threatening, hence inspired CO₂ should be zero or near zero. Rising inspired CO₂ concentrations indicate that the patient is rebreathing exhaled breath and this usually results from a faulty breathing circuit, inadequate gas supply from the anaesthetic machine, or exhaustion of the CO₂ absorber.

The capnograph measures end-tidal CO₂ (ETCO₂) and is one of the most important monitors in anaesthesia. It provides robust evidence of tracheal intubation; expired CO₂ confirms endotracheal placement while the absence of an alveolar waveform is strongly suggestive of oesophageal intubation.

'End-tidal' refers to the concentration at the very end of expiration and is taken to be representative of alveolar gas. The ETCO₂ is therefore useful to confirm the adequacy of alveolar ventilation and identify hypoventilation and hyperventilation.

In metabolic states such as malignant hyperpyrexia and thyroid storm, a rising ETCO₂ on capnography can assist in diagnosis.

Capnography can also play a part in the identification of a number of cardiorespiratory abnormalities including a falling cardiac output, pulmonary embolus, and V/Q mismatch.

Inspired/end-tidal anaesthetic agent concentration

By sampling the concentration (or partial pressure) of anaesthetic vapours in the expired breath, the anaesthetic partial pressure in the alveolar gas and hence the arterial blood and brain can be estimated. This is a reliable way of

monitoring anaesthetic depth because the dose-response curves (or more accurately the partial pressure-response curves) for these agents show very little inter-individual variation.

Airway pressure and tidal volume

Measurement of airway pressure and expired volume is important, particularly during mechanical ventilation. Airway pressure is influenced by the compliance (or elastance) of the lung and chest wall and by the resistance to airflow. Compliance is influenced by muscle paralysis, surgical manipulation and pneumothorax. Sudden changes in airway pressure resulting from increased resistance to airflow may result from bronchospasm, endotracheal tube displacement or compression by a Boyle Davis gag.

Temperature

Patients tend to cool during anaesthesia and inadvertent hypothermia is associated with adverse effects which include delayed wound healing, depressed immunity, increased risk of pressure sores and impaired coagulation.

Defined as a core temperature below 36°C, hypothermia develops as a consequence of:

- heat loss to the environment (cold theatre, exposed body surface/cavities, vasodilation caused by anaesthetic drugs)
- altered thermoregulation under anaesthesia
- loss of the behavioural response to cold.

Effective temperature management begins with accurate measurement. The thermistor probe is the most commonly used type of measurement device. Common sites for placement include oro/nasopharynx, tympanic membrane, rectum and bladder. Several different types of patient warming device are available for prevention and treatment and the National Institute for Health and Clinical Excellence (NICE) recommends forced air convection warming (e.g. Bair-Hugger) and the Inditherm warming mattress. Fluid warmers are of value should the administration of cold products such as blood or blood products be required.

Monitoring of neuromuscular function

Neuromuscular blockade is measured by means of a peripheral nerve stimulator, now considered essential when using muscle relaxants. Four successive supra-maximal stimuli are delivered at 2 Hz, 50 mA by two adhesive electrodes placed on the skin over a convenient peripheral nerve (usually the ulnar, facial or common peroneal). With increasing degrees of block, the twitches in the train of four progressively fade. The only reliable guarantee of return of safe motor function is a train of four ratio >0.9.

This differs from the facial nerve monitor used by the ENT surgeon, which detects microvolts of EMG activity, rather than gross movement. It is possible for patients to

be moderately but adequately blocked from the anaesthetic perspective but sufficiently unblocked for safe facial nerve monitoring. The important point here is that if this approach is used, the surgeon needs to be aware of it.

The problems of neuromuscular blockade in the context of facial nerve monitoring in middle ear and parotid surgery are discussed below.

Central venous pressure/pulmonary artery wedge pressure/cardiac output/transoesophageal echocardiography

This is **not** routine monitoring, but is used where indicated by:

- the patient's pre-operative medical condition (e.g. left ventricular failure, sepsis)
- surgery that is likely to produce significant deviations in these parameters (e.g. large blood loss or compression of the mediastinum and great vessels).

The aim is to detect and correct changes in left and/or right ventricular preload, afterload or contractility indicated by changes in venous and pulmonary pressures, arterial pressure and cardiac output.

Transoesophageal echocardiography (TOE) has grown in popularity as it provides information on ventricular volume rather than pressure. Initially used mainly as a monitor of left ventricular ischaemia, it now provides real-time dynamic information about heart physiology and can be used to guide therapy in haemodynamically unstable patients

Depth of anaesthesia monitors: EEG/AEP/BIS

A number of devices that measure and process EEG signals are available for estimating anaesthetic depth during surgery. Such monitors are recommended in patients at greater risk of awareness and in patients receiving TIVA. However, data on effectiveness remains mixed and such devices should be used along with clinical observation. For patients breathing spontaneously and unparalyzed, 'awareness' under anaesthesia has an incidence of 1 : 136 000. In contrast, the incidence rises to 1 : 8000 when muscle relaxants are used. This likely reflects difficulty in detecting the early warning signs of awareness such as movement and coughing in this group.

ANAESTHETIC TECHNIQUE: PRINCIPLES FOR SPECIFIC ENT OPERATIONS

The above sections indicate broad principles used to determine choice of anaesthetic drugs, airway device, mode of induction and monitoring. We now turn to some specific operations in ENT surgery and the particular

TABLE 32.1 Considerations for anaesthesia in ENT

Shared airway	<ul style="list-style-type: none"> • Communication • Surgical access • Inaccessible airway intra-operatively (head position distant to anaesthetist) • Disconnection/displacement/compression potential • Airway soiling • Hidden blood loss
Positioning	<ul style="list-style-type: none"> • Reverse Trendelenburg to reduce bleeding, neck extension and complications
Dental trauma	<ul style="list-style-type: none"> • From anaesthetic or surgical access
Laser	<ul style="list-style-type: none"> • Airway fire prevention
Nerve monitoring	<ul style="list-style-type: none"> • E.g. facial/recurrent laryngeal nerve
Post-operative	<ul style="list-style-type: none"> • PONV • Airway soiling • Tracheostomy care • Airway irritation (coughing) • Post-operative airway oedema

challenges posed. In general terms, anaesthesia for ENT has many unique considerations and these are summarized in [Table 32.1](#).

Tonsillectomy and adenoidectomy

In adults, the most common indication for adenotonsillectomy is chronic or recurrent infection. Although tonsillitis is less common in adults than in children, it tends to be more severe and in some cases is complicated by peritonsillar abscess (quinsy). Obstructive sleep apnoea syndrome (OSA), snoring resulting from upper airway obstruction secondary to tonsillar hypertrophy and excision biopsy for suspected malignancy are also strong indications.

PERIOPERATIVE MANAGEMENT

Tonsillectomy in adults is associated with an increased risk of post-operative bleeding and pain when compared with the paediatric population.

Pre-operative consideration should include identification and assessment of OSA.

Either intravenous or inhalational induction with sevoflurane can be employed but the intravenous route is preferred in adults because hypertrophied adenotonsils can be associated with early airway obstruction and a more challenging induction.

In management of the shared airway, an endotracheal tube or reinforced laryngeal mask can be placed. A pre-formed south-facing RAE endotracheal tube is commonly used to protect the airway from soiling by blood and to facilitate ventilation. Secured in the midline, it is designed to point 'south' (or caudad) thereby facilitating surgical access by allowing placement in the split blade tongue depressor of the Boyle-Davis gag. A careful check of ventilation and airway pressures should be made when the gag is deployed to exclude obstruction or displacement of the tube. Alternatively, a reinforced tube with an integral

metallic spiral in the shaft provides protection from external compression and kinking.

The flexible, reinforced version of the LMA is also kink resistant and with a narrower shaft than the standard LMA, provides good surgical access. In adenotonsillar hypertrophy, initial placement may be problematic but dislodgement on neck extension is rare. The inflated cuff sits around the outside of the laryngeal inlet and acts as an effective barrier to lung soiling with blood. There is no requirement for neuromuscular blockade and the device is well tolerated at emergence with a low incidence of coughing. Complications include laryngospasm and, as with an endotracheal tube, airway obstruction from the throat gag.

Neck extension is necessary to facilitate surgical access and is most commonly achieved with a pad under the shoulders. Care should be taken to ensure that the ETT or LMA has not been displaced by movement.

Opioid analgesia is the mainstay of perioperative analgesia but non-steroidal anti-inflammatory drugs and paracetamol also have an important part to play. A Cochrane database review suggests that the use of NSAIDs in tonsillectomy does not increase the incidence of bleeding but that nausea and vomiting may be reduced. Paracetamol administered orally (pre-operatively), rectally (in children) or intravenously (intra-operatively) reduces the opioid requirement. Local anaesthetic administration into the tonsillar bed has not been shown to reduce post-operative pain.

The incidence of post-operative nausea and vomiting is high without antiemetic prophylaxis and may be a cause of prolonged stay. High dose dexamethasone decreases the incidence of nausea and vomiting and may also reduce pain, although higher doses may be associated with an increase in haemorrhage.

Ketamine and dexmedetomidine have been used as analgesics but as yet their benefit is unclear and they are not in routine use.

EXTUBATION/RECOVERY

At the end of the case, the laryngeal inlet is examined under direct vision to confirm haemostasis and the oro/nasopharynx judiciously suctioned. In intubated adult patients, extubation is most commonly performed awake after the return of protective reflexes. Deep extubation reduces the risk of immediate haemorrhage by reducing coughing but is associated with a higher risk of laryngospasm. During this time, the risk of blood or secretions soiling the airway can be reduced if the patient is placed in the left lateral/head down 'tonsil position' and this should be maintained until laryngeal reflexes return.

In the post-anaesthesia care unit (PACU), oxygen should be administered until the patient is fully recovered. Opiates may be required and regular paracetamol and ibuprofen should be prescribed if appropriate. Routine observations should include pulse and blood pressure for evidence of post-operative bleeding, and respiratory rate and pain scores should also be recorded.

Variant Creutzfeldt-Jakob disease may be transmitted between patients undergoing tonsillectomy due to

the presence of prions in lymphoid tissue. Single use ETTs, LMAs and either sheathed or single use laryngoscope blades are recommended to reduce the risk of cross-contamination.

The post-operative bleeding tonsil

This is a serious complication. Bleeding can occur in the first 24 hours following the operation (primary), or later (secondary). Patients with secondary bleeds frequently present between 5 and 9 days after their procedure. Management is based on **fluid resuscitation, airway protection and haemostasis at the bleeding site**. Most of the blood may have been swallowed so blood loss cannot be measured and fluid resuscitation may be required prior to theatre. Induction poses special problems for the anaesthetist due to the probability of a full stomach and a high risk of regurgitation and aspiration. A rapid sequence induction minimizes the risk. At the same time the trachea may be difficult to intubate due to the presence of blood in the oropharynx and oedema from the recent surgery. There must be good communication between the teams and the surgeon must be prepared to establish an emergency surgical airway or tracheostomy should tracheal intubation fail. At the end of the procedure, extubation should be performed awake. A prolonged stay in PACU is advisable to ensure that the bleeding has stopped.

Thyroid and parathyroid surgery

THYROIDECTOMY

Thyroid surgery is the most common endocrine surgery and is almost always elective. Indications include thyroid cancer, symptomatic goitre or failure of medical treatment in hyperthyroidism. Patients with uncontrolled myxoedema or hyperthyroidism are at considerable risk and pre-operative management seeks to achieve a euthyroid state.

In hyperthyroidism, a thyroid storm is life-threatening and function can be normalized pre-operatively with radioactive iodine ablation, antithyroid drugs such as propylthiouracil, and Lugol's solution, which may help reduce iodine uptake and the vascularity of the gland. In the presence of uncontrolled hyperthyroidism, additional treatment with beta blockers in addition to steroid may be required. Increased risk extends into the post-operative period and care should continue in a high dependency unit (HDU) setting.

From an anaesthetic perspective, it is important to define the size and location of the thyroid in relation to the trachea and vascular structures. Laryngeal deviation, tracheal compression, vocal cord changes or previous thyroid or neck surgery raise the possibility of difficulties with airway management. Assessment should include diagnostic indirect laryngoscopy and CT scanning.

The vast majority of thyroidectomies are carried out under general anaesthesia using a reinforced ETT to maintain airway patency. The more recent use of intra-operative nerve monitoring requires optimal placement of a specialist silicone wired reinforced endotracheal tube

with embedded or surface electrodes in contact with the vocal cords (Nerve Integrity Monitor EMG ETT – see above). This allows monitoring of the recurrent laryngeal nerve directly or indirectly via vagal stimulation. Muscle relaxation is contraindicated.

Alternatively, a laryngeal mask and spontaneous breathing allows endoscopic evaluation of vocal cord movement. Total intravenous anaesthesia may be of benefit by reducing the incidence of coughing and improving the quality of recovery.¹⁰ However, the risk of mask displacement is high and careful team work is required.

Local anaesthesia with deep and superficial cervical plexus blocks used in combination with sedation or general anaesthesia has also been described but remains uncommon.

Post-operatively, surgical infiltration with local anaesthetic, simple analgesics such as non-steroidal anti-inflammatories and paracetamol, or weak opioids are usually sufficient to provide good post-operative analgesia.

PARATHYROID SURGERY

Primary hyperparathyroidism (PHPT) is most commonly caused by a benign parathyroid adenoma and surgery is the only curative treatment. Secondary hyperparathyroidism is a compensatory response to hypocalcaemia from another disease process and the majority of patients are managed with medical therapy, although in around 25% this is unsuccessful. Pre-operatively, symptomatic patients or those with significantly raised calcium levels require medical control with adequate hydration, diuretics and bisphosphonates. Cardiac arrhythmias resulting from hypercalcaemia should be excluded.

With improved identification of the parathyroid gland, minimally invasive surgery can be performed under local anaesthesia in some patients. In more challenging cases or those with concomitant thyroid disease a general anaesthetic is required, the considerations being similar to those described above for thyroid surgery.

Hypocalcaemia is a common problem after parathyroidectomy but is usually mild and transient. In 'hungry bone syndrome' hypocalcaemia is rapid in onset and severe with associated hypophosphataemia and hypomagnesaemia. It results from sudden removal of the effect of high circulating levels of parathyroid hormone (PTH) in patients with severe PHPT and pre-operative high bone turnover. Plasma calcium levels should be monitored post-operatively to allow early detection and prompt management.

Salivary gland surgery

Salivary gland excision may be performed for tumour, stone or chronic infection. The most common procedure is complete or superficial parotidectomy and carries with it the risk of facial nerve injury. EMG monitoring may minimize this by identifying the facial nerve and its branches. Needle electrodes are placed in the orbicularis oculi and oris muscles and these detect EMG potentials generated as a result of surgical or electrical stimulation of the facial nerve. The electrical activity is converted into an audible

signal, which warns of the proximity of the nerve. A functioning neuromuscular junction is a prerequisite and muscle relaxants should be avoided or used with caution. Long-acting neuromuscular blockers should be avoided altogether but it is possible to use a short-acting alternative to facilitate intubation on the premise that the effect will have worn off by the time monitoring is required. Offset of muscle relaxation should be confirmed with a peripheral nerve stimulator. Partial neuromuscular blockade does not significantly interfere with the facial EMG but the information derived may be unreliable.

Alternatively, intubation may be accomplished without muscle relaxants by administration of high doses of opioids or volatile anaesthetic agents. An infusion of remifentanyl often produces good conditions for intubation and allows stable levels of anaesthesia during surgery.

The facial nerve monitor can be tested before surgery by using the peripheral nerve stimulator. A short burst of tetanic stimulation applied in front of the ear over the facial nerve produces visible muscle contractions and both visual and audible alerts from the monitor.

Laryngeal microsurgery

Direct laryngoscopy is performed for diagnostic or therapeutic purposes and may be combined with an examination of the pharynx, oesophagus or bronchial tree. Rigid instruments are used requiring the atlantoaxial joint to be fully extended and so underlying pathology should be excluded. Often, lasers are used to treat isolated lesions of the larynx.

Competition for space within the airway necessitates the use of a small size (6 mm or less) microlaryngeal tube that is sufficiently flexible and long that it does not interfere with the surgical field. If lasers are to be used an appropriate laser-resistant type is required. Alternatively, a tubeless technique using jet ventilation can be used (see above).

The operation is usually relatively short, but a severe sympathetic-mediated stress response may be provoked with up to 4% of patients showing signs of cardiovascular ischaemia post-operatively.

Laryngospasm, bleeding or post-operative airway obstruction due to oedema of the vocal cords may occur. The risk of oedema may be minimized if steroid (for example dexamethasone 8 mg intravenously) is used perioperatively.

Laser surgery

The use of laser has become widespread, especially for laryngeal microsurgery. Also used for stapedectomy, tympanoplasty, turbinate surgery and oropharyngeal surgery, there are various types of laser (CO₂, Nd:Yag, KTP) all named after the source of substrate for the laser beam and producing light at different wavelengths. Most commonly used in ENT surgery is the CO₂ laser, which can be used as a precision cutting tool or to vaporize tissue.

The neodymium-doped yttrium-aluminium-garnet (Nd:Yag) laser was introduced in the 1980s and penetrates tissue more deeply than the CO₂ laser. It can also

be delivered by means of a flexible fibre-optic light cable that can be used in conjunction with a fibre-optic bronchoscope to treat lesions in the trachea and bronchi. The potassium titanyl phosphate (KTP) laser is a variant of the Nd:Yag, in which the laser beam is passed through a potassium titanyl phosphate crystal.

Airway management in laser surgery can be challenging. Aside from the underlying pathology and its impact on safe airway management, the greatest concern is the possibility of uncontrolled combustion of either tissues or extraneous materials including airway devices and surgical drapes. A fire in the airway is always serious and often fatal. Oxygen and nitrous oxide both support combustion; nitrous oxide should be replaced by air as the carrier gas and the lowest inspired oxygen concentration which maintains oxygen saturation should be used. In practice, inspired oxygen concentration is usually between 21% and 30%. A number of special laser-resistant endotracheal tubes are available.¹¹ These diminish but do not abolish the risk of tube fire and reflection damage to adjacent tissue. The cuffs of tracheal and SAD devices are more vulnerable to laser strike than are the shafts. Therefore, the cuffs should be filled with saline (or water coloured with methylene blue) rather than air. This protects them, to some extent, from combustion with laser strike; it slows any deflation of the cuff after strike; it aids, to some extent, in preventing spread of any fire; and the leak of fluid allows the surgeon to see that the cuff has been ruptured.

Surgical access can be improved by use of a 'tubeless' technique employing jet ventilation. This may reduce the fire risk because there is no endotracheal tube as a source of ignition. However, not every patient can be successfully ventilated by jet, and there is a risk of barotrauma including pneumothorax and pneumomediastinum. A TIVA technique is required.

Post-operatively, airway obstruction can arise from tissue oedema. This may be delayed following Nd:YAG use. Again intra-operative dexamethasone can reduce oedema as well as acting as an antiemetic.

BEST PRACTICE IN LASER SURGERY

- ✓ Direct laser strikes to the airway device should be avoided. This risk might be minimized during oral surgery if a Boyle Davis gag without the Doughty modification is used, thus protecting the shaft of most airway devices. If the Doughty modification is used, then the shaft of the airway device might be protected using damp gauze or swabs.
- ✓ The minimum power output of the laser should be used and the duration of laser strike limited. The risk of combustion increases with duration of strike at the same power.
- ✓ Eye protection for both patient and staff is important as CO₂ lasers are associated with corneal injuries and Nd:YAG with retinal damage. For patients, taping the eyes shut and then covering them with saline soaked gauze provides protection. For staff, protective goggles matched to the wavelength of light emitted by the laser are used.
- ✓ A smoke evacuator and appropriate face masks should be used especially if virus particles are present to reduce the potential risk of cross-infection.

Laryngectomy

Usually performed for tumour of the larynx, a total laryngectomy involves removal of all the tissues from the vallecula (and sometimes base of tongue) to the second or third tracheal rings. Occasionally, the thyroid gland also needs to be removed. The pharynx is closed in a T-shape, and the trachea is brought out to the skin as a stoma (so no special tube is required long term to maintain airway patency). There are variations of this operation. A supra-glottic laryngectomy involves resection of all tissue from the base of tongue to the vocal cords (which are left intact). The strap muscles are also preserved. A temporary tracheostomy is required post-operatively. A hemilaryngectomy involves removal of the epiglottis and just one half of the larynx (including one true and false vocal cord).

Areas of consideration for anaesthesia include:

- pre-operative comorbidities
- tracheal intubation at induction
- change of airway device during surgery.

PRE-OPERATIVE PATIENT STATE

Laryngeal tumours most commonly occur in elderly smokers, often with coexistent cardiovascular and respiratory disease. Where possible, coexistent medical conditions should be optimized pre-operatively with particular attention to nutritional status. Intra-operatively, invasive arterial pressure, and less commonly central venous monitoring placed distant to the site of surgery, may be necessary. If lung function is poor, a period of elective post-operative ventilation in intensive care may be required.

TRACHEAL INTUBATION

The presence of a laryngeal tumour may make tracheal intubation difficult. Previous radiotherapy is also a risk factor and may make bag and mask ventilation difficult. Imaging, which may include nasendoscopy, in combination with good communication between surgeon and anaesthetist, is essential in formulating a management plan.

Specialized techniques such as awake fibre-optic intubation may be necessary and these are further discussed in [Chapter 31](#), 'Recognition and management of the difficult airway'.

THE AIRWAY DURING SURGERY

To facilitate access as surgery proceeds, the oro/nasotracheal tube is exchanged for a tracheal tube inserted percutaneously into the trachea and shaped to lie against the neck, pointing caudally. Examples include the Montandon tube, RAE tube or reinforced flexible tube. Then when the permanent end-tracheostomy is fashioned the tracheal tube is removed. Thus, the anaesthetist needs to have ready a number of sterile airway devices, sterile connectors and tubing, which often need to be sited directly by the surgeon. Close communication is clearly necessary.

Tracheo-oesophageal puncture allows the placement of a voice prosthesis between the trachea and the oesophagus. The voice prosthesis is a one-way valve that allows air to pass from the trachea to the pharynx when the tracheal stoma is occluded, thus preserving voice, but preventing contamination of the trachea from above.

KEY POINTS

- Anaesthesia for head and neck surgery epitomizes the quintessential anaesthetic 'art' of airway mastery.
- It requires a unique dialogue between surgeon and anaesthetist who share the same territory. As such it requires, perhaps more than any other branch of surgery, an understanding of, and respect for each other's contribution towards a common end.

Nasal and sinus surgery

Nasal surgery is performed for cosmetic or functional restoration of the nasal airway, and includes operations such as septoplasty (operation to the nasal septum), rhinoplasty (operation to move the nasal contour), turbinectomy or these combined. Sinus surgery is performed to eliminate infection, polyps or neoplastic conditions of the sinuses, and the goal is to provide aeration of the sinuses so that secretions can drain adequately into the nasopharynx.

Anaesthetic considerations for all these operations are similar. An oral rather than nasal airway device is necessary, usually an ETT in combination with a throat pack to collect any debris from the nose. Topical cocaine mixtures have long been used to shrink the nasal mucosa, reduce bleeding and so improve the surgical field. The intense vasoconstriction is accompanied by a local anaesthetic action that contributes to post-operative analgesia. However, mucosal surface uptake is rapid and large doses are associated with severe hypertension and dysrhythmias. Cophenylcaine (Phenylephrine 0.5% and Lidocaine 5%) may be a safer alternative,¹² but again the maximum safe dose should not be exceeded.

At the end of surgery, coughing and straining can exacerbate bleeding and smooth extubation may be challenging. The nose is usually packed so a good oral airway is essential. Swallowed blood can be an irritant and anti-emetic prophylaxis should be given intra-operatively.

Ear surgery

Surgery on the external ear is performed for a variety of reconstructive or cosmetic indications.

Middle ear surgery is performed to restore hearing, eliminate infection, treat cholesteatoma and rarely for neoplasm. Outcomes have been improved by advances in technology including high magnification microscopes, enhanced imaging and improved nerve monitoring. Surgery tends to be complex, long and delicate. The principle aim of anaesthesia is to obtain a clear dry operative field by minimizing even small amounts of bleeding that could obscure the view. This can be achieved by maintaining a stable depth of anaesthesia, having a moderate

degree of hypotension (without compromising vital organ perfusion particularly in the elderly) and restricting or preventing extrinsic movement caused by monitoring or patient movement.

Blood in the surgical field may arise from arterial, capillary or venous bleeding. Arterial bleeding is directly proportional to mean arterial blood pressure (MABP). Moderate controlled hypotension to achieve a MABP of 60–70 mmHg provides optimal operating conditions. Techniques to reduce the blood pressure using hypotensive agents such as beta blockers (esmolol or labetalol), sodium nitroprusside or calcium channel blockers have in general been superseded by the use of short acting opioid agents. Remifentanyl is an effective and titratable hypotensive agent during ear surgery.¹³

Capillary bleeding depends on local flow in the capillary bed, which in turn is dependent on upstream arterial pressure and downstream venous tone, in addition to local metabolic factors. Capillary bleeding can be moderated by the use of locally infiltrated adrenaline (although the systemic effects of this will transiently confound the anaesthetist's attempts to control blood pressure) and by reduction in arterial and venous partial pressure of carbon dioxide (PCO₂) by hyperventilation.

A reduction in venous tone and backpressure will reduce both capillary and venous bleeding. Venous tone can be moderated by the use of intravenous nitrates, and a 25° head up tilt can reduce the hydrostatic venous pressure.

The surgical approach is often a post-auricular route through the mastoid. The head must be turned so that the ear on which the operation occurs is uppermost. Unlike most other ENT procedures, the airway is not 'shared' and so anaesthetic rather than surgical considerations predominate in choice of airway. Access may be difficult intra-operatively and so tracheal intubation using a south facing ETT and IPPV ventilation is commonly employed. A flexible SAD is an alternative and may reduce coughing at emergence. However, there is a greater risk

of displacement, particularly if controlled ventilation is required to prevent hypoventilation.

Facial or cranial nerve monitoring may be required and the use of muscle relaxants is best avoided post-induction. Smooth emergence and prevention of post-operative nausea and vomiting are important to prevent graft failure.¹³

Where tympanoplasty, tympanomeatal flaps, stapedotomy or stapedectomy is performed it is advisable to avoid nitrous oxide. Due to its relative solubility, nitrous oxide enters the middle ear cavity at a rate faster than nitrogen (the ambient gas in the air) leaves the space. Consequently, there is a rise in middle ear pressure that can displace the structures being operated on. Care must be taken to prevent extensive head turning and to protect the eyes from corneal abrasions.

Myringoplasty, mastoidectomy and stapedectomy are increasingly carried out as day surgery procedures and TIVA is commonly used. Advantages include improved cardiovascular stability, decreased post-operative nausea and vomiting and a short recovery time. Post-operative pain is relatively low and is well managed with paracetamol and NSAIDs except in the mastoidectomy group when opioid analgesia is required. Routine use of antiemetic prophylaxis with dexamethasone and a 5HT₃ antagonist is advisable.

KEY POINTS

- Care should be taken when positioning patients for ear surgery.
- Moderate hypotension may help to reduce bleeding in the surgical field.
- Short acting opioids such as remifentanyl allow greater control of cardiovascular stability and facilitate moderate hypotension.
- Hypotension should be limited in patients with uncontrolled hypertension, cerebrovascular or ischaemic disease.

FUTURE RESEARCH

Looking into the future, several new issues are emerging.

The imperatives of improving quality of care, reducing length of stay and limiting the physiological impact of surgery so that return to 'normal' is rapidly achieved provide significant drivers for change.

Current IV anaesthetic agents have limitations. To address the broadening agenda, new drugs based on etomidate, benzodiazepines and propofol are under development

In the search for a hypnotic agent with pharmacokinetic properties similar to remifentanyl, methoxycarbonyl etomidate showed initial promise. This has an ester moiety which is very rapidly hydrolyzed by plasma esterases but potency is low and therefore large amounts are required. To overcome these limitations, other spacer linked etomidate esters are under development and these are more potent and metabolized more slowly.

Remimazolam is a benzodiazepine that acts on gamma-aminobutyric acid (GABA) receptors but has organ dependent metabolism similar to remifentanyl. Following prolonged infusions,

residual effects are minimal. Preliminary data suggest that it has potential for sedation in theatre and ITU.

Fospropofol is a prodrug of propofol. Unlike propofol, it is water-soluble and benefits include less pain at the site of intravenous administration, less potential for hyperlipidemia with prolonged administration, and a reduction in the incidence of bacteraemia. Slower in onset than propofol, further research is needed to establish an appropriate role for fospropofol in sedation, anaesthesia and the management of the critically ill.

The search for new drugs that minimize or treat post-operative nausea and vomiting (PONV) is also important. PONV is a significant cause of patient distress and effective management not only improves quality of life but also reduces costs by reducing delayed discharge from hospital. Neurokinin-1 receptor antagonists such as aprepitant were originally developed for chemotherapy-induced nausea and vomiting. When used in surgery, aprepitant may decrease the incidence of vomiting by 70–80% and has similar efficacy against nausea and greater efficacy

against vomiting compared with other commonly used antiemetics. Administered orally, its expense currently limits its use to high-risk patients. An intravenous preparation is also available.

Outwith the development of novel drugs in anaesthesia, recent advances in airway management have seen the introduction of videoscopes such as Airtrach and McGrath. These have reduced the requirement for expensive fibre-optic techniques, which also require considerable training and expertise. Further development of equipment for the management of the difficult airway in head and neck surgery that is low-cost and requires minimal expertise remains desirable. However, developing such devices or techniques will require far more understanding of the reasons underlying the concept of the 'difficult airway' than we have at present.

Beyond the more technical aspects of anaesthesia described above, attention is turning towards the dramatic variation in patient outcomes for major surgery between different centres. Although harm directly attributable to the conduct of anaesthesia is rare (less than 1 : 50 000 mortality), these differences have spurred interest in the role of the anaesthetist as perioperative physician. Stretching across the care pathway, from pre-operative optimization to intra-operative management, which includes measures to reduce post-operative side effects and into the post-operative management of pain and identification and treatment of early complications, the changing contribution of the anaesthetist may well be an important driver of future improvement.

KEY POINTS

- Anaesthesia for ENT surgery requires constant communication and cooperation between anaesthetist and surgeon. The pre-operative surgical brief is particularly important in planning management to achieve a satisfactory outcome.
- Anaesthetic technique must balance safe airway management with surgical requirements such as nerve integrity monitoring, difficult access requiring a tubeless field or laser surgery.
- In patients undergoing head and neck surgery, the complications associated with a 'shared airway', positioning of the patient to facilitate surgery and the high risk of dental trauma should be considered.
- The post-operative bleeding tonsil is a serious complication which poses special problems for the anaesthetist due to the probability of a full stomach and obscured laryngoscopy.

Ear surgery

- A stable depth of anaesthesia, moderate hypotension without compromising vital organs perfusion particularly in the elderly may help to reduce bleeding in the surgical field.
- Best practice during laser surgery should be maintained at all times to ensure patient and staff safety.

Tonsillectomy and adenoidectomy

- Evidence supports the use of either endotracheal tube or laryngeal mask airway and the choice is one of operator preference.

ADULT CRITICAL CARE

Robert I. Docking and Andrew Mackay

Introduction	351	Death and dying in ICU	358
Organ support.....	352	References	359
The interface between critical care and ENT	356		

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: critical care, sepsis, ventilation and organ support.

INTRODUCTION

The development of modern critical care started during the polio epidemic of the 1950s, when the need to deliver positive pressure ventilation on a widespread scale encouraged the design and production of ventilators that allowed the continuation of ventilation into the post-operative period. This facility allowed surgeons to undertake more invasive and complicated procedures that would be impossible without an option for extending recovery (ruptured aneurysms, cardiothoracic surgery), and the experience gained was then used to improve the support of critically ill medical patients.

Modern critical care units are now essential to the function of any acute hospital, with resources including equipment, medical and nursing staff as well as ancillary support including physiotherapy and outreach teams. Traditionally in the UK, medical staffing has originated from anaesthesia, but the recent establishment of the Faculty of Intensive Care Medicine has led to creation of an independent specialty that allows doctors from a wide range of disciplines to complete training as critical care specialists.

Normally a high dependency unit (HDU) would care for Level 1 and Level 2 patients (**Box 33.1**), whereas an intensive care unit (ICU) would take in Level 2 and Level 3 patients. A national trend towards specialization and centralization of specialist and tertiary services has led to consolidated critical care areas, based on the premise that caring for higher volumes of patients leads to improved outcomes through refinement of processes

and more rapid cycling of quality improvement measures. This has led to larger units with a broader spread of intensity from patients with simple post-operative analgesia requirements such as an epidural catheter to patients receiving multiple modes of organ support. Having units with such diverse intensity, or a geographically close HDU/ICU setup means that ‘stepping up’ and ‘stepping down’ as the clinical case evolves is easier and more efficiently done.

Critical care is truly a multidisciplinary specialty. The medical and nursing teams should be trained specifically in critical care, and be supported by the referring teams for specific issues. Critical care units will also have

BOX 33.1 Definitions

In 2000 the United Kingdom Department of Health authored a document, *Comprehensive Critical Care*, which sought to classify critical care as to the intensity of care delivered:

- **Level 0:** Patients whose needs can be met through normal ward
- **Level 1:** Patients at risk of their condition deteriorating or with higher levels of care whose needs can be met on advice and support from the critical care team
- **Level 2:** Patients requiring more detailed observation or intervention, single failing organ system or post-operative care, and higher levels of care
- **Level 3:** Patients requiring advanced respiratory support alone or basic respiratory support together with support of at least two organ systems. This level includes all complex patients requiring support for multi-organ failure

significant requirements for physiotherapy, nutrition, microbiological and laboratory input. The medical staff should have no competing commitments during their time working in the unit, and should be easily accessible both to referring teams and the nursing staff. The lead clinician should spend the majority of their time in the critical care environment, and be able to take an overview of the issues confronting the unit. In terms of physical environment, the unit should have the space to safely look after patients, with suitable distance between beds to minimize cross-infection rates and facilitate patient care and procedures.

The management of critical care has been subject to several models. To illustrate differing approaches one may look at 'open' versus 'closed' models of care. The open model allows all admission and treatment decisions to be made by the referring specialties, with the critical care team providing only the procedural and nursing input as outlined by the referrer. This is difficult to support as continuity of care is hard to maintain, and treatment decisions can be delayed and potential harm incurred. The closed model sees all decisions made by the critical care team, often without reference to the originating parent team. While this aids continuity and speeds decision-making time, it can lead to professional friction and barriers and removes the valuable knowledge resource of the referring team when it comes to specialist input. A more cohesive approach aims to involve referring teams in the ongoing care of their patients, but with clear boundaries regarding the decision-making process.

The decision to admit a patient to critical care is often a challenging one, made after consultation with the patient, their family and their parent team. However, the nature of critical illness is such that often many of the discussions that would be useful are impossible to pursue in the available time period. Admission to critical care should only be made when there is a potential for reversal of pathology/organ failure, and with an assessment as to whether the burden of treatment is acceptable for the patient. A stay in critical care carries with it substantial physical and psychological ramifications, with recovery to a similar pre-morbid level often taking a year or more following hospital discharge. This must therefore inform part of the decision-making process prior to and during an admission to critical care.

Scoring systems

Illness severity scores are widely used in the critical care environment to predict outcome, assess organ dysfunction and analyse use of resources. The multitude of scoring systems that have been developed support the fact that there is no single gold standard; each system will have individual merits and a composite of these scores is likely to be most useful. Scoring systems in ICU can be broadly divided into:

- scores that assess disease severity at point of admission in an attempt to predict outcome (Acute Physiology and Chronic Health Evaluation (APACHE),

Simplified Acute Physiology Score (SAPS), Mortality Probability Model (MPM))

- scores that assess the presence and severity of organ dysfunction (Multiple Organ Dysfunction Score (MODS), Sequential Organ Failure Assessment (SOFA))
- scores that assess nursing workload use (Therapeutic Intervention Scoring System (TISS)).

The most commonly used system is APACHE-II. The original APACHE score was described in 1981 and scored both physiological derangement of the acute illness and an assessment of chronic health. APACHE-II was a refinement of the original with fewer physiological variables, each scored on the most deranged value in the first 24 hours, combined with age and chronic health evaluation to give a score of up to 71, which is then combined with admission diagnosis to give a predicted mortality.¹ Although on an individual basis scoring systems have little value, as ICU survival is a binary outcome, the score permits population studies and objective comparison of outcomes between patient groups or even different units.

ORGAN SUPPORT

The fundamental approach of critical care is diagnosing the cause of illness, and direct efforts to treat the underlying cause while providing appropriate organ support until such point that the patient's intrinsic organ function returns. Multiple negative trials of 'magic bullet' interventions (Activated Protein C, TNF-alpha antagonists, steroid use for septic shock) have reinforced the need for reliable and safe implementation of relatively uncomplicated modes of support, and the introduction of 'bundle' approaches to help clinicians achieve the reliability that is required in the high-risk critical care environment.

At all times the progress of the patient should be considered, and if improvement is either slow or absent then alternative diagnoses should be investigated. A failure to improve at an expected time course is often a sign that either the wrong diagnosis has been made, or that the severity of the illness has been underestimated. Complications often have differing implications depending upon the diagnosis. For example, atrial fibrillation in the setting of pneumonia is a sign of disease severity whereas following an oesophagectomy it may suggest an anastomotic leak with mediastinitis and therefore the investigation and treatment of the same arrhythmia will differ significantly.

Respiratory support

For many, the provision of respiratory support is the defining element of critical care. There has been a rapid increase in the range, variety and nomenclature of modes of both non-invasive and invasive ventilation in the last decade, but the fundamental aim remains the same: to augment oxygenation and to clear carbon dioxide while limiting iatrogenic harm.

The provision of intensive ratios of nursing care means that critical care units are the only places outwith theatre where prescribed oxygen therapy can be reliably and accurately provided. Humidification of delivered gases reduce the toxic drying effects of high flow gas, and allied to regular physiotherapy help mobilization of secretions and reversal of atelectasis.

The classification of respiratory support suffers from a variety of differing nomenclature, driven by both clinicians and manufacturers. **Table 33.1** separates those that require tracheal intubation, and those that do not:

Institution of invasive respiratory support carries with it both benefits and risks. It reduces or eliminates the work of breathing, which reduces patient discomfort and oxygen consumption, and allows access to the lower respiratory tree for clearance, suction and reinflation. However, it usually requires sedation, bypasses the usual defence mechanisms of the upper airways and equally opens the lower respiratory tree up to damage by excesses of pressure, volume and infection – so-termed ventilator induced lung injury (VILI).

Weaning off respiratory support is the process whereby support is gradually reduced to the point where the patient can breathe unaided. There is little to support one way of doing this over another, but it generally takes the form of establishing a spontaneous mode of ventilation then reducing the support until extubation can occur. For any weaning process to be successful, several things need to have occurred:

- The underlying diagnosis needs to have been appropriately treated.
- The patient needs an adequate respiratory drive.
- Any source of pain needs to be identified and controlled.
- The patient needs a reasonable cough and swallow mechanism.

Predicting successful extubation is not an exact science, but reintubation is associated with poorer outcomes in critical care. Whether this is associative or causative is more difficult to ascertain. The use of non-invasive ventilation as a treatment for failed extubation is difficult to support, unless there is strong evidence of chronic obstructive pulmonary disease in which case extubating straight to non-invasive ventilation is an option. In all but this subset there seems to be an excess mortality associated

with non-invasive ‘rescue’, most probably due to delaying reintubation and loss of reserve.

Acute respiratory distress syndrome (ARDS) is a clinical and pathological diagnosis that is the common final pathway of many disparate pulmonary and extra-pulmonary conditions, typified by bilateral diffuse airspace oedema, without overt ventricular failure, and resultant hypoxaemia. The current consensus criteria² are:

- acute onset, <1 week after insult
- bilateral widespread radiological infiltrates unexplained by other pathology
- no clinical signs of LV failure or fluid overload
- hypoxaemia, with a PaO₂/FiO₂ ratio of <40 for mild ARDS, <27 for moderate ARDS and <13 for severe ARDS.

The treatment of ARDS can exacerbate the underlying disease process by using harmful techniques to try and ‘normalize’ physiological parameters. Many therapies have been tried, but the best evidence supports relatively simple interventions including ‘lung protective ventilation’, a strict attention to management of fluid balance and early treatment of infection. The best evidence for ventilation comes from the ARDSnet RCT from 2000,³ which compared a ventilatory strategy that aimed to normalize blood gas values with high tidal volumes and pressures (12 ml/kg tidal volume and plateau airway pressures of <50 cmH₂O) and a low volume strategy (6 ml/kg tidal volume and pressures of <30 cmH₂O). This large RCT was stopped early due to a mortality reduction of 8.8% in the low volume group, and this has formed the central tenet of modern ventilatory strategy for ARDS.

The realization that ventilation can exacerbate, prolong and worsen the pathophysiological effects of critical illness has led to a renewed interest in alternative treatment strategies, particularly extracorporeal membrane oxygenation (ECMO). This approach of using an extracorporeal circuit to oxygenate and remove carbon dioxide from blood has evolved from cardiopulmonary bypass techniques, and has been well established in the neonatal and paediatric critical care environment. A protagonist-driven RCT from the UK,⁴ randomizing patients with severe ARDS to management in their hospital of origin, or transfer to a centre for consideration of ECMO showed a small but significant reduction in mortality or disability.

TABLE 33.1 Classification of respiratory support

Non-invasive		Invasive
Variable performance devices (concentration depends on effort/rate)	<ul style="list-style-type: none"> • Nasal cannulae • Hudson masks • Non-rebreathing ‘trauma’ masks 	<ul style="list-style-type: none"> • Spontaneous modes (CPAP, ASB, APRV) • Mandatory modes (VCV, PCV) • Mixed modes (SIMV, BIPAP, ASV)
Fixed performance devices (concentration is independent of effort/rate)	<ul style="list-style-type: none"> • Venturi masks • High-flow nasal oxygen 	
Pressure delivery devices	<ul style="list-style-type: none"> • Continuous pressure airway pressure masks (CPAP) • Bilevel airway pressure masks (NIV, NIPPV, BiPAP) 	

This was published during an H1N1 influenza pandemic that resulted in a large number of young critically hypoxic patients presenting to critical care, and encouraged the formation of regional specialist centres where ECMO can be used to reduce iatrogenic lung damage. The circuits require the use of significant anticoagulation and there are appreciable complications involving spontaneous bleeding, albeit in a patient group with a high predicted mortality.

Cardiovascular support

The primary function of the heart is to deliver oxygen to tissues, which requires a flow from the lungs, through the left heart and on to the peripheral tissues. At that point uptake can be blocked on a cellular or mitochondrial level, but generally the aim of critical care cardiorespiratory support is to increase tissue oxygen delivery.

As can be seen from the equations in [Box 33.2](#), increasing oxygen delivery can be achieved in a number of ways, including using fluid challenges, vasoactive drugs, transfusion of blood and optimizing oxygenation. Choosing which of these methods to use, and how to assess the efficacy of the chosen intervention is an ongoing source of debate in the critical care community.

BOX 33.2 Increasing oxygen delivery

$$DO_2 = CO \times CaO_2$$

$$CO = HR \times SV$$

$$CaO_2 = (Hb \times 1.34 \times SaO_2) + (0.003 \times PaO_2)$$

Abbreviations: DO_2 =oxygen delivery; CO =cardiac output; CaO_2 =arterial oxygen content; HR =heart rate; SV =stroke volume; Hb =haemoglobin; SaO_2 =arterial oxygen saturation; PaO_2 =dissolved arterial oxygen tension

Commonly used ways of assessing both inadequate oxygen delivery and the response to treatment include: trends in serum lactate as a marker of anaerobic metabolism; central venous oxygen saturation as an index of oxygen extraction; and more basic methods like peripheral warmth and capillary refill time.

In the past extrapolation of the use of pulmonary artery catheters (PACs) in high-risk surgical patients led to the widespread use of PAC as cardiac output monitoring in the majority of critical care patients.⁴ Following a prospective trial,⁵ and large retrospective database analyses, no evidence for benefit was found and significant numbers of procedure-related complications have resulted in far lower rates of use. Less invasive cardiac output monitors have been introduced to the market with reasonable concordance with PAC-derived values, but there remains a lack of evidence that their use improves outcome. The modes vary in their alleged benefits as detailed below, but can give trending values of most haemodynamic variables. Some of these are directly measured but many are calculated using a variety of assumptions based on normative data that may or may not be true in the critically ill patient. A summary of the available cardiac monitors can be seen in [Table 33.2](#).

In terms of the drugs used to aid the cardiovascular system during critical illness, the majority are related to the catecholamine family and increase sympathetic tone. Unlike in theatre where intermittent boluses are given, most patients receiving vasoactive drugs will receive them as continuous infusions with nursing staff adjusting dosage in response to monitored variables. Alpha agonists like noradrenaline predominantly produce increased vascular tone and therefore raise blood pressure, while beta agonists like dobutamine or adrenaline increase myocardial contractility and heart rate and thus increase cardiac output directly. Catecholamines all increase myocardial oxygen consumption, and have diverse effects including modulation of the immune response, glycaemic metabolism and gut blood flow.

TABLE 33.2 Cardiac output monitors

	Mode of action	Strengths	Weaknesses
Pulmonary artery catheter	Inserted as a central line, measures thermodilution in pulmonary circulation, Fick principle	<ul style="list-style-type: none"> • 'Gold standard' • Direct measurements of flow and pressure 	<ul style="list-style-type: none"> • Invasive • Potential complications include PA rupture • Infections
Oesophageal Doppler	Nasal Doppler probe that measures blood flow in thoracic aorta	<ul style="list-style-type: none"> • Easy to insert • Few complications 	<ul style="list-style-type: none"> • Prone to movement and measurement artefact • Poorly tolerated unless deeply sedated
LiDCO	Pulse contour analysis of arterial line, calibrated with transpulmonary lithium dilution	<ul style="list-style-type: none"> • Easy to use • Does not require central access 	<ul style="list-style-type: none"> • May not respond accurately to interventions • Inaccurate with dysrhythmias
PiCCO	Pulse contour analysis of arterial line, calibrated with transpulmonary thermodilution	<ul style="list-style-type: none"> • Relatively easy to use • Large number of displayed variables 	<ul style="list-style-type: none"> • Requires central access and modified arterial line • Inaccurate with dysrhythmias
Echocardiography	Ultrasound examination of heart and great vessels, either trans-thoracic or trans-oesophageal	<ul style="list-style-type: none"> • Direct visualization • Able to diagnose cause of low/high cardiac output 	<ul style="list-style-type: none"> • User dependent • Interpretation variable • Intermittent observation

Fluids

In the early stages of a critical care admission there is often the need for large volume fluid resuscitation, either to correct overt hypovolaemia or relative underfilling in vasodilated states like sepsis. The debate as to what is the ideal replacement fluid is ongoing, as is the debate as to how to assess response to therapy.

In terms of fluid type, both crystalloid and colloids are available for use. Crystalloids have a better safety profile in terms of anaphylaxis and cost less, but larger volumes may be required to produce an equivalent response. The disparity between the two is probably far less than the previously quoted 3:1 ratio, and crystalloids seem to have less of a deleterious effect upon the glycocalyx of the basement membrane than colloids. Use of balanced 'physiological' solutions is on the rise, as non-physiological solutions like 0.9% NaCl being linked to hyperchloraemic acidosis and impaired renal function.

Colloids are solutions with polymers suspended within them. Examples include gelatins like Gelofusin, starches like Voluven and non-synthetic colloids like human albumin solution. Many fluid optimization papers have used colloids for their bolus regimes, but concerns over safety have led to the decline of colloid use and withdrawal of starches from the European market.

After the initial resuscitation period fluid requirements revert to basal needs. These needs can be met by intravenous fluid, gastric feed and drugs. Patients on multiple antibiotics and drug infusions can receive over 2L of fluid a day from drugs alone, and without a watchful eye on fluid balance can become cumulatively overloaded. Positive fluid balance during a critical care stay has a strong association with poorer outcomes and although causation is harder to prove, avoiding fluid overload in the post-resuscitation phase is a worthwhile aim. In the case of ARDS, a restrictive fluid therapy regime improved gas exchange, shortened duration of ventilation and had no harmful effects on renal function.⁶ Conversely, positive fluid balance has been shown to worsen outcomes in acute kidney injury although this again may well be indicative of disease severity.

Renal support

The development of renal failure in critical care is usually multifactorial, with sepsis as the most common aetiology. The degree of failure can be quantified by looking at changes in serum creatinine or urine output with the RIFLE or AKIN criteria.⁷ Support focuses on treating the underlying condition, ensuring adequate hydration and lack of urinary tract obstruction and if complications supervene then providing renal replacement therapy (RRT).

Generally accepted indications for RRT include:

- hyperkalaemia
- acidosis
- uraemia – urea > 30

- fluid overload/pulmonary oedema
- toxic drug accumulation

RRT can be achieved using either dialysis or haemofiltration,⁸ with the latter being the most common modality used in critical care. A dedicated large bore central line is used to pump blood through a membrane lined filter, which utilizes a concept called 'solute drag', whereby water that passes out of the filter pores draws solutes like urea and creatinine alongside it. This results in a large amount of ultrafiltrate that needs to be replaced and therefore commercially manufactured replacement fluids containing physiological concentrations of solutes are added to the 'return' limb of the renal line. This extracorporeal circuit normally requires a degree of anticoagulation to reduce the likelihood of clot formation, and most units use an unfractionated heparin infusion for this purpose.

The optimum dose of renal replacement therapy is another area of contention. More intense sessions, either judged by frequency of dialysis or volume of replacement in haemofiltration, have a physiological rationale for providing better clearance of waste products. This was examined in a single centre trial⁹ where three separate effluent doses were targeted for patients receiving haemofiltration. This trial showed a significantly increased mortality in the low dose group, and no significant complications in the higher dose groups. This work was replicated in the field of intermittent haemodialysis,¹⁰ comparing three times a week dialysis with six times a week, showing a significant mortality benefit in the more frequent group. This concept of intensity has been re-examined by two much larger studies,^{11, 12} which were unable to replicate the mortality benefit. There is likely to be a complex dose-response curve with renal replacement, and while under-dosing should be avoided there is insufficient evidence to support higher dose intervention.

Nutritional support

In order to survive critical illness, nutrition must be maintained and supported. For short stays of < 48 hours there is no rush to institute feeding, but for stays longer than this an assessment of how to feed must be made. There is little firm evidence that enteral nutrition is necessarily better than parenteral nutrition other than the risk of central line associated infection, but most units will pursue the enteral route as first line. If the enteral route fails, or is contraindicated, then parenteral nutrition should be used through a dedicated feeding line if possible.

Feeding can be difficult to establish due to slow gastric emptying, impaired hormonal flux and altered enteral circulation. Methods of encouraging successful enteral nutrition include gradually increasing feeding rate, prokinetic drugs and insertion of postpyloric feeding tubes rather than the standard nasogastric placement. The standard approach is to target an energy intake of 25 kcal/kg/24 hrs, with a mix of protein, fat, carbohydrate and essential vitamins. Enthusiasm has waxed and waned for 'immunonutrition' with supplementation of substances purported

to boost immune function, but there is not enough evidence to support this when subjected to meta-analysis.

Poor glycaemic control is linked to increasing infection rates, poorer wound healing and worse outcomes in a variety of disease states. Critically ill patients tend to develop hyperglycaemia in response to a number of factors including the stress response, relative insulin resistance, increased circulating levels of cortisol, catecholamines as well as exogenous administration of drugs including steroids and additional catecholamines as part of their support. Interest was raised when a 2001 RCT¹³ comparing a 'tight' glycaemic control protocol targeting blood glucose values of 4.4 to 6.1 mmol/L against a 'conventional' protocol target of 10 to 12 mmol/L was published and showed a raft of positive effects including reduction in all-cause mortality, incidence of AKI needing RRT, bloodstream infections and critical care acquired weakness. Many centres adopted this so-called 'intensive insulin therapy' approach, but a subsequent trial by the same group¹⁴ looking at a wider range of patients (as opposed to the original cardiac surgery cohort) failed to support the same findings. A more recent 2009 RCT,¹⁵ far larger than the previous cohorts, compared the intensive target to a conventional target of <10 mmol/L and showed an increased all-cause mortality in the intensive group, seemingly independent of the effects of hypoglycaemia. Certainly hyperglycaemia should be avoided and treated if it occurs, but intensive control cannot be supported.

Sedation

The majority of patients in critical care will require some form of sedation or analgesia to help provide their care. The presence of an endotracheal tube is intensely stimulating, so the use of opioids for their anti-tussive effects is key. Acute pain related to operations, critical care related procedures and positioning is extremely common and critical illness interrupts the sleep-wake cycle meaning that sedation is also often required.

The most commonly used regime involves the short-acting anaesthetic agent propofol, alongside an opioid (morphine, alfentanil, remifentanil). Benzodiazepines, such as midazolam, have lost favour due to the implication of increasing the incidence of delirium. Stopping sedation on a regular basis may help to shorten stay, and allows for more accurate assessment of neurological function.¹⁶

Delirium, an acute alteration in consciousness and alertness associated with many disease states, has recently become far more readily recognized in critical care. Up to 70% of critical care patients will experience an episode of delirium, and it is associated with longer stays, longer duration of ventilation, increased mortality and long-term cognitive decline. There are no proven interventions to treat delirium, but generally non-pharmacological measures (sedation breaks, orientation aids like clocks and natural light) have fewer side effects than the pharmacological measures like haloperidol and atypical antipsychotics.

THE INTERFACE BETWEEN CRITICAL CARE AND ENT

Post-operative care

Like all other surgical specialties, patients undergoing ENT operations may be admitted to critical care either in a planned or unplanned fashion. The type of admission can be generalized into one of three categories as follows:

1. Caused by the acute illness (e.g. the ongoing management of shock following post-tonsillectomy haemorrhage)
2. Caused by the nature of the surgery (e.g. major head and neck operations where it is anticipated that airway swelling or compromise may persist for several days after the operation)
3. Caused by pre-existing disease processes (e.g. severe left ventricular dysfunction in someone undergoing an unrelated ENT procedure)

Early discussion with critical care allows for potential pre-operative optimization, or modification of intra-operative management to aid post-operative recovery. Depending on developments in the post-operative period these admissions may be brief, or unexpectedly protracted. Regular communication between the ENT and critical care team allows for both sides to improve decision-making processes and support the patient and family during what is an emotionally fraught time.

Sepsis

ENT can be involved in the management of sepsis in critical care either in ENT patients who have developed perioperative sepsis either as a primary or secondary infection, or in the investigation of occult sepsis in non-ENT patients. Most critical care patients have indwelling tubes through the nasal passages, and as such are at increased risk of sinusitis that may be difficult to diagnose. In such cases ENT may be asked to help investigate, or provide washouts to remove a potential source of sepsis.

Although the terminology has been well defined, various phrases are used interchangeably, which can lead to diagnostic confusion. Initial consensus definitions derived three states of sepsis, increasing in severity: sepsis; severe sepsis; and septic shock. The most recent iteration of the Surviving Sepsis Campaign (SSC) guidelines¹⁷ classes these as shown in [Table 33.3](#).

The underlying pathophysiology of sepsis is that of an uncontrolled physiological response to infection leading to systemic vasodilation produced by a host of cytokines including, but not limited to, Il-6, Il-18, TNF- α , inducible nitric oxide synthase and arginine. The 'classic' septic patient will display a hyperdynamic circulatory pattern with low filling pressures, maintained or increased cardiac output and microcirculatory dysfunction. This textbook presentation is often not seen, with a wide range of patients from those with a maintained blood pressure but

TABLE 33.3 Three states of sepsis

Sepsis	Severe sepsis	Septic shock
Documented or suspected infection with the presence of systemic manifestations of infection	Sepsis with signs of organ hypoperfusion (hypotension, raised creatinine, raised bilirubin, prolonged INR, hypoxia, thrombocytopenia, lactataemia)	Severe sepsis with hypotension refractory to initial resuscitation – classed as a MAP <70 mmHg or systolic <90 mmHg after 30 ml/kg fluid resuscitation and initial vasopressor use

organ dysfunction, to those with marked sepsis-induced myocardial dysfunction who are far from hyperdynamic.

The early and aggressive management of sepsis has been a focus of recent media attention with campaigns including Surviving Sepsis and the UK-based Sepsis Six, based on work that suggests that both early administration of antibiotics¹⁸ and resuscitation targeted to endpoints¹⁹ reduced mortality and morbidity in sepsis. Management hinges on having a high suspicion of the diagnosis, investigating the potential sources using microbiology, radiology and surgery early, restoring tissue oxygen delivery by resuscitation and administering appropriate broad-spectrum antibiotics tailored to the most likely source of sepsis. The following list summarizes the Sepsis Six approaches that are recommended to be implemented within this first hour of a patient being diagnosed with sepsis:

1. Administer high flow oxygen.
2. Take blood cultures.
3. Give broad spectrum antibiotics.
4. Give intravenous fluid challenges.
5. Measure serum lactate.
6. Measure hourly urine output.

This bundle approach aims to make the early diagnosis and management of sepsis more reliably achieved within a short timeframe by junior staff, but does require ongoing senior input including making the escalation to critical care if appropriate.

Improving tissue oxygen delivery relies upon the restoration of both an appropriate circulating volume, and perfusing pressure. As previously mentioned, the SSC guidelines advocate the use of a 30 ml/kg crystalloid resuscitation approach, with early use of noradrenaline as the first-line vasopressor alongside fluid resuscitation to restore organ autoregulatory flow. Suggested endpoints for resuscitation include trends in lactate, venous oxygen saturations, or urine output. In cases of reduced cardiac output suggested by findings such as low venous oxygen saturations, echocardiography or lack of response to vasoconstrictor therapy, predominantly inotropic agents like dobutamine or adrenaline are indicated.

Airway management

The involvement of ENT with airway management in critical care falls into two main groups. The first is the management of difficult or potentially difficult airways in critical care, while the second is the provision of tracheostomies for patients with an ongoing need for ventilatory support.

DIFFICULT AIRWAYS

Difficult airways can be known, suspected or not recognized. The experience of the clinician assessing the airway is key, as is access to previous documentation if available. A national UK survey of airway complications²⁰ showed that 20% of all reported complications occurred in the critical care unit, and that the degree of harm that occurred to these patients was far higher than those that happened in theatre or the emergency department. The majority of complications were related to tracheostomies, both new and existing, but securing *de novo* airways also featured heavily. Common reasons identified for complications included lack of training, lack of equipment and lack of preparation. Reasons for increased complication rates include the above, but also the rapid need for intubation in the critically ill, the lack of cardiorespiratory physiological reserve, and the regular lack of an escape option where abandoning the need for ventilation is not possible.

The difficult airway can be due to obstruction or distortion at any level, and the potential management options will vary due to aetiology:

- supralaryngeal – tumour, infection, anaphylaxis
- laryngeal – infections, tumours, surgery, anaphylaxis
- infralaryngeal – tumour, infection, tracheomalacia, subglottic stenosis.

Where possible, the most senior staff available should be present, with full monitoring as would occur in theatre, and with trained skilled assistance. If predicted to be difficult there is a strong case for attempting the intubation in a theatre setting.

TRACHEOSTOMY

For patients who have an ongoing need for ventilation, there are several potential benefits for exchanging a trans-laryngeal tube for a tracheostomy tube. These include:

- reduced sedation needs due to lack of glottic stimulation
- reduced deadspace (probably less important than previously thought)
- reduced tube resistance and work of breathing
- improved mouth care
- ongoing bronchial toilet when weaned.

These benefits need to be balanced against the complications of tracheostomy insertion, the patient specific factors like coagulopathy or body habitus and the predicted duration of ventilation need. There is little evidence to support the optimal timing of tracheostomy insertion, with a

recent UK trial²¹ comparing early (before day 4) and late (after day 10) tracheostomy insertion. This trial stopped early due to difficulties in recruitment, but with 900 of 1200 planned recruited patients failed to show a benefit in mortality with early tracheostomy insertion with similar lengths of stay, ventilation and antibiotic use.

The method of tracheostomy insertion is essentially between a percutaneous dilational technique, most often performed by critical care staff under bronchoscopic control, and traditional open surgical tracheostomies. Meta-analysis²² has shown equivalence of the techniques, with a percutaneous approach leading to less wound infections and a similar complication rate. The percutaneous techniques involve partial withdrawal of the endotracheal tube under general anaesthesia and neuromuscular blockade, then a Seldinger based technique of needle insertion, guidewire pass and dilation using a serial dilator, graduated dilator or blunt forcep dilation before placing the tracheostomy tube over the wire.

There are situations where surgical techniques are more appropriate and these include:

- obesity, more for the availability of suitable percutaneous kit
- anatomical variance including previous surgery and goitres
- coagulopathy or bleeding diatheses.

ASSESSING VOCAL CORDS

This may be asked for in patients who have failed extubation, who have impaired cough mechanisms or suspected recurrent aspiration. Cord dysfunction may be due to mechanical issues after long-term intubation, surgical complications especially after thyroid or parathyroid surgery, or some apical lung tumours. Other nerve dysfunction should be sought, including bulbar or pseudobulbar dysfunction that may suggest alternative diagnoses. Assessment can be performed at the bedside using either rigid or flexible bronchoscopy methods, ideally without neuromuscular blockade.

DEATH AND DYING IN ICU

Mortality in critical care is steadily decreasing, despite dealing with ageing populations with increasing comorbidity. Figures vary between countries and case mix, but in a mixed medical and surgical ICU in a first world country, one would expect a unit mortality of around 20% and a hospital mortality of 35%. While improvements in mortality are encouraging, this still means that around one in five patients admitted will die and therefore medical and nursing staff need to be familiar with the caring of the dying patient and the support of their family.

Communication

Communication with both the patient and their family is a key part of the critical care workload. Often critically ill

patients are unable to communicate or retain information, and the bulk of the communication given is to the family. This carries with it issues surrounding confidentiality and it is always best to have the patient give their permission prior to such conversations. This is not always possible, and the situation must be approached with tact and careful judgement. It should be remembered that having a relative who is critically ill is a heavy emotional burden for any family, and that even simple messages may have to be repeated at each conversation to ensure understanding.

Identification of the next-of-kin is a useful approach, allowing for clarity of communication and the reduction of misinterpretation. It is a laudable aim for a senior clinician to meet with a family within the first day following admission, and to have continuity of communication throughout the stay especially if prolonged.

Regardless of communication content, a few key points are universal:

- Time for communication must be made, ideally free from interference, in a dedicated relatives' area.
- Introductions should be clear, outlining roles and responsibilities and ensuring that you know who you are addressing.
- It is valuable to spend time at the beginning of each conversation investigating what has previously been said, and what has been understood – this can help to reduce 'mixed messages'.
- Be familiar with the case, including dates of admission and significant events.
- Always aim to summarize your conversation aims at the end, and allow time for questions.

Care of the dying in critical care

Every day in a large critical care unit there will be a patient who has their focus of care changed from a curative intent to the provision of palliation. This change in focus can happen quickly, or follow a more indolent course. It is usually due to a patient worsening, or a recognition that the patient would not wish to survive with such a marked reduction in functional outcome or quality of life. The latter is a particularly difficult decision to make, and needs to be carefully approached given the inherently subjective nature of such judgements.

Such decisions should be made in conjunction with the patient if their condition allows it, the family, and the referring team.²³ Concordance in the decision is the most desirable outcome, and if there is dissent then the best approach is to address this openly and to continue ongoing support until an agreement is reached.²⁴ As the emotional element of such decisions is so high, the process can often be reached over a longer period of time allowing time for grieving and acceptance of the situation at hand. Pursuing a decision in the face of unease or unhappiness is a common finding in complaints.

In critical care, the change of focus to palliation often encompasses either limitation of therapy or withdrawal of organ support. From an ethical standpoint the two are identical, but some will struggle with withdrawal

of support more than non-institution. Regardless of the mode of palliation, the comfort and the dignity of the patient are paramount, and only interventions that will increase patient comfort should be pursued. This may include starting or increasing analgesic infusions, extubation if appropriate, and cessation of blood sampling whilst continuing to ensure good oral cleaning, regular position changes and good nursing care. Communication should continue with the family, and addressing any concerns they may have during the process.

'Do not attempt resuscitation' (DNAR) orders are ways of communicating advance decisions regarding the appropriateness of undertaking cardiopulmonary resuscitation. The forms themselves are not legally mandated in the UK, but are seen as good clinical practice as they prompt medical teams to discuss decisions about resuscitation with patients and their families. Controversies surrounding DNAR decisions mainly stem from lack of communication, and misunderstanding of the role and realistic outcomes of cardiopulmonary resuscitation.

FUTURE RESEARCH

One of the major problems facing research in critical care is the application of single interventions to heterogeneous disease states. A desire to classify and compartmentalize broadly similar presentations has led to umbrella terms, such as ARDS or sepsis. While these approaches make sense in terms of broadly similar pathophysiology or clinical presentation, the application of targeted treatments to clustered disease states does lead to potentially missing true treatment effects.

A common theme in modern critical care developments has been the early identification of organ dysfunction. A promising area of research is the development of reliable biomarkers of organ dysfunction that could allow early intervention and prevention of further deterioration. For example, serum lactate has been identified as a marker of tissue hypoxaemia that can be used to guide resuscitation and monitor progress in sepsis;

and development of point-of-care tests could allow for quicker detection of the critically ill patient. This and other potential biomarkers would all have to be validated and suitable levels of sensitivity and specificity agreed upon.

As mentioned earlier in the chapter, an admission to critical care carries with it a substantial morbidity and the effect this has on future quality of life in survivors forms a key research priority. There is emerging evidence that an episode of acute inflammation such as a critical illness can lead to a chronic low-grade pattern of inflammation. This can have effects upon an individual's ability to recover from their acute event, and upon the potential for future accelerated organ deterioration. Both qualitative and quantitative research in this area is needed to help inform clinicians about the burden of admission on patients.

KEY POINTS

- Critical care has evolved to occupy a central role in the modern acute hospital.
- The most important interventions in critical care are the assiduous application of good basic medical and nursing care.
- Critical care admission is a multifactorial decision incorporating acute and chronic medical, social and ethical considerations.
- Advanced organ support is crucial to optimize the physiological state and permit time for definitive interventions to take effect.
- The majority of interactions between ENT and critical care will be for the provision of elective and emergency post-operative care and for advanced airway intervention, including difficult airway management and tracheostomy.
- Due to the high mortality rate among ICU patients, management of death and the dying patient is of paramount importance, as is recognizing that effective and empathetic communication assists this process.

PAEDIATRIC INTENSIVE CARE

Louise Selby and Robert Ross Russell

Introduction	361	Major surgery	365
General principles	361	Summary	366
ENT emergencies in PICU	363	References	367

SEARCH STRATEGY

Data for this chapter are mostly generic management strategies for children in intensive care. The target audience is ENT surgeons involved in caring for children, rather than paediatric intensivists who are looking after ENT patients. The material is relevant to both groups within the chapter.

The data were gathered through reference to standard texts on paediatric intensive care, notably Rogers and Nichols' *Textbook of Paediatric Intensive Care*.¹ Specific information on ENT trauma in children was obtained through PubMed using the keywords: 'laryngeal trauma and laryngeal injury', limiting the search to children aged 0–18 years. This revealed 90 review articles of which 7 were found relevant and scrutinized. Information on bronchoscopy was located on PubMed using the keywords: 'fiberoptic bronchoscopy and intensive care', limiting the search to children aged 0–18 years. This yielded five papers, but by looking at related citations we were able to find two relevant articles.^{2,3}

INTRODUCTION

Children are liable to present acutely with ENT pathologies, many of which are specific to the paediatric population and may require intensive care management. Those children undergoing major ENT surgery also frequently require admission to a paediatric intensive care unit in the post-operative period. This chapter aims to outline the general management principles of ENT patients within the paediatric intensive care setting. Important differences in the anatomy and physiology of children compared to adults are reviewed. A systematic approach to evaluation of children admitted to the paediatric intensive care unit (PICU) is outlined, together with general principles of fluid and analgesia management in children. Specific issues relating to the care of the major paediatric emergencies, as well as the post-operative management of patients undergoing major ENT surgical procedures are discussed. Finally, indications for performing flexible and rigid bronchoscopy are outlined.

GENERAL PRINCIPLES

Anatomical and physiological considerations

The paediatric airway differs from the adult airway in many aspects. Understanding these differences in structure is essential in order to manage the paediatric airway successfully. The head of the infant and small child is proportionately larger, accounting for nearly 10% of body surface area compared to 3.5% in adults. Infants and young children have a more prominent occiput with a shorter neck and these factors in combination increase neck flexion. Children also have a relatively large tongue and a small mandible, potentially making airway access difficult.⁴

In all young children the epiglottis is a 'horseshoe shape' and the larynx sits high (opposite the third cervical vertebrae, compared to the fifth or sixth in an adult) and anterior. The larynx itself is conical, unlike the cylindrical

TABLE 34.1 Physiological parameters at different ages

Age	Heart rate (bpm)	Respiratory rate (bpm)	Mean BP (mmHg)
Newborn	110–140	50–60	50–60
1 year	90–110	30–40	70–90
2–5 years	75–90	25–30	80–100
5–12 years	60–90	20–25	90–110
>12 years	50–80	15–20	100–120

adult larynx and the narrowest part lies at the cricoid cartilage. Finally the tracheal cartilage is often less rigid than in adults, and may compress if the neck is overextended.⁵

Infants up to the age of 6 months are obligate nasal breathers.⁵ When this is combined with the relatively small airways and risk of mucus obstruction, airway compromise is common. Between 3 and 6 years of age, tonsillar and adenoidal hypertrophy further contribute to airway obstruction.

Physiologically, there are also substantial and important differences. Respiratory muscle function is affected by the position of the ribs in infants, which lie perpendicular to the spine rather than running caudally as in adults. This makes the diaphragm the only effective inspiratory muscle. Infants and children have a faster respiratory rate than adults (**Table 34.1**), which is partly related to an increased metabolic rate. In infants, increased chest wall compliance can increase the work of breathing substantially.

In the cardiovascular system, a limited stroke volume necessitates a faster heart rate in children and they also display a lower mean blood pressure. Their response to cardiovascular stress is limited and cardiac output can only be increased significantly by increasing the heart rate, therefore tachycardia is common.

Evaluation

Admission of a child into the PICU is a difficult and important moment in the child's care. The care of the child is transferred to a new team of doctors and nurses and the family are moved to a new and stressful environment. It is essential that handover of the child is structured and complete. Ideally there should be a face-to-face handover between medical and nursing teams involved in the care of the child. The background history, current problems and care plan should be clearly documented.

The family of the child need to be included in this handover. When the admission is planned, for example post-operatively, families should be offered the chance to visit the intensive care unit prior to the surgery so they have met some of the staff and seen the environment. There should be an area for them to stay whilst procedures are being carried out and regular progress updates from medical and nursing staff.

The doctors admitting the child also need to evaluate the child carefully on admission. This should follow a standard 'ABC' assessment, assessing the airway,

TABLE 34.2 Issues to be considered on admission of a child to PICU

	Issues to consider
Airway	Clear? ETT position? ETT secured properly?
Breathing	Air entry? Adequate ventilation?
Circulation	Peripheral perfusion? Adequate access?
Fluids	Drug infusions? Blood sugar? Urine output?
Analgesia/sedation	Pain control and sedation adequate? Muscle relaxant needed?
Tests	Blood gas? Electrolytes? Full blood count?

breathing and circulation. Issues regarding fluid balance, medications and results of investigations should also be clarified (**Table 34.2**).

Fluid management

The principles of fluid balance in children are the same as in adults but there are complicating factors. Any fluids that need to be given are based on a child's weight or occasionally body surface area (tables for which are found in the British National Formulary for Children). The distribution of fluids between compartments is different for adults and children. Total body water is distributed between the intracellular, interstitial and intra-vascular spaces, moving from one compartment to another. At birth approximately 80% of a baby's body weight is water, with this percentage falling gradually to 60% in adulthood. The infant has approximately one third of their body weight as interstitial fluid – twice as much as in an adult.¹

Normally fluid balance is tightly controlled by thirst, hormonal responses and renal function. In illness and injury there may be rapid fluid shifts with clinical consequences.

THE NEWBORN INFANT

The full term infant requires approximately 150 ml/kg per day of fluid from day 5 of life (less in the first few days). Of this, approximately 30 ml/kg will be accounted for by insensible losses. Normal fluid intake is entirely as milk, which provides fluid and nutrition for approximately the first 6 months of life. Fluid requirements (per kg) gradually reduce thereafter as shown in **Table 34.3**; however, these requirements may require adjustment in disease.⁵

Electrolyte requirements also vary with age, though not as dramatically as fluid volume. In the infant, immature renal function increases the salt requirements and 3 mmol/kg of sodium and 2 mmol/kg of potassium are required daily. In older children this falls to approximately 2 mmol/kg per day of each ion. Calcium, magnesium and other ions are broadly in the same dose (per kg) as adults.

Glucose requirements are critical, especially in young children. The daily calorie requirement of infants is approximately 100 kcal/kg, more than double that in adults.

TABLE 34.3 Fluid and electrolyte requirements at different ages

Age	Daily fluid requirements	Sodium/potassium requirements
1 day	60 ml/kg	2–3 mmol/kg/day
5 days	150 ml/kg	2 mmol/kg/day
1 month	120 ml/kg	1–2 mmol/kg/day
6 months	110 ml/kg	
1 year	100 ml/kg	
> 1 year	1000 ml for the first 10 kg, 500 ml for the next 10 kg, then 20 ml/kg for the rest of body weight	

Maintenance of adequate glucose levels in infants is critically important and hypoglycaemia can cause brain damage. In infants and small children, enough glucose must be given to maintain blood glucose levels.

THE UNWELL CHILD

Fluid requirements following surgery can be quite variable. In most units, children are started on a regime restricting their input to approximately two-thirds of normal requirements. This is especially true if oral feeds are not to be used and fluids are being given intravenously. Intravenous fluids should be chosen with care. A National Patient Safety Agency (NPSA) alert in 2007 prompted the removal of hypotonic fluids (0.18% saline) from paediatric wards following incidences of mortality secondary to hyponatraemia.⁶ Solutions containing adequate sodium (such as 0.9% saline, or 0.45% saline and 5% dextrose) are therefore recommended. Whatever regime is used, it needs to be remembered that children are prone to becoming dehydrated or fluid-overloaded quite rapidly (particularly during illness) and need to be monitored carefully. In infants especially, blood glucose levels need to be measured up to every 4 hours.

Analgesia

Appropriate analgesia needs to balance the sedative and respiratory suppressive effects of opiates against the need for good pain control. Oral paracetamol and other non-steroidal anti-inflammatory drugs (NSAIDs) may be adequate, but opiates (e.g. morphine) may be needed. A morphine infusion of 10–30 mcg/kg/hour can be given or as a patient-controlled analgesia pump for older children. Infusions can be set up to give background rates of 10 mcg/kg/hour with additional boluses for breakthrough pain but should be discussed with an anaesthetist. Midazolam is a sedative and amnesic drug and may be needed for patients in the PICU, especially if they are ventilated or undergoing painful procedures. Midazolam can be given as bolus doses of 0.1 mg/kg up to every 4 hours or as an infusion (50 – 250 mcg/kg/hour). Patients need close observation of physiological parameters with either bolus dosing or intravenous infusions.⁵

ENT EMERGENCIES IN PICU

Trauma

All trauma cases, including those who have sustained craniofacial trauma should be managed acutely according to paediatric life support guidelines, with immediate evaluation of airway, breathing and circulation.⁵ Laryngeal trauma consists of a rare but precarious set of injuries, often requiring a high index of suspicion to promptly diagnose and appropriately treat. Cases of blunt laryngeal trauma are rare. Laryngeal trauma is seen less frequently in infants and children because of their involvement in fewer car crashes and cases of ‘interpersonal conflict’.⁷ They may occur if a child is unrestrained in a car involved in a road traffic accident if they hit the dashboard when the head and neck are in a hyperextended position. In the child presenting with laryngotracheal injuries in the absence of such a history, the possibility of non-accidental injury with a direct blow to the anterior neck should be considered as a possible aetiology.

Children surviving a near strangulation event are at risk for significant airway compromise. Studies looking at near hanging events between 2001 and 2010 found four cases with documented laryngeal injury and one child requiring a tracheostomy.⁸ ‘Near hanging’ or ‘choking games’ are reported in the teenage population.⁹

Management of laryngeal trauma must begin by evaluating the adequacy and patency of the airway. If airway obstruction is a concern, a surgical airway in the form of emergency tracheostomy should be established urgently. The preferred management in children consists of gas anaesthesia with rigid bronchoscopy to evaluate the injuries as well as securing the airway so tracheostomy can be performed over the rigid bronchoscope.⁸ Orotracheal intubation must be undertaken with caution to avoid extending damage or losing the airway.

In patients with moderate injuries, the degree of damage can be further assessed using CT scanning once the airway has been protected. Open exploration is recommended where the injuries are severe, and laryngeal trauma is commonly associated with other injuries to the neck or chest.⁸

Upper airway obstruction

The small cross sectional area and conical shape of the paediatric airway renders children particularly susceptible to upper airway obstruction. Airway resistance is inversely proportional to the fourth power of the radius of the airway. Therefore a relatively small reduction in the radius of the airway through mucosal oedema, secretions or a foreign body results in a significant increase in airway resistance.⁵

Stridor on inspiration is indicative of upper airway obstruction. In children where severe upper airway obstruction is suspected as a diagnosis it is imperative to avoid all invasive procedures and aspects of the examination that may distress the child as this may cause complete upper airway occlusion. Children should be kept warm and calm while experienced anaesthetic and surgical staff are assembled. Examination can then be undertaken in a

controlled manner. A full examination of the child is also needed at a convenient point. Birthmarks and haemangiomas should be recorded as this may indicate there is a vascular laryngeal lesion. If a child is dysmorphic, a genetic opinion may help identify a syndrome that may have airway implications. Patients with micrognathia as seen in Pierre Robin syndrome, Robin sequence and Treacher Collins syndrome, and those with the mucopolysaccharidoses where progressive dermatan sulphate accumulation in body tissues including the oropharynx and airway, can make airway management challenging.⁴

The patient recovering from burns presents additional challenges. Contractures of the face, neck and chest may result in microstomia, granuloma formation, subglottic stenosis, tracheomalacia and fixed flexion of the neck.¹⁰

EPIGLOTTITIS

The vaccine included in childhood immunization schedules should protect against *Haemophilus Influenzae B* (Hib) infections and has led to a marked decline in the incidence of epiglottitis such that it is a rare condition. Occasional cases do occur in unimmunized children or in those in whom the vaccine has failed.

The clinical presentation is a child usually aged between 2 and 7 years who is toxic, stridulous and drooling. Immediate management is to secure the airway either by endotracheal intubation by experienced personnel or by emergency tracheostomy. The child will remain ventilated in intensive care whilst receiving intravenous antibiotics (third generation cephalosporins) until the swelling of the epiglottis has reduced, usually within 24–36 hours.¹¹

CROUP

Acute viral laryngotracheobronchitis (viral croup) is a common cause of upper airway obstruction in children characterized by hoarseness, barking cough and inspiratory stridor. *Parainfluenzae* virus type 1 is the agent most commonly identified in cases of croup. Only severe cases require admission to the PICU.

Localized inflammation and oedema of the upper airway caused by a virus can increase airway resistance and significantly increase the work of breathing in young children. Glucocorticoids in the form of nebulized budesonide or systemic dexamethasone are believed to reduce the degree of upper airway inflammation and swelling leading to decreased effort in breathing. A recent Cochrane review found when corticosteroids were compared to placebo in treatment for croup, dexamethasone and budesonide were effective in relieving symptoms as early as 6 hours after treatment, resulting in reduced hospital stay and fewer hospital re-admissions.¹² Some clinical improvement can occur within 30 minutes of glucocorticoid dose.⁵

If airway obstruction is severe, short-term relief can be achieved by nebulizing adrenaline (1 ml/kg of 1:1000 up to a maximum dose of 5 ml) with oxygen. A small number of children with croup (<5%) will require intubation. However glucocorticoids and nebulized adrenaline

TABLE 34.4 Features of croup vs epiglottitis

	Croup	Epiglottitis
Age	1–3 years	2–7 years
Cause	Parainfluenza viruses	Hib
Prodrome	1–2 days coryza	Hours, sore throat, dysphagia, drooling.
Fever	<38°C	>38°C
Appearance	Lethargic	Pale and toxic, drooling and dysphagia, sitting with neck extended
Stridor	Barking cough, loud stridor	Muffled stridor
Hypoxia	Unusual	Frequent
Severity	<5% hospitalized cases require intubation	All require intubation

have both been shown to reduce length of hospital stay in management of croup.^{12, 13} A comparison of the clinical features of croup and epiglottitis are included in [Table 34.4](#).

Bacterial tracheitis

Bacterial tracheitis, or pseudomembranous croup, is much less common than viral croup but it is potentially life threatening. The majority of patients (over 80%) will require intubation to secure their airway whilst receiving treatment with intravenous antibiotics. The responsible pathogens are usually *staphylococcus aureus*, *streptococci* or *Haemophilus influenzae B*, which infect the tracheal mucosa causing necrosis and the production of purulent secretions that may occlude the upper and lower airway. Clinically, a child with bacterial tracheitis is septic with a high fever, barking cough and signs of progressive upper airway obstruction. Coughing without drooling can help to distinguish it from epiglottitis.⁵

Foreign body inhalation and ingestion

Foreign body inhalation most commonly occurs in children aged 1 to 3 years and should be suspected if there is sudden onset of stridor and upper airway obstruction with no preceding fever or illness (please see [Chapter 31](#) for more details). Without early treatment it is a cause of morbidity in children, sometimes resulting in a fatal outcome.¹⁴ Foreign body injuries can be described by anatomical site. Upper airway involvement varies from complete obstruction with hypoxia and cardiorespiratory compromise to partial obstruction with cough, stridor, and respiratory distress. Lower airway involvement can lead to pulmonary changes depending on the site of the impaction including collapse and consolidation of the bronchopulmonary segment seen on chest X-ray.¹⁵ Foods, particularly nuts and seeds, are the usual cause. However, small magnets or other metallic parts found within some toys can become lodged in the hypopharynx

or oesophagus and rapidly cause pressure necrosis of mucosal tissues.¹⁶

If a child presents with increasing dyspnoea, apnoea or loss of consciousness that has not responded to simple airway manoeuvres then advanced paediatric life support guidelines for managing a choking child should be followed. Blind finger sweeps of the mouth are not recommended as these can push the object tighter into the larynx. In the older child the Heimlich manoeuvre can be safely attempted, or if the child is unconscious and supine then abdominal thrusts may be as effective.⁵

On clinical examination there may be unilateral wheeze and reduced breath sounds. A chest X-ray may show air trapping possibly with (mediastinal shift), atelectasis, pneumothorax or have a normal appearance.¹⁵ Patients require general anaesthetic for rigid bronchoscopic removal and may require admission to the PICU post procedure. Complications of delayed diagnosis of inhaled foreign body can include tracheal lacerations, inflammation, oedema, atelectasis and bronchopneumonia^{12, 13} contributing to prolonged hospital stay. There can also be bleeding with manipulation of the object and it can be difficult to dislodge and retrieve.¹⁶

Laryngopharyngeal injury can also occur following accidental ingestion, particularly of liquid detergent capsules. These contain irritant cleansing ingredients that can cause rapid onset of mucosal oedema. Consequences can be severe, with possible oesophageal perforation and necrotic extension to the tracheobronchial tree requiring endotracheal intubation or tracheostomy.¹⁷

MAJOR SURGERY

Craniofacial surgery and cleft lip and palate

Children who undergo craniofacial surgery or a cleft lip or palate repair may require admission to the PICU or high dependency unit (HDU), particularly if there is a risk of the airway becoming compromised by post-operative swelling. If the child returns from theatre ventilated, sedation and analgesia need to be maintained for the duration of ventilation. A partially sedated child may struggle against an endotracheal tube (ETT) and this may damage a palatal or laryngeal repair. It may be necessary to muscle relax a child once they are adequately sedated, usually by using short acting anaesthetic agents, so if extubation is planned the child can be woken quickly. Using longer-acting drugs can lead to accumulation of the drug within the tissues and a period of suboptimal wakefulness as it is metabolized.

Other important considerations include the use of an orogastric rather than nasogastric tube best sited intra-operatively (nasogastric tubes can traumatize a palate repair). Nursing staff should be aware to use a soft wide-bore flexible suction catheter to remove visible oral secretions. Patients should not be nursed close to other children who may be infectious if at all possible.

Surgery of the nose and upper airway

Patients who have nasal surgery rarely require admission to the PICU in the post-operative period; however, infants requiring surgery for choanal atresia or stenosis may require a nasal stent and close observation for the first few days post-operatively.

Those undergoing surgery to the upper airway are frequently admitted to the PICU for a period post-operatively due to the high risk of developing upper airway obstruction as oedema evolves around the surgical site. This includes operations for laryngeal reconstruction but also for more minor procedures such as aryepiglottoplasty and those children who have undergone adenotonsillectomy for severe sleep apnoea. It is therefore important to ensure a PICU/HDU bed is available before proceeding with surgery. Children who have major upper airway surgery, such as laryngotracheal reconstruction, are electively ventilated for a period of 5 to 7 days post-operatively to allow the oedema to resolve before the ETT is removed. In these patients, sedation and analgesia are critical (see 'Craniofacial surgery and cleft lip and palate', above). Muscle relaxants are used in this patient group to prevent trauma to the surgical site and exacerbation of upper airway oedema due to movement of the ETT whilst *in situ*. Close observation of cardiovascular parameters in muscle-relaxed patients will detect tachycardia and hypertension suggestive of inadequate sedation or pain. It is important that if a significant leak is allowed to develop around the ETT before extubation is attempted this may signify that the post-operative oedema is resolving and that extubation is more likely to be successful.

Laryngeal surgery and tracheostomy

Managing a tracheostomy in the PICU involves the management of the newly formed stoma, care of an established tracheostomy and training requirements for families looking after long-term tracheostomies. In children, tracheostomy is most frequently performed in the first year of life as a result of premature infants requiring prolonged ventilation.¹⁸

In the first week after a tracheostomy is formed the airway is dependent on the tracheostomy stent (i.e. the tube) to maintain airway patency. Loss of the stent over this period can allow the airway to close, and reinsertion of a tube through an immature tracheostomy can be difficult, as the tracheal opening can be obscured and the tube can easily be passed into the wrong place causing airway obstruction and ventilation of the neck tissues. This complication, known as accidental tube dislodgement, is minimized in a fresh tracheostomy when stay sutures are used. These are attached to the edges of the trachea at surgery and allow the trachea to be brought to the surface of the neck in an emergency, facilitating tube reinsertion. Additionally, maturation sutures attach skin directly to the edge of the trachea to reduce creation of a false passage during the first tracheostomy tube change. Velcro tracheostomy tube ties can also be used if available.¹⁸

However, many departments prefer to use ties rather than Velcro in the early post-operative phase.

If a tracheostomy tube does become dislodged in this period and cannot easily be reinserted, then (in a child with an adequate upper airway), a conventional ETT should be inserted to secure the airway. This allows planned replacement of the tracheostomy tube at a later stage.

Following the first tracheostomy tube change (usually at 7 days post-operatively), the tracheostomy is more secure. Care of an established stoma involves the establishment of routine tube changes, tape care and training for care givers. The development of difficulties with tube insertion or bleeding should raise the possibility of obstructive granuloma formation.¹⁸

Bronchoscopy in PICU

FIBREOPTIC BRONCHOSCOPY

Fibreoptic bronchoscopy is a safe and effective method of investigating airway problems when used in a planned and controlled manner.² It is a useful technique to directly visualize the lung by passing a fibreoptic scope through an ETT. The scope can visualize all lobes of the lung and identify static (e.g. mucus plugging) and dynamic (e.g. bronchomalacia) problems. The general difficulties with bronchoscopy include hypoxia and hypercapnia as a result of an inability to effectively ventilate through the scope and a narrow suction channel that blocks easily. The scope can be passed through a rubber valve in the ETT allowing continued ventilation around the scope, but this is difficult if the scope diameter is close to that of the ETT. Ventilation may also be worsened for hours after the procedure due to removal of endogenous lung surfactant and atelectasis. The main contraindication to bronchoscopy is that it may provide no useful information.^{2,3}

Bronchoscopy can be classed as 'diagnostic' to assess airway patency and anatomy or obtain lavage specimens to aid diagnosis or 'therapeutic' to aid secretion clearance for example.¹⁹

RIGID BRONCHOSCOPY

This technique is much more effective at removing debris from the airway, and may be easier to use in the very unstable patient as ventilation can be continued through the scope during the procedure.

There are several indications for either fibreoptic or rigid bronchoscopy in PICU:

- **Persistent collapse of lobe/lung:** Ventilated children may develop complete collapse of a lung, usually secondary to blockage of the major airways with secretions and mucus plugs (secondary to severe pneumonia). This can lead to major ventilatory problems with shunting. Fibreoptic bronchoscopy down the ETT can often identify the degree of blockage but a rigid bronchoscope may be needed to clear thick secretions. Intra-tracheal recombinant human DNAase (rhDNase) has been reported to be of benefit in segmental collapse.¹⁸
- **Assessment of malacia:** Clinical tracheo or bronchomalacia may be difficult to confirm. Flexible bronchoscopy may help locate the site and degree of weakness, but needs to be carried out with the patient self-ventilating as positive pressure ventilation can stent the airway open artificially.
- **Assisted intubation:** This is a rare indication as conventional intubation is usually relatively easily accomplished. However if a child has a craniofacial syndrome that may make this particularly difficult and bronchoscopic intubation may be indicated. The bronchoscope is threaded through an appropriately sized ETT and the endotracheal tube is advanced over the fibreoptic bronchoscope into position.
- **Collection of broncho-alveolar lavage:** The diagnosis of lung pathogens can be difficult, particularly in patients who are immunosuppressed. Many probable pathogens for pneumonia in these patients are not tracheal commensals. Broncho-alveolar lavage may be very useful in this situation. It can be carried out 'blind' by passing a nasogastric tube into the lungs, washing in 0.9% saline then aspirating or using a fibreoptic scope to direct the lavage to a particular part of the lung. If a good quality lavage is negative then an open lung biopsy may be necessary.

SUMMARY

Principles of care for children are similar to those of adults, but physiological responses seen in children vary with age. Some ENT procedures are also specific to the younger age group, and in units that are not undertaking paediatric surgery frequently, well maintained guidelines for the care of these children is essential.

BEST CLINICAL PRACTICE

- ✓ General principles:
 - ✓ Anatomical and physiological differences between adults and children need to be recognized.
 - ✓ Fluid and electrolyte administration must be age and weight appropriate.
 - ✓ Appreciation of family carers and their involvement is essential.
- ✓ ENT emergencies in PICU:
 - ✓ Laryngeal trauma in children may require a tracheostomy.
 - ✓ Epiglottitis is now rare in the UK because of the Hib vaccination.
 - ✓ Foreign body inhalation is an important, if uncommon, cause of acute respiratory distress in young children.

- ✓ Major surgery:
 - ✓ Muscle relaxation may be needed following palatal and tracheal surgery to avoid damage from a struggling child.
 - ✓ Infection is a major cause of palatal breakdown in children following surgery.
- ✓ Flexible bronchoscopy in children can clear secretions, but the size of the bronchoscope limits its suctioning ability.
- ✓ Suspected foreign bodies should be removed through a rigid bronchoscope.

FUTURE RESEARCH

Many of the clinical practices on PICU have evolved through sharing of experience rather than being substantiated by medical evidence or clinical trials and the potential for research projects aimed at providing evidence to support or refute current practices is huge. However there are significant practical

limitations to undertaking such research, for example the ethics of research in children, difficulties obtaining parental consent for entry into trials and recruiting sufficient numbers of patients to achieve adequate power.

KEY POINTS

- Paediatric anatomy and physiology differs significantly to that of an adult.
- Foreign body inhalation (or ingestion) should be suspected in any child with unexplained stridor or respiratory problems.
- Fluid and electrolyte prescriptions for children individually according to body weight.
- All patients with suspected epiglottitis require intubation.
- Trauma and infection are threats to palatal repairs.
- Good evidence to support clinical practice in PICU is limited.

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: otolaryngology, training, surgical education, educational models, clinical competence, academic legislation & jurisprudence, European Union and United Kingdom.

PRINCIPLES OF TRAINING

A training programme in any postgraduate medical specialty, which includes otorhinolaryngology (ORL), is designed to ensure that a doctor progressing through that programme is competent to perform as an independent specialist within the healthcare system in which they work. It follows that the first goal to agree upon, when designing a programme, is the level at which competence should be set and what the scope of the competencies should be. A curriculum will then be written, agreed upon by stakeholders and published. A curriculum has the following areas of content:

- aims and objectives
- content or syllabus
- resources
- assessment strategy
- evaluation.

Aims and objectives

A clearly stated aim of a curriculum is required to ensure that it has the right content and assessment strategy. In the UK in 2016 the aim of the curriculum in ORL for postgraduate training is to train a surgeon who is emergency safe and has the ability to develop an area of special interest. Being emergency safe requires a high degree

of knowledge as well as technical and clinical skills, not least because of the need to manage a wide range of unselected patients with a variety of conditions. To demonstrate safe management of emergencies the curriculum can identify elective procedures that may be used as proxy for the less common emergency procedures. For example, competence in a (relatively common) selective neck dissection can, in conjunction with clinical, non-operative experience, be used as a proxy for competence in managing neck trauma and deep neck abscesses. This requirement for a high level of technical expertise in managing emergencies has the consequence of lengthening training time compared to a programme where competence in emergency care is not a prerequisite for completion of training. Shorter specific fellowship programmes should also have a curriculum with specific aims so that one can assess competence against curriculum objectives. So, for example, an advanced otology fellowship programme may state that an aim of the programme is ‘competence in cochlear implant surgery’.

The aim of a curriculum should take into account a variety of stakeholders. Indeed, one motivation could be political, whereby a particular programme is designed with a public health policy in mind that needs to be implemented. A specialist needs to be ‘fit for purpose’ and capable of working effectively within a healthcare system. Therefore, when designing a curriculum, it is imperative to consult patient groups, employers,

commissioners, trainee representatives and, importantly, those responsible for delivering training (e.g. in England these are the Local Education and Training Boards (LETBs)) to ensure that a specialist is in the best position to deliver care to those who receive it (the patients) and those who commission it (ultimately the government). With increasing input from lay people and non-specialists in the design of surgical curricula, there has been a greater emphasis on professional and leadership skills where the importance of effective communication, leadership, teaching and keeping up to date is made, as well as assessed.

In the UK, the General Medical Council (GMC), along with specialty input, is responsible for the design and delivery of curricula. The process of curriculum approval by the GMC is governed through the Curriculum Advisory Group (CAG), where medical royal colleges, faculties and specialty associations are held accountable to the standards and requirements for curricula and assessment systems in accordance with the Medical Act 1983.^{1,2}

Syllabus

Once the primary aim of a curriculum is established, a syllabus then needs to be formulated that allows the delivery of curriculum objectives in a clear, unambiguous way. A syllabus will define in a variable amount of detail the areas that need to be learnt and the requirements needed to demonstrate competence to ensure the aim is realized. A syllabus will usually be written in sections or topics where the knowledge, clinical and technical skills required are defined against the level of competence necessary. A syllabus is defined by a specialty curriculum group which takes into account the breadth of skills required, the caseload available for training, as well as the level of expertise at which those who are awarded a Certificate of Completion of Training (CCT) should expect to be competent. The concept of ‘desirability’ of inclusion of topics, with the understandable aspiration for expertise in all areas, must be balanced with ‘deliverability’ whereby a pragmatic approach to setting competence levels should be adopted so that competence can be achieved by all. For example, it is unnecessary in the UK programme for all trainees to be expected to be competent in stapedectomy and neither is it realistic to be able to deliver this training opportunity to all. A syllabus indicates the supreme aims of a programme through ensuring that trainees understand what is required to achieve competence, and in what areas they will be assessed to demonstrate competence, prior to certification.

Resources

Once an aim of a programme is agreed and a syllabus written, the resources required to deliver it need to be established. If appropriate resources are not available, then the curriculum may need to be reviewed and modified, as it is a *sine qua non* that a curriculum can only be achieved if the resources required to fulfil it are

available to all. The following resources are required for curriculum delivery:

- **Caseload:** Enough cases are needed to enable *all* trainees to have equitable access sufficient to meet training needs. With healthcare delivery evolving this requires regular evaluation. For example, over the next few years exposure to transnasal oesophagoscopy (TNO) is likely to increase in the UK, whilst with the changing management of head and neck oncology, exposure to total laryngectomy is likely to reduce.
- **Faculty:** There should be adequate access to expert faculty to train those going through the programme. In surgical programmes faculty is represented by consultant surgeons who have competing interests for their professional responsibilities. Faculty need to be trained and accredited for their role within a teaching programme.
- **‘Off the job’ training:** Increasingly there is an emphasis on simulated or technology enhanced learning, which has the principle of providing a safe environment to hone essential technical and non-technical skills before exposure to real patients (e.g. in human factors training).³ There is some evidence that simulation training improves the rate of acquisition of skills, but this has to be balanced with the increased cost of equipment, time away from patient care and requirements for trained faculty to supervise learning in this environment. There is a move in the UK towards mandatory simulated surgical training in order to satisfy some aspects of the curriculum.
- **Time for training:** A purely supernumerary trainee is aspirational, with the tradition for service delivery as a means of acquiring competence embedded in UK training. Training lists and clinics take longer than pure service lists, and the balance needs to be struck between the two. Skilful supervision will mitigate the time lost to training whilst developing a trainee’s skills and this is one of the aims of courses in educational supervision.
- **Pastoral support:** Support for those experiencing difficulties in achieving outcomes is necessary to ensure all trainees have the opportunity to achieve the aims of the curriculum of the programme they are training in.

Assessment

Trainees within programmes need to be assessed to ensure they are on track in their development and to prove that they have achieved the aims of the programme. Assessments may be formative (assessment for learning), which tend to use workplace-based assessments (WPBA) on a regular basis, or summative (assessment of learning), which are high stakes assessments (i.e. a pass/fail exam). Each is complementary, but a continuous cycle of low stakes ‘on the job’ assessments will, when used correctly, encourage reflective learning and steady development in clinical, technical and professional skills. Summative assessments need to be developed and assured that they are assessing the whole curriculum and assessing trainees at the correct level in their training.

In the UK this is overseen by the GMC as part of its role in quality assuring all aspects of postgraduate training.

Evaluation

Programmes also need to be evaluated to ensure that they are fit for purpose, that is, delivering a surgeon capable of achieving the aim of the programme. This can be achieved by ‘triangulation’ of feedback from trainees, faculty and users of the service. Analysis of assessments can also demonstrate that a programme is delivering a properly trained surgeon. Evaluation should feed into the review of a curriculum so that it can be modified appropriately to best reflect the requirements of service users, whilst also ensuring trainees are being treated fairly and receiving support and opportunities to accomplish their aims. In the UK the annual GMC and Joint Committee on Surgical Training (JCST) trainee survey is producing increasingly meaningful data capable of evaluating programmes and helping to identify areas for development. Analysis of data from workplace-based assessments within trainee portfolios are being used to demonstrate the validity and utility of such tools.⁴

GMC STANDARDS OF ASSESSMENT

The GMC supervises the standards that medical royal colleges, faculties and specialty associations must apply in developing, monitoring and assessing curricula. The GMC defines an assessment system as an integrated set of assessments that is in place for the entire postgraduate training programme and that is blueprinted against and supports the approved curriculum. The importance of a robust assessment system is to:⁵

- determine whether trainees are meeting the standards of competence and performance specified at various stages in the curriculum for surgical training
- provide systematic and comprehensive feedback as part of the learning cycle
- determine whether trainees have acquired the common and specialty-based knowledge, clinical judgement, operative and technical skills, and generic professional behaviour and leadership skills required to practise at the level of CCT in the designated surgical specialty
- address all the domains of *Good Medical Practice* and conform to the principles laid down by the GMC.⁶

In order to be included in an assessment system, the assessment methods selected must meet the following criteria:⁵

- **Validity:** To ensure face validity, WPBAs comprise of direct observations of workplace tasks. The complexity of the tasks increases in line with progression through the training programme. To ensure content validity all the assessment instruments have been blueprinted against all standards of *Good Medical Practice*.

- **Reliability:** In order to increase reliability, there will be multiple measures of outcomes. Intercollegiate Surgical Curriculum Programme (ISCP) assessments make use of several observers’ judgements, multiple assessment methods (triangulation) and take place frequently. The planned, systematic and permanent programme of assessor training for trainers and assigned educational supervisors (AES) through the Deaneries/LETBs is intended to gain maximum reliability of placement reports.
- **Feasibility:** The practicality of the assessments in the training and working environment has been taken into account. The assessment should not add a significant amount of time to the workplace task being assessed and assessors should be able to complete the scoring and feedback part of the assessment in 5–10 minutes.
- **Cost-effectiveness:** Once staff have been trained in the assessment process and are familiar with the online ISCP portfolio, the only significant additional costs should be the extra time taken for assessments and feedback and the induction of a new AES. The most substantial extra time investment will be in the regular appraisal process for units that did not previously have such a system.
- **Opportunities for feedback:** All the assessments, both those for learning and of learning, include a feedback element. Structured feedback is a fundamental component of high-quality assessment and should be incorporated throughout workplace-based assessments.
- **Impact on learning:** The workplace-based assessments are all designed to include immediate feedback as part of the process. A minimum number of three appraisals with the AES per clinical placement is built into the training system. The formal examinations all provide limited feedback as part of the summative process. The assessment process thus has a continuous developmental impact on learning, a process enriched further with emphasis on reflective practice within the portfolio.

EVOLUTION OF SURGICAL TRAINING

Postgraduate surgical training has undergone significant change over recent decades. Historically surgical training in the UK was considered to be an apprenticeship, taking several years to learn the theoretical background and cultivate operative competence to achieve expertise.⁷ Although there were advantages to the conventional time-based apprenticeship model of training and it did successfully produce competent consultant surgeons over many years, several limitations did exist and it gradually became outdated. Training was considered unstructured, occurring over an undefined period of time, and often consisted of unsupervised service rather than training. This was associated with an inherent difficulty in measuring trainee competence and was criticized for lacking transparency, reliability and validity. This not only failed to meet training needs, but also did not satisfy the changing expectations and demands of both patients and an evolving

National Health Service requiring a greater number of consultants to deliver care and train the next generation of surgeons, due to both the mounting demands of patient safety and the ever increasing medico-legal unacceptability of complications due to inexperience.

The Calman Report in 1993 outlined the future direction of training and this was reinforced further in the chief medical officer's report, *Unfinished Business*, in 2002, in which recommendations were made for the establishment of a national benchmark for training, comprehensive specialty curriculums and regular assessment of trainee competence, as well as consultant-delivered, rather than consultant-led, patient care.^{8, 9} As a result, Modernising Medical Careers (MMC) was initiated in 2003 and this was followed by the implementation of a shortened, restructured continuous pathway of specialty training based on a model of proficiency in developing trainee competence according to predetermined approved standards.¹⁰ A shift to a more competency-based form of training has assured the provision of a high standard of training with less importance placed on service delivery and a greater emphasis on formal supervision from consultant trainers appropriately qualified to train, assess and give feedback. Following satisfactory completion of training, having developed the required competencies to practice independently and having reached a definite educational end point after a predetermined period of time, a trainee is awarded a certificate of completion of training (CCT) and is able to practice as a consultant.

A further challenge has been the delivery of a shortened and reorganized training paradigm within the restrictions imposed by the compulsory implementation of the European Working Time Directive (EWTD).^{11, 12} The significant reduction in the time available to train has had a

dramatic impact, especially on surgical specialties, where developing and achieving expertise relies heavily on operative experience and exposure. The concept of experiential learning suggests that to truly understand something a learner must experience it first-hand.¹³ With a traditional time-based model of training, trainees would have had an estimated 25–30,000 hours of training before reaching consultant level, allowing deliberate practice so that replication of events leads to a full understanding and the development of subconscious pattern recognition. The current competency-based training is thought to only offer around 6000 hours.¹⁴ To attain a level of expertise in a certain field subconscious pattern recognition is vital, and it has been suggested that at least 10,000 hours of training is necessary for this to occur.¹⁵

As such, a greater need has been identified in order to maximize learning, develop acquired competences, accelerate skills acquisition and reduce learning curves in order to meet the educational needs of surgical trainees within the confines of a 48-hour working week. Accordingly, higher surgical training curricula have also evolved to incorporate alternate educational modalities, such as simulation, in order to bridge this gap and compensate for the significant reduction in the time available for training (Figure 35.1). Simulation provides a realistic exposure equivalent environment that allows deliberate practice in order to achieve expertise in a non-threatening environment without risk to patients.¹⁵ Behavioural models have shown high fidelity controlled environments akin to real life can show correct practice and through accumulative experience cement learning.¹⁶ Objective assessment is also possible, enhancing the learning process by facilitating reflection and reinforcing positive behaviours and identifying negative actions.

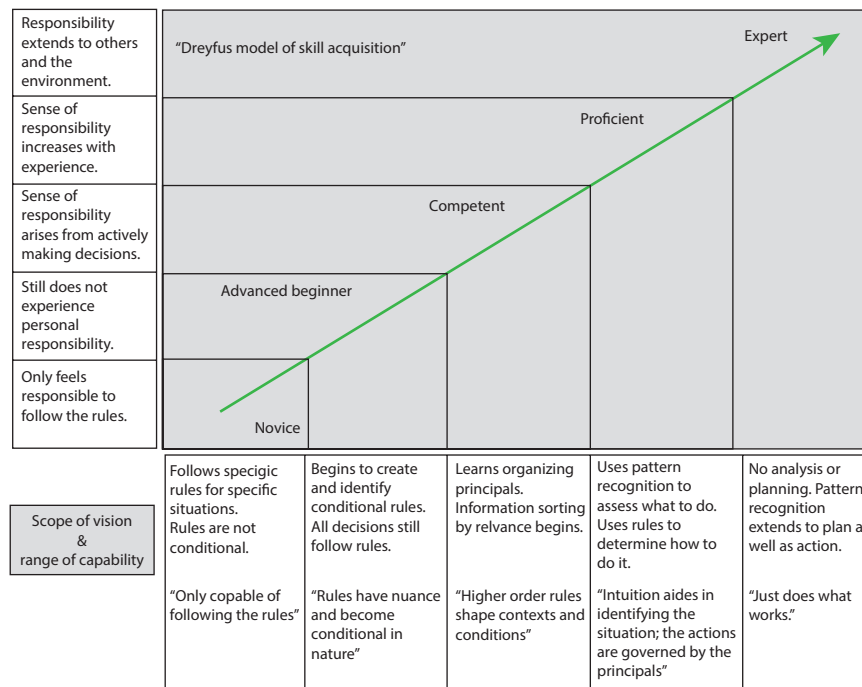

Figure 35.1 Dreyfus model of skills acquisitions. Learning through simulation hopes to alter the trajectory to quicken the learning curve passing from novice to attaining expertise.¹⁷

STRUCTURE OF UK POSTGRADUATE AND ENT SPECIALTY TRAINING

Trainees begin their postgraduate medical education by entering the foundation training programme, which was implemented in 2005 as part of MMC. This has replaced the traditional house officer and senior house officer grades, and allows junior doctors to rotate through core disciplines in order to develop the generic skill set required to practice safely in their onward specialties. Those wishing to pursue a career in surgery then apply to a generic 2-year Core Surgical Training (CST) programme, themed to their chosen surgical discipline (Figure 35.2). The CST programme is a broad-based initial training in surgery that enables trainees to establish the necessary competences, fundamental skills and breadth of experience required for progress on to higher specialty training (HST). Membership of the Royal College of Surgeons (MRCS) and Diploma in Otolaryngology – Head and Neck Surgery (DOHNS), or alternatively the MRCS (ENT) examinations are sat at this stage, and are, along with other defined mandatory criteria, an essential component of satisfactory completion of CST, before being eligible to apply to an HST programme. Recruitment to both CST and HST is through competitive national selection.

ORL HST is a 6-year programme that allows trainees to develop the necessary competencies in order to achieve a CCT. During this period a trainee can embark on additional out of programme activities (OOPA) in addition to conventional training, such as alternative training or experiences (OOPT/OOPE), research (OOPR) or fellowships. Towards the end of HST, the Fellowship of the Royal College of Surgeons (FRCS(ORL-HNS)) exit exam is sat.

Subspecialization in ENT surgery has been well established for many years and trainees are encouraged to show a special interest in a particular subspecialty during their

training period. Fellowship programmes offer this additional training opportunity to pre- and post-CCT trainees and are available both in the UK and abroad. The JCST interface group, in conjunction with allied surgical specialties, offer interface fellowship programmes for UK trainees in ORL, plastics and maxillofacial surgery.¹⁸ These fellowship programmes are accredited and have a structured, defined syllabus, and are monitored regularly for quality assurance. Alternative UK, European and international fellowships in other subspecialties also exist.

The Certificate of Eligibility for Specialist Registration (CESR) is a route to entry onto the specialist register for those doctors who have not entered through HST but are able to demonstrate experience, skills and knowledge equivalent to CCT. The application process is arbitrated by the GMC, and the JCST has issued specialty-specific guidelines for applicants applying through this process that outline the relevant supporting evidence, mapped to the four domains of *Good Medical Practice*, which are required.¹⁸ Applications should also be supported by six consultant referees who are able to give a structured report regarding a candidate's clinical and non-clinical performance. The submitted documents are assessed against these requirements, as well as against the current ORL HST curriculum, by a GMC-approved assessor before CESR is awarded.

DELIVERY OF TRAINING

The aim of a competency-based surgical curriculum is to provide an assured, high quality of surgical training to ensure it produces proficient trainees able to deliver a high standard of surgical care, safely to patients. A competency model of training satisfies the need for an objective measurement of surgeon competence and performance. This delivers reassurances to the public that surgeons are being trained to an appropriate standard, whilst providing evidence to educational peers that trainees are demonstrating

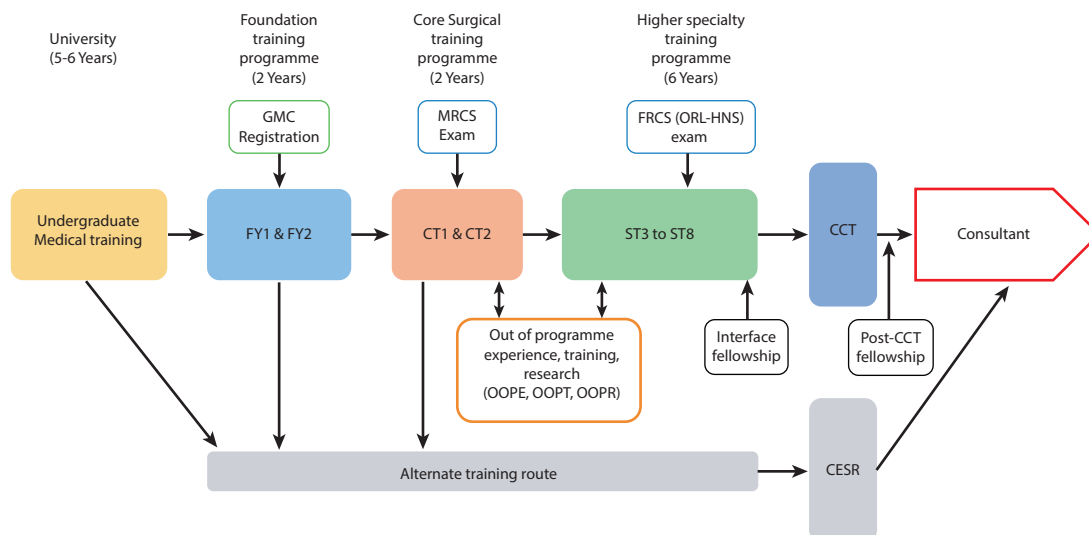

Figure 35.2 Current typical UK postgraduate training pathway for a career in ORL.

continuous development commensurate with their stage of training. The ISCP, a real time, online web portfolio (<https://www.iscp.ac.uk>), allowing an interface between trainer and trainee, has become a central component in supporting this process.⁵ It has a clearly defined competency-based syllabus to which trainees are able to integrate their completed WPBA and additional educational achievements and map them to the curriculum as evidence of progress through training. Summative records of formal educational meetings and annual appraisal are also recorded to form a comprehensive record of training.

During their 6 years, ENT specialty trainees will expect to rotate to at least three different training units within their Deanery/LETB in order gain exposure to all the ENT subspecialties and to develop the required skill set and competences to satisfy curriculum standards. Rotation to a particular unit may be decided by trainee preference, individual educational requirements and stage of training. Each training placement is expected to be able to provide:

- at least three or more consultant supervised outpatient clinics per week, including a combination of routine, emergency and special interest clinics, limited to 10–14 new and follow-up patients
- four (or more) supervised operating sessions per week with a suitable elective and emergency case mix in a unit with a minimum output of 500 cases per year per trainee
- opportunities to manage patients presenting acutely at least once a week
- weekly formal local teaching, as well as regular regional teaching
- exposure to audit, research and other educational activities to develop teaching, management and leadership skills.

For each placement a trainee will have an AES with an overall educational and supervisory responsibility for the trainee, along with other departmental consultant trainers, or clinical supervisors (CS), who will also deliver teaching, train and have involvement in the assessment process. Traditionally, it may have been assumed that all consultants were good trainers. However, it is increasingly apparent that this is not true, and the skills required to teach, train and give feedback may not necessarily be inherent, but instead need to be learned and developed. The key to an effectively deployed competency-based curriculum are suitably qualified trainers able to reliably assess and give constructive feedback. As such, there is an increasing expectation that consultant trainers, and even trainees during their higher specialty training, undergo formal training or gain a higher qualification in teaching principles and methodology before they assume a formal role as a trainer.

Although consultant trainers do have a facilitatory role, the responsibility of training remains primarily with the trainee. At the start of each placement a 'learning agreement' (LA) is set by the trainee with their AES, agreeing on the educational objectives for the forthcoming placement. This is recorded on the ISCP and is revisited

with the trainee during interval formative and summative appraisals typically in the middle and at the end of the placement. Throughout the placement trainees are expected to complete a set number and a variety of WBAs assessing knowledge, clinical judgement, procedural and technical competences, as well as professional behaviour and attitudes such as communication, team working and management skills. These include:

- case-based discussion (CBD)
- clinical evaluation exercises (CEX)
- direct observation of procedural skills (DOPS)
- procedure-based assessment (PBA)
- multi-source feedback (MSF).

Assessment is made to determine whether a trainee is meeting curriculum standards of competence and performance expected for their stage of training. Each completed WPBA can be linked to the ISCP syllabus as evidence and can be used to demonstrate evolving progression up to demonstrating fully competent, independent practice as a trainee progresses through specialty training. As training is no longer time-defined, assimilating acquired competences may vary according to trainee exposure and ability. In addition, WPBAs can also effectively be used as a formative tool at the time of completion. The process of reflection and feedback helps consolidate the learning process by reinforcing positive practice, but also enables the trainee to identify specific learning points for onward development. Learning through objective feedback is an essential component of enhancing the educational process by directing learning towards desired outcomes. WPBAs can, however, be incorrectly used and seen as a time-consuming 'tick-box' exercise, which can have a negative impact on the reliability and validity of the assessment. In order for these assessments to retain their educational value, they must be used correctly, as a continuous, formative tool to provide constructive feedback to trainees.

Collectively, WPBAs, in addition to the end of placement AES and CS reports, and additional recorded evidence of educational activity (including involvement in audit, research, publications, attendance at courses and conferences), are evaluated in an annual review of competence progression (ARCP). This summative face-to-face appraisal is to assess whether a trainee is developing satisfactorily and has achieved the necessary competencies in order to progress to the next stage of training. Equally, if a trainee is underperforming, this can be identified and additional support given to meet their specific educational needs.

Towards the end of specialty training, and provided a trainee is meeting their educational requirements of training, they are able to sit the FRCS(ORL-HNS) exit exam. This traditional summative assessment complements competency-based training positively by formally assessing what has been learnt throughout specialty training. In order for recommendation to be made to the GMC for an award of the CCT, a trainee should have gained all required curricula competencies, passed the FRCS(ORL-HNS), and

completed a pre-defined number of 'index' operative procedures (elective and emergency) to a specified level of competence, in addition to the total number of defined major operations required to be completed in the generality of ORL so as to cover the fundamental subspecialties (head and neck, rhinology, otology and paediatric ORL).

MAINTENANCE OF SKILLS

Continuing professional development (CPD) is the engagement in lifelong self-directed learning outside formal post-graduate training. It is the duty of all doctors to keep up to date, and maintain and improve their knowledge and skills in order to provide a high standard of care to patients and the public throughout their career. The obligations of doctors are specified in *Good Medical Practice* and *Good Surgical Practice*.^{6,19} The key points addressed are:

1. The essence of CPD is to be competent and up to date across all clinical and non-clinical aspects of the practice.
2. CPD should be a combination of formal and informal teaching and should include the activities within the local institution as well as at regional, national and international levels. Surgeons should aim for a mix of at least three activities including clinical, academic and professional (including managerial).
3. The minimum requirement for CPD in the UK is 50 credits per annum. One credit represents one hour of activity. To encourage a range of activities, normally no more than 20 of the minimum 50 hours per year should come from a single activity.²⁰
4. Surgeons are encouraged to record the activities electronically, such as in the 'surgeons portfolio' developed by the Royal College of Surgeons (RCS), which helps to record the activities securely and assists surgeons with the appraisal and revalidation process ([Table 35.1](#)).²⁰
5. There is a range of organizations that accredit the CPD activities including the medical royal colleges, specialty associations and LETBs. The RCS has established criteria and standards for accreditation of CPD activities.²¹ ENT-UK accredits educational activities relevant to the specialty. The organization seeking accreditation must demonstrate compliance to the academic and competence standards:
 - CPD is awarded on the basis of course content and delegates' feedback.
 - The activity should have clear scientific and educational purpose and should address the learning needs of the participants.
 - The course organizers and faculties should have a proven relevant expertise, and appropriate skills and knowledge.
 - Robust quality assurance is required with course inspection and evaluation.
 - Attendance records should be maintained.
 - Feedback forms should be submitted for further accreditations of the event.

APPRAISAL AND REVALIDATION FOR SURGEONS: SPECIALTY-SPECIFIC GUIDELINES

Appraisal and revalidation is based on the principles of *Good Medical Practice*. Doctors practising in the UK must participate in an annual appraisal process to reflect on their practice and performance based on which the responsible officer (RO) makes recommendation to the GMC to renew their licence to practice every 5 years. The GMC and RCS have provided a number of documents to describe the supporting information required for appraisal and revalidation.²³ The surgeons are expected to collect and maintain a portfolio of supporting information to demonstrate that they are continuing to meet the principles and values set out in *Good Medical Practice*, which consists of four domains as follows:⁶

1. Knowledge, skills and performance
2. Safety and quality
3. Communication, partnership and teamwork
4. Maintaining trust.

Checklists are available to guide the surgeon through the suggested components of the revalidation process ([Table 35.2](#)).

Individual surgeon and departmental outcome measures are playing an increasing role in the surgical appraisal

TABLE 35.1 Examples of activities that will qualify for CPD ⁶

	Internal	External	Personal
Clinical	Courses, workshops and meetings	Courses, workshops and meetings	Self directed learning, e.g. reading journals
Academic	Audit, research	Participating in national audits, research trials and presentations	Publications and peer-reviewing articles
Professional	Teaching, training and mentoring activities	Examiner, e.g. undergraduates, MRCS, FRCS Standard setting for exams	Courses on management, leadership and teaching/training

Note: The list in this table is not exhaustive and individuals should discuss with their appraiser to plan the activities that will address individual educational needs.

TABLE 35.2 Supporting information for revalidation checklist based on the Academy of Medical Royal Colleges and Faculties' Core Guidance²⁵

General information	Personal information Scope of work Record of annual appraisal Personal development plan (PDP) Probity Health	Current job plan Description of clinical and non-clinical activities Appraisal portfolio Agreed objectives from previous PDP Self declaration of Probity and health
Keeping up to date	CPD	Evidence of CPD activities
Review of current practice	Clinical audit Review of clinical outcome Case review or discussion Clinical incidents	Details of participation in local/national audits Details of outcome data Participation mortality and morbidity meeting Records of clinical incidents and reflection
Feedback on your practice	Patients' feedback Colleagues' feedback Complaints and compliments	Multisource feedback from colleagues and patients Details of complaints and compliments

and revalidation process. This supports best practice and ultimately improves patient care. ENT-UK supports the participation in national clinical audit and, for example, has previously jointly collaborated with RCS of England to conduct and publish outcomes of the national prospective tonsillectomy audit. Currently ENT-UK is managing surgeon activity data for laryngeal surgery and airway intervention registry for paediatric balloon dilatation procedures for airway stenosis. It is important to also mention that some recorded individual surgeon's outcome data can be published and subsequently accessed by the public, a development aiming for greater transparency and accountability. For example, members of the British Association of Endocrine and Thyroid Surgeons (BAETS) are required to participate in the UK Registry of Endocrine and Thyroid Surgery (UKRETS), which is an electronic audit of endocrine operations. All thyroid surgeries must be recorded in UKRETS, which is the published openly via the surgeon specific outcomes report for endocrine surgery.

FUTURE OF TRAINING IN ENT

The specialty of ORL has evolved significantly over the last four decades with expanding subspecialization, introduction of new technologies and as a result of the development of new surgical techniques. Furthermore, the move in the UK to the provision of full '7-day working' and an anticipated shift of the provision of ORL services to both community outpatient-based and super-specialized tertiary centres will have a dramatic impact on the provision of training and the expectations of the ENT surgeon. This will inevitably need to be matched by constant review and subsequent modifications of learning curricula in future ORL surgical training. The challenge is to address new advancements and potential changes in training within a safe timeframe in order to continue to create a surgical workforce that is able to deliver competent, safe and high quality patient care.

KEY POINTS

- The objective of the curriculum for higher surgical training in ENT is to train a surgeon who is emergency safe and competent to practice independently in the healthcare system.
- In the UK, the General Medical Council (GMC) supervises the standards of the curriculum developed by the Royal colleges, faculties, and specialty associations.
- The syllabus is written in sections where the knowledge, clinical and technical skills required are defined against the level of competence necessary. The trainees are expected to achieve those set competencies in order to progress in their training to obtain completion of certification of training.
- In the UK, post-graduation training begins with two years of foundation training and a further two years core surgical training in a chosen specialty to gain broad-based initial training prior to progressing on to higher surgical training which is six years for ENT.
- Throughout the placement, trainees are expected to complete a set number of work-based assessments to assess the knowledge, clinical and procedural skills, professional behavior and attitudes. To gain CCT, trainees are expected to achieve all competencies outlined in the curriculum, completion of FRCS (ORL-HNS) and performance of a defined number of 'Index' procedures.
- Doctors practising in the UK must participate in an annual appraisal process and revalidation once in every five years to renew their license to practice by the GMC. The above process is to ensure doctors are up to date, maintain their skills and knowledge to provide a high standard of care to the patients.
- ENT specialty is evolving rapidly with expanding subspecialization and introduction of new diagnostic and surgical techniques. There is a need for constant review and modification in the surgical curriculum and training in future to match the changes.

SEARCH STRATEGY

Data in this chapter may be updated by Medline, Embase and PsychINFO searches using the keywords: communication skills, doctor-patient communication, communication skills and surgeons, training communication for health professionals, communication and clinical outcome.

INTRODUCTION

How important is it for a surgeon to have good communication skills? Not many people would think this to be of ‘life-and-death’ importance. Unfortunately, this was exactly the case for one plastic surgeon in Madrid, who was killed by one of his dissatisfied patients. That was not a unique incident. Between 1995 and 2005, five surgeons were killed by disgruntled patients in the USA.¹ Although these extreme acts of violence are rare, many surgeons face abuse, complaints or legal actions due to communication problems between them and patients. Every day of our working lives we rely upon communication skills to build up relationships with our patients. These skills are vital in establishing trust with those who come to us with problems. This chapter explores the communication issues related to outpatient visits. Since practical communication training is available in various formats such as written material, workshops, videos and online training, this chapter will focus on the fundamentals to deliver a broader perspective.

As a doctor, consultation is the most common clinical procedure we employ. Our communication with a patient has a therapeutic effect. Compared to other therapeutic modalities, communication has an

immediate palliative effect as it can reduce a patient’s distress instantly. Comparatively, it has a wider therapeutic index since this treatment-related morbidity and mortality has never occurred! The most common problem observed regarding its use is suboptimal dosing.² Good communication is not just ‘being nice’ or having a ‘touchy-feely’ talk. It is a specific task and observable behaviour that includes interviewing a patient to obtain clinical information, explaining diagnosis or prognosis, and giving treatment advice and information needed for an informed consent to undergo procedures. It also involves providing counselling to patients to motivate participation in the management.³ Conventionally our management tends to focus only on bio-medical aspects of the treatment since we adopt a ‘disease perspective’.⁴ Lately there has been a realization of the limitation of a narrow ‘disease perspective’ and the need to treat the patient from an ‘illness perspective’. When doctors interact with the patient through the ‘illness perspective’ the impact of a disease on the patient from a personal aspect is taken into account so that the care becomes ‘patient-centred’. Patient-centred care entails involving the patient in decision-making and activating their sense of responsibility.⁵ Without appropriate communication skills the surgeon will not be able to deliver patient-centred care.

WHY COMMUNICATION SKILLS ARE IMPORTANT FOR DOCTORS

There are various advantages of taking the skill of communication seriously:

- A skilful interview improves diagnostic accuracy by gathering a superior quantity and quality of information.⁶
- Doctors with excellent communication skills establish good understanding with their patients and consequentially improve the patients' compliance and outcomes.⁷
- In contrast, poor communication seems to be correlated with patient dissatisfaction.⁸ Studies have shown that communication skills are the single most important factor in patients' satisfaction. Practising surgeons will be interested to know that a satisfied patient will tell, on average, three other patients about their positive experience. On the other hand, patients who are dissatisfied with their encounter will tell, on average, 19 other individuals about their unpleasant experience.⁹

WHY COMMUNICATION SKILLS ARE IMPORTANT FOR SURGEONS

Communication between surgeons and their patients is particularly important. A randomized trial specific to surgical communication showed that patients undergoing surgery had better pain scores and lower analgesic use post-operatively when the pre-operative communication with the patient was appropriately conducted.⁷ Patients visiting surgeons, in comparison to visiting other specialists, may be more anxious due to the concerns of undergoing invasive procedures. Surgeons need to conduct conversations about complicated medical issues, treatment choices and complexities of surgical options, and they have to address patients' anxieties.¹⁰

A study that analysed surgeons' communication behaviours identified that failure to adequately explain the medical condition, failure to show interest in the patient, failure to ask whether they had any questions and failure to answer their questions were the main factors for patients not recommending the surgeon.¹¹ There is evidence showing that very few patients or their families are able to absorb what the surgeon has explained to them before surgery. Six months after surgery, patients may be unable to recall what kind of information the surgeon gave to them during the informed consent process. Additionally, some patients may even deny that this process occurred despite the existence of objective evidence.¹²

A stereotypical image of a surgeon is someone who is not a very good communicator.¹³ Studies have found disparities between surgeons' self-assessments and patient's perceptions about the surgeons' communication skills.¹⁴ There is a need to acknowledge these gaps and to make efforts to reduce them. It has been observed that when surgeons improve their communication skills, it is not just

patients but the surgeons themselves who are beneficiaries. Good communication makes working in a specialty more enjoyable and acts as a preventative factor to burnout.^{15, 16} After an untoward incidence in surgical practice, the possibility of the matter ending up in court is greater if the communication with the patient is not handled satisfactorily. Sometimes malpractice suits are the results of differences in expectations between a patient and the surgeon. Good communication helps the surgeon to understand patient expectations, thereby reducing liability exposure.¹⁷

WHY COMMUNICATION SKILLS ARE IMPORTANT FOR ENT SURGEONS

For ENT surgeons there is a need to take a particular interest in communication for various reasons. Otorhinolaryngology is a unique surgical specialty dealing with clinical problems that have a wide range of psychological implications for the patient. Otolaryngologists perform procedures like rhinoplasty purely for cosmetic improvement but also head and neck cancer surgery to improving a patient's survival. We perform emergency procedures, such as the removal of a foreign body, that give immediate relief, and we perform surgical interventions in rhinosinusitis where the patient may continue to experience some symptoms despite surgery. Some patients with sensorineural deafness may not be offered a cure but with a successful stapedectomy, hearing improvement is instant. Thus we need to prepare the patient, as well as ourselves, for the anticipated outcome, whatever that may be.

Patients visiting otolaryngologists experience symptoms that have an emotional contribution. Significant percentages of patients who experience symptoms such as dysphonia, vertigo or facial pain have underlying psychological problems.¹⁸ Unless these psychological factors are addressed, symptom resolution will not be achieved. Chronic pain anywhere in the body invokes emotional reactions and pain in the facial region carries far more emotional reaction. An otolaryngologist with good communication skills will be able to pick up psychological cues, thereby avoiding delay in symptomatic relief.

Otolaryngologists come across patients (e.g. those with allergic rhinosinusitis) for whom curative surgery is not possible or for whom surgery will offer only partial relief. Appropriate consultation will help the patient to accept the best possible treatment. In some cases, like inoperable malignancy, the surgeon will be not be able to offer the patient anything apart from empathetic conversation, the efficacy of which is directly proportional to the surgeon's communication skills.

Otolaryngologists deal with patients who have difficulties with important sensory organs (i.e. hearing). There is a special responsibility to be sensitive to the sensory loss and at the same time not to underestimate the patient's ability to adapt.¹⁹ This can be understood only with the help of efficient communication.

In the era of technological development and implementation of new techniques, adequate communication between otolaryngologist and patient is very important. This is especially relevant if the procedure is not very well established. In the event of a complication after the use of an uncommon or novel technique, the surgeon may be accused of not adequately explaining the consequences.²⁰

LITERATURE

Despite the importance of effective communication to surgeons, the vast majority of literature in the field of medical communication has focused on primary care interactions. There have been relatively few studies describing communication between surgeons and patients.²¹ The first ever study on communication between surgeon and patient was published in 1999.⁴ This study underscored the differences in both the content and process of routine surgical visits compared with primary care visits. The study concluded that unlike other medical specialties, surgical consultations had a narrow biomedical focus with little consideration of the psychosocial problems the patient might experience due to the disease.

A systematic review on directly observed surgeon–patient communication was recently published.²² The reviewers evaluated 2794 citations, 74 full-text articles, 21 studies and 13 companion reports. This systematic review highlighted the gaps that need to be addressed by training both trainee and practicing surgeons. The studies confirmed that surgeons spend the majority of consultation time in educating patients and discussing treatment options.^{4, 23} Thus, surgeons use the communication mostly for the purpose of informed decision-making. Studies found that surgeons are good in providing information about the surgical conditions.^{10, 24} However, they are lacking in areas such as assessing patients' understanding of therapeutic options and discussing risks. Since these elements are important for patients to make good informed choices, there is a need to improve the quality of informed decision-making conversations in surgery. It is also felt that surgeons need to focus greater attention on the emotional aspects of consultation.

LEARNING COMMUNICATION SKILLS

Although the clinical value of these skills has been known for the last few years, it has traditionally been difficult for many to accept the idea that something as supposedly intuitive as communication could or should be influenced by teaching. It was a commonly held belief that communication skills could not be taught; they were natural talents – inborn attributes of the 'good doctor' – and a young doctor was either endowed with them or not. It was debated whether these techniques could be learned, and whether anything could be done to bring the awkward communicator to a reasonable level. Mounting evidence has clearly shown that these goals are achievable and that

these skills can be taught, do change patient satisfaction and can be retained over time.²⁵

Surgeons receive limited formal education in the communication skills necessary for patient-centred care, although they perform more than 100 000 consultations during their careers.²⁶ In one study researchers developed an innovative empathy-relational skills training protocol focusing on the underlying neurobiological mechanisms of empathy and the interpersonal processes that positively affect the patient–doctor relationship. The authors tested the effectiveness of this protocol with ENT trainees. The results showed that a brief series of three empathy-training sessions significantly improved the surgeon's knowledge of the neurobiology and physiology of empathy, as well as their self-reported capacity to empathize with patients. As a result of improved empathetic consultation, improvement in patient satisfaction was observed.

From a practical perspective, improving communication skills is similar to improving operating skills. It involves seeking information, implementing the techniques and evaluating the outcome. The efforts that are put into improving clinical communication do make an indelible impression on patients. If done poorly, the patient may never forgive the surgeon; if done well, they may never forget the surgeon!²⁷

COMMUNICATION MODELS

There have been various attempts to describe the overall structure of a doctor–patient relationship and to create a standard model of conversation between the two that aims to facilitate training and the learning of communication skills.²⁷ The Calgary-Cambridge model is one model that describes a sequence of tasks to aid an effective consultation.²⁸

There is no single way that a consultation plays out. Every interaction is unique, as it depends on how the surgeon and the patient contribute and react to the interactions. However, if a surgeon is aware of the basic tenets of an ideal consultation, it will provide a useful framework to build upon ([Figure 36.1](#)).

Engagement

Engaging the patient requires making a personal connection with him/her. This can be achieved by appropriate body language and introductory conversation. Initial questions like 'How can I help you?' will initiate the engagement. It is strongly recommended that you listen to the response to this question patiently. Patients usually disclose most of the useful information within the first two minutes; however, it is observed that a surgeon often interrupts a patient in less than half a minute and starts asking specific or closed questions.⁶ Closed questions at this stage of the conversation are unlikely to reveal what is of greatest concern to the patient. Instead of closed questions, comments like 'tell me more about that' or 'what concerns do you have about that' will allow the patient to give their own view and initiate the engagement.

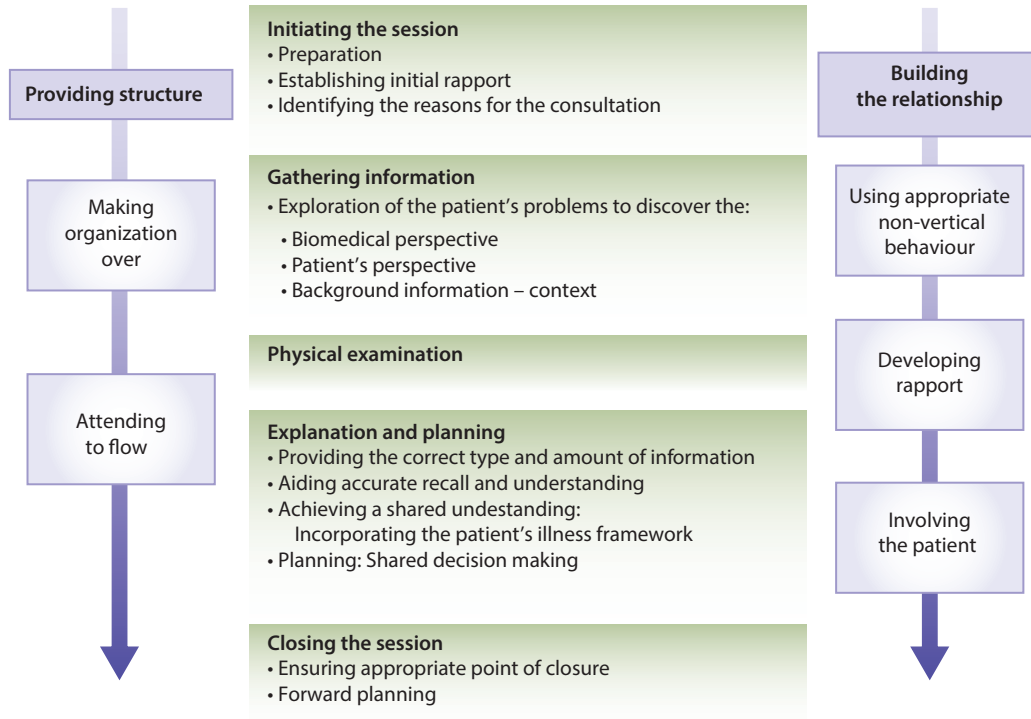

Figure 36.1 Expanded framework.

BOX 36.1 The 5 Es of communication

A review by Tongue et al. offered a framework and practical tips on conducting an interview.²⁹ It describes the 4 Es of communication:

1. Engagement
2. Empathy
3. Education
4. Enlistment
5. Ending

These 4 Es supplement the 3 Fs of clinical surgical practice:

1. Find the problem (diagnosis)
2. Fix the problem (treatment)
3. Furnish the service (delivery)

Adapted from Refs 29 and 30. (Figure 36.2).

Empathy

‘The patient will never care how much you know until they know how much you care.’³¹

Unfortunately, the most common weakness in communication with patients is a failure to demonstrate an empathic response. Studies show that surgeons often miss opportunities to express empathy.³² The potential effect of this is that patients may feel that their surgeons have not addressed their concerns. The gaps between the patient's expectations and the surgeon's approach leads to patient dissatisfaction.^{33, 34}

Empathetic conversation reveals the surgeon's understanding of and concern about the patient's thoughts. It involves acknowledging the emotional content of the communication, without necessarily sharing the emotion itself. It is necessary to clarify the difference between

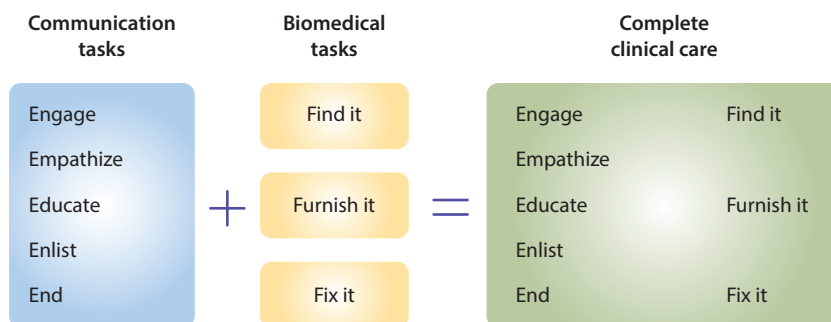

Figure 36.2 The five Es and three Fs of communication. From Tongue JR, Epps HR, Forese L. Communication skills for patient-centered care: Research-based, easily learned techniques for medical interviews that benefit orthopaedic surgeons and their patients. *J Bone Joint Surg* 2005; **87**(3): 652–58.

empathy and sympathy. Sharing the emotion fully would be sympathy and, although we may be sympathetic with some emotions, we generally do not share the emotions of most of our patients. It is not expected – in fact, it may be unhelpful for a surgeon to experience what the patient is feeling. As the saying goes, you don't need to have pain in your own right iliac fossa in order to diagnose a patient's appendicitis.

However, good communicators are expected to reflect a patient's emotion in the conversation, for example: 'It must be frightening to lose your hearing suddenly. Many people would feel that way.'

The process of acknowledging emotions is not too complex. The empathic response consists of three steps:

1. Identifying the emotion
2. Identifying the source of the emotion
3. Responding in a way that shows you have made the connection between the first two steps.

Surgeons may run short of time during consultations; hence they may be reluctant to address emotional issues, thinking that it may lengthen the consultation. However, several studies have uncovered a positive relationship between addressing the emotions and the length of the visit. Levinson et al. found that visits in which the surgeon directly addressed a patient's clue about a concern or worries were shorter than visits in which the clue was ignored.³⁵ This observation could be explained as the patients whose worry was addressed were able to put the concern to rest more quickly than those whose concern was unaddressed. Similarly, Braddock et al. found that visits with more complete, informed, decision-making conversations were only modestly longer than those that were less complete.³⁶

Education

Educating the patient involves providing the diagnosis, the prognosis and the options for treatment in a language that the patient understands. It is necessary to be aware that the amount of information the patient requires will vary. It may be helpful to ask, 'Does that match what you have been thinking about this problem?' That will allow the patient to bring up other outstanding issues. In the later part of the consultation it is a good idea to check that important details have been understood. Providing supplementary written material – especially about important pre-operative or post-operative instructions – should be considered.

Enlistment

Enlisting or enrolling extends an offer to the patient to actively participate in decision-making. Enlistment acknowledges that the patient controls much of what can happen in his or her healthcare treatment plan.³⁷ Different surgeons and patients will vary in their preferences about the degree of patient involvement. Orienting patients to the process of care and discussing risks frankly but positively will help to empower patients facing surgery.

Ending

The last E that needs to be considered is Ending the consultation on a positive note, with an expectation of a satisfactory outcome, phrased accordingly. Closing in a manner that gives patients hope is an effective strategy. It is worth reiterating that after leaving the consulting room, patients normally forget a significant part of what has been said during the consultation. Written material can supplement, but not replace, effective communication.

NON-VERBAL COMMUNICATION

Patients are particularly sensitive to non-verbal cues from their doctors, although many doctors are unaware of their influence in this respect. It is said that in a consultation less than 35% of contact is established through verbal means, while 65% is conveyed through non-verbal cues including facial expression and eye contact.³⁸ It is important to recognize the importance of subtle behavioural cues that are highly influential in determining the direction of consultation and the subsequent outcome.

Some consideration of how some non-verbal factors are effective through the clinic set-up arrangements is necessary. These factors include the layout of furniture, the relative positions of doctor and patient and the distance between them. A relaxed interaction is likely when both chairs are positioned at the same height to ensure good eye contact. The ideal positioning between a surgeon and the patient is approximately 2–4 ft (0.6–1.2 m). It is advisable for the surgeon not to stand while the patient is seated during the medical interview.

A desk represents a potential barrier between the doctor and patient and may be an important factor limiting the free flow of conversation. In one interesting experiment, the influence of the desk was analysed during consultations between a cardiologist and his patient. On alternate days the cardiologist removed the desk from his consulting room to assess the impact upon non-verbal cues and body language. When the desk was absent, more than half of all patients sat back and relaxed, but when the doctor was positioned behind the desk fewer than 1 in 10 assumed a relaxed body posture and this corresponded with a drop in the level of meaningful interaction between the two.³⁸

Knapp looked into the importance of seating arrangement. He identified four sitting positions for any interaction: the corner position, the cooperative position and the competitive-defensive position (Figure 36.3). In the corner position, the individuals are positioned in such a way that the corner of the desk intervenes. It usually results in casual friendly conversation. It allows unlimited eye contact and a full appreciation of gesture. The corner of the desk behaves as a partial barrier but does not intrude as a territorial division.³⁹

The cooperative position differs from the corner position in the absence of any barrier and a straight face-to-face sitting posture. While this favours a mutualistic

Figure 36.3 Examples of seat and desk arrangements. (a) The corner position; (b) The cooperative position; (c) The competitive-defensive position (the territorial line); Redrawn from Ref. 39, with permission.

relationship, a number of individuals feel threatened by the lack of a firm boundary. In the competitive-defensive position, the desk constitutes a firm physical barrier. Not only does this prevent intimacy, but it may also create competition for control of the consultation.

BOX 36.2 Optimizing communication

Behaviours in Western culture that can communicate to the patient that the surgeon is making an effort to optimize the personal aspect of the communication experience include:⁴⁰

- shaking hands
- maintaining eye contact
- welcoming the patient
- thanking the patient for coming
- apologizing for being late
- appearing relaxed
- appearing genuinely interested
- acknowledging emotions
- not writing and listening at the same time.

COMMUNICATING ADVERSE INCIDENTS

Bad news is a routine part of many surgical practices. A good surgeon will offer the appropriate words and actions in the setting of a dangerous operation or devastating diagnosis. Patients need to be able to absorb bad news, and they need to be able to prepare for the worst while hoping for a cure. This requires careful, balanced communication. Learning the skills to break bad news can prevent interactions in which it is delivered insensitively or too bluntly. Such ‘hit and run’ delivery of bad news may result from a surgeon’s own emotional discomfort.

Sharing bad news with patients is difficult to do well. A number of simple techniques may help you to undertake this more sensitively. Some techniques may appear obvious, like planning the consultation in advance, checking the facts and avoiding interruptions to ensure privacy. Breaking bad news can take a significant amount of time and it is important to avoid being rushed. The use of simple straightforward language and avoiding jargon is helpful. Many patients value an invitation to bring a relative or close friend for support, and it is necessary to establish the nature of their relationship in order to understand how the news will impact upon them also.

As mentioned earlier, non-verbal messages are as important as verbal ones. Patients need to be given sufficient time for silence, tears or anger. Even when the future looks bleak, we need to be careful in using the phrase ‘nothing can be done’. There are always ways of encouraging hope in any dire situation. However, it is equally important to admit when we do not know the answers to difficult questions, such as life expectancy after a diagnosis of terminal disease. Most patients value the offer of ongoing support, and follow-up is especially valuable.

BOX 36.3 SPIKES

Oncologist Robert Buckman has suggested a framework called SPIKES when breaking bad news, standing for setup, perception, invitation, knowledge, emotions, summarize and strategy.⁴¹

- **Setup** refers to finding an appropriate time and place for a discussion, somewhere quiet, private, seated, at eye level and free of distractions.
- **Perception** indicates the technique of asking the patient what he/she knows about the situation. This is a good starting point for the discussion as they may already know the bad news or have guessed it. However, they still want further clarification.
- **Invitation** means asking the patient what else they would like to know or whether they would like to know more.
- **Knowledge** implies offering information. Many patients want to know all that the doctor knows or understands.
- **Emotions** are commonly expressed when facing loss of health or loss of life. These emotions should be acknowledged and empathized with. Sometimes silence on behalf of the surgeon may constitute effective communication. ‘I wish’ statements can be used to convey empathy.
- **Summarize and strategy.**

ADDRESSING ISSUES AROUND LOSS

Patients may experience concern about potential disfigurement and loss of function as a result of surgery. The surgeon has a duty to address these issues in appropriate depth. Within otolaryngology, patients undergo loss of speech, swallowing, balance or hearing. Perhaps not surprisingly, those who cope less well with the loss of body function are those with a history of pre-morbid anxiety or depression, and these are factors that are easy to overlook in a busy consultation. Consequently, a professional assessment of mental health may be useful part of pre-operative planning for some patients prior to surgery.⁴²

The effect of hearing loss depends greatly on the age of onset and the extent of any residual function. The distinction between truly deaf individuals and those who become deafened later in life is important. Properly nurtured, the congenitally deaf individual is able to develop normal communication skills within the deaf community without any requirement for the spoken word. However, the individual who encounters hearing loss after normal development suffers an immeasurable handicap without augmentation or alternative aids.

For patients with acquired hearing loss there are a number of simple methods for improving communication within the consultation. Slow, deliberate speech of adequate volume in a room with low ambient noise will assist those with a modest hearing loss. A face-to-face position and clear enunciation of words enables lip-reading in those with long-standing loss. Other simple measures include diagrams and picture boards.

DISCUSSING MEDICAL ERRORS

Surgical error seems pervasive today, mostly because it is increasingly sought and increasingly recognized. Surgeons face a difficult dilemma when deciding whether and how to disclose a harmful error to a patient. When a patient has had an adverse outcome and if the surgeon's reaction is defensive, it results in the patient not being fully informed. However, it is recommended to follow appropriate disclosure. A study found that patients who had received full disclosure after an error were less likely to change doctor and had greater satisfaction⁴³ than patients who did not receive full disclosure. In some cases, disclosure decreased the risk of legal action, although a positive response was not guaranteed since it was dependent on the clinical outcome and the details and severity of the error.⁴⁴ In another study, investigators assessed the attitudes of 149 randomly chosen adults about medical errors. Patients were more likely to commence litigation following moderate and severe errors if there had been no disclosure.⁴⁵

A study, the first to assess how surgeons currently disclose errors, revealed that surgeons vary widely in their approach and in many cases, surgeons fail to use recommended error disclosure skills.⁴⁶ After a harmful error patients expect reliable information: an explicit statement that an error occurred, what the error was, why the error

happened, how the error will impact their health and an apology. They want someone to take responsibility. Many surgeons struggle with these aspects. A surgeon's reluctance to state explicitly that an error has occurred might in part reflect the advice they receive that the disclosure of an error should not include any statements that could constitute an admission of liability. However, a surgeon's failure to communicate clearly about errors can make patients feel angry and misled, feelings that frequently contribute to the decision to file a malpractice claim.^{47, 48}

While communicating errors, direct, clear statements are important, as are their delivery, particularly the tone of voice. One interesting study analysed the quality of surgeons' speech and malpractice history.⁴⁹ They observed that surgeons who were judged to be more dominant in their tone were more likely to have been sued than those who sounded less dominant. These findings indicate that even brief exposure to a surgeon's speech may be perceived by patients as expressing dominance and lacking concern. Dominance in the voice may imply a surgeon's indifference and lead a patient to launch a malpractice suit when poor outcomes occur.

Empathetic communication is especially important when discussing difficult issues like error. However, some aspects of errors, such as a surgeon's discomfiture about an error or concerns about liability, may make it difficult for them to discuss empathetically. Validating patients' views may also conflict with the surgeon's desire to persuade the patient that the error was not as serious as it may appear to them. However, failing to communicate empathetically with patients may give an impression that the surgeon is not concerned about what happened.^{50, 51}

There are some techniques that are useful in communicating adverse error events. The conversation may start with, 'I am afraid I have some bad news'. It is advised to communicate in a manner that is open as well as acknowledging emotional responses. Complex reactions of fear, anger and mistrust can be expected. An apology without assigning blame is acceptable and does not denote an admission of liability. Statements like 'I am sorry this has happened to you' will go some way in that regard. Many patients also want to know that steps are being taken to continue their care or rectify the error, and that steps are being taken to minimize a similar error happening in future. Thus, at the end of the discussion it will be effective if the patient is given an explicit plan of the support to be provided.

Communication is of significant importance with a somatizing patient. These are patients for whom no organic cause for their symptoms can be found and they fail to respond to the standard treatment. In interacting with these patients, surgeons experience a sense of frustration or irritation; some identify them as 'heart-sink' patients. These patients need to be managed by improved communication strategies including the identification of underlying situations that cause the stress that is responsible for the lack of therapeutic response. A number of special skills exist to combat the heart-sink encounter including a 'holding strategy' for listening and understanding the patient's problem without feeling the need to tackle all issues in that consultation.

BOX 36.4 Compliance

Research has shown that compliance depends on three factors:

1. Good understanding of advice
2. High level of satisfaction
3. An ability to recall information given by the doctor.

Evidence suggests that following the end of the consultation the patient retains surprisingly little factual information. For example, in one study over a third of patients failed to recall the name of their prescription medicine and a quarter failed to appreciate the duration of the course of their medication. Simple and effective techniques for increasing compliance include provision of written information, keeping explanations simple and repeating important points.⁵²

CONCLUSION

As clinicians, consultation is the most common clinical procedure we employ. Our communication with patients has a therapeutic effect, and can be positive as well as negative. A stereotypical image of a surgeon is someone who is not a very good communicator. It has been observed that when surgeons improve their communication skills, it is not just patients but surgeons themselves who are beneficiaries. Mounting evidence has shown that improvement in communication skills is achievable and that these skills can be taught, do change patient satisfaction, and can be retained over time. Improving communication skills is similar to improving operating skills. It involves seeking information, implementing the techniques and evaluating the outcome.

KEY POINTS

- Communication is the most commonly used therapeutic tool in ENT practice.
- The surgeon needs to be mindful of verbal as well as non-verbal communication.
- Like operative skill, good communication is a skill that needs to be developed. It involves seeking information, applying appropriate techniques and monitoring outcome.
- There are various models of doctor-patient communication. One needs to choose appropriate model according to the situation and personalities.
- Special consideration is advisable in communicating undesired.

SEARCH STRATEGY

Data in this chapter may be updated by a Medline search as well as reports for the Department of Health and website Institute of Health Improvement (IHI) using the keywords: clinical governance, patient safety, quality improvement and adverse events.

HISTORICAL BACKGROUND

‘The only way to be sure that they do the right thing is to keep an eye on them, to challenge them, to hold them to account and, above all, to take part in them.

The Nolan Committee¹

The last decade of the twentieth century saw some colossal tragedies in our practice of medicine in the UK, including the cases of Beverly Allit,² Harold Shipman³ and Bristol Paediatric Cardiology practice.⁴ While we were coming to terms with these tragedies, trying to make sense of and learn from them, on the other side of the Atlantic the Institute of Medicine (IOM) published a report that sent shock waves around the world. *To Err Is Human: Building a safer health system*⁵ made a conservative estimate that 98 000 people die in hospitals in the United States every year due to medical errors while they are receiving some form of healthcare intervention. The US Department of Health and IOM set out robust steps to reduce the mortality by 50% in the 5 subsequent years. The patient safety revolution crossed many geographical and political boundaries and the World Health Organization set up the World Alliance for Patient Safety in response.

To Err Is Human helped us to understand that medical errors are often the result of multifactorial problems within a healthcare delivery system – it is rarely the fault of a single individual. The importance of teamwork in patient safety and quality improvement emerged as a more fundamental need. The focus shifted from the healthcare professional to the structural clarity and robustness of the operating system, that is, the organization (microsystem, mesosystem, macrosystem).

Dealing with the serious public repercussions of a number of significant tragedies in the National Health Service, the then Labour government came up with a new plan to reform the health service with a new philosophical concept of practice: clinical governance. In December 1997, the new Labour government published a White Paper,⁶ *The New NHS*. In July 1998, the Chief Medical Officer, Liam Donaldson, co-authored a paper in the *British Medical Journal* titled ‘Clinical governance and the drive for quality improvement in the new NHS in England’.⁷ We saw the birth of clinical governance – an eclectic concept that was strangely alien to most of the frontline workers in the NHS. As a new cognitive structure, it incorporated **clinical audit, risk management, incident reporting** and **continuous professional development (CPD)**. It was described

as a package that housed all the disparate and fragmented practice of quality improvement.

DEFINITION

‘Clinical governance is a system through which NHS organizations are accountable for continuously improving the quality of their services and safeguarding high standards of care by creating an environment in which excellence in clinical care will flourish.’⁸

A robust framework of a high-performance system was proposed where healthcare professionals and managers would be working together towards a common goal of delivering safe and high quality care to our patients. This vision of a healthcare system was described based on an integrated intelligent matrix of communication pathways connecting all its parts and people. The capability of preserving and learning from our experience (memory) of individuals and groups on the front line was described. This new phrase clinical governance was partly harvested from the Cadbury report (1992)⁹ on the financial aspects of corporate governance with some intrinsic support from the NHS constitution. For the first time, quality improvement was put at the heart of medical practice in the NHS. The chief executive officers of the NHS hospital and primary care trusts were made accountable for the quality of care provided by their organization. The attention was expected to shift from the traditional target- and performance-driven, management-led organizational culture, to a refreshingly appropriate practice of medicine within an established framework of patient safety and quality improvement, led by senior clinicians. Safe, effective, patient-centred care with efficient utilization of resources and focused practice of risk management became the essence of good quality service. In 1997, the Department of Health introduced a 10-year programme to improve the quality of clinical care provided by NHS organizations and positively change the public perception. The National Institute for Clinical Excellence (NICE) was created to establish clear national standards through National Services Frameworks. The Clinical Governance Support Team, National Patient Safety Agency and National Clinical Assessment Authority were also established to support the development and good practice of clinical governance. The Commission for Health Improvement (CHI) was founded in 2000 by the Health Act 1999, as an external body to review the performance of each healthcare provider.¹⁰

Scally and Donaldson⁷ described the integrated approach to the practice of clinical governance under six interconnected domains:

1. Culture:
 - good leadership
 - ethos of teamwork
 - patient partnership
 - education and research valued
 - open and participative
2. Coherence:
 - goals of individuals, teams, organizations aligned
 - excellent communication
 - external partnership forged
3. Infrastructure:
 - access to evidence
 - time allowed to plan
 - training and development strategies
 - information technology supports practice
4. Risk avoidance:
 - well trained staff
 - safe environment
 - clear procedures
5. Quality methods:
 - good practice spread
 - clinical policies evidence based
 - lessons learned from failures
 - improvement process integrated
6. Poor performance:
 - early recognition
 - decisive intervention
 - effective self-regulation
 - feedback on performance.

It is important to note the World Health Organization has used the term clinical governance in relation to building high quality healthcare service. WHO had described it as four dimensions of quality:

1. Patient satisfaction
2. Professional performance
3. Risk management
4. Resource allocation.

In essence, clinical governance is a framework of safety with a whole system integrated approach to care and continuous quality improvement.

The main principles of clinical governance are:

- clear lines of responsibility and accountability for the overall care
- a comprehensive programme of quality improvement
- education and training
- clear policies for risk management
- managing poor performance.

In 1999, the Secretary of State for Health stipulated proposals for professional regulations of staff in the consultation document, *Supporting doctors, protecting patients*. Professional regulation of individuals working at the frontline of the NHS was considered necessary and plans were unveiled. *An organisation with a memory*¹¹ was published in the year 2000. This report of an expert group on learning from adverse events in the NHS highlighted the extent of the harm patients could face when under the care

BOX 37.1 The 7 pillars of clinical governance

1. Patient and public involvement
2. Risk management
3. Clinical audit
4. Staffing and staff management
5. Education and training
6. Clinical effectiveness
7. Use of information

of our NHS hospitals. It stated that adverse events resulting in patient harm occur in around 10% of all admissions to NHS hospitals. This is equivalent to an incidence in excess of 850 000 patients per year. The estimated cost of managing this is £2 billion a year in additional hospital stays alone. The establishment of NICE in 1999 and CHI in 2000 aimed to safeguard patient care through evidence-based support and regulation. CHI described clinical governance as a platform held up by the 7 pillars of clinical governance (Box 37.1). It was widely perceived that changing organizational culture and creating a robust, well-connected system with clarity of structure and function was the essential key to successful clinical governance and the survival of the NHS beyond its 50th birthday.

THE 7 PILLARS OF CLINICAL GOVERNANCE

Patient and public involvement

The National Health Service belongs to the citizens of the UK and is run on public funding. The voices of patients and the public are essential to maintain its integrity, growth and evolution. Feedback from patients and the public should be dealt with carefully so as not to miss any learning opportunity that may come with it. The creation of clear structures for handling such feedback ensures the generation of functional memory and creates a learning environment that allows us to improve our provision of care every day.

Risk management

DEFINITION OF RISK

Risk can be defined as any potential for the occurrence of an unwanted effect because of an intended action.

RISK TO PATIENTS

The practice of medicine is a high-risk business. Every healthcare intervention must be risk assessed and continuously monitored to reduce any risk to patients. All incidents and near misses must be reported, recorded in the organizational memory and carefully analyzed. Knowledge gained from these and through significant clinical event analysis should change behaviours of clinical practice with resultant reduction of both non-human factors and human factor-related risk and incidents. All critical events

must be audited. The introduction of surgical checklists has led to a reduction of risk and adverse incidents in surgical patients. Statutory regulatory bodies (i.e. Medicine Control Agency, Data Protection Act, etc.) can help in the reduction of risks and incidents. The use of software (e.g. DATIX) can facilitate all aspects of risk management and the successful use of these has been reported by some health organizations. Regular training of staff and routine and random checks of systems and practices are essential for maintenance of the highest standards of safety.

RISK TO THE PRACTITIONER

Protecting healthcare professionals from occupational hazards by immunization, improving and creating a safe work environment, assessing and reducing human factor-related incidents are recommended good practice.

RISK TO THE NHS ORGANIZATION

Any incidence of poor practice has the potential to damage the professional reputation of an organization. Significant events of poor practice are usually the reflection of poor organizational culture and serious lack of leadership across all parts of the system. Examples of such tragedies are plentiful in our recent history (i.e. Bristol, Mid-Staffordshire, Lanarkshire, Blackpool, etc.). The Francis, Keogh and Berwick reports will speak of the risk associated with poor organizational culture for decades to come. We must not miss the opportunity to learn from these situations.

Aligning the individual, team and organizational values creates resonance and avoids conflicts of interest. This is essential for the success of clinical governance.

Clinical audit

Clinical audit is a quality improvement process that seeks to improve patient care and outcomes through systematic review of care against explicit criteria and implementation of change.^{12, 13}

In 1989, medical audit was introduced in the NHS by the Department of Health,¹⁴ with clear instructions for all hospital doctors to take part in audit by 1991. This had been duly endorsed by the General Medical Council in its advice to all doctors. In 1997, clinical audit was integrated into clinical governance. Clinical audit comprises the essential core of clinical governance. It is the most appropriate way to check for the safety, effectiveness and quality of all healthcare interventions, both processes and outcomes. When applied carefully and methodically, clinical audit is excellent in its ability to monitor healthcare delivery services in its entirety. The recommendations from the Report of the Public Inquiry into Children's Heart Surgery at Bristol Royal Infirmary (1984–95) strongly supported audit to be the tool for monitoring clinical performance. It also stressed that clinical audit should be thoroughly supported by all healthcare organizations and all healthcare professionals should be contractually bound to take part in local audits. The recent introduction of the revalidation

process for renewal of doctors' licence to practise by the General Medical Council requires all doctors to perform clinical audits.

Factors contributing to the success of any audit are:¹⁵

- organizational support
- evidence-based guidelines
- participation of patients
- good relationship with patient support groups
- improved record-keeping
- good use of information technology
- professional help and support in designing and application.

Lack of ring-fenced time within doctors' job plans, lack of resources, poor microsystems and organizational culture and deficient managerial support in efforts towards clinical quality improvement can all be significant deterrents to effective clinical audit. Johnston et al. reviewed 93 publications to explore the barriers and facilitating factors for effective clinical audit. They have highlighted professional attitudes and presence of coherent strategies as significant variables influencing outcomes of clinical audits.¹⁶

The tragedies of Bristol Royal Infirmary should deter anyone from dismissing the significant role of clinical audit in achieving patient safety and quality improvement.¹²

Staffing and staff management

Recruiting highly trained staff with a passion for working in the NHS is fundamental to providing excellent patient care. Of equal importance in the provision of safe, effective and patient-centred care is ensuring the optimum skill mix of well supported staff in every clinical area. Tired, harassed, psychologically disengaged staff cannot provide good quality care.¹⁷

Education and training

Continuous professional development through well supported in-house and national courses is essential to keep all NHS staff up to date with the rapid pace of progress of modern medicine. The reduction of junior doctors' training hours to comply with European working time directives has certainly caused difficulties in terms of the training of doctors because of the significant lack of the most important resource – time. The introduction of consultant contracts with 90% of time spent in direct patient care, with a paucity of time and funding for study leave time, has a serious detrimental effect on the education and training of senior doctors.

The education and training of all healthcare professionals, throughout their career, must be supported and guarded as sacrosanct in order to allow safe and best quality practice to thrive. It is a duty of all employers to safeguard this. A very good example of this is the work of NHS Education for Scotland.¹⁸

Clinical effectiveness

Ensuring that each and every patient gets safe and effective healthcare is the core function of clinical effectiveness. Standards of safety and quality of care must not fluctuate across timelines or postcodes. All aspects of healthcare should be based on the current body of evidence and be patient centred. Clinical effectiveness is all about doing the right intervention, for the right patient, at the right time, in the right way. Eradicating wastage, minimizing harm and variations of practice should be at the heart of the practice of clinical effectiveness. In essence, clinical effectiveness measures how good an intervention is at achieving what it is intended for and is weighed up by the hierarchy of evidence. This has been derived from the evidence-based medicine movement of the 1990s.

The development of CHI, NICE and the Scottish Intercollegiate Guidelines Network (SIGN) have been at the heart of the promotion of good practice based on the best evidence. It has also been established that safe and effective practice is also more cost-effective.

Use of information

Effective and efficient management of information is the key to the ultimate success of an operational system, that is, the NHS organization (macrosystem). This involves understanding data protection, methods of collection, evaluation, interpretation and application of all relevant data to improve processes and, therefore, the outcomes of a system. A good example of this is the improvement of clinical performance based on monthly or annual outcome data of one or many interventions. Data are extremely powerful tools to show the quality of any practice (i.e. patient feedback information allows us to improve our care pathways). Data handling is hugely labour intensive. Every NHS organization needs to ensure modern technology and appropriately trained staff are in place to harvest and make good use of data. This is a key infrastructure requirement for the success of clinical governance.

RELATIONSHIP BETWEEN CLINICAL GOVERNANCE, PATIENT SAFETY AND QUALITY IMPROVEMENT

The concept of clinical governance was introduced by the Department of Health in 1997 as an integrated framework within the NHS to safeguard patient safety and continuous quality improvement. For clinical governance to be successful it is imperative that an organization will have safe, effective and patient centred care in day-to-day practice. Patient safety and continuous quality improvement are at the heart of clinical governance and should not be separated. However, NHS organizations often show separation and conflicts between clinical and managerial approaches to patient safety and quality improvement.

Realignment of organizational goals with the goals of the frontline healthcare professionals will ensure that patient safety remains at the heart of the practice of clinical governance.

FRANCIS, KEOGH AND BERWICK REPORTS

Hope is not a plan and a plan is not always a good strategy that can survive the test of time. 2013 saw the publication of several landmark government-funded reports into failures of healthcare delivery systems. Many devastating high-profile failures of provision of care, mishaps and deplorable quality of practice plagued us throughout the early twenty-first century. The second cycle of the Francis report made 290 recommendations over 1782 pages.¹⁹ The essential recommendations were: openness, transparency and candour throughout the healthcare system (including a statutory duty of candour); fundamental standards for healthcare providers; improved support for compassionate caring; committed nursing; and stronger healthcare leadership.

Bereaved and angered patients' families and friends had questions. Many of these questions sadly still remain unanswered. A review of mortality figures in 14 hospitals in England was the next revelation to hit the medical profession. Keogh summarized his recommendations as eight ambitions.²⁰ Listening to the frontline staff (i.e. the nurses and junior doctors) is one of the most highlighted areas, along with the need for the creation of a climate of safety and positive organizational culture.

Don Berwick, founder and past president of the IHI, a physician, philosopher and a passionate believer of robust systems, individual accountability and the human touch in patient care, was the third leader invited by the government to analyze and report on the problems affecting patient safety in NHS hospitals. Berwick expressed his thoughts succinctly in the form of four eloquent letters in a document, *A promise to learn – a commitment to act: improving the safety of patients in England*.²¹ The summary of his recommendations is simple, clear, extremely powerful and poignant (Box 37.2).

BOX 37.2 Four recommendations by Don Berwick

1. Engage, empower, and hear patients and carers throughout the entire system, and at all times.
2. Foster wholeheartedly the growth and development of all staff, especially with regard to their ability and opportunity to improve the processes within which they work.
3. Insist upon, and model in your own work, thorough and unequivocal transparency, in the service of accountability, trust and the growth of knowledge.
4. Embrace transparency unequivocally and everywhere, in the service of accountability, trust and the growth of knowledge.

CURRENT ISSUES

There are a number of issues that can be highlighted to show why clinical governance has not thrived:

- lack of defined input, structure and process for clinical governance
- poor organizational culture
- poor and deficient leadership
- disengaged, disillusioned staff
- historical glass walls of poor culture or practice separating clinicians and managers
- financial targets and misaligned performance indicators
- disconnected microsystems
- confines and silos of good practice
- poor, cumbersome feedback system
- lack of patient involvement and regular public scrutiny.

ROLE OF CEO, NHS BOARD AND SENIOR MANAGEMENT

In 1998, chief executives of all NHS primary and secondary care organizations were made directly accountable for the quality of the service provided by their organizations. In the absence of a clear, defined framework of safety, clinical governance will fail to meet any of its lofty goals. The chief executive officer with the senior management team and board members need to ensure there is an environment where good practice thrives. The lines of accountability and responsibility for overall patient safety and quality improvement must be clearly identified. Organizational goals aligned with those of individual healthcare professionals dedicated to value-based practice will create an environment in which clinical governance will thrive.

CONCLUSIONS

Primum non nocere, the Hippocratic Oath of first doing no harm in our every endeavour, has been at the core of our medical practice for centuries. Patient safety and quality improvement is everyone's business. Without willing contribution from the majority of NHS staff, the goals of patient safety and quality improvement will never be realized. However, we urgently need some effective measures to engage our disillusioned staff in value-based patient care. This will not be possible until the clinical priorities are met.

It should be our goal to see that all staff are well connected, well informed, well supported and working in resonance towards their common goal of delivering safe, effective and patient-centred care to every patient every time, 365 days a year. Financial, political and performance related goals should not override the goals for patient safety and quality improvement.

The National Health Service²² was born on 5 July 1948. It did not have any intrinsic or extrinsic system for safety or quality improvement for the first four decades

of its existence. The 10 years leading to its 50th birthday saw some major failures, with consequent public scrutiny. This triggered a deluge of white papers, reforms and introduction of laws. Despite the implementation of all these measures, British citizens have seen repetitions of many mistakes in the NHS. Sadly its recent history has demonstrated that the NHS as an organization does not have a functional memory and has failed to learn from

its major mistakes. We cannot solve a problem with the same level of intelligence that created it – a paradigm shift in organizational culture is required to ensure that patient safety and continuous quality improvement are at the heart of the practice of medicine throughout the NHS.²³ This will only be possible with strong leadership from front-line clinicians in partnership with excellent senior managers.

KEY POINTS

- Clinical governance is a system through which NHS organizations are accountable for continuously improving the quality of their services and safeguarding higher standards of care by creating an environment in which excellence in clinical care will flourish.
- Clinical audit comprises the essential core of clinical governance.
- Data are a key infrastructure requirement for the success of clinical governance.
- Medical errors are often the result of multifactorial problems within a healthcare delivery system – it is rarely the fault of a single individual.
- Feedback from patients is the most valuable resource. It should be actively encouraged at all parts of a patients' journey.
- Risk can be defined as any potential for the occurrence of an unwanted effect because of an intended action.
- Tired, harassed, psychologically disengaged staff cannot provide a decent quality of care.

Methods in ethics	396	Conclusions	406
Important concepts in ethics.....	397	References	406

SEARCH STRATEGY

Data in this chapter may be updated by a PubMed search using the keywords: ethics, methods, autonomy, interests, welfare, principles, consequentialism, deontology, reasons, informed consent, children, relativism, research ethics, resource allocation, truth-telling and confidentiality.

WHAT IS ETHICS?

*'The purpose of ethical reflection is to help us to decide how to act in the real world, all things considered. This means ethical reflection must take into account all aspects of a proposed course of action, it must rely on good factual evidence and on an understanding of the social and legal contexts in which action has to take place.'*¹

Sometimes decisions in medical ethics are presented as though they are separate from mainstream medical decisions, but this is not so. Succinctly, good medicine demands good ethics and this requires correct facts: ethics necessarily cannot be divorced from the real world.

Two broad academic approaches can be distinguished in ethics. The first, empirical ethics, describes ethical interactions through the methods of social sciences, using questionnaires, interviews and focus groups (amongst others) in studying what happens, or how people approach situations that involve ethics. The methods are both quantitative and qualitative and often come from psychology or sociology.² The other broad approach (adopted in this chapter) is philosophical, or analytic, ethics. This is the study of what *ought* to be done and includes questions such as what ethics is and how doctors should behave towards patients and each other. Ethical questions in this tradition are about what *should* happen, not about what does happen. Within this approach to ethics, some consider more abstract questions, such as whether there are moral facts

or whether moral truths are relative to society. This discipline is called meta-ethics. These questions are not immediately relevant to clinical practice. Others ask more down to earth questions, such as: What is needed for research to be ethical? Is abortion acceptable? This discipline is called normative ethics. Meta-ethics and normative ethics are not independent, as answers to meta-ethical questions may inform normative conceptions and vice versa. The important difference between these disciplines and empirical ethics is that these studies describe the world, recounting how things are, whereas philosophical ethics concentrates on what would be *right* or how things *should* be. As an example of the distinction, empirical ethics can report on whether or not abortion is carried out and the reasons that people offer for their involvement (or non-participation) in abortion, but philosophical ethics attempts to answer the question of whether or not abortion should be performed. That abortion is (or is not) performed does not indicate whether it ought to be performed.

The distinction between how things are and how they should be, or between what people do and what they should do is one manifestation of the 'is-ought gap'. Hume argued, 'In every system of morality which I have hitherto met with, I have always remarked, that the author proceeds for some time in the ordinary way of reasoning, and establishes the being of a God, or makes some observations concerning human affairs; when of a sudden I am surprised to find that instead of the usual copulations of propositions, *is*, and *is not*, I meet with no proposition that is not connected with an *ought*, or an *ought not* ... a reason should be given, for what seems altogether inconceivable,

how this new relation can be a deduction from others, which are entirely different from it'.³ This distinction is important: clinicians are educated in biomedical scientific methodology, but the methods, and knowledge, of ethics are different from those that they are used to.

Most pressingly, ethics asks the question: What should I do? As Singer argues in criticising relativism, 'Anyone who has thought about a difficult ethical decision knows that being told what our society thinks we ought to do does not settle the quandary. We have to reach our own decision.'⁴ When a clinician is confronted by an ethical decision, particularly one that is disputed or troubling, the choice that must be made seems deeply personal, and in that way is different from technical questions in medicine (such as the choice of antibiotic to treat sinusitis in a previously well 20-year-old). Although colleagues or confidantes can offer advice and guidance, there is much less sense that an expert can know the right decision when it comes to matters of ethics than in matters of technical medicine (indeed, the notion of whether or not there are ethics experts is contested).^{5, 6} However, what I want to emphasize is the strong sense that what I do in ethics matters personally.

At different times different questions have concerned those interested in medical ethics. Partly this has been driven by advances in biomedical knowledge and expertise (an example is the advances in reproductive techniques) and partly this has been driven by a change in the focus of ethical interest to different aspects of medical practice. In the recent past medical ethics was more concerned with the professional behaviour of doctors (for example, the acceptability of advertising, and in relationships between doctors); then focus turned to the relationship between the individual clinician and the patient. More recently attention has turned more towards public health ethics and the ethics of the distribution of the social determinants of health.

Some people believe that it is unlikely that there will be progress in ethics because ethics have been studied for several thousand years, so there is nothing new to say, but others are more optimistic: 'Some people believe that there cannot be progress in Ethics, since everything has already been said ... I believe the opposite. How many people have made Non-Religious Ethics their life's work? ... Non-Religious Ethics has been systematically studied, by many people, only since the 1960s. Compared with the other sciences, Non-Religious Ethics is the youngest and least advanced.'⁷

In this chapter I will briefly consider the methods that are used in ethics, then continue to consider some important concepts that are used in ethics and conclude by considering some topics of relevance to practising otolaryngologists. Although I will review the ethics of clinical research there are topics that I will not consider (including, for example, the concerns around stem cell therapies).

METHODS IN ETHICS

The emphasis, in clinical medicine, is on the evidence-base that justifies the performance of diagnostic tests and the effectiveness of medical interventions. Medical decisions

that are not supported by a high standard of empirical evidence are taken to be suspect. But this approach will not work in ethics as the questions are different. Ethics involves claims about what *should* be done and what *ought* to happen. These normative questions are different from the questions of evidence-based medicine. To answer these different questions, different methods are needed.

The methods of ethics are essentially those of philosophy or critical thinking and include the critical evaluation of concepts and the use and evaluation of rational arguments in a logical and consistent fashion. The techniques are many and varied but a sense of them can be found in books such as *The Philosopher's Toolkit*⁸ and *Thinking from A to Z*⁹ and can often be found in introductory textbooks such as *Medical Ethics and Law: The Core Curriculum*.¹⁰ However, as well as philosophy, a broad range of disciplines contribute to medical ethics including, amongst others, legal scholars and lawyers, theologians and historians alongside practising clinicians and other healthcare professionals.

Reasoning and rational justification is at the heart of ethics. In ethics it is important that the conclusions are justified by reasons (though it is important to acknowledge the position that emotion may have in ethics). An important commitment in ethics is that judgements are universalizable. This means that is that there is a requirement to treat all similar cases in the same way. There can be no special pleading along the lines of 'she's my daughter': a reason for your daughter is a reason for all daughters, for all girls, for all children. This means that significant weight is placed on deciding whether two cases are morally similar, or alternatively morally different. One approach in ethics that has achieved prominence in recent times is reflective equilibrium.¹¹ In this approach all of a person's beliefs and theories are involved when making a decision. Neither the facts of the situation, nor any high level abstract principles take priority over other beliefs, there is a to-and-fro examination of the complete set of a person's beliefs in an attempt to develop a coherent approach. Should there be disagreement or inconsistency, then all of the person's beliefs may be revisited in order to achieve a coherent and consistent set of thoughts. Importantly, all beliefs are subject to revision. Abstract principles do not necessarily trump more down-to-earth concerns.

Within the discipline of normative ethics several different approaches are used to analyze the ethics of medical interventions. These methods include principlism, the claim that principles guide moral action. The most popular principlist approach is the four principles advocated by Beauchamp and Childress,¹² but this is only one form of principlism. Another approach is casuistry, which objects to the 'top-down' approach that starts with abstract principles, insisting that we should attend to the particular circumstances of individual cases. Virtue ethics, another approach, characterizes ethical actions as those in which the virtuous person will 'assess each situation individually, searching for action guidance in considering what a characteristically virtuous person would do'.¹³ And yet another is the ethics of care, originating in the work of

Carol Gilligan, emphasizing empathy and compassion, describing ethics in terms of relationships. Gilligan found (in empirical work) that women took the care ethics approach, whereas men appealed more to abstract principles (such as ‘justice’) in ethical analysis. This is not an exhaustive list of the approaches to ethical analysis.

Importantly, although ethics and law are related, the two are separate disciplines. Some laws neither have nor need an ethical underpinning (the legal requirement to drive on one side of the road for example). Other laws may have some ethical justification, but even in these cases the relationship between ethics and law is not straightforward: some actions are legal but unethical (some would want to describe abortion – legal in many countries – in this way). Some actions are ethical but illegal (some would want to describe assisted suicide, which is illegal in the UK, as an example). And even if there were clear agreement over which actions were ethical and which were not, it is a separate question whether an action that is unethical should be illegal: ‘it is one thing to show what a woman ought to do in relation to her unborn child and quite another thing to say that this obligation ought to be enforced’.¹⁴ One way in which it is clear that there is not a direct relation between the law and ethics is the differences in laws between adjacent, but similar, countries. For example, abortion is illegal in Ireland, but legal, in certain circumstances, a 30-minute flight away in the UK. Furthermore, although there is some moral obligation to obey the law, there are also circumstances in which there may be a moral obligation to disobey a bad law. The civil disobedience campaigns in the United States are examples of this.

Similarly the relation between religion and ethics is troubled. Important contributions have been made to ethical thought by religious scholars (amongst other examples in the analysis of the doctrine of double effect), but the foundations of religious ethics – that they are the revealed word of God, or some equivalent, and so their authority is unquestioned – are not accepted by all. And this is compounded by the several different competing religions in pluralistic societies (alongside the arguments of militant atheism). No one dominant religious approach is able to claim a secure knowledge of the good.

Many different institutions and agencies develop and have developed prescriptive guidance on matters of ethics. For example, in the UK, the body responsible for licensing doctors, the General Medical Council (GMC), produces guidance¹⁵ in the form of pamphlets guiding medical practice in general, and pamphlets that also address specific areas of practice such as dealing with children, or research. In law, the GMC’s guidance is often taken to indicate the correct approach. As well as GMC guidance, professional bodies such as the British Medical Association and the Royal Colleges (responsible for postgraduate medical education in the UK) produce ethical guidance. Although the guidance may be useful in practice, it requires interpretation by the practitioner to be applied. As well as this, even with clear guidance, there may be conflict between different components of the guidance. Again, interpretation and ethical wisdom is needed in the clinical application of advice.

IMPORTANT CONCEPTS IN ETHICS

Relativism

Relativism is the claim that ethical judgments are made relative to a particular society and time. If this is true, there is no single correct ethical judgement for all and ‘when in Rome, do as the Romans do’ is true. One support for relativism is the presence of differences between societies in their approaches to ethics. This evidence then leads to the claim that there are no right answers in ethics, just different right answers in different contexts. But this need not be the response; in some circumstances disagreement just indicates that one side is wrong. If we disagree about the distance from Paris to London it doesn’t mean that there isn’t a right answer, just that one (or both) of us is wrong.

With the prominence of respect for autonomy, relativism can seem the correct response to the challenge ‘who are you to judge?’ Amongst the advantages of relativism is that it is sensitive to the criticism of ethical imperialism and, in avoiding the claim that a person is wrong, may encourage negotiation instead of confrontation. Confrontation is likely to entrench disagreement whereas negotiation may lead to reasoned agreement.

However, there are significant problems with relativism. Firstly, relativism implies that there is no progress in ethics. If ethical relativism is true, then in slave-owning societies slavery is not wrong. The recognition of the wrongs of slavery and the moral progress in banning slavery is not acknowledged. A second problem for relativism is that ethical disagreement becomes a matter of fact. So again, the claim that slavery is wrong is just a factual claim about a society. But the wrong of slavery is not something that anthropology can judge. Ethical wrongs are not anthropological disagreement.

Importantly, there are different ways that a person can be a ‘relativist’, and so two relativists can disagree with one another. This brief review only skims the complexity of relativism.¹⁶

Principles

Principles are laws or truths that offer guidance in ethics. The dominant approach in medical ethics is the four principles approach of Beauchamp and Childress.¹² There are several different principled approaches (see Veatch¹⁷ for a summary of some of these), all with competing justifications. The justification that is often offered is that the chosen principles best condense moral intuitions, or best reflect common-sense morality. Perhaps the most famous principle-based approach is that of Kant¹⁸ with his single categorical imperative (see below).

Not all ethical approaches depend on principles. Some reject a principled approach. Moral particularism claims that ‘moral judgment can get along perfectly well without any appeal to principles ... abandoning the mistaken link between morality and principles is if anything a defence of morality rather than an attack on it’.¹⁹ As well as this, other approaches, such as virtue ethics, do not depend on principles.

Autonomy

Respect for autonomy has become the pre-eminent value of our times, and not just in medical ethics: ‘to be autonomous is to be one’s own person, to be directed by considerations, desires, conditions, and characteristics that are not simply imposed externally upon one, but are part of ... one’s authentic self’.²⁰ Although autonomy may seem straightforward, it is highly contested. It includes, at least, freedom from external manipulation (neither physical nor emotional control by others) as well as an internal ability to control oneself (a person does not choose unwisely, driven by impassioned urges or addiction).^{20, 21} As rational, morally responsible people, we should adopt our own long-term commitments, goals and values and make our own important decisions about how to live our own lives. Only in this way are we truly human, living a genuine life as a rational person.

Respect for autonomy replaced a more paternalistic model of medicine, where because the technical expertise of the doctor in medicine was respected and accepted, the clinician chose what was best for the patient. However, requirements of autonomy are such that although the clinician has technical expertise, the person with the medical problem knows better the effects of the disease and the therapies on their own life and life goals. In this way it is only the person, guided by the clinician, who is able to make the right decisions about medical interventions.

Kant’s morality grounds autonomy in the demands of pure reason. Kant distinguished a hypothetical imperative from the moral categorical imperative. A hypothetical imperative recognizes that one should act in a certain way to achieve a specific goal: consult the map *if* you want the quickest route to the next town. The categorical imperative (the rational demand of morality) is universal, and (in one construction) states, ‘Act as if the maxim of your action were to become through your will a universal law of nature’ [Kant, 1948; 84].¹⁸ An autonomous decision then is not just simply an individual’s choice, it is a supremely rational decision, devoid of misinformation and faulty reasoning, standing for all people for all time: it is the right action. Amongst the criticisms is that such a choice is an impossibly demanding standard. Importantly, many choices do not approach this stringency and so are not (in this sense) autonomous. A different justification that personal choice should be respected comes from libertarianism – such as Mill’s. Mill set out the harm principle, ‘the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant.’²² This is because when another person chooses they are ‘quite as likely to be wrong as right’.²² Even so, Mill recognizes some limits. He gives the example of a person crossing an unsafe bridge who may be ‘seized and turned back’ if unaware of the danger. A Millian justification of respect for choice is less demanding than a Kantian justification.

An autonomous decision is one that affects only the individual involved. So preventing smoking in public based

on the risks of passive smoking does not conflict with the respect that is due to autonomous choices (it is not paternalistic). One criticism is that very few, if any, decisions have repercussions only for the individual concerned. Almost all of us have family and friends: we are not atomic individuals bound by rights. The Nelsons argued that the locus for medical decisions should be the family and not the individual.²³ Feminist criticism of autonomy draws attention to the fiction of the lone ‘autonomous’ individual free of ties, drawing attention to the relational nature of autonomy. A further criticism of autonomy is that pervasive discrimination can impoverish a person’s self-esteem and so desires. If so, the choices a person makes are not truly autonomous: ‘our desires are shaped by our expectations which are shaped by our circumstances’.²⁴

Sometimes autonomous individuals can choose a course that seems (at least to others) not to be good for the individual (even the individual themselves may come to recognize their choice was mistaken). Some deny this, arguing that an autonomous individual is always the best judge of their welfare (for example, ‘Competent adults are allowed to define their own concept of “best interests”...’²⁵). That an individual makes the correct choice about their welfare depends on the individual being informed and reasoning correctly. We can all recognize episodes when we have been mistaken about what would be good for us as individuals, in which our choices have not been to our benefit. In this way there is a tension between autonomous choices and an individual’s welfare. Bosk observed that ‘the dark side of patient autonomy is abandonment’.²⁶

An ethics based on respect for autonomy does not account for public health commitments (to water fluoridation or to clean water and air as examples). These cannot be a matter of autonomous choice for individuals, as it is unlikely that all individuals will choose (or refuse) them.

Some people are not autonomous, lacking some – or all – of the abilities needed to be autonomous. Young children are one group. They will be considered later on. Another is incompetent adults. When dealing with incompetent adults, all attempts should be made to maximize the person’s capacity. Incompetence may be temporary (perhaps while ill or intoxicated) or permanent (in severe dementia). Sometimes a person’s capacity, and so their competence, fluctuates. The broad approach to those who lack autonomy (if they were previously competent) is to choose as the individual would have chosen. Medical decisions can be guided by written instructions that the individual has left (an advance directive). Alternatively, the now incompetent person may have chosen someone to make decisions on their behalf (in the UK this is named a Lasting Power of Attorney). In the absence of these, evidence of the incompetent person’s preferences (from family and friends) guides medical decisions, in order to choose as the person would have chosen (a substituted judgement). As well as this, the views of the not competent individual should be sought so that their views may be included. In the absence of all of these, the decision for an incompetent person will be based on some objective or impersonal sense of the individual’s best interests.²⁷

Welfare, well-being, ‘good for’, in a person’s (best) interests, beneficence

Often the role of medicine is taken to be to make people better, specifically to improve their health, but there can be disagreement about what this means. One problem is that there is not a clear boundary between health and disease, nor is there a clear boundary between treating disease, preventing disease and improving health. Some believe that although doctors treat disease caused by smoking, clinicians overreach their role in campaigning against smoking or advocating restrictions on smoking. Importantly non-healthcare interventions can improve health. Literacy campaigns reduce overall mortality and neonatal mortality,²⁸ but would not usually be taken to be a healthcare intervention. Some seek to define the role of medicine as the treatment of physiological disorders, appealing to the role of disturbances to what is ‘scientifically’ normal function. There are many difficulties with these approaches. One example is in reproduction. Medical roles encompass both abortion, in terminating pregnancy, and assisted reproductive techniques in initiating and maintaining pregnancy. A physiological definition of medical goals is unhelpful here. Importantly, as well as benefits for physical health, mental well-being is also important.

Medicine is not limited to the treatment of disease (an example is the importance of health promotion exemplified by vaccination programmes) but how far into the promotion of health medicine should go is controversial. The WHO defines health as ‘a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity’.²⁹ Daniels responds, ‘Health is not all there is to well-being or happiness, contrary to the famous World Health Definition (WHO) definition ... The WHO definition risks turning all of social philosophy and social policy into health care.’³⁰ In general in medicine, clinicians act in a way that is ‘good for’ their patients, though their actions are limited both by the law and by the consent of the patient.

This aim can be expressed in several different ways: that clinicians should do good for their patients; that they should act in their patients’ interests; or best interests; or with attention to their patients’ welfare or well-being or for their good. In this sense, a person’s interests are at the core of ethics. Or, describing it another way, when acting or choosing between actions, a significant (although perhaps not the only) factor in ethics is the effect the action will have on people’s interests.

However, in modern pluralist societies there are often different senses of what would be good for someone. In a well-rehearsed example, Jehovah’s Witnesses believe that the voluntary acceptance of blood transfusion leads to damnation, so a blood transfusion, even when life-saving, is not in their interests. Others would see that a blood transfusion is clearly beneficial. Can we resolve these dilemmas? Philosophers disagree about how best to conceptualize a person’s interests, some (utilitarians) arguing that what is best is what makes most people most ‘happy’ (though they may disagree about what is meant

by happiness). Others argue that what is best is where more of a person’s desires are fulfilled and fewer desires are left unfulfilled (desire-satisfaction theories). A further approach is that some things are just good for people (sufficient food) and some things are just bad for people (pain). To be healthy is just good. This is called an objective list account. There is insufficient space in this chapter to take this further (but see Degrazia’s³¹ paper or Griffin’s book *Wellbeing*²⁴), but we should recognize that not only do we not have a clear grasp of a person’s interests but we also do not have a clear way to go about working out what a person’s interests are. These concerns led the House of Lords to claim “‘best interests’ is probably the most abused and misunderstood phrase in health and social care. It has too often been the vehicle for poor decision-making’.³²

It is rare that any medical intervention is a source of unmitigated benefit; all interventions have some adverse effects in terms of pain or unpleasantness, or even (for the most trivial of interventions) the time that the intervention requires could have been spent more profitably. So in considering the benefit to an individual, the severity and the likelihood of harm (maleficence) must be considered alongside the extent and likelihood of benefit in coming to a conclusion about the benefits of medical intervention. For example, in the Belmont Report (considering the ethics of research), harm is included in the calculation of beneficence which is described as ‘(1) do not harm and (2) maximize possible benefits and minimize possible harms.’³³ Beauchamp and Childress,¹² in their influential four principles, separate beneficence from non-maleficence.

Non-maleficence

Avoidance of harm is sometimes prioritized as a first principle, often phrased in the Latin *primum non nocere* – above all do no harm. I have argued already that it is usually necessary to balance benefits and harms each against the other in judging the overall advantage (or disadvantage) of medical interventions. If the first, overriding, responsibility is taken to be to do no harm, then it is likely to rule out all medical interventions as none can be guaranteed to be without adverse effects.

A reason to separate non-maleficence from beneficence is that a person may have a broader responsibility to avoid harm to others, than to do good to them. A clinician has a responsibility to benefit her patients, but she need not help others. The clinician, though, does have a more general responsibility to avoid harm even to those who are not her patients.

Paternalism

Paternalism describes an intervention that is done solely to benefit a person, but which that person has not chosen, or perhaps would not choose (there are different forms of paternalism). This sort of intervention is excluded by Mill’s harm principle. Failing to intervene (refusing to refer for abortion for example) can also be paternalistic. Because of the importance of the principle of respect for

autonomy the objection ‘you’re being paternalistic’ is generally taken to knock down a proposed action. The only justification for intervention should be that an autonomous individual has consented to it. However, paternalism is manifest in different forms and there is some sense of appropriate paternalism: “paternalistic” in an innocent, non-pejorative sense, namely that of “protective in a manner characteristic of parents”.³⁴ Others resist this claim, arguing that paternalism is always wrong.

Paternalism has been characterized further, to distinguish when paternalism may be appropriate, though the terms used are used inconsistently (see for example Dworkin³⁵ and Childress³⁶). Amongst other distinctions, some interventions involve autonomous persons, others non-autonomous persons, and sometimes the person’s autonomy is uncertain. Another distinction lies in separating pure paternalism (the intervention solely benefits the person involved) from impure paternalism (justified by benefits both to the person involved and to others – such as laws restricting smoking that benefit both the smoker and those around her). A further distinction is found when the intervention helps a person to achieve values they hold (soft paternalism) contrasted with hard paternalism where the person does not accept the goals of the intervention. Accepting these distinctions, it is clear that paternalistic interventions need not be wrong and the important point lies in deciding when paternalism is unjustified. The waters have been muddied still further by the inclusion of ‘maternalism’¹ and nudging, efforts to guide people in the right direction.

Rights

Rights are commonly, and increasing commonly, used in moral discourse. Codes or declarations of rights, having started with the UN Declaration of Human Rights in 1948 (provoked by the outrages of the Second World War) are increasing in number. Legal rights must be distinguished from moral or natural rights. Legal rights are enshrined in law, and are a matter for legal debate, for lawyers to resolve, and so are not the concern here. I will consider natural or moral rights that are independent of and go beyond the law, so that a person in a country where there is no right to free speech (for example) can say, ‘I have a right to speak’. This is an appeal to a human right, not a legal right. Some dispute the existence of human rights at all, most famously Bentham: ‘right with me is the child of the law ... a natural right is a son that never had a father’.³⁷

How could we know whether a claim is a human right or just a matter of convention, politeness or good manners? One response is to look to the codes or declarations of rights, but problematically the codes differ in their content. Furthermore, this response just pushes the question back one step: why are *those* rights in the declaration?

Regardless of these concerns, rights-based claims are common. The power of rights-based claims is in demanding access to healthcare for individuals and groups who are ignored or discriminated against. They are less useful

in clinical problems where conflicting rights may not clearly be resolvable. Diane Pretty (afflicted by multiple sclerosis) used the European Convention of Human Rights (her right to life, a prohibition from torture, and a right to private and family life alongside a prohibition of discrimination) to ask that her husband would not be prosecuted should he assist her in ending her life. The UK government argued successfully against her claimed rights.³⁸ Often, when rights come into conflict there is no clear way to decide which right should triumph and which will be vanquished.

Justice

The concept of justice used in medical ethics is that of distributive justice. A formal statement of justice is that equals should be treated equally, but the presence of significant morally relevant differences indicates individuals should be treated differently.

The weight then is placed on deciding which differences are morally relevant. Most would want to agree that age or gender are not relevant differences in determining medical interventions. Some diseases are a consequence of personal choice (for example, smoking-inflicted diseases, such as coronary artery disease). If we agree that people are responsible for the consequences of the choices that they make, and if we agree that personal choices are an important cause of some diseases, then (the argument runs) treatment for smokers should be assigned a lower priority, than treatment for (the same conditions) for non-smokers. And the reason for the lower priority is that smokers deserve a lower priority because they are at least partly responsible for their disease. There are several concerns with this argument. One response is that smokers are addicted to smoking: smoking is not the free, uncoerced ‘autonomous’ choice that people should be held responsible for. Furthermore, many smokers started smoking when they were young (often when they were less than 16 years old), at the age when children should be protected from unwise choices. Similar arguments run for other diseases that may be self-inflicted (such as those provoked by alcohol or obesity). These arguments for responsibility are less often used for other self-inflicted diseases (the orthopaedic injury of the sportsman) and the concern here is that we are then imposing our choice of values on individuals who should be free to make their own choices. Be this as it may, the concept of justice is that if people are to be treated differently then there should be clear reasons why this is justified.

Consequentialism

Consequentialist approaches to ethics distinguish the ethically correct course as that which produces the best outcomes. Consequentialists differ in the outcomes that they value. Utilitarianism is one form of consequentialism in which the outcome that matters is ‘utility’ taken as the balance between pleasure and pain. Utilitarians seek to maximize overall utility.

Consequentialism is implicitly appealing to many healthcare practitioners, in seeking the best outcome: when choosing between two treatments, it seems obvious to choose the intervention, which has the least mortality or highest function or whatever, both for an individual patient and for populations. In fact it is a puzzle to many why anything other than the best outcome should be sought (I will consider a contrasting approach – deontology – in the next section). A consequentialist approach underlies the use of quality adjusted life years (QALYs) in the allocation of limited healthcare resources. There are often ethical decisions to be made about what is the ‘best’ outcome.

Consequentialist approaches can differ in what is taken to be the best outcome. One difference lies in the outcome that is taken to be best. As an example, a longer life is usually taken to be a better outcome, but some would choose a life of 60 years of full health with a sudden end in contrast to a life of 65 years, the last 10 years of which are blighted by unremitting pain. Another difference lies in the way that outcomes are amalgamated. In maximizing consequentialism, the best outcome is sought with no attention to the distribution of the outcomes. Often in health promotion programmes those who are most likely to suffer from the disease are least likely to take advantage of the programme. If so the intervention with the greatest efficiency in reducing disease increases inequality.³⁹ Most would agree that inequality matters and that it should not be exacerbated by healthcare interventions. I do not intend to resolve the debate here, just to note that even if consequentialism is taken to be a preferred approach, there are important questions about which form of consequentialism should be adopted.

Deontological

Consequentialism is often contrasted with deontological approaches. Deontology has its origin in the Greek work *deon*, meaning duty. Deontological theories are those that characterize ethics in terms of duty: actions are obligatory, permissible or forbidden. The paradigmatic deontological approach (though not by any means the only one) is the well-worked out ethics of the Roman Catholic Church.

Deontological approaches can be seen in contrast to consequentialist theories. One criticism of consequentialist theories is that they are too demanding. In consequentialist approaches, an individual is obliged always to choose the action that will maximize the good. Consequentialists may recognize no distinction between acts and omissions. A person then should act in the best way for the overall outcome. If so a person may have no time for their own projects, indeed they almost cease to be a person (with characteristics and individual values) becoming a machine to produce the best outcome. In contrast a deontological approach is characterized by permissible and forbidden actions. Some actions are required (for example those of a parent in relation to their child), but the required actions are much less frequent than the forbidden actions. Because of this, the deontologist does not face the overwhelming demands of a consequentialist (see, for example, Singer⁴).

Another distinction between deontology and consequentialist theories is that consequentialism permits too much. If only consequences matter, then any action may be acceptable in pursuing the outcomes. An example of these fears is the well-worked transplant example. Imagine that a surgeon has two dying patients, whose lives could be saved by organ transplantation. Some consequentialists would allow (or even demand) the sacrifice of a randomly chosen individual whose organs could save the two (or more) lives.⁴⁰ Deontological approaches, in which some actions are impermissible, forbid the taking of an innocent life, whatever the potential gains.

Medical practice, in which doctors are guided or constrained by the guidance provided by the various official bodies, often seems to have a deontological underpinning.

The four principles approach (Beauchamp and Childress)

Beauchamp and Childress¹² developed and popularized the four principles approach, which has become the dominant paradigm in Western medical ethics. The four principles are: respect for autonomy; beneficence; non-maleficence; and justice. These have been considered individually. Although used to the greatest extent in medical ethics these four principles are claimed to underlie a common approach to ethics. As Gillon has it, ‘the four principles approach to ethics will be recognized to have far wider moral relevance than its application to health care ethics. Indeed I predict its increasing acceptance as the basis for a global ethics, compatible with and acceptable across the range of the world’s moral cultures, sensitively negotiating the delicate path between moral relativism and moral imperialism.’⁴¹

There are many other approaches that are advocated by their supporters; several have been mentioned already. There is insufficient space to discuss the other approaches in any detail. The important point is that although the four principles may seem to be the only approach, there are other approaches used to analyze the ethics of medicine. Introductions to the other approaches can be found in *Principles of Health Care Ethics*⁴² or in the Festschrift edition of the *Journal of Medical Ethics*⁴³ devoted to methods in ethics.

SOME PRACTICAL MATTERS IN MEDICAL ETHICS

Informed consent

Given the importance of autonomous choice, consent becomes crucial for medical interventions. In an early medico-legal case Cardozo stated, ‘Every human being of adult years and sound mind has a right to determine what shall be done with his own body; and a surgeon who performs an operation without his patient’s consent, commits an assault’.⁴⁴ For significant interventions, consent is usually written, giving proof that a consent discussion

took place (and perhaps in giving a signature the person recognizes a greater significance to the consent discussion) but what is important is the consent of the person – not the signature. Should someone withdraw consent, the document is no longer evidence of consent.

Consent requires a persistent sense of self with personal values, an understanding and knowledge of the available choices, and an ability to reflect on (and judge between) the options, and having done this, to communicate the decision. The person must have sufficient information about the available options. What counts as ‘sufficient’ information is disputed, but broadly it is the information that would affect the person’s choice, recognizing that different factors may be important to different individuals. There is a tension between an attempt to limit the information needed to make decisions easier for those on the boundaries of competence (to prevent people being overwhelmed by information), but also to provide more information (so that people are more fully informed). Consent suggests that the patient agrees to one of the options put forward by the clinician; true respect for autonomy requires negotiation and agreement and is perhaps better described as concordance.

Consent may be modified in various ways. Implied consent is not explicit. An example is when a patient pulls their sleeve up when informed a blood test is needed, though no formal consent discussion has taken place. Another form of consent is assumed consent, where interventions are assumed to have consent. Patients may have been informed by posters or by mailed information. Examples of assumed consent are to the use of data collected for other purposes, and to patients being examined by students. Here assumed consent is often not consent at all, but a lack of resistance or lack of dissent. A further modification of consent is deferred consent. In emergencies, the research subject may be unconscious and so unable to consent, or the intervention may need to be administered quickly allowing no opportunity for an informed consent discussion. Here deferred consent may be used. The question here is: what is the person consenting to when asked later on? Not to the intervention (which has already taken place) but to the use of their information, or to continuing participation in the research, if the intervention is continuing. And if so, then the justification for the research intervention at the time it starts is different from the justification offered by ‘true’ consent.

Consent is important in medical ethics, but some adults are unable to consent. They will be considered in the next section.

The incompetent adult

Some adults are not competent to make decisions about their own healthcare. The presumption is that adults are competent to make their own choices, but some adults are temporarily (perhaps through drugs or disease), and others permanently incompetent to make their own decisions. All attempts should be made to ensure that a person is most able to make decisions for themselves, perhaps by delaying decisions if there is a prospect that

competence may return. If not, decisions are made in a variety of ways, which have been discussed above.

The fact that a patient disagrees with a clinician’s proposed treatment does not in itself indicate that the patient is incompetent; a competent patient may disagree with a clinician. However, if disagreement over treatment is likely to harm a patient, then the patient’s competence may come into question (though it may not were he to agree with proposed treatment).

Children

Children range from a newly born baby, totally dependent on others, to adolescents on the cusp of competence who may fare perfectly well on their own and so have varied abilities. All are described as children. Not all children are incompetent to make their own medical decisions (in England and Wales this is established as the concept of Gillick Competence⁴⁵ and in the United States there is the concept of mature minors).

Children differ from others who are incompetent for a variety of reasons. Children grow towards personhood and the most important achievements of their lives, whereas most adult incompetents fall away from moral personhood: their achievements lie behind them. As well as this, parents play a particularly important role in their child’s life that is not matched by the role of relatives of grown adults. Importantly, the way that children are treated will affect, sometimes determining, the adult that the child becomes. Parents are offered broad latitude, though not complete freedom, in the way that they bring up their children.

Young children cannot be taken to be competent. The mainstream approach is that parents consent for treatment that is in their child’s interests, and the only treatment that should be offered is treatment that is in the child’s interests. But it is not so simple. Firstly there may be dispute about what treatment is in a child’s interests (an example is male circumcision, which some will claim is in a child’s interests though others deny this). Secondly, sometimes parental authority extends to the refusal of treatment that is unequivocally in a child’s interests (the requirement for parental consent for vaccination is an example of this). As children grow older, the approach to medical decisions changes so that the child’s views should be taken into account when decisions are taken, but medical decisions are still made by the child’s parents. And as children approach maturity, they may be recognized to be competent to make their own medical decisions.

I have already described problems with knowing a person’s interests, and because children have the potential to develop in many different ways, one response to this is to claim a ‘right to an open future’ for children.³⁴ children should mature with as many life choices as possible. One practical application is that interventions with momentous consequences should (when possible) be delayed until the child is able to make their own decision. But this is not always possible. Cochlear implantation provides an example. Two broad approaches can be adopted for deaf children. Conventionally, deafness is taken to be

a disability. Oralism encourages the use of spoken language. Hearing aids (and now cochlear implants) maximize the child's ability to hear, and are combined with intensive speech therapy. Sign language is banned in some cases, to encourage children to interact with spoken language. Some deaf children, particularly those with some hearing, achieve success with this route, but others, especially those with profound deafness, don't. The second strategy embraces Deaf culture and the Deaf World (with a capital 'D'), encouraging signing and rejecting spoken language. Deaf culture is celebrated. Communication is fundamentally different: imagine poetry in sign language. As a result there are two separate paths for deaf children: oralism or Deaf culture. The earlier a person starts to sign, the better their signing becomes and vice versa. Compounding this, those who have some hearing or use verbal communication may not be taken to be 'properly' deaf and so are excluded from the Deaf community. The reverse may also be true. In deciding how to rear their deaf child, Deaf parents are at some advantage. They have their own experiences, and they may have considered the possibility of a deaf child (and indeed some have chosen a deaf child*). A compounding problem is that the Deaf community may have expectations of the choices that Deaf parents should make (to preserve the Deaf community). Parents of deaf children have important choices to make at an early stage in their child's lives: 'Deaf people in the hearing world are always going to be at a disadvantage. So the question is whether people prefer to be marginal in a mainstream world, or mainstream in a marginal world and many people quite understandably prefer the latter.'⁴⁷ And the question must be answered when the child is young. An attempt to keep both options open – a right to an open future – is unlikely to lead to success in either option.

Research

Research is vital to maintain and advance scientific medical practice. Whereas interventions by clinicians are intended to benefit the patient in front of them, the aim of research is to further knowledge. Although research may benefit patients in the future, the advantage may not accrue to individual research participants. There are many examples in medical research, where the new 'better' intervention has worse outcomes than the traditional 'control' therapy (and indeed the point of therapeutic research is to determine which of the tested treatments is better).

Appropriate ethical standards in research are protected by the requirement that research should only take place with the consent of the research participant, and through an extensive system of research governance, policed by the healthcare practitioners' professional bodies (the GMC and the World Medical Association as examples), and the academic journals and universities and hospitals, and (in many countries) by the law. An important principle is that

research depends on the consent of the research participant. An influential statement dates from the Nuernberg War Crimes Trial: 'the voluntary consent of the human subject is absolutely essential'.⁴⁸ Since then it has generally been accepted that all research should be preceded by consent. Any variation to this requirement requires good reasons (for example, deferred consent may be acceptable in emergency situations where prior consent is impossible). This statement could be taken to exclude research participation by children, but an equivalent for children's participation is generally taken to be the consent of the child's parents and (if appropriate) the assent of the child.

As well as this, there are extensive systems of research governance, professional standards are often reinforced by the law. The Nuernberg standards for research were updated in the World Medical Association's Declaration of Helsinki (and are kept up to date by further revisions). The requirements are broad and include that research is reviewed before it starts, that the research is performed to standards to ensure the scientific validity of the findings, and that research participants are protected (as best they can be) from harm. As part of the review, the risks and benefits of the project to participants are assessed and minimized, and must be proportionate to the benefits of the research. An important part of the review is that patients should be involved in determining research priorities and designing trials.

There are different sorts of research, some involving medical interventions, perhaps with random allocation, some involving patients, but with more trivial interventions and some involving only identifiable information about patients. Different standards may be required for these different forms of research.

Sometimes the boundary between research and audit is unclear. Some projects are clearly research – for example, the random allocation of children to different fluid resuscitation regimes – but some projects are clearly audit – for example, monitoring post-operative mortality or infection rates. The distinction between research and audit is taken to be important because of the rigour of research governance. However, this may not be the important distinction. Merely because an activity is taken to be audit does not mean that it is ethically unproblematic, as audit may produce the same sort of ethical concerns (confidentiality, for example) as research. And the correct response is to recognize that research and audit should be carried out to the same standards.

The distinction between acts and omissions

A common view is that we are more responsible for the consequences of our acts than we are for our omissions. This may be why some believe that it is acceptable not to intervene towards the end of life ('passive' euthanasia) whereas an act to shorten life ('active' euthanasia) is often taken to be wrong. Others do not recognize the distinction between acts and omissions. Consequentialists judge actions by their outcomes, and so hold a person as

* 'A deaf lesbian couple in the United States deliberately created a deaf child. Sharon Duchesneau and Candy McCullough used their own sperm donor, a deaf friend with five generations of deafness in his family, to ensure that their child would be deaf.'⁴⁶

responsible for the consequences that follow from a failure to act as they do for those that result from actions. Rachels seeks to undermine what some see as the clear difference between acts and omissions. He asks us to imagine two uncles. Smith deliberately drowns his cousin in the bath in order to benefit from a large inheritance. In another family, Jones enters the bathroom to drown his cousin (to benefit from an inheritance) to see that his cousin has slipped, is submerged unconscious, and will drown if unaided. Jones merely stands by while his cousin drowns. Rachels asks, ‘Smith killed the child, whereas Jones “merely” let the child die ... Did either man behave better from a moral point of view?’⁴⁹

Despite Rachels’ arguments, there is a strong intuition that we are more responsible for our acts than our omissions. Why is this? It may be that there are other aspects that often go along with the distinction between acts and omissions, but that are separable from it. These include the fact that causation is often stronger for actions. Another difference between acts and omissions is the intention of the person involved. But the moral importance of intention can be questioned and our ability to know another’s intention must be questioned.

Perhaps the solution is that the distinction between acts and omissions is blurred. Ethics depends on many overlapping considerations and the distinction between acts and omissions is one, but only one, amongst many factors that need to be evaluated in assessing the morality of an action.

The doctrine of double effect

The doctrine of double effect (DDE) is sometimes invoked towards the end of life, allowing that interventions that may have adverse effects (and so that by deontology’s values are *always* forbidden) may be used if the bad results are *foreseen* but not *intended*. The paradigm case is the use of opiates towards the end of life to alleviate pain, whilst accepting that opiates may shorten life (a bad effect is foreseen but not intended). The origins of the DDE lie in Aquinas’ justification of murder in self-defence. For the DDE to be applicable, several conditions must be fulfilled: the act itself must be morally good or indifferent; the agent must not intend (but merely foresee) the bad effect; the benefit must not be obtained *by* the bad effect (DDE could not be invoked for euthanasia for a patient in severe pain, as the benefit occurs through the bad effect); and the final condition is that there is proportionality between the bad effect and good effect.

Although these may seem clear conditions, there are several problems with the DDE. How can the outcomes that are ‘intended’ be distinguished from those that are merely ‘foreseen’? The criticism is that the DDE is just sophistry: wordplay allows an unacceptable action to become acceptable.

Rationing and resource allocation

Rationing, or resource allocation decisions, recognizes that there are situations where treatment is not determined solely by the autonomous choice of the patient

(or the welfare of an incompetent patient) but that – at times – limited resources must be distributed in some way that is fair.

Resource allocation decisions need to be made at different levels. The highest (macro) level decisions involve decisions at governmental level regarding the total spending on health, and how much allocation within the whole of the health budget should be on geriatrics and how much on paediatrics, amongst many other decisions. The micro-allocation level involves direct clinical decisions at the level of individual patients. So an example would be the decision in a flu epidemic of which of two patients who need intensive care should be admitted to the single remaining critical care bed. There are other resource allocation decisions that must be made between these two levels.

Sometimes these decisions are made by default, or on the basis of historical priorities. In the UK, the National Institute for Health and Care Excellence (NICE) was established so that decisions about NHS resource allocation are made in a consistent and structured way. These decisions may be less pressing when healthcare is purchased and so distributed to those who are able to pay, but even in these systems during periods of limited resources, or excessive demand (such as a flu epidemic), decisions about resource allocation may be needed. There are a variety of ways in which these decisions can be made, none of which are agreed.

Truth-telling, deception, and disclosure of errors

Until recent times, medicine was practised paternalistically: clinicians often deliberately concealed diagnoses and treatments and were certainly less likely to inform patients. There was greater respect for expertise and alongside the power imbalance between doctor and patients, the expectations that patients would be fully informed and (on occasion) even told the truth were lower. But with acknowledgement of the importance of autonomous choice, truth-telling is fundamental to respect for people and consent. Consent is essentially meaningless if it is uninformed.

What then are the circumstances under which a commitment to truth-telling may be undermined? A relatively straightforward justification is when the context is entirely inappropriate. For example, if a clinician is in the supermarket and encounters a patient who asks, ‘My tests were okay, weren’t they Doc?’, the clinician may justifiably dissemble if they weren’t, and arrange an early appointment.

Another threat to honest communications comes from patient’s relationships. A patient may require that relatives are not informed of a diagnosis, sometimes to ‘protect’ them. Parents may sometimes not fully inform their children (of the risks of death or the unpleasantness of therapies) and may ask that the clinical team join in their deception. As parents play a fundamental role in the care of a child their requirements may seem reasonable in some circumstances (perhaps with younger children) but may seem wrong in other circumstances (with older children).

With deception, there is always the possibility of inadvertent disclosure by staff who are used to dealing with fully informed patients. The child themselves may see they are admitted to the oncology ward and ask what oncology is. Some clinicians may accept a passive role in failing to inform the child but cannot condone a direct lie. The relationship with the child will be destroyed if the clinician isn't honest and the lie is discovered, but the therapeutic relationship with the parents may be destroyed if clinicians refuse to join in the deception. In these situations it is sensible to explore the parent's reasons for withholding information from their child in order that any misunderstandings can be corrected. Many children understand more than their parents believe. Often both parents and child will benefit from the opportunity for a frank discussion with acknowledgement of the reality of the situation.

In a discussion of truthfulness, it is important to acknowledge that there are many steps between complete truth and a deliberate lie. It may be acceptable to fail to mention a complication (if it is rare or of minor importance) but a direct question about the same complication deserves an honest response. Although there is a fundamental commitment to full and honest disclosure, at times, as Higgs (a strong proponent of truth-telling) argues, 'unwavering honesty can seem as pathological as paternalistic concealment'.⁵⁰ In these situations a deviation from truthfulness demands explicit reasons.

An important part of truth-telling is that errors should be disclosed to patients when they have happened. This is for several reasons. Firstly, we should treat patients with respect, and this means that they deserve full information. This is how we would choose to be dealt with ourselves. A further reason is that, following medical accidents or an adverse outcome, many patients give their reasons for suing as the fact that no one would tell them what had happened. It is likely that giving patients full information at the time would prevent at least some of the malpractice lawsuits.

Confidentiality/privacy

Confidentiality is the requirement that the information that is disclosed in the course of healthcare consultations should remain confidential to the treating clinical team. This is justified by respect for the patient's autonomy and by the doctor's professional responsibilities and duties. There are also pragmatic justifications that if it were known that clinical teams did not keep information confidential then people would be cautious in disclosing information to clinicians that could be embarrassing or harmful. Without complete clinical information, diagnosis and treatment become more difficult.

Healthcare has become more dependent on technology, which has provided many challenges to confidentiality, with the development of computerized records adding the problems of loss or deliberate hacking of electronically stored information to concerns in confidentiality. As well as this, as healthcare is more often delivered by large teams and as healthcare governance teams extend the number of those who need (or believe that they need)

information, the demands in maintaining confidentiality are not as simple as they were in the past.

The right to confidentiality is not absolute and, if there are good reasons, confidentiality may be broken. Situations where it may be appropriate to breach confidentiality include those where there is a threat of harm to the patient or to others. If confidentiality is to be broken, it may be appropriate to negotiate the disclosure with the patient. Where the individual lacks capacity and is incompetent to make choices about their own healthcare, it is likely to be appropriate to disclose information in the patient's interests, but again the disclosure should be negotiated with the patient. The disclosed information should be limited to that which is necessary and no more, and should be to the appropriate authorities.

The threat of harm to a competent individual (and harm only to that person) is unlikely to justify disclosure of confidential information. However, disclosure of confidential information can be justified if there is the prospect of harm to another individual. Again there should be an attempt to negotiate disclosure with the person: they may agree. However, there may be situations where disclosure is justified, even when the person does not agree. Indeed, disclosure of confidential information is sometimes required by law; for example, the Abortion Act (1991) in the UK requires that the name and address of the woman is notified to the appropriate authorities. There are several other statutory obligations in the UK (listed by the GMC).⁵¹

Clinical ethics committees and consultation

In some situations, clinicians may be concerned about the ethics of a particularly complex clinical situation, or a novel clinical scenario. When ethical concerns appear, what can clinicians do? A first response is to discuss the circumstances and the focus of the concern with colleagues. Even just laying out the problem to another may lead to a solution, but if not, talking through the problem with clinical colleagues may provide a solution to the ethical concerns. Another approach is to consult official guidance and policy. In the UK these include sources such as the Royal Colleges, who oversee education, or the institutions responsible for licensing doctors (in the UK the GMC offers useful advice in pamphlets that are available on its website) and the medical societies (the British Medical Association in the UK, for example, has an ethics department, and the specialist societies often have written guidance and policies). However, the guidance is rarely directly applicable to individual situations and needs to be interpreted in application to clinical problems.

More recently the importance of clinical ethics advice has been acknowledged and clinical ethics has developed as a specialism. Many hospitals have appointed clinical ethics specialists and have established clinical ethics committees.⁵² These are often distinct from the longer-established research ethics committees. The committees may have several roles, but one important role is to advise on clinical case consultations. Other roles may involve

policy development, education and the organizational ethics of the hospital. Usually there is a broad representation of healthcare staff on the committee, alongside members from those outside the organization. Specific disciplines that are often included are lawyers and religious representatives such as chaplains or leaders of other faiths. Some committees encourage the participation of patients and their families when considering ethical problems, and indeed it would seem wrong to fail to canvass the opinion of the patients and those close to them.

CONCLUSIONS

In this chapter I have given a brief introduction to medical ethics. Medical ethics is a large and developing field, in which some of the more outlandish claims made by some who are remote from clinical practice may cause clinicians to dismiss medical ethics as irrelevant to clinical practice. This is the wrong response. The correct response when challenged by conclusions that seem to be incorrect is to engage with

the arguments that are given, to work out the flaws in the arguments, and so demonstrate the weaknesses of the mistaken claim. It is also useful to rehearse the arguments of one's own position, making sure that these are sufficiently strong. Good arguments for one's own position are insufficient in their own right: if each side has good arguments to support their position, but neither can demonstrate a flaw in the opposing arguments, there is insufficient reason to come to a conclusion. Often it is through the conflict of two claims that a third, more defensible solution is found.

Should the reader wish to study ethics further, several useful texts are given in the reference list. *Medical Ethics and Law: The Core Curriculum*¹⁰ is a sound introductory text. Beauchamp and Childress¹² book is almost the bible of medical ethics, but advocates strongly for only one approach – the four principles. The second edition of the *Principles of Health Care Ethics*⁴² is intimidatingly large, but magisterial and comprehensive. There are several short courses in ethics and many universities have developed Master's level degrees in medical ethics, often combined with law, for further study.

KEY POINTS

- The methods used in ethics generally – and so in medical ethics – are different from the methods of evidence-based medicine.
- Respect for the informed autonomous choice of a patient is a dominant approach in western medical ethics.
- The patient's (and patients') welfare, well-being or interests are an important factor in medical decisions for incompetent patients, children and populations.

SEARCH STRATEGY

Data in this chapter are based largely on the author's long experience as an expert witness and on landmark legal judgements, some of which are alluded to in the text.

INTRODUCTION

The last two decades have seen some changes in how claims of clinical negligence are decided but the developments in other fields such as consent, confidentiality and clinical performance have been much more significant. The medical profession in general has been put in the spotlight by very major events that were subject to intense media interest. The Bristol Royal Infirmary Inquiry into unacceptable complication rates in the paediatric cardiac surgery unit and the events following the trial of Harold Shipman, who was convicted of murdering an unknown number of his patients, have changed the way that the public views the medical profession. The response from politicians has been to try to tighten the legal framework in which doctors practise so that the public can be reassured that such events can never happen again.

The law differs in different jurisdictions, even within the UK, but most of the principles are the same. The first major subdivision is into criminal law and civil law. In criminal law, the state prosecutes an individual or an organization (the defendant) alleging breach of a law or statute. If the case is proven, the individual or organization is subject to a sentence, often a fine or a custodial term of some kind. In civil law, one individual or organization (now known as the claimant) brings a suit for

damages against a defendant and seeks redress from that defendant. Ideally, the damages would exactly redress the loss suffered by the claimant. For instance, a claimant proved to have been swindled out of his car by a defendant might be happy merely to have his car back. In medical negligence cases, it is manifestly impossible to restore negligently caused losses so the damages are monetary. There are three important forms of monetary damages in clinical negligence: general; special; and punitive or exemplary.

General damages are those awarded to compensate the successful claimant for pain and suffering. Special damages are those awarded to take account of loss of income, special nursing needs and so on, arising from the negligence. Punitive damages are exactly what they say they are: damages awarded to the claimant to punish the negligent defendant. These are similar in a way to a fine in criminal cases but are not awarded in clinical negligence cases in the UK where most defendants have insurance to cover any damages awarded against them.

Civil and criminal processes differ in two other important ways: in the standard of proof required and in the influence of statutes. In criminal cases, the standard of proof is 'beyond reasonable doubt', which is often taken to imply a probability of guilt of at least 95%. In civil cases the standard of proof is 'on the balance of probabilities' which means greater than 50% probability. The source of the criminal law is founded in the common law and on statutes passed by Parliament and European law.

Statutes, precedent and European legislation state what actions constitute criminal behaviour. In the course of a criminal trial, counsel may well cite a precedent of what has been said and what decisions were made by courts in the past in similar cases. In a civil trial, there may be no statute that has any relevance to the questions to be decided so the decisions are based almost entirely on what happened in previous cases. This is referred to as the common law. The common law is in a state of continuous development as civil cases are tried by high courts, such as the Court of Appeal and the House of Lords, which can introduce subtle changes in decisions that then become the common law. Much argument may then occur as to what exactly their Lordships meant. Was what they said in a previous case relevant to the one currently being tried? Even more debatable is whether or not the important remark was part of a judgement or some sort of subjunctive aside to the judgement in the form of ‘if this case had been similar to case A then I would have decided as follows’. The next section of the chapter (see ‘Causation’, below) illustrates exactly how one word in a judgement can be important when the case referred to as *Bolitho*¹ is considered.

Besides major sections devoted to clinical negligence and the duties of an expert medical witness, this chapter examines the two most common issues raised via a medical indemnity organization’s helpline: consent and the doctor’s duty of confidentiality. The criminal law and the role of the coroner as they are likely to apply to surgeons in their professional activities are discussed. The duties of a consultant surgeon as a doctor and the mechanisms that are or shortly will be in place to ensure that these are complied with are described and the additional duties of that consultant as a trainer are also mentioned.

TORT

Before discussing clinical negligence and consent issues, it is relevant to review the legal principle on which these are largely based. This is the law of tort or wrong done by one party to another. The two forms of tort that are relevant to surgeons are negligence, and assault and battery.

There are four essential elements of the legal tort of negligence:

- there must be a duty of care
- there must be a breach of that duty
- harm must have occurred
- the breach must have caused the harm.

Negligence occurs when party A is considered to owe a duty of care to party B, to have breached that duty and, as a result, harm has come to B. It must be shown that A could reasonably have foreseen that the breach might cause the harm. For instance, a driver travelling quickly on a country road should have it in mind that there might be a cyclist just around the corner. A second important aspect of negligence on which many clinical negligence cases fail is causation. This works on the so-called

‘but for’ test. It must be proved that, ‘but for’ the breach of duty by the defendant, the damage suffered by the claimant would not have occurred.

Assault is the threat of physical violence, and battery is any unlawful touching or physical contact of one person by another. Only with consent does a medical examination become lawful. Without consent, approaching a patient with a shining Lack’s tongue depressor at the ready is an assault and using it to depress the tongue is a battery. Although the act of opening the mouth probably implies consent, the patient has the option of lodging a civil claim alleging battery or even of reporting a possible criminal battery to the police. It is important to note that civil actions for battery, unlike those for negligence, do not require that there has been any harm. Patients seeking damages for lack of adequate consent can sue either in negligence (where the ‘but for’ test applies but consent must be truly informed) or in battery (where causation is not an issue but a much less rigorous consent is enough to refute the allegations).

NEGLIGENCE

Standard of skill and care

In deciding negligence the claimant must establish first the four essential elements of tort.

To establish a duty it is necessary for a doctor/patient relationship to be in existence. There is no Good Samaritan law in the UK, and doctors only have a legal responsibility to people they have agreed to treat. In general practice the agreement arises by virtue of accepting a patient onto one’s list. In a hospital setting, the agreement arises either out of the doctor’s terms and conditions of employment or, with private patients, as a result of contract.

Patients tend to be seen by several different doctors and, therefore, the question ‘who owes the duty of care?’ may be a pertinent one. In the National Health Service (NHS), the employing authority will usually be named as first defendant as it would be liable to pay damages arising from any successful action by virtue of the principle of vicarious liability. Individual doctors may then be named as subsequent defendants.

An unresolved issue is who should be sued if a patient is placed on a waiting list but suffers additional damage in the time it takes to receive a first appointment. Is the defendant the referring GP, or the authority, or the NHS Trust at whose clinic the patient is awaiting an appointment?

The standard of care is that of the reasonably skilled and experienced doctor. The appropriate test, known as the *Bolam (Bolam v. Friern Hospital Management Committee)* test,² states that it is:

the standard of the ordinary skilled man exercising and professing to have that special skill. A man need not possess the highest expert skill; it is well-established law that it is sufficient if he exercises the ordinary skill of an ordinary competent man exercising that particular art.

The standard of care relates to the specialty in which the doctor practises. A GP will not be required to possess the skills of a specialist. An inexperienced doctor cannot rely on his lack of experience as a defence to alleged negligence (*Wilsher v. Essex Area Health Authority*).³ However, a junior doctor may discharge his duty by seeking the help of a superior.

While a doctor is under a duty to keep him- or herself apprised of developments in his area, this is subject to the bounds of reasonableness. Failure to read one article, which might have prevented the negligent act, could be excusable, while failure to be aware of new techniques that have become widespread may be inexcusable (*Crawford v. Board of Governors of the Charing Cross Hospital*).⁴

A doctor will not be negligent simply because he acted in a way that another doctor would not have done. The Bolam test establishes that a man is not negligent if he is acting in accordance with a practice merely because there is a body of medical opinion that would take a contrary view, provided there is a responsible body of opinion that supports the practice. A body of opinion must consist of at least two people. This statement has recently been qualified by the case referred to as Bolitho (*Bolitho v. City and Hackney Health Authority*).¹

Causation

In Bolitho, a registrar in paediatrics was accepted to be in breach of her duty of care by failing to visit an infant with breathing difficulties. Her defence was that, given the clinical circumstances at the time she should have visited, she would not have intubated the infant. The Court of Appeal had found that the failure to attend the infant constituted negligence. The House of Lords heard opposite expert opinions, one asserting that there was a body of opinion that would undoubtedly have intubated in those circumstances and the other that there was also a responsible body of opinion that would not have intubated. Their Lordships then reversed the judgement saying that the defendant's assertion that she would not have intubated, a practice supported by a reasonable body of opinion, meant that on the balance of probabilities the brain damage would have occurred even if the registrar had visited. The causal link from the failure to discharge her duty of care by visiting the patient to the harm suffered was therefore broken so no negligence could be proved.

Bolitho is important because it clearly brings Bolam into the field of causation and also because of the dissenting judgement of Lord Browne-Wilkinson. Referring to the reasonable body of medical opinion that would allow a Bolam-based defence, Lord Browne-Wilkinson said, 'The use of these adjectives – responsible, reasonable and respectable – all show that the court has to be satisfied that the exponents of the body of opinion relied on can demonstrate that such opinion has a logical basis' (our emphasis). Later in judgement he qualified this by saying, 'it will very seldom be right for a judge to reach the conclusion that views genuinely held by a competent medical expert are unreasonable'. It is not yet clear how these comments will be used as precedents for future cases but

they certainly will be. An example might be the practice of stripping all the mucosa from a vocal cord in Reinke's oedema. There may still be a body of expert opinion that would condone the practice but, in view of our knowledge of the physiology of the superficial lamina propria, is it logical to operate in this way and can that body of expert opinion be considered responsible?

Proof of medical negligence

The onus lies upon the claimant to prove that the surgeon's negligent treatment caused the injury. It is not sufficient simply to prove that the surgeon's actions were reprehensible or even reckless if the claimant cannot go on to show that their injury is directly attributable to the surgeon's poor performance. Hence, while it was clear that a casualty officer was in breach of his duty of care when he failed to examine a patient attending his department with the obvious signs of poisoning, there was a complete defence (*Barnett v. Chelsea & Kensington Hospital*)⁵ when it was shown that there was no antidote to the poison taken by the patient. This is similar to the reasoning in Bolitho above, although that case was much more complicated than Barnett. In Barnett, it was a straightforward and uncontested statement that the workmen who had accidentally ingested arsenic in their tea were doomed whether or not they received medical attention. In Bolitho the courts had to decide whether or not, on balance of probabilities, the hypoxic brain damage would have occurred even if the registrar had visited the child.

The standard to which the claimant must prove his case is on the balance of probabilities. This means that the claimant must show that his version of events and expert analysis are more likely to be true than those put forward by the defence. If the case for each side is evenly balanced then the claimant will fail. Hence, where a patient suffers a nerve palsy that could equally have been due to negligence, or could have occurred as an inherent risk of the operation even when performed with proper skill and care, the claimant's case will fail in the absence of some item of evidence to tip the scales in favour of negligence (*Ashcroft v. Mersey Regional Health Authority*).⁶

An apparent reversal of the burden of proof can occur where the likelihood of negligence is so obvious that it 'speaks for itself' (*res ipsa loquitur*). In other words, a defendant may find that he is obliged at least to provide an explanation of the patient's injury that is consistent with reasonable care having been taken, even where the claimant has no positive evidence of negligence, where:

- there is no evidence as to how or why the accident occurred
- the accident is such that it would not occur without negligence
- the defendant is proved to have been in control of the situation in which the accident occurred.⁷

The doctrine first evolved in simple personal injury cases concerning falling objects (*Scott v. London & St Katherine's Docks*,⁸ *Byrne v. Boadle*⁹ and *Pope v. St Helen's Theatre*¹⁰),

but has obvious attractions to a claimant in a medical case, where there may well be very real uncertainty as to how an injury came about, and where the often unconscious patient is entirely under the control of the medical team. Despite the fact that it is often pleaded, in England the doctrine has more often been conceded than litigated in medical cases, and so its ambit is unclear.¹¹ In practice the courts are reluctant to apply a doctrine derived from the relatively simple ‘bumps and thumps’ of stevedoring to the complex issues of causation found in medical litigation. It has been said (*Girard v. Royal Columbian Hospital*¹²):

*The human body is not a container filled with a material whose performance can be predictably charted. ... because of this medical science has not yet reached the stage where the law ought to presume that a patient must come out of an operation as well or better than when he went into it.*¹²

Thus, as a matter of law, the onus of proving negligence will almost always fall on the claimant, although in cases where there is a strong and obvious inference of negligence from the very facts themselves (e.g. a retained swab (*Mahon v. Osborne*)¹³ or where the claimant woke from his anaesthetic with the septic finger still attached and an adjacent one in the bucket¹⁴) the defence may well find that onus discharged unless they are able to provide some alternative theory, not involving negligence, to answer the claimant’s case.

Damages

A claimant having established negligence, and having proved injury as a consequence, the question turns to the assessment of the compensation to be paid. The court must award a sum of money that will, as nearly as possible, put the injured person in the same position as he would have been had he not been injured (*Livingstone v. Rawyards Coal Company*).¹⁵ In some jurisdictions (notably the United States) an element of punitive damages may be awarded. Such an approach has been rejected in England and Wales (*Kralj v. McGrath*)¹⁶ and the rest of the UK for mere inadvertent negligence.

Damages are broadly classified into two categories: general damages and special damages.

GENERAL DAMAGES

These include damages for pain, suffering and loss of amenity. This is the aspect of the claimant’s loss that is not ascertainable by a mathematical calculation of economic loss and, in the past, was determined by a jury (*Ward v. James*).¹⁷ Juries were effectively abolished in personal injury trials in the mid-1960s. While the level of general damages will depend on the claimant’s circumstances, and the suffering which the particular injury has caused the individual, a general bracket for a particular injury will be determined with reference to awards (adjusted for inflation) from previously decided cases. Obviously, it is impossible to ‘compensate’ someone for loss of a limb or for a

life of continual pain so the awards are essentially conventional figures. As a guide, the current conventional figure for injuries of the utmost severity is between £150 000 and £170 000, and so injuries of lesser significance will be a proportion of that ‘maximum’.

SPECIAL DAMAGES

These are the specific ‘out-of-pocket’ monetary expenses and losses the claimant has incurred up until the date of the trial. These will include loss of earnings, medical expenses, travel costs and the cost of any special equipment consequent upon the injury. Often there will be a claim for losses expected in the future. (Future loss is technically an item of general damages as its assessment is uncertain and it was formerly a matter for the jury to determine. As a matter of practice, the calculation of future loss is inseparable from that of past loss, many of the same arguments rehearsed in both, and one flows naturally to the other.) The amount of money at issue will depend almost exclusively on the particular circumstances of the claimant (*Lim v. Camden Health Authority*),¹⁸ guided by the principle that a claimant should only recover what he has lost as a result of the injury. He must prove that his expenditure was (or will be) reasonably necessary, and that his needs cannot be met more cheaply by other reasonable means.

As a rule, English law seeks to compensate a claimant by way of a single lump sum award. This creates obvious problems where a claimant is likely to remain unemployed or requires continuing care for many years in the future. The only certain result is that the claimant will be either under- or overcompensated, depending on how circumstances unfold. This problem has not been solved, but ameliorated in certain cases. Where a claimant suffers a condition that may deteriorate significantly in the future, rather than receive a small sum to represent the risk, they can apply for an order for ‘provisional damages’, which leaves it open to the claimant to come back to court at a later date.¹⁹

In very large claims where the claimant’s life expectancy will determine the level of the award, the risk can be borne by an insurance company by the purchase of an annuity. This is known as a ‘structured settlement’.

Dealing with medical negligence claims

What happens when a surgeon is sued?²⁰ The 86th update of The Civil Procedure Rules 1998²¹ came into effect on 3 October 2016. They require that, in cases of clinical disputes, a pre-action protocol be followed. This sets procedures and time limits for various stages of the process of being sued. There are also recommendations for Trusts about how they should respond to a claim and what processes should be in place to ensure that they are able to respond in an appropriate and timely way. In effect, the pre-action protocol will penalize a Trust that has such a poor clinical governance structure that it is unable to respond to a claim in a relatively short time.

What the individual consultant surgeon will experience if his patient sues him alleging negligence will differ in

some ways, depending whether the patient was a private patient or an NHS patient. The first stage of the proceedings is the same: the patient, having found some means of financial support for his or her claim against the healthcare provider (a matter outside the remit of this chapter but considerably more difficult than formerly) will request, via a solicitor, release of notes. In private practice, the consultant will need to release these notes himself and is wise to check with his anaesthetist, the private hospital and other doctors involved in the secondary care that they will do the same. The consultant would be most unwise at this stage if he did not inform his medical indemnity organization and seek their help and advice. If the case is an NHS one, the matter must be referred to the Trust's legal department immediately. If the clinical governance system in the Trust is working well, there is a good chance that the events have already been reported to the legal section via an incident form and that contemporaneous statements have already been taken and filed in preparation for a potential claim. Alternatively, the claimant may already have used the NHS complaints procedure so all the statements from that will be available. A Trust is vicariously liable for the actions of its employees and so the legal department should take over all further responses to solicitors and communication with the defendant legal team. Both Trusts and independent practitioners have 40 days to provide the copy medical records and failure to meet this deadline will prejudice any defence.

The potential claimant's solicitors will now obtain an expert report on the medical records with examination of their client, if appropriate, and can decide whether or not the claim has merit. If it has, they will serve a letter of claim on the healthcare provider setting out a summary of facts, the main allegations of negligence, description of injuries and an outline of losses. This may include an offer to settle. The defendant organization or individual must provide a reasoned answer within three months of receipt.

In addition, the defendant's solicitors will be concerned to obtain guidance from experts swiftly and, once received, be able to form an initial view about whether or not the claim is defensible. The assessment of a claim at this stage will be facilitated by recent rule changes that have been made concerning the conduct of personal injury actions, including medical negligence litigation. These changes require that at the time of service of a writ, a claimant must also submit a medical report setting out the claimant's condition and prognosis, together with a Schedule of Special Damages said to result from any alleged negligence. Traditionally, such information was not available until much later in the litigation process. The change has resulted in a defendant's solicitors being able to assess the potential value of a claimant's claim at an early stage. Accordingly, following that initial expert opinion, a settlement can be proposed early in the proceedings on behalf of the otolaryngologist, if appropriate.

If settlement is desired but cannot be negotiated between the solicitors, then the solicitors acting for the otolaryngologist may try to settle the claim by what is known as a 'payment into court'. In making a payment into court, the defendant can make an assessment of the

damages that might be awarded in due course at trial, if negligence is established. If the trial judge awards a sum higher than the level of the payment in, the claimant will receive his or her costs in the usual way. If, however, the sum awarded is the same or a lesser sum then, as a general rule, all costs of the action, including the defendant's costs after the payment into court, must be borne by the claimant. The claimant has 21 days to decide whether or not to accept the payment in. Thereafter the costs conservancies will operate. In cases where the claimant is legally aided, this device is of more limited assistance to a defendant. In other circumstances, there may well be a strong incentive to a claimant to accept a payment into court through fear of being prejudiced on costs in this way.

Following the service of a defence, in response to allegations contained in the statement of claim, both parties may raise requests for further information about their respective pleadings, and the claimant may choose to file a reply to the defence.

Directions concerning the conduct of a claim will be given by the court, usually after the pleadings are completed. In the High Court, a formal hearing will take place to consider these directions, but in personal injury actions brought in the County Court, a series of so-called automatic directions is given by the court. These are rarely, if ever, appropriate in medical negligence cases and it is therefore usual for the parties to apply to the court for specific directions to be given. These directions will provide for, among other things, the disclosure of witness statements as to fact and expert reports. It is usual for witness statements to be disclosed, followed shortly thereafter by expert reports, in order that experts can consider this information available from the other side in preparing the report. The exchange of both statements and reports gives a further opportunity for review of the case, both by claimant and medical defendant. At this stage the claimant may realize that the claim is weak and the case may be discontinued. Equally, the defence may feel that the case is not defensible and settlement negotiations or a payment into court may follow.

TRIAL AND PREPARATION FOR TRIAL

If the exchange of witness statements and expert reports does not promote the settlement of a claim, then the case proceeds towards trial. In medical negligence actions, a fixed date for trial will usually be given by the court because of the significant number of clinicians who may have to make themselves available, either as experts or as witnesses of fact.

By way of preparation for trial, both parties should arrange conferences with counsel in order to review the case in detail, and ensure all preparations are complete. If the defence considers that the case should be settled, or there are certain aspects of the case where a defendant may be vulnerable, a payment into court may be made. The payment in may be limited to those aspects of the claim where the defendant could be found liable. The claimant has 21 days within which to accept the payment in before the penalty of costs starts to run. As a significant

proportion of the costs of an action result from the trial itself, the defendants are usually anxious to make any payment into court before 21 days in advance of the trial. Thereafter bundles of documents must be prepared for use in the court by all parties, which will include the pleadings, medical records, witness statements and expert reports.

A proportion of cases are settled literally at the doors of the court, the last opportunity for compromise before further significant costs of trial are incurred.

If no compromise can be reached, the trial will commence with an explanation of the case to the judge by counsel for the claimant, setting out the relevant events and the nature of the allegations. The claimant's counsel will then call witnesses of fact, usually followed then by expert witnesses. Each witness will be cross-examined in turn by the defence, and then re-examined by claimant's counsel if necessary. When the claimant's evidence has been called, the defence case is then put in the same way, and usually in the same order.
