Psychiatric Mental Health Nursing

Concepts of Care in Evidence-Based Practice

Mary C. Townsend
Karyn I. Morgan

STEP #1
Build a solid foundation.

Communication Exercises let you practice your communication skills with vignettes and questions that prepare you for clinical and practice.

Communication Exercises

1. Hal, a patient on the psychiatric unit, has a diagnosis of schizophrenia. He lives in a halfway house, where last evening he began yelling that "aliens were on the way to take over our bodies! The message is coming through loud and clear!" The residence supervisor became frightened and called 911. Hal tells the nurse, "I'm special! I get messages from a higher being! We are in for big trouble!"

One of the Quality and Safety in Nursing Education (QSEN) criteria identified by the Institute of Medicine (IOM) (2003) stresses that the patient must be at the center of decisions about treatment (patient-centered care), and this type of assessment tool provides an opportunity to actively engage the patient in describing what medications have been effective or ineffective and identifying side effects that may impact willingness to adhere to a medication regimen.

Quality and Safety Education for Nurses (QSEN) Activities help you attain the knowledge, skills, and attitudes required to fulfill the initiative's quality and safety competencies.

NEW! "Real People. Real Stories" features interviews with patients to bring their experiences to life.

MOVIE CONNECTIONS

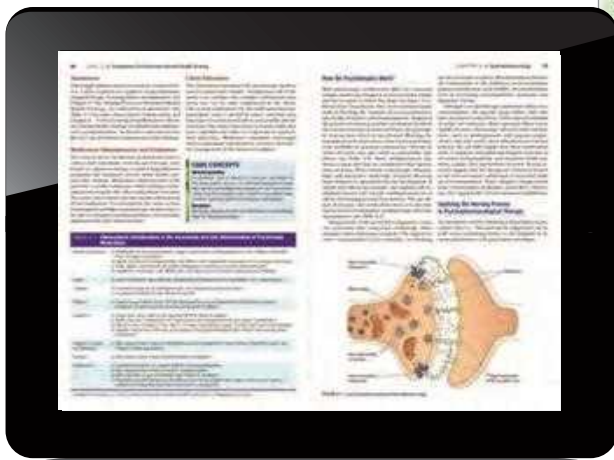
I Never Promised You a Rose Garden (schizophrenia) · *A Beautiful Mind* (schizophrenia) · *The Fisher King* (schizophrenia) · *Bennie & Joon* (schizophrenia) · *Out of Darkness* (schizophrenia) · *Conspiracy Theory* (delusional disorder) · *The Fan* (delusional disorder)

Movie Connections list films that demonstrate the conditions and behaviors you may not encounter in clinical.

Table 24-4 | CARE PLAN FOR THE CLIENT WITH SCHIZOPHRENIA

NURSING DIAGNOSIS: DISTURBED SENSORY PERCEPTION: AUDITORY/VISUAL
RELATED TO: Panic anxiety, extreme loneliness, and withdrawal into the self
EVIDENCED BY: Inappropriate responses, disordered thought sequencing, rapid mood swings, poor concentration, disorientation

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client will discuss content of hallucinations with nurse or therapist within 1 week. **Long-Term Goal** • Client will be able to define and test reality, reducing or eliminating the occurrence of hallucinations. This goal may not be realistic for the individual with severe and persistent illness who has experienced auditory hallucinations for many years. A more realistic goal may be: • Client will verbalize understanding that the voices are a result of his or her illness and demonstrate ways to	1. Observe client for signs of hallucinations (listening pose, laughing or talking to self, stopping in midsentence). Ask, "Are you hearing the voices again?" 2. Avoid touching the client without warning him or her that you are about to do so. 3. An attitude of acceptance will encourage the client to share the content of the hallucination with you. Ask, "What do you hear the voices saying to you?" 4. Do not reinforce the hallucination. Use "the voices" instead of words like "they" that imply validation. Let client know	1. Early intervention may prevent aggressive response to command hallucinations. 2. Client may perceive touch as threatening and may respond in an aggressive manner. 3. This is important to prevent possible injury to the client or others from command hallucinations. 4. It is important for the nurse to be honest, and the client must accept the perception as unreal before hallucinations can be eliminated.

Therapeutic Communication Icon identifies helpful interventions and guidance on how to speak with your patients. Look for this icon in Care Plan sections.


A FREE ebook version of your text is available with each new printed book to make studying and reviewing easier. Use the access code on the inside front cover.

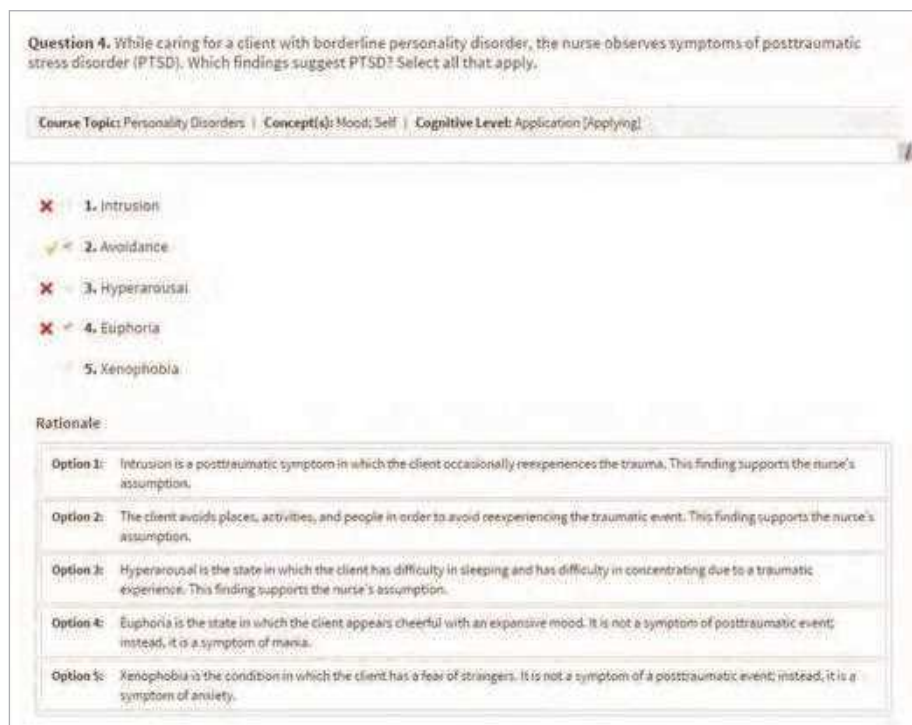
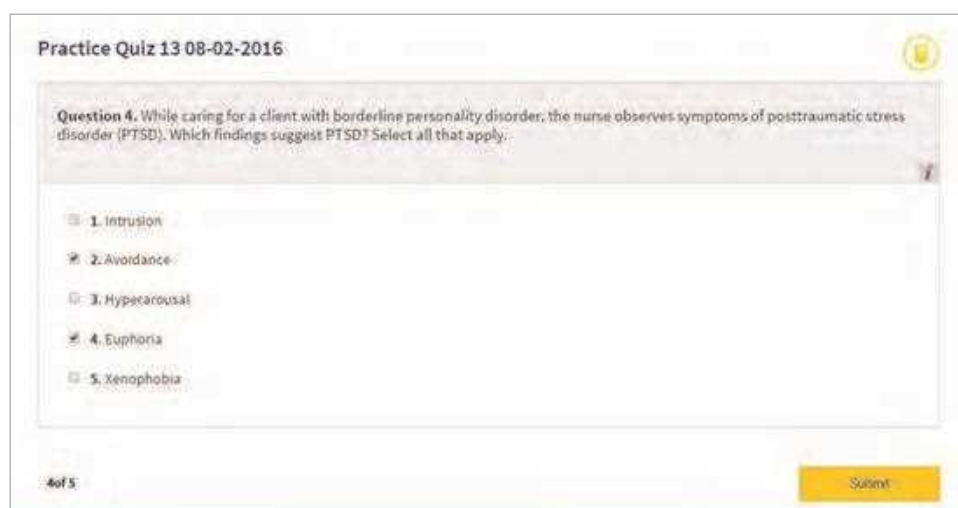
LEARNING

ASSESSING

STEP #2

Practice in a safe environment.

Clinical Scenarios on www.Davis*Plus*.com walk you through the nursing process with client summaries, multiple-choice questions with rationales, drag- and drop activities, and so much more.




STEP #3
Study smarter, not harder.

Davis Edge is the interactive, online Q&A review platform that provides the practice you need to master course content and to improve your scores on classroom exams. Access it from a laptop, tablet, or mobile device for review and study on the go.

Practice Quiz 13 08-02-2016

Question 4. While caring for a client with borderline personality disorder, the nurse observes symptoms of posttraumatic stress disorder (PTSD)? Select all that apply.

☐ 1. Intrusion
☑ 2. Avoidance
☐ 3. Hyperarousal
☑ 4. Euphoria
☐ 5. Xenophobia

4 of 5   Submit

Question 4. While caring for a client with borderline personality disorder, the nurse observes symptoms of posttraumatic stress disorder (PTSD). Which findings suggest PTSD? Select all that apply.

Course Topic: Personality Disorders | Concept(s): Mood; Self | Cognitive Level: Application [Applying]

✗ 1. Intrusion
✓ ✓ 2. Avoidance
✗ 3. Hyperarousal
✗ ✓ 4. Euphoria
   5. Xenophobia

Rationale

Option 1:	Intrusion is a posttraumatic symptom in which the client occasionally reexperiences the trauma. This finding supports the nurse's assumption.
Option 2:	The client avoids places, activities, and people in order to avoid reexperiencing the traumatic event. This finding supports the nurse's assumption.
Option 3:	Hyperarousal is the state in which the client has difficulty in sleeping and has difficulty in concentrating due to a traumatic experience. This finding supports the nurse's assumption.
Option 4:	Euphoria is the state in which the client appears cheerful with an expansive mood. It is not a symptom of posttraumatic event; instead, it is a symptom of mania.
Option 5:	Xenophobia is the condition in which the client has a fear of strangers. It is not a symptom of a posttraumatic event; instead, it is a symptom of anxiety.

Assignments are made by your instructor. Or, create your own practice quizzes to review before an exam.

Question 1. While communicating with a client, the nurse finds that the client spends more than 1 hour folding and arranging clothes five times a day. Which nursing intervention would be beneficial to the client in this situation?

Course Topic: Anxiety, Obsessive-Compulsive and Related Disorders | **Concept(s):** Cognition; Mood; Assessment; Critical Thinking | **Cognitive Level:** Application [Applying]

1. Distract the client with other activities.
2. Report to the primary health-care provider.
3. Discuss the triggers provoking this behavior.
4. Administer antianxiety medication to the client.

Rationale

Option 1:	Distracting the client with other activities does not prevent ritualistic behaviors.
Option 2:	The nurse should report to the primary health-care provider if the client's condition is painful and self-mutilating.
Option 3:	The client should first learn to recognize the precipitating factors to avoid the anxiety. Therefore, the nurse should discuss the anxiety-provoking triggers with the client that precipitates the ritualistic behavior.
Option 4:	Administering antianxiety medications provides relief from the immobilizing effects of anxiety.

Comprehensive rationales explain why your responses are correct or incorrect. Page-specific references direct you to the relevant content in *Psychiatric Mental Health Nursing.*

The Success Center offers a snapshot of your progress and identifies your strengths and weaknesses.

The Feedback Report drills down to show your performance in individual content areas. It's easy to create new practice quizzes that focus on your areas of weakness or to select the topics or concepts you want to study.

To the Instructor

Currently in progress, implementation of the recommendations set forth by the New Freedom Commission on Mental Health has given enhanced priority to mental health care in the United States. Moreover, at the 65th meeting of the World Health Assembly (WHA) in May 2012, India, Switzerland, and the United States cosponsored a resolution requesting that the World Health Organization, in collaboration with member countries, develop a global mental health action plan. This resolution was passed at the 66th WHA in May 2013. By their support of this resolution, member countries have expressed their commitment for "promotion of mental health, prevention of mental disorders, and early identification, care, support, treatment, and recovery of persons with mental disorders." With the passage of this resolution, mental health services may now be available for millions who have been without this type of care. More recently, national initiatives have sought to address the growing crises of deaths related to suicide and opiate overdoses. Mental health and mental illness continue to gain attention globally in the wake of these and other critical issues but much still needs to be done to reduce stigmatization and premature loss of life in this population.

Many nurse leaders see this period of mental healthcare reform as an opportunity for nurses to expand their roles and assume key positions in education, prevention, assessment, and referral. Nurses are, and will continue to be, in key positions to assist individuals to attain, maintain, or regain optimal emotional wellness.

As it has been with each new edition of *Psychiatric Mental Health Nursing: Concepts of Care in Evidence-Based Nursing*, the goal of this ninth edition is to bring to practicing nurses and nursing students the most up-to-date information related to neurobiology, psychopharmacology, and evidence-based nursing interventions. This edition includes changes associated with the latest(fifth) edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders (DSM-5).*

Content and Features New to the Ninth Edition

All content has been updated to reflect the current state of the discipline of nursing.

All nursing diagnoses are current with the NANDA-I *2015–2017 Nursing Diagnoses Definitions and Classifications.*

Communication Exercises are included in Chapters 13, Crisis Intervention; 17, Suicide Prevention; 21, The Recovery Model; 22, Neurocognitive Disorders; 23, Substance Use and Addictive Disorders; 24, Schizophrenia Spectrum and Other Psychotic Disorders; 25, Depressive Disorders; 26, Bipolar and Related Disorders; 27, Anxiety, Obsessive-Compulsive, and Related Disorders; 30, Issues Related to Human Sexuality; 31, Eating Disorders; 32, Personality Disorders; 35, Survivors of Abuse or Neglect; and 37, The Bereaved Individual. These exercises portray clinical scenarios that allow the student to practice communication skills with clients. Examples of answers appear in an appendix at the back of the book.

A new feature, "Real People, Real Stories," includes interviews conducted by one of the authors, Karyn Morgan, in which individuals discuss their experience of living with a mental illness and their thoughts on important information for nurses to know. These discussions can be used with students to explore communication issues and interventions to combat stigmatization and to build empathy through understanding individuals' unique experiences. "Real People, Real Stories" interviews are in Chapters 8, Therapeutic Communication; 17, Suicide Prevention; 23, Substance Use and Addictive Disorders; 24, Schizophrenia Spectrum and Other Psychotic Disorders; 25, Depressive Disorders; 30, Issues Related to Human Sexuality and Gender Dysphoria; and 38, Military Families.

New QSEN icons (in addition to the existing QSEN Teaching Strategy boxes) have been added selectively throughout chapters to highlight content that reflects application of one or more of the six QSEN competencies (patient-centered care, evidence-based practice, teamwork and collaboration, maintaining safety, quality improvement, and informatics).

Chapter 4, Psychopharmacology, has been moved from DavisPlus to the textbook. While each class of psychoactive substances is discussed in this chapter, lists of commonly used agents have been retained in the chapters that discuss specific disorders. For example, a list of commonly used antipsychotic agents (along with dosage ranges, half-life, and pregnancy categories) appears in Chapter 24, Schizophrenia Spectrum and Other Psychotic Disorders. These lists also appear online at DavisPlus.

New content on motivational interviewing appears in Chapters 8 and 23.

New content describing the concept of emotional intelligence is included in Chapter 14, Assertiveness Training.

New content on RAISE (Recovery After an Initial Schizophrenia Episode), based on the NIMH initiative is included in Chapter 24.

New content on gender dysphoria and transgender issues appears in Chapter 21.

Updated and new psychotropic drugs approved since the publication of the eighth edition are included in the specific diagnostic chapters to which they apply.

Features That Have Been Retained in the Ninth Edition

The concept of **holistic nursing** is retained in the ninth edition. An attempt has been made to ensure that the physical aspects of psychiatric-mental health nursing are not overlooked. In all relevant situations, the mind/body connection is addressed.

Nursing process is retained in the ninth edition as the tool for delivery of care to the individual with a psychiatric disorder or to assist in the primary prevention or exacerbation of mental illness symptoms. The six steps of the nursing process, as described in the American Nurses Association *Standards of Clinical Nursing Practice,* are used to provide guidelines for the nurse. These standards of care are included for the *DSM-5* diagnoses, as well as those on the aging individual, the bereaved individual, survivors of abuse and neglect, and military families, and as examples in several of the therapeutic approaches. The six steps include:

Assessment: Background assessment data, including a description of symptomatology, provides an extensive knowledge base from which the nurse may draw when performing an assessment. Several assessment tools are also included.

Diagnosis: Nursing diagnoses common to specific psychiatric disorders are derived from analysis of assessment data.

Outcome Identification: Outcomes are derived from the nursing diagnoses and stated as measurable goals.

Planning: A plan of care is presented with selected nursing diagnoses for the *DSM-5* diagnoses, as well as for the elderly client, the bereaved individual, victims of abuse and neglect, military veterans and their families, the elderly homebound client, and the primary caregiver of the client with a chronic mental illness. The planning standard also includes tables that list topics for educating clients and families about mental illness. Concept map care plans are included for all major psychiatric diagnoses.

Implementation: The interventions that have been identified in the plan of care are included along with rationales for each. Case studies at the end of each *DSM-5* chapter assist the student in the practical application of theoretical material. Also included as a part of this particular standard is Unit 3, Therapeutic Approaches in Psychiatric Nursing Care. This section of the textbook addresses psychiatric nursing intervention in depth and frequently speaks to the differentiation in scope of practice between the basic-level psychiatric nurse and the advanced practice–level psychiatric nurse.

Evaluation: The evaluation standard includes a set of questions that the nurse may use to assess whether the nursing actions have been successful in achieving the objectives of care.

Following are additional features of this ninth edition:

- **Internet references** for each *DSM-5* diagnosis, with website listings for information related to the disorder.
- **Tables that list topics for client/family education** (in the clinical chapters).
- **Boxes that include current research studies** with implications for evidence-based nursing practice (in the clinical chapters).
- **Assigning nursing diagnoses to client behaviors** (diagnostic chapters).
- **Taxonomy and diagnostic criteria from the *DSM-5* (2013).** Used throughout the text.
- **All references have been updated throughout the text.** Classical references are distinguished from general references.
- **Boxes with definitions of core concepts** appear throughout the text.
- **Comprehensive glossary.**
- **Answers to end-of-chapter review questions** (Appendix A).
- **Answers to communication exercises** (Appendix B).
- **Sample client teaching guides** (online at www.davisplus.com).
- **Website.** An F.A. Davis/Townsend website that contains additional nursing care plans that do not appear in the text, links to psychotropic medications, concept map care plans, and neurobiological content and illustrations, as well as student resources including practice test questions, learning activities, concept map care plans, and client teaching guides.

Additional Educational Resources

Faculty may also find the teaching aids that accompany this textbook helpful. These Instructor Resources are located at www.davisplus.com:

- **Multiple choice questions** (including new format questions reflecting the latest NCLEX blueprint).
- **Lecture outlines** for all chapters

- **Learning activities** for all chapters (including answer key)
- **Answers to the Critical Thinking Exercises** from the textbook
- **PowerPoint Presentation** to accompany all chapters in the textbook
- **Answers to the Homework Assignment Questions** from the textbook
- **Case studies for use with student teaching**

Additional chapters on Theories of Personality Development, Relaxation Therapy, Complementary and Psychosocial Therapies, and Forensic Nursing are presented online at www.davisplus.com.

It is hoped that the revisions and additions to this ninth edition continue to satisfy a need within psychiatric-mental health nursing practice. The mission of this textbook has been, and continues to be, to provide both students and clinicians with up-to-date information about psychiatric-mental health nursing. The user-friendly format and easy-to-understand language, for which we have received many positive comments, have been retained in this edition. We hope that this ninth edition continues to promote and advance the commitment to psychiatric/mental health nursing.

Karyn I. Morgan

Basic Concepts in Psychiatric-Mental Health Nursing

1 The Concept of Stress Adaptation

KEY TERMS

adaptive responses
fight-or-flight syndrome
general adaptation syndrome

maladaptive responses
precipitating event
predisposing factors

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *adaptation* and *maladaptation*.
2. Identify physiological responses to stress.
3. Explain the relationship between stress and "diseases of adaptation."
4. Describe the concept of stress as an environmental event.
5. Explain the concept of stress as a transaction between the individual and the environment.
6. Discuss adaptive coping strategies in the management of stress.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. How are the body's physiological defenses affected when under sustained stress? Why?
2. In the view of stress as an environmental event, what aspects are missing when considering an individual's response to a stressful situation?
3. In their study, what event did Miller and Rahe (1997) find produced the highest level of stress reaction in their participants?
4. What is the initial step in stress management?

Psychologists and others have struggled for many years to establish an effective definition of the term *stress.* This term is used loosely today and still lacks a definitive explanation. Stress may be viewed as an individual's reaction to any change that requires an adjustment or response, which can be physical, mental, or emotional. Responses directed at stabilizing internal biological processes and preserving self-esteem can be viewed as healthy adaptations to stress.

Roy (1976), a nursing theorist, defined an **adaptive response** as behavior that maintains the integrity of the individual. Adaptation is viewed as positive and is correlated with a healthy response. When behavior

disrupts the integrity of the individual, it is perceived as maladaptive. **Maladaptive responses** by the individual are considered to be negative or unhealthy.

Various 20th-century researchers contributed to several different concepts of stress. Three of these concepts include stress as a biological response, stress as an environmental event, and stress as a transaction between the individual and the environment. This chapter includes an explanation of each of these concepts.

CORE CONCEPT

Stressor
A biological, psychological, social, or chemical factor that causes physical or emotional tension and may contribute to the development of certain illnesses.

Stress as a Biological Response

In 1956, Hans Selye published the results of his research on the physiological response of a biological system to an imposed change on the system. Since his initial publication, his definition of stress has evolved to "the state manifested by a specific syndrome which consists of all the nonspecifically induced changes within a biologic system" (Selye, 1976). This combination of symptoms has come to be known as the **fight-or-flight syndrome.** Schematics of these biological responses, both initially and with sustained stress, are presented in Figures 1–1 and 1–2. Selye called this phenomenon the **general adaptation syndrome.** He described three distinct stages of the reaction:

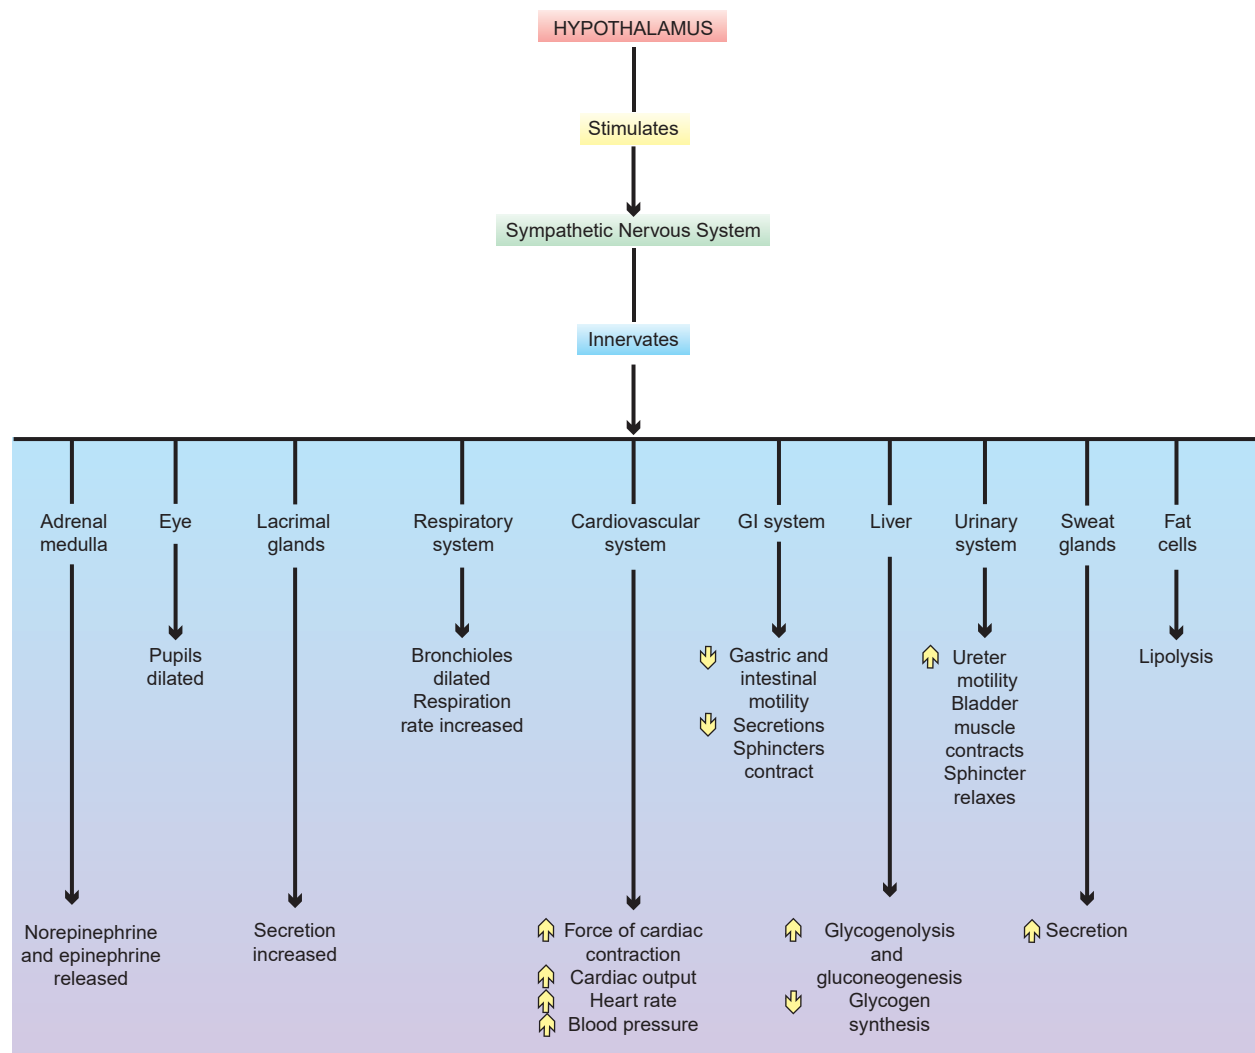
1. **Alarm reaction stage:** During this stage, the physiological responses of the fight-or-flight syndrome are initiated.


FIGURE 1–1 The fight-or-flight syndrome: The initial stress response.
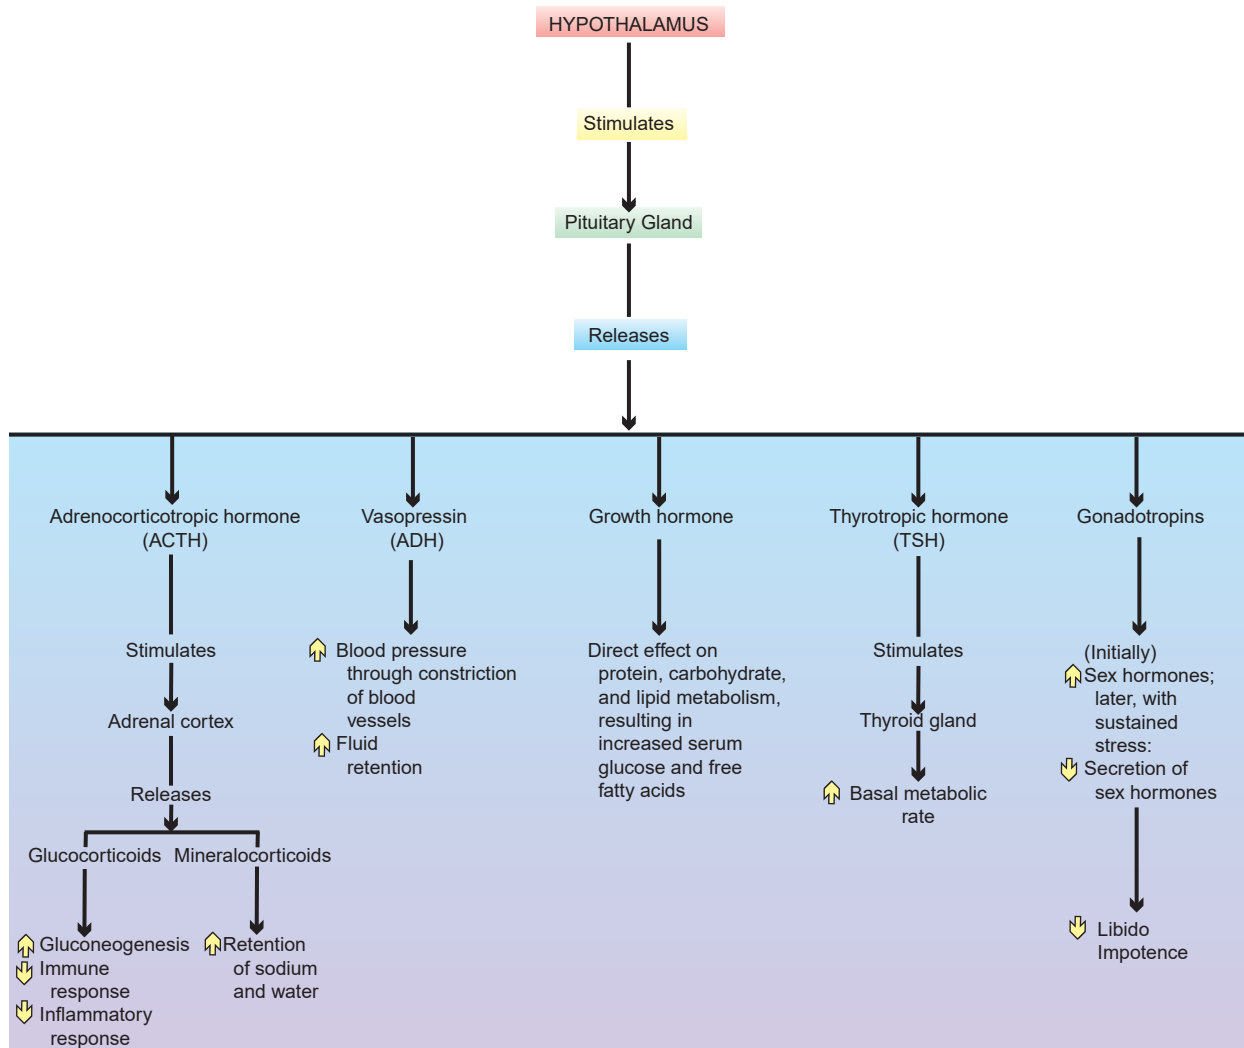

FIGURE 1–2 The fight-or-flight syndrome: The sustained stress response.

2. **Stage of resistance:** The individual uses the physiological responses of the first stage as a defense in the attempt to adapt to the stressor. If adaptation occurs, the third stage is prevented or delayed. Physiological symptoms may disappear.
3. **Stage of exhaustion:** This stage occurs when the body responds to prolonged exposure to a stressor. The adaptive energy is depleted, and the individual can no longer draw from the resources for adaptation described in the first two stages. Diseases of adaptation (e.g., headaches, mental disorders, coronary artery disease, ulcers, colitis) may occur. Without intervention for reversal, exhaustion and, in some cases, even death, ensues (Selye, 1956, 1974).

The fight-or-flight response undoubtedly served our ancestors well. Those *Homo sapiens* who had to face the giant grizzly bear or the saber-toothed tiger as part of their struggle for survival must have used these adaptive resources to their advantage. The response was elicited in emergency situations, used in the preservation of life, and followed by restoration of the compensatory mechanisms to the preemergent condition (homeostasis).

Selye performed his extensive research in a controlled setting with laboratory animals as subjects. He elicited the physiological responses with physical stimuli, such as exposure to heat or extreme cold, electric shock, injection of toxic agents, restraint, and surgical injury. Since the publication of his original research, it has become apparent that the fight-or-flight syndrome of symptoms occurs in response to psychological or emotional stimuli just as it does to physical stimuli. Psychological or emotional stressors are often not resolved as rapidly as physical stressors, so the body may be depleted of its adaptive energy more readily than it is from physical stressors. The fight-or-flight response may be inappropriate or even

dangerous in our modern lifestyle in which stress has been described as a pervasive, chronic, and relentless psychosocial state. When the stress response becomes chronic, the body's existence in the aroused condition for extended time periods promotes susceptibility to disease.

CORE CONCEPT
Adaptation
Adaptation is said to occur when an individual's physical or behavioral response to any change in his or her internal or external environment results in preservation of individual integrity or timely return to equilibrium.

Stress as an Environmental Event

A second concept defines stress as an "event" that triggers an individual's adaptive physiological and psychological responses. The event creates change in the life pattern of the individual, requires significant adjustment in lifestyle, and taxes available personal resources. The change can be either positive, such as outstanding personal achievement, or negative, such as being fired from a job. The emphasis here is on *change* from the existing steady state of the individual's life pattern.

Miller and Rahe (1997) have updated the original Social Readjustment Rating Scale devised by Holmes and Rahe in 1967 to reflect an increased number of modern stressors. Just as in the earlier version, numerical values are assigned to various common life events based on the stress these events create. In their research, Miller and Rahe found that women react to life stress events at higher levels than do men, and unmarried people gave higher scores than married people for most of the events. Younger participants rated more events at a higher stress level than did older participants. A high score on the Recent Life Changes Questionnaire (RLCQ) places the individual at greater susceptibility to physical or psychological illness. The questionnaire may be completed considering life stressors within a 6-month or 1-year period. Six-month totals equal to or greater than 300 life change units (LCUs) or 1-year totals equal to or greater than 500 LCUs are considered indicative of a high level of recent life stress, thereby increasing the individual's risk of illness. The RLCQ is presented in Table 1–1.

It is unknown whether stress overload merely predisposes a person to illness or actually precipitates it, but there does appear to be a link (Amirkhan, 2012). Individuals differ in their reactions to life events, and these variations are related to the degree to which the change is perceived as stressful. Life changes

TABLE 1–1 **The Recent Life Changes Questionnaire**			
LIFE CHANGE EVENT	LCU	LIFE CHANGE EVENT	LCU
HEALTH		Troubles at work:	
An injury or illness which:	74	With your boss	29
Kept you in bed a week or more, or sent		With coworkers	35
you to the hospital		With persons under your supervision	35
Was less serious than above	44	Other work troubles	28
Major dental work	26	Major business adjustment	60
Major change in eating habits	27	Retirement	52
Major change in sleeping habits	26	Loss of job:	
Major change in your usual type/amount of recreation	28	Laid off from work	68
		Fired from work	79
WORK		Correspondence course to help you in your work	18
Change to a new type of work	51		
Change in your work hours or conditions	35	**PERSONAL AND SOCIAL**	
		Change in personal habits	26
Change in your responsibilities at work:		Beginning or ending school or college	38
More responsibilities	29	Change of school or college	35
Fewer responsibilities	21	Change in political beliefs	24
Promotion	31	Change in religious beliefs	29
Demotion	42		
Transfer	32

		Major purchase	37
		Foreclosure on a mortgage or loan	58

LCU, life change unit.

questionnaires have been criticized because they do not consider the individual's perception of the event. These types of instruments also fail to consider cultural variations, the individual's coping strategies, and available support systems at the time when the life change occurs. Amirkhan (2012) developed a tool to assess stress overload that attempts to correct for these limitations by asking a series of 30 questions that all begin with "In the past week have you felt . . ." followed by choices such as calm, inadequate, depressed, and others. The emphasis in this tool is on the individual's perception of events rather than on the events themselves. Although the approaches to assessing for stress and vulnerability vary, it is clear that positive coping mechanisms and strong social or familial support can reduce the intensity of

stressful life changes and promote a more adaptive response.

Stress as a Transaction Between the Individual and the Environment

The concept of stress as a transaction between the individual and the environment emphasizes the *relationship* between internal variables (within an individual) and external variables (within the environment). This concept parallels the modern concept of disease etiology. No longer is causation viewed solely as an external entity; whether or not illness occurs depends also on the receiving organism's susceptibility. Similarly, to predict psychological stress as a reaction, the internal characteristics of the person in relation to the environment must be considered.

Precipitating Event

Lazarus and Folkman's seminal theory (1984) defines stress (and potentially illness) as a psychological phenomenon in which the relationship between the person and the environment is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being. A **precipitating event** is a stimulus arising from the internal or external environment and perceived by the individual in a specific manner. Determination of an event as stressful depends on the individual's cognitive appraisal of the situation. *Cognitive appraisal* is an individual's evaluation of the personal significance of the event or occurrence. The event "precipitates" a response on the part of the individual, and the response is influenced by the individual's perception of the event. The *cognitive response* consists of a primary appraisal and a secondary appraisal.

Individual's Perception of the Event

Primary Appraisal

Lazarus and Folkman (1984) identify three types of primary appraisal: irrelevant, benign-positive, and stressful. An event is judged *irrelevant* when the outcome holds no significance for the individual. A *benign-positive* outcome is one that is perceived as producing pleasure for the individual. *Stress appraisals* include harm or loss, threat, and challenge. *Harm* or *loss* appraisals refer to damage or loss already experienced by the individual. Appraisals of a *threatening* nature are perceived as anticipated harms or losses. When an event is appraised as *challenging,* the individual focuses on potential for gain or growth rather than on risks associated with the event. Challenge produces stress even though the emotions associated with it (eagerness and excitement) are viewed as positive, and coping mechanisms must be called upon to face the new encounter. Challenge and threat may occur together when an individual experiences these positive emotions along with fear or anxiety over possible risks associated with the challenging event.

When stress is produced in response to harm or loss, threat, or challenge, a secondary appraisal is made by the individual.

Secondary Appraisal

The secondary appraisal is an assessment of skills, resources, and knowledge that the person possesses to deal with the situation. The individual evaluates by considering the following:

- Which coping strategies are available to me?
- Will the option I choose be effective in this situation?
- Do I have the ability to use that strategy in an effective manner?

The interaction between the primary appraisal of the event that has occurred and the secondary appraisal of available coping strategies determines the quality of the individual's adaptation response to stress.

Predisposing Factors

A variety of elements influence how an individual perceives and responds to a stressful event. These **predisposing factors** strongly influence whether the response is adaptive or maladaptive. Types of predisposing factors include genetic influences, past experiences, and existing conditions.

Genetic influences are those circumstances of an individual's life that are acquired through heredity. Examples include family history of physical and psychological conditions (strengths and weaknesses) and temperament (behavioral characteristics present at birth that evolve with development).

Past experiences are occurrences that result in learned patterns that can influence an individual's adaptation response. They include previous exposure to the stressor or other stressors, learned coping responses, and degree of adaptation to previous stressors.

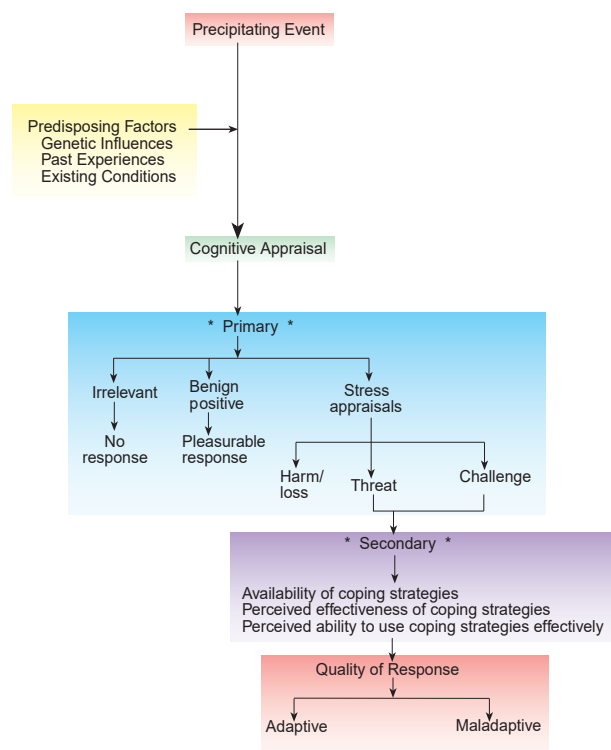
Existing conditions incorporate vulnerabilities that influence the adequacy of the individual's physical, psychological, and social resources for dealing with adaptive demands. Examples include current health status, motivation, developmental maturity, severity and duration of the stressor, financial and educational resources, age, existing coping strategies, and a caring support system. Hobfoll's conservation of resources theory (Hobfoll 1989; Hobfoll, Schwarzer, & Chon, 1998) adds that as existing conditions (loss or lack of resources) exceed the person's perception of adaptive capabilities, the person not only experience stress in the present but also becomes more


FIGURE 1–3 Transactional model of stress and adaptation.

vulnerable to the effects of stress in the future due to a "weaker resource reservoir to call on to meet future demand" (Hobfoll et al., 1998, p. 191). All of the preceding concepts and theories are foundational to the transactional model of stress and adaptation that serves as the framework for the process of nursing in this text. A graphic display of the model is presented in Figure 1–3.

CORE CONCEPT

Maladaptation

Maladaptation occurs when an individual's physical or behavioral response to any change in his or her internal or external environment results in disruption of individual integrity or in persistent disequilibrium.

Stress Management*

The growth of stress management into a multimillion-dollar-a-year industry unto itself attests to its importance in our society. Stress management involves the use of coping strategies in response to stressful situations. Coping strategies are adaptive when they

---

*Some stress management techniques are discussed at greater length in Unit 3 of this text and in the Complementary and Psychosocial Therapies chapter available online at www.DavisPlus.com.

protect the individual from harm (or additional harm) or strengthen the individual's ability to meet challenging situations. Adaptive responses help restore homeostasis to the body and impede the development of diseases of adaptation. Positive adaptation, particularly in response to adversity, has also been referred to as *resilience.*

Responses are considered maladaptive when the conflict goes unresolved or intensifies. Energy resources become depleted as the body struggles to compensate for the chronic physiological and psychological arousal experienced in response to the stressful event. The effect is a significant vulnerability to physical or psychological illness. One key to stress management is to identify factors and practices that contribute to adaptive coping and resilience.

Adaptive Coping Strategies
Awareness

The initial step in managing stress is awareness—to become aware of the factors that create stress and the feelings associated with a stressful response. Stress can be controlled only when one recognizes the signs that it is occurring. As an individual becomes aware of stressors, he or she can choose to omit, avoid, or accept them.

Relaxation

Individuals experience relaxation in different ways. Some people relax by engaging in large motor activities, such as sports, jogging, and physical exercise. Others use techniques such as breathing exercises and progressive relaxation. A discussion of relaxation therapy may be found online at Davis*Plus.*

Meditation

Meditation has been shown to produce a lasting reduction in blood pressure and other stress-related symptoms when practiced for 20 minutes once or twice a day (Scott, 2016). The practice of mindfulness meditation is foundational to many psychosocial interventions aimed at reducing anxiety and improving engagement in problem-solving. Meditation involves assuming a comfortable position, closing the eyes, casting off all other thoughts, and concentrating on a single word, sound, or phrase that has positive meaning to the individual. It may also involve concentrating on one's breathing or other mindfulness practices. The technique of meditation is described in detail online at Davis*Plus.*

Interpersonal Communication

As previously mentioned, the strength of an individual's available support system is an existing condition that significantly influences his or her adaptation when coping with stress. Sometimes just "talking the problem out" with an empathetic individual can interrupt

escalation of the stress response. Writing about one's feelings in a journal or diary can also be therapeutic.

Problem-Solving

Problem-solving is an adaptive coping strategy in which the individual is able to view the situation objectively (or to seek assistance from another individual to accomplish this if the anxiety level is too high to concentrate) and then apply a problem-solving and decision-making model such as the following:

- Assess the facts of the situation.
- Formulate goals for resolution of the stressful situation.
- Study the alternatives for dealing with the situation.
- Determine the risks and benefits of each alternative.
- Select an alternative.
- Implement the alternative selected.
- Evaluate the outcome of the alternative implemented.
- If the first choice is ineffective, select and implement a second option.

Pets

Studies show that those who care for pets, especially dogs and cats, are better able to cope with the stressors of life (Mayo Clinic, 2015). The physical act of stroking a dog's or cat's fur can be therapeutic, giving the animal an intuitive sense of being cared for and providing the individual the calming feeling of warmth, affection, and interdependence with a reliable, trusting being. Studies have also shown that individuals with companion pets demonstrate improvements in heart health, allergies, anxiety, and mental illnesses such as depression (Casciotti & Zuckerman, 2016, Donehy, 2015).

Music

It is true that music can "soothe the savage beast." Studies have shown multiple benefits of listening to music, including relieving pain, improving motivation and performance, improving sleep, enhancing blood vessel function, reducing stress, relieving symptoms of depression, improving cognition, and easing recovery in stroke patients (Christ, 2013).

Summary and Key Points

- Stress has become a chronic and pervasive condition in the United States.
- Adaptive behavior is a stress response that maintains the integrity of the individual with a timely return to equilibrium. It is viewed as positive and is correlated with a healthy response.
- When behavior disrupts the integrity of the individual or results in persistent disequilibrium, it is perceived as maladaptive. Maladaptive responses by the individual are unhealthy.

- A stressor is defined as a biological, psychological, social, or chemical factor that causes physical or emotional tension and may be a factor in the etiology of certain illnesses.
- Hans Selye identified the biological changes associated with a stressful situation as the fight-or-flight syndrome.
- Selye called the general reaction of the body to stress the "general adaptation syndrome," which occurs in three stages: the alarm reaction stage, the stage of resistance, and the stage of exhaustion.
- When individuals remain in the aroused response to stress for an extended period of time, they become susceptible to diseases, including headaches, mental disorders, coronary artery disease, ulcers, and colitis.
- Stress may also be viewed as an environmental event, which results when a change from the existing steady state of the individual's life pattern occurs.
- When an individual experiences a high level of life change events, he or she becomes susceptible to physical or psychological illness.
- Limitations of the environmental concept of stress include failure to consider the individual's perception of the event, coping strategies, and available support systems at the time when the life change occurs.
- Stress is more appropriately expressed as a transaction between the individual and the environment that is appraised by the individual as taxing or exceeding his or her resources and endangering his or her well-being.
- The individual makes a cognitive appraisal of the precipitating event to determine the personal significance of the event or occurrence.
- Primary cognitive appraisals may be irrelevant, benign-positive, or stressful.
- Secondary cognitive appraisals include assessment and evaluation by the individual of skills, resources, and knowledge to deal with the stressful situation.
- Predisposing factors influence how an individual perceives and responds to a stressful event. They include genetic influences, past experiences, and existing conditions.
- Stress management involves the use of adaptive coping strategies in response to stressful situations in an effort to impede the development of diseases of adaptation.
- Examples of adaptive coping strategies include developing awareness, relaxation, meditation, interpersonal communication with caring other, problem-solving, pets, and music.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Sondra, who lives in Maine, hears on the evening news that 25 people were killed in a tornado in south Texas. Sondra experiences no anxiety upon hearing of this stressful situation. What is the most likely reason that Sondra experiences no anxiety?
   a. She is selfish and does not care what happens to other people.
   b. She appraises the event as irrelevant to her own situation.
   c. She assesses that she has the skills to cope with the stressful situation.
   d. She uses suppression as her primary defense mechanism.

2. Cindy regularly develops nausea and vomiting when she is faced with a stressful situation. Which of the following is most likely a predisposing factor to this maladaptive response by Cindy?
   a. Cindy inherited her mother's "nervous" stomach.
   b. Cindy is fixed in a lower level of development.
   c. Cindy has never been motivated to achieve success.
   d. When Cindy was a child, her mother pampered her and kept her home from school when she was ill.

3. When an individual's stress response is sustained over a long period, the endocrine system involvement results in which of the following?
   a. Decreased resistance to disease
   b. Increased libido
   c. Decreased blood pressure
   d. Increased inflammatory response

4. Why is stress management extremely important in today's society?
   a. Evolution has diminished the human capability for fight-or-flight responses.
   b. The stressors of today tend to be ongoing, resulting in a sustained response.
   c. We have stress disorders that did not exist in the days of our ancestors.
   d. One never knows when one will have to face a grizzly bear or saber-toothed tiger in today's society.

5. Elena has just received a promotion on her job. She is very happy and excited about moving up in her company, but she has been experiencing anxiety since receiving the news. Her primary appraisal is that she most likely views the situation as which of the following?
   a. Benign-positive
   b. Irrelevant
   c. Challenging
   d. Threatening

6. John comes to the mental health clinic with reports of anxiety and depression. According to the transactional model of stress and adaptation, which of the following are important to consider when assessing John's complaints? (Select all that apply.)
   a. John's perception of precipitating events
   b. Past stressors and degree of positive coping abilities
   c. Existing social supports
   d. Physical strength
   e. Pupillary adaptation to light

2 Mental Health and Mental Illness: Historical and Theoretical Concepts

CHAPTER OUTLINE

KEY TERMS

anticipatory grieving

bereavement overload

defense mechanisms

   compensation

   denial

   displacement

   identification

   intellectualization

introjection

isolation

projection

rationalization

reaction formation

regression

repression

sublimation

suppression

undoing

humors

mental health

mental illness

neurosis

psychosis

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss the history of psychiatric care.
2. Define *mental health* and *mental illness*.
3. Discuss cultural elements that influence attitudes toward mental health and mental illness.
4. Describe psychological adaptation responses to stress.
5. Correlate adaptive and maladaptive responses to the mental health/mental illness continuum.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Explain the concepts of *incomprehensibility* and *cultural relativity.*
2. Describe some symptoms of panic anxiety.
3. Jane was involved in an automobile accident in which both her parents were killed. When you ask her about it, she says she has no memory of the accident. What ego defense mechanism is she using?
4. In what stage of the grieving process is the individual with delayed or inhibited grief fixed?

The consideration of mental health and mental illness has its basis in the cultural beliefs of the society in which the behavior takes place. Some cultures are quite liberal in the range of behaviors that are considered acceptable, whereas others have very little tolerance for behaviors that deviate from the cultural norms.

A study of the history of psychiatric care reveals some shocking truths about past treatment of individuals with mental illness. Many were kept in control

by means that today could be considered less than humane.

This chapter deals with the evolution of psychiatric care from ancient times to the present. **Mental health** and **mental illness** are defined, and the psychological adaptation to stress is explained in terms of the two major responses: anxiety and grief. Behavioral responses are conceptualized along the mental health/mental illness continuum.

Historical Overview of Psychiatric Care

Primitive beliefs regarding mental disturbances took several views. Some cultures thought that an individual with mental illness had been dispossessed of his or her soul and wellness could be achieved only if the soul was returned. Others believed that evil spirits or supernatural or magical powers had entered the body. The "cure" for these individuals involved a ritualistic exorcism to purge the body of these unwanted forces. This purging often consisted of brutal beatings, starvation, or other torturous means. Still other cultures considered that the individual with mental illness may have broken a taboo or sinned against another individual or God, for which ritualistic purification was required or various types of retribution were demanded. The correlation of mental illness to demonology led to some individuals with mental illness being burned at the stake.

These ancient beliefs evolved with increasing knowledge about mental illness and changes in cultural, religious, and sociopolitical attitudes. Around 400 BC, the work of Hippocrates was the first to place mental illness in a physical rather than supernatural context. Hippocrates theorized that mental illness was caused by irregularity in the interaction of the four body fluids: blood, black bile, yellow bile, and phlegm. He called these body fluids **humors** and associated each with a particular disposition. Disequilibrium among these four humors was often treated by inducing vomiting and diarrhea with potent cathartic drugs.

During the Middle Ages (AD 500 to 1500), the association of mental illness with witchcraft and the supernatural continued to prevail in Europe. During this period, many people with mental illness were set to sea alone in sailing boats with little guidance to search for their lost rationality, a practice from which the expression "ship of fools" was derived. But in Middle Eastern countries, a change in attitude began to occur that led to the perception of mental illness as a medical problem rather than a result of supernatural forces. This notion gave rise to the establishment of special units for clients with mental illness within general hospitals as well as residential institutions specifically designed for this purpose. They can likely be considered the first asylums for individuals with mental illness.

Colonial Americans tended to reflect the attitudes of the European communities from which they had emigrated. Particularly in the New England area, individuals were punished for behavior attributed to witchcraft. In the 16th and 17th centuries, institutions for people with mental illness did not exist in the United States, and care of these individuals became a family responsibility. Those without family or other resources became the responsibility of the communities in which they lived and were incarcerated in places where they could do no harm to themselves or others.

The first hospital in America to admit clients with mental illness was established in Philadelphia in the middle of the 18th century. Benjamin Rush, often called the father of American psychiatry, was a physician at the hospital. He initiated the provision of humanistic treatment and care for clients with mental illness. But although he included kindness, exercise, and socialization in his care, he also employed harsh methods such as bloodletting, purging, various types of physical restraints, and extremes of temperatures, reflecting the medical therapies of that era.

The 19th century brought the establishment of a system of state asylums, largely the result of the work of Dorothea Dix, a former New England schoolteacher who lobbied tirelessly on behalf of the mentally ill population. She was unfaltering in her belief that mental illness was curable and that state hospitals should provide humanistic therapeutic care. This system of hospital care for individuals with mental illness grew, but the mentally ill population grew faster. The institutions became overcrowded and understaffed, and conditions deteriorated. Therapeutic care reverted to custodial care in state hospitals, which provided the largest resource for individuals with mental illness until the initiation of the community health movement of the 1960s (see Chapter 36, Community Mental Health Nursing).

The emergence of psychiatric nursing began in 1873 with the graduation of Linda Richards from the nursing program at the New England Hospital for Women and Children in Boston. She has come to be known as the first American psychiatric nurse. During her career, Richards was instrumental in the establishment of a number of psychiatric hospitals and the first school of psychiatric nursing at the McLean Asylum in Waverly, Massachusetts, in 1882. This school and others like it provided training in

custodial care for clients in psychiatric asylums—training that did not include the study of psychological concepts. Significant change in psychiatric nursing education did not occur until 1955, when incorporation of psychiatric nursing into the curricula became a requirement for all undergraduate schools of nursing. This new curricula emphasized the importance of the nurse–patient relationship and therapeutic communication techniques. Nursing intervention in the somatic therapies (e.g., insulin and electroconvulsive therapy) provided impetus for the incorporation of these concepts into the profession's body of knowledge.

With the increasing need for psychiatric care in the aftermath of World War II, the government passed the National Mental Health Act of 1946. This legislation provided funds for the education of psychiatrists, psychologists, social workers, and psychiatric nurses. Graduate-level education in psychiatric nursing was established during this period. Around the same time, the introduction of antipsychotic medications made it possible for clients with psychoses to more readily participate in their treatment, including nursing therapies.

Knowledge of the history of psychiatric-mental health care contributes to the understanding of the concepts presented in this chapter and those in the online chapter (available at www.DavisPlus .com), which describe the theoretical models of personality development according to various 19th- and 20th-century leaders in the mental health movement. Modern American psychiatric care has its roots in ancient times. A great deal of opportunity exists for continued advancement of this specialty within the practice of nursing.

Mental Health

A number of theorists have attempted to define the concept of mental health. Many of these concepts deal with various aspects of individual functioning. Maslow (1970) emphasized an individual's motivation in the continuous quest for self-actualization. He identified a "hierarchy of needs," with the most basic needs requiring fulfillment before those at higher levels can be achieved and with self-actualization defined as fulfillment of one's highest potential. An individual's position within the hierarchy may revert from a higher level to a lower level based on life circumstances. For example, an individual facing major surgery who has been working to achieve self-actualization may become preoccupied, if only temporarily, with the need for physiological safety. A representation of this needs hierarchy is presented in Figure 2–1.

Maslow described self-actualization as being "psychologically healthy, fully human, highly evolved, and fully mature." He believed that self-actualized individuals possess the following characteristics:

■ An appropriate perception of reality
■ The ability to accept oneself, others, and human nature
■ The ability to manifest spontaneity
■ The capacity for focusing concentration on problem-solving
■ A need for detachment and desire for privacy
■ Independence, autonomy, and a resistance to enculturation
■ An intensity of emotional reaction
■ A frequency of "peak" experiences that validate the worthwhileness, richness, and beauty of life
■ An identification with humankind
■ The ability to achieve satisfactory interpersonal relationships
■ A democratic character structure and strong sense of ethics
■ Creativeness
■ A degree of nonconformance

Jahoda (1958) identified a list of six indicators that are a reflection of mental health:

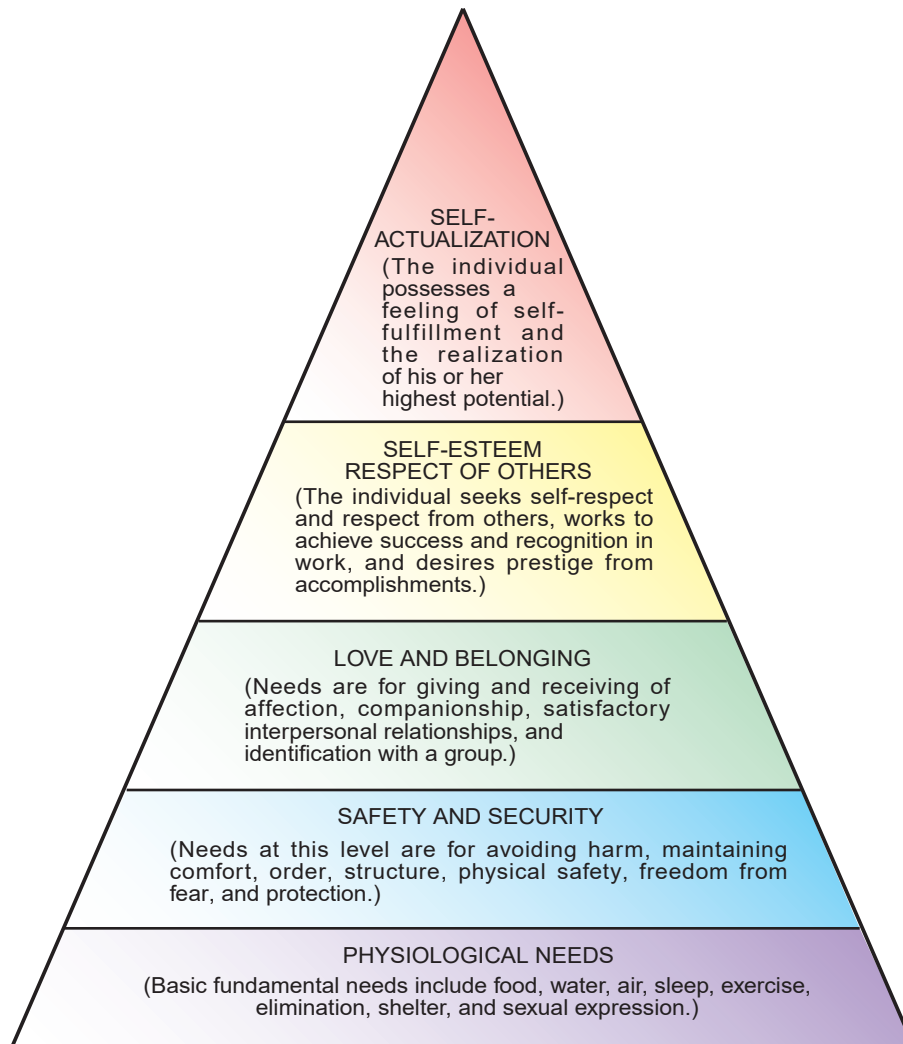
1. **A positive attitude toward self:** This indicator refers to an objective view of self, including knowledge and acceptance of strengths and limitations. The individual feels a strong sense of personal identity and security within his or her environment.
2. **Growth, development, and the ability to achieve self-actualization:** This indicator correlates with whether the individual successfully achieves the tasks associated with each level of development (see Erikson, in the online chapter Theoretical Models of Personality Development). With successful achievement in each level, the individual gains motivation for advancement to his or her highest potential.
3. **Integration:** The focus of this indicator is on maintaining equilibrium or balance among various life processes. Integration includes the ability to adaptively respond to the environment and the development of a philosophy of life, both of which help the individual maintain a manageable anxiety level in response to stressful situations.
4. **Autonomy:** This indicator refers to the individual's ability to perform in an independent, self-directed manner. He or she makes choices and accepts responsibility for the outcomes.
5. **Perception of reality:** Accurate reality perception is a positive indicator of mental health. It includes


FIGURE 2–1   Maslow's hierarchy of needs.

perception of the environment without distortion as well as the capacity for empathy and social sensitivity—a respect and concern for the wants and needs of others.

6. **Environmental mastery:** This indicator suggests that the individual has achieved a satisfactory role within the group, society, or environment and is able to love and accept the love of others. When faced with life situations, the individual is able to strategize, make decisions, change, adjust, and adapt. Life offers satisfaction to the individual who has achieved environmental mastery.

Black and Andreasen (2014) describe mental health as a state of being that is relative rather than absolute but marked by the successful performance of mental functions such as adapting to change, coping with stressors, fulfilling relationships with others, and the accomplishing productive activities.

Robinson (1983) offers the following definition of mental health:

> A dynamic state in which thought, feeling, and behavior that is age-appropriate and congruent with the local and cultural norms is demonstrated. (p. 74)

For purposes of this text, and in keeping with the framework of stress and adaptation, a modification of Robinson's definition of mental health is considered. Thus, *mental health* is viewed as "the successful adaptation to stressors from the internal or external environment, evidenced by thoughts, feelings, and behaviors that are age-appropriate and congruent with local and cultural norms."

Mental Illness

Arriving at a universal concept of mental illness is difficult because of the cultural factors that influence such

a definition. However, certain elements are associated with individuals' perceptions of mental illness, regardless of cultural origin. Horwitz (2010) identifies two of these elements as (1) incomprehensibility and (2) cultural relativity.

Incomprehensibility relates to the inability of the general population to understand the motivation behind an individual's behavior. When observers are unable to find meaning or comprehensibility in behavior, they are likely to label that behavior as mental illness. Horwitz states, "Observers attribute labels of mental illness when the rules, conventions, and understandings they use to interpret behavior fail to find any intelligible motivation behind an action" (p. 17). The element of *cultural relativity* considers that these rules, conventions, and understandings are conceived within an individual's own particular culture. Behavior that is considered "normal" and "abnormal" is defined by one's cultural or societal norms. Horwitz identified a number of cultural aspects of mental illness, which are presented in Box 2–1.

The American Psychiatric Association (2013), in its *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5),* defines mental disorder as

a syndrome characterized by clinically significant disturbance in an individual's cognitions, emotion regulation, or behavior that reflects a dysfunction in the psychological, biological, or developmental processes underlying mental functioning. Mental disorders are usually associated with significant distress or disability in social, occupational, or other important activities. An expected or culturally approved response to a common stressor or loss such as the death of a loved one is not a mental disorder. (p. 20)

For purposes of this text, and in keeping with the transactional model of stress and adaptation, mental illness is characterized as "maladaptive responses to stressors from the internal or external environment, evidenced by thoughts, feelings, and behaviors that are incongruent with the local and cultural norms and that interfere with the individual's social, occupational, and/or physical functioning."

Psychological Adaptation to Stress

All individuals exhibit characteristics associated with both mental health and mental illness at any given point in time. Chapter 1, The Concept of Stress Adaptation, describes how an individual's response to stressful situations is influenced by physiological factors, his or her personal perception of the event, and a variety of predisposing factors such as heredity, temperament, learned response patterns, developmental maturity, existing coping strategies, and support systems of caring others.

BOX 2–1 Cultural Aspects of Mental Illness

1. Usually, members of the community, not a psychiatric professional, initially recognizes that an individual's behavior deviates from societal norms.
2. People who are related to an individual or who are of the same cultural or social group are less likely to label an individual's behavior as mentally ill than are people who are relationally or culturally distant. Relatives and those who share a culture try to normalize the behavior by looking for an explanation.
3. Often, psychiatrists see a person with mental illness only when the family members can no longer deny the illness. Recognition or acknowledgment of possible mental illness typically occurs when behavior is at its worst as defined by local or cultural norms.
4. Individuals in lower socio-economic classes usually display more mental illness symptoms than do people in higher socio-economic classes. However, they tend to tolerate a wider range of behaviors that deviate from societal norms and are less likely to consider these behaviors as indicative of mental illness. Mental illness labels are most often applied by psychiatric professionals.
5. The higher the social class, the greater the recognition of mental illness behaviors. Members of the higher social classes are likely to be self-labeled or labeled by family members or friends. Psychiatric assistance is sought near the first signs of emotional disturbance.
6. The more highly educated the person, the greater the recognition of mental illness behaviors. However, even more relevant than the *amount* of education is the *type* of education. Individuals in the more humanistic professions (lawyers, social workers, artists, teachers, nurses) are more likely to seek psychiatric assistance than are professionals such as business executives, computer specialists, accountants, and engineers.
7. Women are more likely than men to recognize the symptoms of mental illness and seek assistance.
8. The greater the cultural distance from the *mainstream* of society (i.e., the fewer the ties with *conventional* society), the greater the likelihood of negative societal response to mental illness. For example, immigrants have a greater distance from the mainstream than the native born, ethnic minorities greater than the dominant culture, and "bohemians" greater than the bourgeoisie. These groups are more likely to be subjected to coercive treatment, and involuntary psychiatric commitments are more common.

Adapted from Horwitz, A.V. (2010). The social control of mental illness. *Clinton Corners, NY: Percheron Press.*

Anxiety and grief have been described as two primary psychological response patterns to stress. A variety of thoughts, feelings, and behaviors are associated with each of these response patterns. Adaptation is determined by the degree to which the thoughts, feelings, and behaviors interfere with an individual's functioning.

CORE CONCEPT
Anxiety
A diffuse, vague apprehension that is associated with feelings of uncertainty and helplessness.

Anxiety

Feelings of anxiety are so common in our society that they are almost considered universal. Anxiety arises from the chaos and confusion that exists in the world. Fear of the unknown and conditions of ambiguity offer a perfect breeding ground for anxiety to take root and grow. Low levels of anxiety are adaptive and can provide the motivation required for survival. Anxiety becomes problematic when the individual is unable to prevent his or her response from escalating to a level that interferes with the ability to meet basic needs.

Peplau (1963) described four levels of anxiety: mild, moderate, severe, and panic. It is important for nurses to be able to recognize the symptoms associated with each level to plan for appropriate intervention with anxious individuals.

- **Mild anxiety:** This level of anxiety is seldom a problem for the individual. It is associated with the tension experienced in response to the events of day-to-day living. Mild anxiety prepares people for action. It sharpens the senses, increases motivation for productivity, increases the perceptual field, and results in a heightened awareness of the environment. Learning is enhanced, and the individual is able to function at his or her optimal level.
- **Moderate anxiety:** As the level of anxiety increases, the extent of the perceptual field diminishes. The moderately anxious individual is less alert to events occurring in the environment. The individual's attention span and ability to concentrate decrease, although he or she may still attend to needs with direction. Assistance with problem-solving may be required. Increased muscular tension and restlessness are evident.
- **Severe anxiety:** The perceptual field of the severely anxious individual is so greatly diminished that concentration centers on one particular detail only or on many extraneous details. Attention span is

extremely limited, and the individual has difficulty completing even the simplest task. Physical symptoms (e.g., headaches, palpitations, insomnia) and emotional symptoms (e.g., confusion, dread, horror) may be evident. Discomfort is experienced to the degree that virtually all overt behavior is aimed at relieving the anxiety.
- **Panic anxiety:** In this most intense state of anxiety, the individual is unable to focus on even one detail in the environment. Misperceptions are common, and a loss of contact with reality may occur. The individual may experience hallucinations or delusions. Behavior may be characterized by wild and desperate actions or extreme withdrawal. Human functioning and communication with others is ineffective. Panic anxiety is associated with a feeling of terror, and individuals may be convinced that they have a life-threatening illness or fear that they are "going crazy," are losing control, or are emotionally weak. Prolonged panic anxiety can lead to physical and emotional exhaustion and can be a life-threatening situation.

A synopsis of the characteristics associated with each of the four levels of anxiety is presented in Table 2–1.

Behavioral Adaptation Responses to Anxiety

A variety of behavioral adaptation responses occur at each level of anxiety. Figure 2–2 depicts these behavioral responses on a continuum of anxiety ranging from mild to panic.

Mild Anxiety

At the mild level, individuals employ any of a number of coping behaviors that satisfy their needs for comfort. Menninger (1963) described the following types of coping mechanisms that individuals use to relieve anxiety in stressful situations:

- Sleeping
- Yawning
- Eating
- Drinking
- Physical exercise
- Daydreaming
- Smoking
- Laughing
- Crying
- Cursing
- Pacing
- Nail biting
- Foot swinging
- Finger tapping
- Fidgeting
- Talking to someone with whom one feels comfortable

Undoubtedly, there are many more responses too numerous to mention here, considering that each individual develops his or her own unique ways to relieve mild anxiety. Some of these behaviors are more adaptive than others.

Mild-to-Moderate Anxiety

Sigmund Freud (1961) identified the ego as the reality component of the personality, governing

TABLE 2–1 **Levels of Anxiety**				
LEVEL	PERCEPTUAL FIELD	ABILITY TO LEARN	PHYSICAL CHARACTERISTICS	EMOTIONAL AND BEHAVIORAL CHARACTERISTICS
Mild	Heightened perception (e.g., noises may seem louder; details within the environment are clearer) Increased awareness Increased alertness	Learning is enhanced	Restlessness Irritability	May remain superficial with others Rarely experienced as distressful Motivation is increased
Moderate	Reduction in perceptual field Reduced alertness to environmental events (e.g., someone talking may not be heard; part of the room may not be noticed)	Learning still occurs but not at optimal ability Decreased attention span Decreased ability to concentrate	Increased restlessness Increased heart and respiration rates Increased perspiration Gastric discomfort Increased muscular tension Increase in speech rate, volume, and pitch	A feeling of discontent May lead to a degree of impairment in interpersonal relationships as individual begins to focus on self and the need to relieve personal discomfort
Severe	Greatly diminished; only extraneous details are perceived, or fixation on a single detail may occur May not take notice of an event even when attention is directed by another	Extremely limited attention span Unable to concentrate or problem-solve Effective learning cannot occur	Headaches Dizziness Nausea Trembling Insomnia Palpitations Tachycardia Hyperventilation Urinary frequency Diarrhea	Feelings of dread, loathing, horror Total focus on self and intense desire to relieve the anxiety
Panic	Unable to focus on even one detail within the environment Misperceptions of the environment common (e.g., a perceived detail may be elaborated and out of proportion)	Learning cannot occur Unable to concentrate Unable to comprehend even simple directions	Dilated pupils Labored breathing Severe trembling Sleeplessness Palpitations Diaphoresis and pallor Muscular incoordination Immobility or purposeless hyperactivity Incoherence or inability to verbalize	Sense of impending doom Terror Bizarre behavior, including shouting, screaming, running about wildly, clinging to anyone or anything from which a sense of safety and security is derived Hallucinations, delusions Extreme withdrawal into self
FIGURE 2–2 Adaptation responses on a continuum of anxiety.

problem-solving and rational thinking. As the level of anxiety increases, the strength of the ego is tested, and energy is mobilized to confront the threat. Anna Freud (1953) identified a number of **defense mechanisms** employed by the ego in the face of threat to biological or psychological integrity. Some of these ego defense mechanisms are more adaptive than others, but all are used either consciously or unconsciously as protective devices for the ego in an effort to relieve mild-to-moderate anxiety. The mechanisms become maladaptive when used by an individual to such a degree that there is interference with the ability to deal with reality, effective interpersonal relations, or occupational performance. Maladaptive use of defense mechanisms promotes disintegration of the ego. The major ego defense mechanisms identified by Anna Freud are summarized in Table 2–2.

TABLE 2–2 Ego Defense Mechanisms

DEFENSE MECHANISM	EXAMPLE	DEFENSE MECHANISM	EXAMPLE
COMPENSATION Covering up a real or perceived weakness by emphasizing a trait one considers more desirable	A physically handicapped boy is unable to participate in football, so he compensates by becoming a great scholar.	**RATIONALIZATION** Attempting to make excuses or formulate logical reasons to justify unacceptable feelings or behaviors	John tells the rehab nurse, "I drink because it's the only way I can deal with my bad marriage and my worse job."
DENIAL Refusing to acknowledge the existence of a real situation or the feelings associated with it	A woman drinks alcohol every day and cannot stop, failing to acknowledge that she has a problem.	**REACTION FORMATION** Preventing unacceptable or undesirable thoughts or behaviors from being expressed by exaggerating opposite thoughts or types of behaviors	Jane hates nursing. She attended nursing school to please her parents. During career day, she speaks to prospective students about the excellence of nursing as a career.
DISPLACEMENT The transfer of feelings from one target to another that is considered less threatening or that is neutral	A client is angry with his physician, does not express it, but becomes verbally abusive with the nurse.	**REGRESSION** Retreating in response to stress to an earlier level of development and the comfort measures associated with that level of functioning	When 2-year-old Jay is hospitalized for tonsillitis he will drink only from a bottle, even though his mother states he has been drinking from a cup for 6 months.
IDENTIFICATION An attempt to increase self-worth by acquiring certain attributes and characteristics of an individual one admires	A teenager who required lengthy rehabilitation after an accident decides to become a physical therapist as a result of his experiences.	**REPRESSION** Involuntarily blocking unpleasant feelings and experiences from one's awareness	An accident victim can remember nothing about his accident.
INTELLECTUALIZATION An attempt to avoid expressing actual emotions associated with a stressful situation by using the intellectual processes of logic, reasoning, and analysis	Sarah's husband is being transferred with his job to a city far away from her parents. She hides anxiety by explaining to her parents the advantages associated with the move.	**SUBLIMATION** Rechanneling of drives or impulses that are personally or socially unacceptable into activities that are constructive	A mother whose son was killed by a drunk driver channels her anger and energy into being the president of the local chapter of Mothers Against Drunk Driving.
INTROJECTION Integrating the beliefs and values of another individual into one's own ego structure	Children integrate their parents' value system into the process of conscience formation. A child says to a friend, "Don't cheat. It's wrong."	**SUPPRESSION** The voluntary blocking of unpleasant feelings and experiences from one's awareness	Scarlett says, "I don't want to think about that now. I'll think about that tomorrow."
ISOLATION Separating a thought or memory from the feeling, tone, or emotion associated with it	A young woman describes being attacked and raped without showing any emotion.	**UNDOING** Symbolically negating or canceling out an experience that one finds intolerable	Joe is nervous about his new job and yells at his wife. On his way home he stops and buys her some flowers.
PROJECTION Attributing feelings or impulses unacceptable to one's self to another person	Sue feels a strong sexual attraction to her track coach and tells her friend, "He's coming on to me!"		

Moderate-to-Severe Anxiety

Anxiety at the moderate-to-severe level that remains unresolved over an extended period of time can contribute to a number of physiological disorders. The *DSM-5* (APA, 2013) describes these disorders under the category "Psychological Factors Affecting Other Medical Conditions." The psychological factors may exacerbate symptoms of, delay recovery from, or interfere with treatment of the medical condition. The condition may be initiated or exacerbated by an environmental situation that the individual perceives as stressful. Measurable pathophysiology can be demonstrated. It is thought that psychological and behavioral factors may affect the course of almost every major category of disease, including but not limited to cardiovascular, gastrointestinal, neoplastic, neurological, and pulmonary conditions.

Severe Anxiety

Extended periods of repressed severe anxiety can result in psychoneurotic behavior patterns. **Neurosis** is no longer considered a separate category of mental disorder. However, the term is still used in the literature to further describe the symptomatology of certain disorders and to differentiate from behaviors that occur at the more serious level of *psychosis.* Neuroses are psychiatric disturbances characterized by excessive anxiety that is expressed directly or altered through defense mechanisms. It appears as a symptom such as an obsession, a compulsion, a phobia, or a sexual dysfunction (Sadock, Sadock, & Ruiz, 2015). The following are common characteristics of people with neuroses:

- They are aware that they are experiencing distress.
- They are aware that their behaviors are maladaptive.
- They are unaware of any possible psychological causes of the distress.
- They feel helpless to change their situation.
- They experience no loss of contact with reality.

The following disorders are examples of psychoneurotic responses to anxiety as they appear in the *DSM-5:*

- **Anxiety disorders:** Disorders in which the characteristic features are symptoms of anxiety and avoidance behavior (e.g., phobias, panic disorder, generalized anxiety disorder, and separation anxiety disorder).
- **Somatic symptom disorders:** Disorders in which the characteristic features are physical symptoms for which there is no demonstrable organic pathology. Psychological factors are judged to play a significant role in the onset, severity, exacerbation, or maintenance of the symptoms (e.g., somatic symptom disorder, illness anxiety disorder, conversion disorder, and factitious disorder).
- **Dissociative disorders:** Disorders in which the characteristic feature is a disruption in the usually integrated functions of consciousness, memory, identity, or perception of the environment (e.g., dissociative amnesia, dissociative identity disorder, and depersonalization-derealization disorder).

Panic Anxiety

At this extreme level of anxiety, an individual is not capable of processing what is happening in the environment and may lose contact with reality. **Psychosis** is defined as a significant thought disturbance in which reality testing is impaired, resulting in delusions, hallucinations, disorganized speech, or catatonic behavior (Black & Andreasen, 2014). The following are common characteristics of people with psychoses:

- They exhibit minimal distress (emotional tone is flat, bland, or inappropriate).
- They are unaware that their behavior is maladaptive.
- They are unaware of any psychological problems (anosognosia).
- They are exhibiting a flight from reality into a less stressful world or one in which they are attempting to adapt.

Examples of psychotic responses to anxiety include schizophrenic, schizoaffective, and delusional disorders.

CORE CONCEPT

Grief

Grief is a subjective state of emotional, physical, and social responses to the loss of a valued entity.

Grief

Most individuals experience intense emotional anguish in response to a significant personal loss. A loss is anything that is perceived as such by the individual. Losses may be real, in which case they can be substantiated by others (e.g., death of a loved one, loss of personal possessions), or they may be perceived by the individual alone, unable to be shared or identified by others (e.g., loss of the feeling of femininity following mastectomy). Any situation that creates change for an individual can be identified as a loss. Failure (either real or perceived) also can be viewed as a loss.

The loss or anticipated loss of anything of value to an individual can trigger the grief response. This period of characteristic emotions and behaviors is called *mourning*. The "normal" mourning process is adaptive and is characterized by feelings of sadness, guilt, anger, helplessness, hopelessness, and despair. An absence of mourning after a loss may be considered maladaptive.

Stages of Grief

Kübler-Ross (1969), in extensive research with terminally ill patients, identified five stages of feelings and

behaviors that individuals experience in response to a real, perceived, or anticipated loss:

Stage 1—Denial: This is a stage of shock and disbelief. The response may be one of "No, it can't be true!" The reality of the loss is not acknowledged. Denial is a protective mechanism that allows the individual to cope in an immediate time frame while organizing more effective defense strategies.

Stage 2—Anger: "Why me?" and "It's not fair!" are comments often expressed during the anger stage. Envy and resentment toward individuals not affected by the loss are common. Anger may be directed at the self or displaced on loved ones, caregivers, and even God. There may be a preoccupation with an idealized image of the lost entity.

Stage 3—Bargaining: During this stage, which is usually not visible or evident to others, a "bargain" is made with God in an attempt to reverse or postpone the loss: "If God will help me through this, I promise I will go to church every Sunday and volunteer my time to help others." Sometimes the promise is associated with feelings of guilt for not having performed satisfactorily, appropriately, or sufficiently.

Stage 4—Depression: During this stage, the full impact of the loss is experienced. The sense of loss is intense, and feelings of sadness and depression prevail. This is a time of quiet desperation and disengagement from all association with the lost entity. It differs from *pathological* depression, which occurs when an individual becomes fixed in an earlier stage of the grief process. Rather, stage 4 of the grief response represents advancement toward resolution.

Stage 5—Acceptance: The final stage brings a feeling of peace regarding the loss that has occurred. It is a time of quiet expectation and resignation. The focus is on the reality of the loss and its meaning for the individuals affected by it.

Not all individuals experience each of these stages in response to a loss, nor do they necessarily experience them in this order. Some individuals' grieving behaviors may fluctuate and even overlap between stages.

Anticipatory Grief

When a loss is anticipated, individuals often begin the work of grieving before the actual loss occurs. Most people reexperience the grieving behaviors once the loss occurs, but preparing for the loss in advance can facilitate the process of mourning, actually decreasing the length and intensity of the response. Problems arise, particularly in anticipating the death of a loved one, when family members experience **anticipatory grieving** and complete the mourning process prematurely. They disengage emotionally from the dying person, who may then experience feelings of rejection by loved ones at a time when this psychological support is so necessary.

Resolution

The grief response can last from weeks to years. It cannot be hurried, and individuals must be allowed to progress at their own pace. In the loss of a loved one, grief work usually lasts for at least a year, during which the grieving person experiences each significant anniversary or holiday for the first time without the loved one present.

Length of the grief process may be prolonged by a number of factors. If the relationship with the lost entity was marked by ambivalence or if there had been an enduring love–hate association, reaction to the loss may be burdened with guilt. Guilt lengthens the grief reaction by promoting feelings of anger toward oneself for having committed a wrongdoing or behaved in an unacceptable manner toward a lost loved one. He or she may even feel that the negative behavior contributed to the loss.

Anticipatory grieving may shorten the grief response in individuals who are able to work through some of the feelings before the loss occurs. If the loss is sudden and unexpected, mourning may take longer than it would if individuals were able to grieve in anticipation of the loss.

Length of the grieving process is also affected by the number of recent losses experienced by an individual and whether he or she is able to complete one grieving process before another loss occurs. This is particularly true for elderly individuals who may experience numerous losses in a span of a few years, including spouse, friends, other relatives, independent functioning, home, personal possessions, and pets. Grief accumulates into a **bereavement overload,** which for some individuals is perceived as difficult or even impossible to overcome.

The process of mourning may be considered resolved when an individual is able to regain a sense of organization, redefine his or her life in the absence of the lost person or object, and pursue new interests and relationships. Disorganization and emotional pain have been experienced and tolerated. Preoccupation with the lost entity has been replaced with a renewed energy and new resolve about ways to keep the memory of the lost one alive. Most grief, however, does not permanently disappear but will reemerge from time to time in response to triggers such as anniversary dates (Sadock et al., 2015).

Maladaptive Grief Responses

Maladaptive responses to loss occur when an individual is not able to satisfactorily progress through the stages of grieving to achieve resolution. These responses usually occur when an individual becomes fixed in the denial or anger stage of the grief process. Several types of grief responses have been identified as pathological, including those that are prolonged, delayed, inhibited, or distorted. The *prolonged* response is characterized by an intense preoccupation with memories of the lost entity for *many years after the loss has occurred.* Behaviors associated with the stages of denial or anger are manifested, and disorganization of functioning and intense emotional pain related to the lost entity are evidenced.

In the *delayed* or *inhibited* response, the individual becomes fixed in the denial stage of the grieving process. The emotional pain associated with the loss is not experienced, but anxiety disorders (e.g., phobias, somatic symptom disorders) or sleeping and eating disorders (e.g., insomnia, anorexia) may be evident. The individual may remain in denial for many years until the grief response is triggered by a reminder of the loss or even by an unrelated loss.

The individual who experiences a *distorted* response is fixed in the anger stage of grieving. In the distorted response, all the normal behaviors associated with grieving, such as helplessness, hopelessness, sadness, anger, and guilt, are exaggerated out of proportion to the situation. The individual turns the anger inward on the self, is consumed with overwhelming despair, and is unable to function in normal activities of daily living. Pathological depression is a distorted grief response.

Mental Health/Mental Illness Continuum

Anxiety and grief have been described as two primary responses to stress. In Figure 2–3, both of these responses are presented on a continuum according to degree of symptom severity. Disorders as they appear in the *DSM-5* are identified at their appropriate placement along the continuum.
FIGURE 2–3   Conceptualization of anxiety and grief responses along the mental health/mental illness continuum.

Summary and Key Points

■ Psychiatric care has its roots in ancient times, when etiology was based in superstition and ideas related to the supernatural.

■ Treatments were often inhumane and included brutal beatings, starvation, or torture.

■ Hippocrates associated insanity and mental illness with an irregularity in the interaction of the four body fluids (humors): blood, black bile, yellow bile, and phlegm.

■ Conditions for care of the mentally ill have improved, largely because of the influence of leaders such as Benjamin Rush, Dorothea Dix, and Linda Richards, whose endeavors provided a model for more humanistic treatment.

■ Maslow identified a hierarchy of needs that individuals seek to fulfill in their quest to self-actualization (one's highest potential).

■ For purposes of this text, the definition of *mental health* is "the successful adaptation to stressors from the internal or external environment, evidenced by thoughts, feelings, and behaviors that are age-appropriate and congruent with local and cultural norms."

■ Most cultures label behavior as mental illness on the basis of incomprehensibility and cultural relativity.

■ When observers are unable to find meaning or comprehensibility in behavior, they are likely to label that behavior as mental illness. The meaning of behaviors is determined within individual cultures. For purposes of this text, the definition of *mental illness* is viewed as "maladaptive responses to stressors from the internal or external environment, evidenced by thoughts, feelings, and behaviors that are incongruent with the local and cultural norms, and that interfere with the individual's social, occupational, and/or physical functioning."

■ Anxiety and grief have been described as two primary psychological response patterns to stress.

■ Peplau defined anxiety by levels of symptom severity: mild, moderate, severe, and panic.

■ Behaviors associated with levels of anxiety include coping mechanisms, ego defense mechanisms, psychophysiological responses, psychoneurotic responses, and psychotic responses.

■ Grief is described as a response to loss of a valued entity. Loss is anything that is perceived as such by the individual.

■ Kübler-Ross, in extensive research with terminally ill patients, identified five stages of feelings and behaviors that individuals experience in response to a real, perceived, or anticipated loss: denial, anger, bargaining, depression, and acceptance.

■ Anticipatory grief is grief work that begins and sometimes ends before the loss occurs.

■ Resolution is thought to occur when an individual is able to remember and accept both the positive and negative aspects associated with the lost entity.

■ Grieving is thought to be maladaptive when the mourning process is prolonged, delayed or inhibited, or becomes distorted and exaggerated out of proportion to the situation. Pathological depression is considered to be a distorted reaction.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Anna's dog, Lucky, her pet for 16 years, was killed by a car 3 years ago. Since that time, Anna has lost weight, rarely leaves her home, and talks excessively about Lucky. Why would Anna's behavior be considered maladaptive?
   a. It has been more than 3 years since Lucky died.
   b. Her grief is too intense over the loss of a dog.
   c. Her grief is interfering with her functioning.
   d. Cultural norms typically do not comprehend grief over the loss of a pet.

Review Questions—cont'd
Self-Examination/Learning Exercise

2. Anna states that Lucky was her closest friend, and since his death, there is no one who could ever replace the relationship they had. According to Maslow's hierarchy of needs, which level of need is not being met?
a. Physiological needs
b. Self-esteem needs
c. Safety and security needs
d. Love and belonging needs

3. Anna's daughter notices that Anna appears to be listening to another voice when just the two of them are in a room together. When questioned, Anna admits that she hears someone telling her that she was a horrible caretaker for Lucky and did not deserve to ever have a pet. Which of the following best describes what Anna is experiencing?
a. Neurosis
b. Psychosis
c. Depression
d. Bereavement

4. Anna, who is 72 years old, is of the age when she may have experienced several losses in a short time. What is this called?
a. Bereavement overload
b. Normal mourning
c. Isolation
d. Cultural relativity

5. Anna has been grieving the death of Lucky for 3 years. She is unable to take care of her normal activities because she insists on visiting Lucky's grave daily. What is the most likely reason that Anna's daughter has put off seeking help for Anna?
a. Women are less likely than men to seek help for emotional problems.
b. Relatives often try to normalize behavior rather than label it mental illness.
c. She knows that all older people are expected to be a little depressed.
d. She is afraid that the neighbors will think her mother is "crazy."

6. Lucky's accident occurred when he got away from Anna while they were taking a walk. He ran into the street and was hit by a car. Anna cannot remember the circumstances of his death. This is an example of what defense mechanism?
a. Rationalization
b. Suppression
c. Denial
d. Repression

7. Lucky sometimes refused to obey Anna's commands to come back to her, including when he ran into the street on the day of the accident. But Anna continues to insist, "He was the very best dog. He always minded me. He always did everything I told him to do." Which defense mechanism is Anna exhibiting?
a. Sublimation
b. Compensation
c. Reaction formation
d. Undoing

8. Anna has been a widow for 20 years. Her maladaptive grief response to the loss of her dog may be attributed to which of the following? (Select all that apply.)
a. Unresolved grief over loss of her husband
b. Loss of several relatives and friends over the last few years
c. Repressed feelings of guilt over the way Lucky died
d. Inability to prepare in advance for the loss

Review Questions—cont'd
Self-Examination/Learning Exercise

9. For what reason would Anna's illness be considered a neurosis rather than a psychosis?
   a. She is unaware that her behavior is maladaptive.
   b. She exhibits inappropriate affect (emotional tone).
   c. She experiences no loss of contact with reality.
   d. She tells the nurse, "There is nothing wrong with me!"

10. Which of the following statements by Anna might suggest that she is achieving resolution of her grief over Lucky's death?
   a. "I don't cry anymore when I think about Lucky."
   b. "It's true. Lucky didn't always mind me. Sometimes he ignored my commands."
   c. "I remember how it happened now. I should have held tighter to his leash!"
   d. "I won't ever have another dog. It's just too painful to lose them."

UNIT 2

Foundations for Psychiatric-Mental Health Nursing

3

Concepts of Psychobiology

CHAPTER OUTLINE

Objectives
Homework Assignment
The Nervous System: An Anatomical Review
Neuroendocrinology
Genetics

Psychoneuroimmunology
Psychopharmacology and the Brain
Implications for Nursing
Summary and Key Points
Review Questions

KEY TERMS

axon
cell body
circadian rhythms
dendrites

genotype
limbic system
neuron
neurotransmitter

phenotype
receptor sites
synapse

OBJECTIVES
After reading this chapter, the student will be able to:

1. Identify gross anatomical structures of the brain and describe their functions.
2. Discuss the physiology of neurotransmission in the central nervous system.
3. Describe the role of neurotransmitters in human behavior.
4. Discuss the association of endocrine functioning to the development of psychiatric disorders.
5. Describe the role of genetics in the development of psychiatric disorders.
6. Discuss the correlation of altered brain function to various psychiatric disorders.
7. Identify diagnostic procedures used to detect alteration in biological functioning that may contribute to psychiatric disorders.

8. Discuss the influence of psychological factors on the immune system.
9. Describe the biological mechanisms of psychoactive drugs at neural synapses.
10. Recognize theorized influences in the development of psychiatric disorders, including brain physiology, genetics, endocrine function, immune system, and psychosocial and environmental factors.
11. Discuss the implications of psychobiological concepts for the practice of psychiatric-mental health nursing.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. A dramatic reduction in which neurotransmitter is most closely associated with Alzheimer's disease?
2. Anorexia nervosa has been associated with a primary dysfunction of which structure of the brain?

3. Many psychotropic medications work by blocking the reuptake of neurotransmitters. Describe the process of *reuptake.*
4. What psychiatric disorder may be linked to chronic hypothyroidism?

In recent years, increased emphasis has been placed on the organic basis for psychiatric illness. This "neuroscientific revolution" studies the biological basis of behavior, and several mental illnesses are now considered physical disorders resulting from malfunctions and/or malformations of the brain. That some psychiatric illnesses and associated behaviors can be traced to biological factors does not imply that psychosocial and sociocultural influences are totally discounted. For example, there is evidence that *psychological* interventions have an influence on brain activity that is similar to that of psychopharmacological intervention (Flor, 2014; Furmark et al., 2002). Other evidence indicates that lifestyle choices such as marijuana use can precipitate mental illness (psychosis) in individuals with genetic vulnerability (National Institutes of Health, 2017). Ongoing research will build a better understanding of the complex interplay of neural activities within the brain and interaction with one's environment.

The systems of biology, psychology, and sociology are not mutually exclusive—they are interacting systems. This interaction is clearly indicated by the fact that individuals experience biological changes in response to environmental events. One or several of these systems may at various times explain behavioral phenomena.

This chapter focuses on the role of neurophysiological, neurochemical, genetic, and endocrine influences on psychiatric illness. An introduction to psychopharmacology is included (discussed in more detail in Chapter 4, Psychopharmacology), and various diagnostic procedures used to detect alteration in biological function that may contribute to psychiatric illness are identified. The implications for psychiatric-mental health nursing are discussed.

CORE CONCEPT

Psychobiology

The study of the biological foundations of cognitive, emotional, and behavioral processes.

The Nervous System: An Anatomical Review

The Brain

The brain has three major divisions, subdivided into six major parts:

1. Forebrain
   a. Cerebrum
   b. Diencephalon
2. Midbrain
   a. Mesencephalon
3. Hindbrain
   a. Pons
   b. Medulla
   c. Cerebellum

Each of these structures is discussed individually. A summary is presented in Table 3–1.

Cerebrum

The cerebrum consists of a right and left hemisphere and constitutes the largest part of the human brain. The two hemispheres are separated by a deep groove and connected to each other by a band of 200 million axons (nerve fibers) called the *corpus callosum*. Because

STRUCTURE	**PRIMARY FUNCTION**
I. FOREBRAIN	
A. Cerebrum	Composed of two hemispheres connected by a band of nerve tissue that houses a band of 200 million axons called the *corpus callosum*. The outer layer is called the *cerebral cortex*. It is extensively folded and consists of billions of neurons. The left hemisphere appears to deal with logic and solving problems. The right hemisphere may be called the "creative" brain and is associated with affect, behavior, and spatial-perceptual functions. Each hemisphere is divided into four lobes
1. Frontal lobes	Voluntary body movement, including movements that permit speaking, thinking and judgment formation, and expression of feelings
2. Parietal lobes	Perception and interpretation of most sensory information (including touch, pain, taste, and body position)
3. Temporal lobes	Hearing, short-term memory, and sense of smell; expression of emotions through connection with limbic system
4. Occipital lobes	Visual reception and interpretation

Continued

TABLE 3–1 **Structure and Function of the Brain—cont'd**	
STRUCTURE	**PRIMARY FUNCTION**
B. Diencephalon 1. Thalamus	Connects cerebrum with lower brain structures Integrates all sensory input (except smell) on way to cortex; some involvement with emotions and mood
2. Hypothalamus	Regulates anterior and posterior lobes of pituitary gland; exerts control over actions of the autonomic nervous system; regulates appetite and temperature
3. Limbic system	Consists of medially placed cortical and subcortical structures and the fiber tracts connecting them with one another and with the hypothalamus. It is sometimes called the "emotional brain"—associated with feelings of fear and anxiety; anger and aggression; love, joy, and hope; and with sexuality and social behavior
II. MIDBRAIN **A.** Mesencephalon	Responsible for visual, auditory, and balance ("righting") reflexes
III. HINDBRAIN **A.** Pons	Regulation of respiration and skeletal muscle tone; ascending and descending tracts connect brainstem with cerebellum and cortex
B. Medulla	Pathway for all ascending and descending fiber tracts; contains vital centers that regulate heart rate, blood pressure, and respiration; reflex centers for swallowing, sneezing, coughing, and vomiting
C. Cerebellum	Regulates muscle tone and coordination and maintains posture and equilibrium

each hemisphere controls different functions, information is processed through the corpus callosum so that each hemisphere is aware of the activity of the other.

The surface of the cerebrum consists of gray matter and is called the *cerebral cortex.* The gray matter is composed of neuron cell bodies that appear gray to the eye. These cell bodies are thought to be the actual "thinking" structures of the brain. The *basal ganglia,* four subcortical nuclei of gray matter (the striatum, the pallidum, the substantia nigra, and the subthalamic nucleus), are found deep within the cerebral hemispheres. They are responsible for certain subconscious aspects of voluntary movement, such as swinging the arms when walking, gesturing while speaking, and regulating muscle tone (Scanlon & Sanders, 2015).

The cerebral cortex is identified by numerous folds called *gyri* and deep grooves between the folds called *sulci.* This extensive folding extends the surface area of the cerebral cortex to permit the presence of millions more neurons than could not be accommodated without the folds (as is the case in the brains of some animals, such as dogs and cats). Each hemisphere of the cerebral cortex is divided into the frontal lobe, parietal lobe, temporal lobe, and occipital lobe. These lobes, which are named for the overlying bones in the cranium, are identified in Figure 3–1.

The Frontal Lobes

Voluntary body movement is controlled by impulses through the frontal lobes. The right frontal lobe controls motor activity on the left side of the body, and the left frontal lobe controls motor activity on the right side of the body. The frontal lobe may also play a role in the emotional experience, as evidenced by changes in mood and character after damage to this area. The prefrontal cortex (the front part of the frontal lobe) plays an essential role in the regulation and adaptation of our emotions to new situations and may have implications for moral and spiritual responses (Sadock, Sadock, & Ruiz, 2015). Neuroimaging tests suggest there may be decreased activity in the frontal lobes of people with schizophrenia (Butler et al., 2012).

The Parietal Lobes

The parietal lobes manage somatosensory input, including touch, pain, pressure, taste, temperature, perception of joint and body position, and visceral sensations. The parietal lobes also contain association fibers linked to the primary sensory areas through which interpretation of sensory-perceptual information is made. Language interpretation is associated with the left hemisphere of the parietal lobe.

The Temporal Lobes

The upper anterior temporal lobe is concerned with auditory functions, and the lower part is dedicated to short-term memory. The sense of smell has a connection to the temporal lobes, as the impulses carried by the olfactory nerves end in this area of the brain. The temporal lobes also play a role in the expression of
FIGURE 3–1 Left cerebral hemisphere showing some of the functional areas that have been mapped. (Adapted from Scanlon, V.C., & Sanders, T. [2015]. *Essentials of anatomy and physiology* [7th ed.]. Philadelphia: F.A. Davis Company, with permission.)

emotions through an interconnection with the limbic system. The left temporal lobe and the left parietal lobe are involved in language interpretation.

The Occipital Lobes

The occipital lobes are the primary area of visual reception and interpretation. Visual perception, the ability to judge spatial relationships such as distance and to see in three dimensions, is also processed in this area. Language interpretation is affected by the visual processing that occurs in the occipital lobes.

Diencephalon

The second part of the forebrain is the diencephalon, which connects the cerebrum with lower structures of the brain. The major components of the diencephalon include the thalamus and the hypothalamus, which are part of a neuroanatomical loop of structures known as the **limbic system.** These structures are identified in Figures 3–1 and 3–2.

Thalamus

The thalamus integrates all sensory input (except smell) on its way to the cortex. This integration allows for rapid interpretation of the whole rather than individual perception of each sensation. The thalamus is also involved in temporarily blocking minor sensations so that an individual can concentrate on one important event when necessary. For example, an individual who is studying for an examination may be unaware of the clock ticking in the room or another person entering because the thalamus has temporarily blocked these incoming sensations from the cortex. The impact of dopamine in the thalamus is associated with several neuropsychiatric disorders.

Hypothalamus

The hypothalamus is located just below the thalamus and just above the pituitary gland. It has a number of diverse functions.

1. **Regulation of the pituitary gland:** The pituitary gland consists of two lobes—the posterior lobe and the anterior lobe.
   a. The *posterior lobe* of the pituitary gland is actually extended tissue from the hypothalamus. The posterior lobe stores antidiuretic hormone (which helps to maintain blood pressure through regulation of water retention) and oxytocin (the hormone responsible for stimulation of the uterus during labor and the release of milk from the mammary glands). Both of these hormones are produced in the hypothalamus. When the hypothalamus detects the body's need for these hormones, it sends nerve impulses to the posterior pituitary for their release.
FIGURE 3–2 Structures of the limbic system. (From Scanlon, V.C., & Sanders, T. [2011]. *Essentials of anatomy and physiology* [6th ed.]. Philadelphia: F.A. Davis Company, with permission.)

b. The *anterior lobe* of the pituitary gland consists of glandular tissue that produces a number of hormones used by the body. These hormones are regulated by *releasing factors* from the hypothalamus. When the hormones are required by the body, the releasing factors stimulate the release of the hormone from the anterior pituitary, and the hormone in turn stimulates its target organ to carry out its specific functions.

2. **Direct neural control over the actions of the autonomic nervous system:** The hypothalamus regulates the appropriate visceral responses during various emotional states. The actions of the autonomic nervous system are described later in this chapter.

3. **Regulation of appetite, temperature, blood pressure, thirst, and circadian rhythms:** Appetite is regulated through response to blood nutrient levels.

4. **Regulation of temperature:** The hypothalamus senses internal temperature changes in the blood that flows through the brain. It receives information through sensory input from the skin about external temperature changes and uses this information to promote certain types of responses (e.g., sweating or shivering) that help maintain body temperature within the normal range.

Limbic System

The part of the brain known as the limbic system consists of portions of the cerebrum and the diencephalon. Its major components include the medially placed cortical and subcortical structures and the fiber tracts connecting them with one another and with the hypothalamus. The limbic system is a group of structures including the amygdala, mammillary body, olfactory tract, hypothalamus, cingulate gyrus, septum pellucidum, thalamus, hippocampus, and fornix. This system has been called the "emotional brain" and is associated with feelings of fear and anxiety; anger, rage, and aggression; love, joy, and hope; and sexuality and social behavior. The amygdala seems

to be a primary gateway for processing emotional stimuli, particularly responses to fear, anxiety, and panic.

Mesencephalon

Structures of major importance in the mesencephalon, or midbrain, include nuclei and fiber tracts. The mesencephalon extends from the pons to the hypothalamus and is responsible for integration of various reflexes, including visual reflexes (e.g., automatically turning away from a dangerous object when it comes into view), auditory reflexes (e.g., automatically turning toward a sound that is heard), and righting reflexes (e.g., automatically keeping the head upright and maintaining balance).

Pons

The pons is a bulbous structure that lies between the midbrain and the medulla as part of the brainstem (Fig. 3–1). It is composed of large bundles of fibers and forms a major connection between the cerebellum and the brainstem. The pons is a relay station that transmits messages between various parts of the nervous system, including the cerebrum and cerebellum. It contains the central connections of cranial nerves V through VIII and centers for respiration and skeletal muscle tone. The pons is also associated with sleep and dreaming.

Medulla

The medulla is the connecting structure between the spinal cord and the pons, and all of the ascending and descending fiber tracts pass through it. The vital centers are contained in the medulla, and it is responsible for regulation of heart rate, blood pressure, and respiration. The medulla contains reflex centers for swallowing, sneezing, coughing, and vomiting, as well as nuclei for cranial nerves IX through XII. The medulla, pons, and midbrain form the structure known as the *brainstem.*

Cerebellum

The cerebellum is separated from the brainstem by the fourth ventricle but is connected to it through bundles of fiber tracts (Fig. 3–1). The cerebellum is associated with involuntary aspects of movement such as coordination, muscle tone, and the maintenance of posture and equilibrium.

Nerve Tissue

The tissue of the central nervous system (CNS) consists of nerve cells called *neurons* that generate and transmit electrochemical impulses. The structure of a neuron is composed of a cell body, an axon, and dendrites. The **cell body** contains the nucleus and is essential for the continued life of the neuron. The **dendrites** are processes that transmit impulses toward the cell body, and the **axon** transmits impulses away from the cell body. The axons and dendrites are covered by layers of cells called *neuroglia* that form a coating, or "sheath," of myelin. *Myelin* is a phospholipid that provides insulation against short-circuiting of the neurons during their electrical activity and increases the velocity of the impulse. The white matter of the brain and spinal cord is so called because of the whitish appearance of the myelin sheath over the axons and dendrites. The gray matter is composed of cell bodies that contain no myelin.

The three classes of neurons include afferent (sensory), efferent (motor), and interneurons. The *afferent neurons* carry impulses from receptors in the internal and external periphery to the CNS, where they are then interpreted into various sensations. The *efferent neurons* carry impulses from the CNS to *effectors* in the periphery, such as muscles (that respond by contracting) and glands (that respond by secreting).

Interneurons exist entirely within the CNS, and 99 percent of all nerve cells belong to this group. They may carry only sensory or motor impulses, or they may serve as integrators in the pathways between afferent and efferent neurons. They account in large part for thinking, feelings, learning, language, and memory.

Synapses

Information is transmitted through the body from one neuron to another. Some messages may be processed through only a few neurons, whereas others may require thousands of neuronal connections. The neurons that transmit the impulses do not actually touch each other. The junction between two neurons is called a **synapse.** The small space between the axon terminals of one neuron and the cell body or dendrites of another is called the *synaptic cleft.* Neurons conducting impulses toward the synapse are called *presynaptic neurons,* and those conducting impulses away are called *postsynaptic neurons.*

Chemicals that act as **neurotransmitters** are stored in the axon terminals of the presynaptic neuron. An electrical impulse through the neuron causes the release of this neurotransmitter into the synaptic cleft. The neurotransmitter then diffuses across the synaptic cleft and combines with **receptor sites** that are situated on the cell membrane of the postsynaptic neuron. The type of combination determines whether or not another electrical impulse is generated. If an electrical impulse is generated, the result is called an *excitatory response* and the electrical impulse moves on to the next synapse, where the same process recurs. If an electrical impulse is not generated by the neurotransmitter-receptor site combination, the result is called an *inhibitory response,* and synaptic transmission

is terminated. Activity at the neural synapse is relevant in the study of psychiatric disorders because excessive or deficient activity of neurotransmitters influences a variety of cognitive and emotional symptoms. The synapse is also believed to be the primary site of activity for psychotropic drugs.

The cell body of the postsynaptic neuron also contains a chemical *inactivator* that is specific to the neurotransmitter released by the presynaptic neuron. When the synaptic transmission has been completed, the chemical inactivator quickly inactivates the neurotransmitter to prevent unwanted, continuous impulses until a new impulse from the presynaptic neuron releases more of the neurotransmitter. Continuous impulses can result in excessive activity of neurotransmitters such as dopamine, which is believed to be responsible for symptoms such as hallucinations and delusions seen in people with schizophrenia. A schematic representation of a synapse is presented in Figure 3–3.

Autonomic Nervous System

The autonomic nervous system (ANS) is considered part of the peripheral nervous system. Its regulation is modulated by the hypothalamus, and emotions exert a great deal of influence over its functioning. For this reason, the ANS has been implicated in the etiology of a number of psychophysiological disorders.

The ANS has two divisions: the sympathetic and the parasympathetic. The sympathetic division is dominant in stressful situations and prepares the body for the fight-or-flight response (discussed in Chapter 1, The Concept of Stress Adaptation). The neuronal cell bodies of the sympathetic division originate in the thoracolumbar region of the spinal cord. Their axons extend to the chains of sympathetic ganglia where they synapse with other neurons that subsequently innervate the visceral effectors. This results in an increase in heart rate and respiration and a decrease in digestive secretions and peristalsis. Blood is shunted to the vital organs and skeletal muscles to ensure adequate oxygenation.

The neuronal cell bodies of the parasympathetic division originate in the brainstem and the sacral segments of the spinal cord and extend to the parasympathetic ganglia where the synapse takes place either very close to or actually in the visceral organ being innervated. In this way, a very localized response is possible. The parasympathetic division dominates when an individual is in a relaxed, non-stressful condition. The heart and respirations are
FIGURE 3–3 Impulse transmission at a synapse. The arrow indicates the direction of electrical impulses. (From Scanlon, V.C., & Sanders, T. [2015]. *Essentials of anatomy and physiology* [7th ed.]. Philadelphia: F.A. Davis Company, with permission.)

maintained at a normal rate, and secretions and peristalsis increase for normal digestion. Elimination functions are promoted. A schematic representation of the ANS is presented in Figure 3–4.

Neurotransmitters

Although neurotransmitters were described during the explanation of synaptic activity, they are discussed here separately and in detail because of the essential function they perform in the role of human emotion and behavior. Neurotransmitters are also central to the therapeutic action of many psychotropic medications.

Neurotransmitters are chemicals that convey information across synaptic clefts to neighboring target cells. They are stored in small vesicles in the axon terminals of neurons. When the action potential, or electrical impulse, reaches this point, the neurotransmitters are released from the vesicles. They cross the synaptic cleft and bind with receptor sites on the cell body or dendrites of the adjacent neuron to allow the impulse
FIGURE 3–4 The autonomic nervous system. The sympathetic division is shown on the left, and the parasympathetic division is shown on the right (both divisions are bilateral). (From Scanlon, V.C., & Sanders, T. [2015]. *Essentials of anatomy and physiology* [7th ed.]. Philadelphia: F.A. Davis Company, with permission.)

to continue its course or to prevent the impulse from continuing. After the neurotransmitter has performed its function in the synapse, it either returns to the vesicles to be stored and used again or is inactivated and dissolved by enzymes. The process of being stored for reuse is called *reuptake*, a function that holds significance for understanding the mechanism of action of certain psychotropic medications.

Many neurotransmitters exist in the central and peripheral nervous systems, but only a limited number have implications for psychiatry. Major categories include cholinergics, monoamines, amino acids, and neuropeptides. Each of these is discussed separately and summarized in Table 3–2.

Cholinergics

Acetylcholine

Acetylcholine was the first chemical to be identified as and proven to be a neurotransmitter. It is a major effector chemical in the ANS, producing activity

TABLE 3–2 **Neurotransmitters in the Central Nervous System**		
NEUROTRANSMITTER	**LOCATION AND FUNCTION**	**POSSIBLE IMPLICATIONS FOR MENTAL ILLNESS**
I. CHOLINERGICS **A.** Acetylcholine	*ANS:* Sympathetic and parasympathetic presynaptic nerve terminals; parasympathetic postsynaptic nerve terminals *CNS:* Cerebral cortex, hippocampus, limbic structures, and basal ganglia *Functions:* Sleep, arousal, pain perception, movement, memory	*Increased levels:* Depression *Decreased levels:* Alzheimer's disease, Huntington's disease, Parkinson's disease
II. MONOAMINES **A.** Norepinephrine	*ANS:* Sympathetic postsynaptic nerve terminals *CNS:* Thalamus, hypothalamus, limbic system, hippocampus, cerebellum, cerebral cortex *Functions:* Mood, cognition, perception, locomotion, cardiovascular functioning, and sleep and arousal	*Decreased levels:* Depression *Increased levels:* Mania, anxiety states, schizophrenia
B. Dopamine	Frontal cortex, limbic system, basal ganglia, thalamus, posterior pituitary, spinal cord *Functions:* Movement and coordination, emotions, voluntary judgment, release of prolactin	*Decreased levels:* Parkinson's disease and depression *Increased levels:* Mania and schizophrenia
C. Serotonin	Hypothalamus, thalamus, limbic system, cerebral cortex, cerebellum, spinal cord *Functions:* Sleep and arousal, libido, appetite, mood, aggression, pain perception, coordination, judgment	*Decreased levels:* Depression *Increased levels:* Anxiety states
D. Histamine	Hypothalamus *Functions:* Wakefulness; pain sensation, inflammatory response	*Decreased levels:* Depression
III. AMINO ACIDS **A.** Gamma-aminobutyric acid	Hypothalamus, hippocampus, cortex, cerebellum, basal ganglia, spinal cord, retina *Functions:* Slowdown of body activity	*Decreased levels:* Huntington's disease, anxiety disorders, schizophrenia, and various forms of epilepsy
B. Glycine	Spinal cord, brainstem *Functions:* Recurrent inhibition of motor neurons	*Toxic levels:* Glycine encephalopathy *Decreased levels:* Correlated with spastic motor movements
C. Glutamate and aspartate	Pyramidal cells of the cortex, cerebellum, and the primary sensory afferent systems; hippocampus, thalamus, hypothalamus, spinal cord *Functions:* Relay of sensory information and in the regulation of various motor and spinal reflexes Glutamate also has a role in memory and learning.	*Increased levels:* Huntington's disease, temporal lobe epilepsy, spinal cerebellar degeneration, anxiety disorders, depressive disorders *Decreased levels:* Schizophrenia

TABLE 3–2 Neurotransmitters in the Central Nervous System—cont'd		
NEUROTRANSMITTER	**LOCATION AND FUNCTION**	**POSSIBLE IMPLICATIONS FOR MENTAL ILLNESS**
D. D-Serine	Cerebral cortex, forebrain, hippocampus, cerebellum striatum, thalamus *Functions:* Binds at NMDA receptors and, with glutamate, is a coagonist whose functions include mediating NMDA receptor transmission, synaptic plasticity, neurotoxicity	*Decreased levels:* Schizophrenia
IV. NEUROPEPTIDES A. Endorphins and enkephalins	Hypothalamus, thalamus, limbic structures, midbrain, brainstem; enkephalins are also found in the gastrointestinal tract *Functions:* Modulation of pain and reduced peristalsis (enkephalins)	Modulation of dopamine activity by opioid peptides may indicate some link to the symptoms of schizophrenia
B. Substance P	Hypothalamus, limbic structures, midbrain, brainstem, thalamus, basal ganglia, spinal cord; also found in gastrointestinal tract and salivary glands *Function:* Regulation of pain	*Decreased levels:* Huntington's disease, Alzheimer's disease *Increased levels:* Depression
C. Somatostatin	Cerebral cortex, hippocampus, thalamus, basal ganglia, brainstem, spinal cord *Function:* Depending on part of the brain affected, stimulates release of dopamine, serotonin, norepinephrine, and acetylcholine, and inhibits release of norepinephrine, histamine, and glutamate; also acts as a neuromodulator for serotonin in the hypothalamus	*Decreased levels:* Alzheimer's disease *Increased levels:* Huntington's disease

ANS, autonomic nervous system, CNS, central nervous system, NMDA, *N*-methyl D-aspartate.

at all sympathetic and parasympathetic presynaptic nerve terminals and all parasympathetic postsynaptic nerve terminals. It is highly significant in the neurotransmission that occurs at the junctions of nerves and muscles. Acetylcholinesterase is the enzyme that destroys acetylcholine or inhibits its activity.

In the CNS, acetylcholine neurons innervate the cerebral cortex, hippocampus, and limbic structures. The pathways are especially dense through the area of the basal ganglia in the brain.

Functions of acetylcholine are manifold and include sleep, arousal, pain perception, the modulation and coordination of movement, and memory acquisition and retention. Cholinergic mechanisms may have some role in certain disorders of motor behavior and memory, such as Parkinson's disease, Huntington's disease, and Alzheimer's disease.

Monoamines

Norepinephrine

Norepinephrine is the neurotransmitter that produces activity at the sympathetic postsynaptic nerve terminals in the ANS, resulting in fight-or-flight responses in the effector organs. In the CNS, norepinephrine pathways originate in the pons and medulla and innervate the thalamus, dorsal hypothalamus, limbic system, hippocampus, cerebellum, and cerebral cortex. When norepinephrine is not returned for storage in the vesicles of the axon terminals, it is metabolized and inactivated by the enzymes monoamine oxidase (MAO) and catechol-*O*-methyl-transferase (COMT).

The functions of norepinephrine include the regulation of mood, cognition, perception, locomotion, cardiovascular functioning, and sleep and arousal. The activity of norepinephrine also has been implicated in certain mood disorders such as depression and mania, in anxiety states, and in schizophrenia (Sadock et al., 2015).

Dopamine

Dopamine pathways arise from the midbrain and hypothalamus and terminate in the frontal cortex, limbic system, basal ganglia, and thalamus. As with norepinephrine, the inactivating enzymes for dopamine are MAO and COMT.

Dopamine functions include regulation of movements and coordination, emotions, and voluntary decision-making ability. Because of its influence on the pituitary gland, it inhibits the release of prolactin (Sadock et al., 2015). Increased levels of dopamine are associated with mania and schizophrenia.

Serotonin

Serotonin pathways originate from cell bodies located in the pons and medulla and project to areas including the hypothalamus, thalamus, limbic system, cerebral cortex, cerebellum, and spinal cord. Serotonin that is not returned to be stored in the axon terminal vesicles is catabolized by the enzyme MAO.

Serotonin may play a role in sleep and arousal, libido, appetite, mood, aggression, and pain perception. The serotoninergic system has been implicated in the etiology of certain psychopathological conditions including anxiety states, mood disorders, and schizophrenia (Sadock et al., 2015).

Histamine

The role of histamine in mediating allergic and inflammatory reactions has been well documented. Its role in the CNS as a neurotransmitter has only recently been confirmed, and the availability of information on this function is limited. The highest concentrations of histamine are found within various regions of the hypothalamus. Histaminic neurons in the posterior hypothalamus are associated with sustaining wakefulness. The enzyme that catabolizes histamine is MAO. Although the exact processes mediated by histamine in the CNS are uncertain, some data suggest that histamine may play a role in depressive illness.

Amino Acids

Inhibitory Amino Acids

Gamma-Aminobutyric Acid Gamma-aminobutyric acid (GABA) has a widespread distribution in the CNS, with high concentrations in the hypothalamus, hippocampus, cortex, cerebellum, and basal ganglia of the brain; in the gray matter of the dorsal horn of the spinal cord; and in the retina. GABA is catabolized by the enzyme GABA transaminase.

Inhibitory neurotransmitters such as GABA prevent postsynaptic excitation, interrupting the progression of the electrical impulse at the synaptic junction. This function is significant when slowdown of body activity is advantageous. Enhancement of the GABA system is the mechanism of action by which the benzodiazepines produce their calming effect.

Alterations in the GABA system have been implicated in the etiology of anxiety disorders, movement disorders (e.g., Huntington's disease), and various forms of epilepsy.

Glycine The highest concentrations of glycine in the CNS are found in the spinal cord and brainstem. Little is known about the possible enzymatic metabolism of glycine.

Glycine appears to be the neurotransmitter of recurrent inhibition of motor neurons within the spinal cord and is possibly involved in the regulation of spinal and brainstem reflexes. It has been implicated in the pathogenesis of certain types of spastic disorders and in *glycine encephalopathy,* which is known to occur with toxic accumulation of the neurotransmitter in the brain and cerebrospinal fluid (Van Hove, Coughlin, & Sharer, 2013).

Excitatory Amino Acids

Glutamate and Aspartate Glutamate and aspartate appear to be primary excitatory neurotransmitters in the pyramidal cells of the cortex, the cerebellum, and the primary sensory afferent systems. They are also found in the hippocampus, thalamus, hypothalamus, and spinal cord. Glutamate and aspartate are inactivated by uptake into the tissues and through assimilation in various metabolic pathways.

Glutamate and aspartate function in the relay of sensory information and in the regulation of various motor and spinal reflexes. Alteration in these systems has been implicated in the etiology of certain neurodegenerative disorders, such as Huntington's disease, temporal lobe epilepsy, and spinal cerebellar degeneration. Recent studies have implicated increased levels of glutamate in anxiety and depressive disorders and decreased levels in schizophrenia (Ouellet-Plamondon & George, 2012). Glutamate also plays a role in memory and learning. Another amino acid, D-serine, has been identified as a neurotransmitter that, with glutamate, may act as a coagonist at NMDA (*N*-methyl D-aspartate) receptors. Hypofunction of these neurotransmitters may be associated with schizophrenia (Balu et al., 2013; Wolosker et al., 2008).

Neuropeptides

Neuropeptides act as signaling molecules in the CNS. Their activities include regulating processes related to sex, sleep, stress and pain, emotion, and social cognition. They may contribute to symptoms and behaviors associated with psychosis, mood disorders, dementia, and autism spectrum disorders (Sadock et al., 2015). Hormonal neuropeptides are discussed in the section of this chapter on neuroendocrinology.

Opioid Peptides

Opioid peptides, which include the endorphins and enkephalins, have been widely studied. They are found in various concentrations in the hypothalamus, thalamus, limbic structures, midbrain, and brainstem. Enkephalins are also found in the gastrointestinal tract. Opioid peptides have natural morphine-like properties and are thought to have a role in pain modulation. Released in response to painful stimuli, they may be responsible for producing the analgesic effect that results from acupuncture. Opioid peptides alter the release of dopamine and affect the spontaneous activity of the dopaminergic neurons. These findings may

have some implication for opioid peptide-dopamine interaction in the etiology of schizophrenia.

Substance P

Substance P, the first neuropeptide to be discovered, is present in high concentrations in the hypothalamus, limbic structures, midbrain, and brainstem. It is also found in the thalamus, basal ganglia, and spinal cord. Substance P plays a role in sensory transmission, particularly in the regulation of pain. Recent studies demonstrated that people with depression and posttraumatic stress disorder (PTSD) had elevated levels of substance P in cerebral spinal fluid (Sadock et al., 2015).

Somatostatin

Somatostatin (also called *growth hormone–inhibiting hormone [GHIH]*) is found in the cerebral cortex, hippocampus, thalamus, basal ganglia, brainstem, and spinal cord, and has multiple effects on the CNS. In its function as a neurotransmitter, somatostatin exerts both stimulatory and inhibitory effects. Depending on the part of the brain affected, it has been shown to stimulate dopamine, serotonin, norepinephrine, and acetylcholine and to inhibit norepinephrine, histamine, and glutamate. It also acts as a neuromodulator for serotonin in the hypothalamus, thereby regulating its release. Somatostatin may serve this function for other neurotransmitters as well. High concentrations of somatostatin have been reported in brain specimens of clients with Huntington's disease, and low concentrations have been found in those with Alzheimer's disease.

CORE CONCEPTS

Neuroendocrinology
The study of the interaction between the nervous system and the endocrine system and the effects of various hormones on cognitive, emotional, and behavioral functioning.

Neuroendocrinology

Human endocrine functioning has a strong foundation in the CNS under the direction of the hypothalamus, which has direct control over the pituitary gland. The pituitary gland has two major lobes—the interior lobe (also called the *adenohypophysis*) and the posterior lobe (also called the *neurohypophysis*). The pituitary gland is only about the size of a pea, but despite its size and because of the powerful control it exerts over endocrine functioning in humans, it is sometimes called the "master gland." Figure 3–5 shows the hormones of the pituitary gland and their target organs. Many of the hormones subject to hypothalamus-pituitary regulation may have implications for behavioral functioning. Discussion of these hormones is summarized in Table 3–3.

Pituitary Gland

The Posterior Pituitary (Neurohypophysis)

The hypothalamus has direct control over the posterior pituitary through efferent neural pathways. Two hormones are found in the posterior pituitary: vasopressin (antidiuretic hormone) and oxytocin. They are actually produced by the hypothalamus and stored in the posterior pituitary. Their release is mediated by neural impulses from the hypothalamus (Fig. 3–6).

Antidiuretic Hormone

The main function of antidiuretic hormone (ADH) is to conserve body water and maintain normal blood pressure. The release of ADH is stimulated by pain, emotional stress, dehydration, increased plasma concentration, and decreases in blood volume. An alteration in the secretion of this hormone is related to the polydipsia seen in patients with diabetes. This may be one of many factors contributing to the polydipsia and water intoxication (a state of hyperhydration related to excessive consumption of water) observed in about 10 to 20 percent of patients with severe mental illness, particularly those with schizophrenia. Other factors correlated with this behavior include adverse effects of psychotropic medications and features of the behavioral disorder itself. Many factors may influence excessive intake of water in patients with severe psychiatric illness. Severe water intoxication can result in electrolyte imbalance and death (Kohli, Shishir, & Sharma, 2011). ADH also may play a role in learning and memory, alteration of the pain response, and modification of sleep patterns.

Oxytocin

Oxytocin causes contraction of the uterus at the end of pregnancy and stimulates release of milk from the mammary glands (Scanlon & Sanders, 2015). It is also released in response to stress and during sexual arousal. Oxytocin may promote bonding between sexes and has been used experimentally with autistic children to increase socialization (Sadock et al., 2015). Its role in behavioral functioning is unclear, although it is possible that oxytocin may stimulate the release of adrenocorticotropic hormone (ACTH) in certain situations, thereby playing a key role in the overall hormonal response to stress.

The Anterior Pituitary (Adenohypophysis)

The hypothalamus produces releasing hormones that pass through capillaries and veins of the hypophyseal portal system to capillaries in the anterior
FIGURE 3–5 Hormones of the pituitary gland and their target organs. (From Scanlon, V.C., & Sanders, T. [2015]. *Essentials of anatomy and physiology* [7th ed.]. Philadelphia: F.A. Davis Company, with permission.)

TABLE 3–3 **Hormones of the Neuroendocrine System**				
HORMONE	**LOCATION AND STIMULATION OF RELEASE**	**TARGET ORGAN**	**FUNCTION**	**POSSIBLE BEHAVIORAL CORRELATION TO ALTERED SECRETION**
Antidiuretic hormone (ADH)	Posterior pituitary; release stimulated by dehydration, pain, stress	Kidney (causes increased reabsorption)	Conservation of body water; maintenance of blood pressure	Polydipsia; altered pain response; modified sleep pattern
Oxytocin	Posterior pituitary; release stimulated by end of pregnancy; stress; during sexual arousal	Uterus; breasts	Contraction of the uterus for labor; release of breast milk	May perform role in stress response by stimulation of ACTH

TABLE 3–3 Hormones of the Neuroendocrine System—cont'd

HORMONE	LOCATION AND STIMULATION OF RELEASE	TARGET ORGAN	FUNCTION	POSSIBLE BEHAVIORAL CORRELATION TO ALTERED SECRETION
Growth hormone (GH)	Anterior pituitary; release stimulated by growth hormone–releasing hormone from hypothalamus	Bones and tissues	Growth in children; protein synthesis in adults	Anorexia nervosa
Thyroid-stimulating hormone (TSH)	Anterior pituitary; release stimulated by thyrotropin-releasing hormone from hypothalamus	Thyroid gland	Stimulation of secretion of needed thyroid hormones for metabolism of food and regulation of temperature	*Increased levels of thyroid hormones (decreased secretion of TSH):* Insomnia, anxiety, emotional lability *Decreased levels of thyroid hormones (increased secretion of TSH):* Fatigue, depression
Adrenocorticotropic hormone (ACTH)	Anterior pituitary; release stimulated by corticotropin-releasing hormone from hypothalamus	Adrenal cortex	Stimulation of secretion of cortisol, which performs a role in response to stress	*Increased levels:* Mood disorders, psychosis *Decreased levels:* Depression, apathy, fatigue
Prolactin	Anterior pituitary; release stimulated by prolactin-releasing hormone from hypothalamus	Breasts	Stimulation of milk production	*Increased levels:* Depression, anxiety, decreased libido, irritability
Gonadotropic hormones	Anterior pituitary; release stimulated by gonadotropin-releasing hormone from hypothalamus	Ovaries and testes	Stimulation of secretion of estrogen, progesterone, and testosterone; role in ovulation and sperm production	*Decreased levels:* Depression, anorexia nervosa *Increased testosterone:* Increased sexual behavior and aggressiveness
Melanocyte-stimulating hormone (MSH)	Anterior pituitary; release stimulated by onset of darkness	Pineal gland	Stimulation of secretion of melatonin	*Increased levels:* Depression

pituitary, where they stimulate secretion of specialized hormones. The hormones of the anterior pituitary gland regulate multiple body functions and include growth hormone, thyroid-stimulating hormone, ACTH, prolactin, gonadotropin-stimulating hormone, and melanocyte-stimulating hormone. Most of these hormones are regulated by a *negative feedback mechanism.* Once the hormone has exerted its effects, the information is "fed back" to the anterior pituitary, which inhibits the release and ultimately decreases the effects of the stimulating hormones.

Growth Hormone

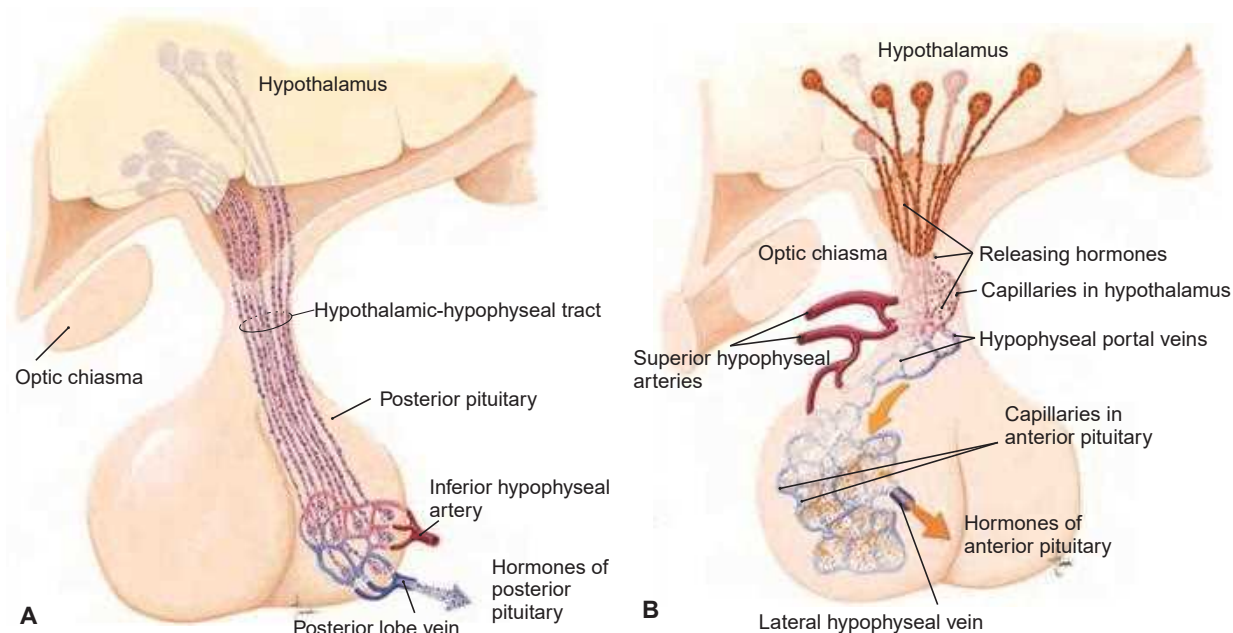
The release of growth hormone (GH), also called *somatotropin,* is stimulated by growth hormone–releasing hormone (GHRH) from the hypothalamus. Its release is inhibited by GHIH, or somatostatin, also from the hypothalamus. It is responsible for growth in children and continued protein synthesis throughout life. During periods of fasting, it stimulates the release of fat from the adipose tissue to increase energy. The release of GHIH is stimulated in response to periods of hyperglycemia. GHRH is stimulated in response to hypoglycemia and to stressful situations. During prolonged stress, GH has a direct effect on protein, carbohydrate, and lipid metabolism, resulting in increased serum glucose and free fatty acids to be used for increased energy. GH deficiency has been noted in many patients with major depressive disorder, and several GH abnormalities have been noted in patients with anorexia nervosa.


FIGURE 3–6 Structural relationships of hypothalamus and pituitary gland. (A) Posterior pituitary stores hormones produced in the hypothalamus. (B) Releasing hormones of the hypothalamus circulate directly to the anterior pituitary and influence its secretions. Notice the two networks of capillaries. (From Scanlon, V.C., & Sanders, T. [2015]. *Essentials of anatomy and physiology* [7th ed.]. Philadelphia: F.A. Davis Company, with permission.)

Thyroid-Stimulating Hormone

Thyrotropin-releasing hormone (TRH) from the hypothalamus stimulates the release of thyroid-stimulating hormone (TSH), or thyrotropin, from the anterior pituitary. TSH stimulates the thyroid gland to secrete triiodothyronine (T_3) and thyroxine (T_4). Thyroid hormones are integral to the metabolism of food and the regulation of temperature.

A correlation between thyroid dysfunction and altered behavioral functioning has been well documented. Common symptoms of hyperthyroidism include irritability, insomnia, anxiety, restlessness, weight loss, and emotional lability, in some instances progressing to delirium or psychosis. Symptoms of fatigue, decreased libido, memory impairment, depression, and suicidal ideation have been associated with chronic hypothyroidism. Studies have correlated various forms of thyroid dysfunction with mood disorders, anxiety, eating disorders, schizophrenia, and dementia.

Adrenocorticotropic Hormone

Corticotropin-releasing hormone (CRH) from the hypothalamus stimulates the release of ACTH from the anterior pituitary. ACTH stimulates the adrenal cortex to secrete cortisol. CRH, ACTH, and cortisol levels all rise in response to stress. Disorders of the adrenal cortex have been associated with mood disorders, PTSD, Alzheimer's dementia, and substance use disorders.

Addison's disease is the result of hyposecretion of the hormones of the adrenal cortex. Behavioral symptoms of hyposecretion include mood changes with apathy, social withdrawal, impaired sleep, decreased concentration, and fatigue. Hypersecretion of cortisol results in Cushing's disease and is associated with behaviors that include depression, mania, psychosis, and suicidal ideation. Cognitive impairments also have been observed.

Prolactin

Prolactin is mainly involved in reproductive functions and milk production in the mammary glands during pregnancy. First-generation antipsychotic medications increase prolactin levels and may be responsible for the undesired side effect of lactation. High prolactin levels are also associated with depression, decreased libido, anxiety, irritability, and the negative symptoms of schizophrenia. Prolactin levels in psychotic patients have been positively correlated with severity of tardive dyskinesia (Sadock et al., 2015).

Gonadotropic Hormones

The gonadotropic hormones are so called because they produce an effect on the gonads—the ovaries and the testes. The gonadotropins include follicle-stimulating hormone (FSH) and luteinizing hormone (LH). In women, FSH initiates maturation of ovarian follicles into ova and stimulates their secretion of estrogen. LH is responsible for ovulation and the secretion of progesterone from the corpus luteum. In men, FSH initiates sperm production in the testes, and LH increases secretion of testosterone by the interstitial cells of the testes (Scanlon & Sanders, 2015).

Limited evidence exists to correlate gonadotropins to behavioral functioning, although some observations

have been made that warrant hypothetical consideration. Studies have indicated decreased levels of testosterone, LH, and FSH in men who have depression. Increased sexual behavior and aggressiveness have been linked to elevated testosterone levels in both men and women. Decreased plasma levels of LH and FSH commonly occur in patients with anorexia nervosa. Supplemental estrogen therapy has resulted in improved mentation and mood in some depressed women.

Melanocyte-Stimulating Hormone

Melanocyte-stimulating hormone (MSH) from the hypothalamus stimulates the pineal gland to secrete melatonin. The release of melatonin appears to depend on the onset of darkness and is suppressed by light. Studies of this hormone have indicated that environmental light can affect neuronal activity and influence circadian rhythms. Correlation between abnormal secretion of melatonin and symptoms of depression has led to the implication of melatonin in the etiology of seasonal affective disorder, in which individuals become depressed only during the fall and winter months when the amount of daylight decreases.

Circadian Rhythms

Human biological rhythms are largely determined by genetic coding, with input from the external environment influencing the cyclic effects. **Circadian rhythms** in humans follow a near-24-hour cycle and may influence a variety of regulatory functions, including the sleep–wakefulness cycle, body temperature regulation, patterns of activity such as eating and drinking, and hormone secretion. The 24-hour rhythms in humans are affected to a large degree by the cycles of lightness and darkness. This occurs because of a "pacemaker" in the brain that sends messages to other systems in the body and maintains the 24-hour rhythm. This endogenous pacemaker appears to be the suprachiasmatic nuclei of the hypothalamus. These nuclei receive projections of light through the retina and in turn stimulate electrical impulses to various other systems in the body, mediating the release of neurotransmitters or hormones that regulate bodily functioning.

Most of the biological rhythms of the body operate over a period of about 24 hours, but cycles of longer lengths have been studied. For example, women of menstruating age show monthly cycles of progesterone levels in the saliva, of skin temperature over the breasts, and of prolactin levels in the plasma of the blood (Hughes, 1993).

Some rhythms may even last as long as a year. These circannual rhythms are particularly relevant to certain medications, such as cyclosporine, which appears to be more effective at some times than others during a period of about 12 months (Hughes, 1993). Clinical studies have shown that administration of chemotherapy during the appropriate circadian phase and at the appropriate time of day can significantly increase the efficacy and decrease the toxic effects of certain cytotoxic agents (Garlapow, 2016; Lis et al., 2003).

The Role of Circadian Rhythms in Psychopathology

Circadian rhythms may play a role in psychopathology. Abnormal circadian rhythms have been associated with a variety of mental illnesses including depression, bipolar disorder, and seasonal affective disorder. Because many hormones have been implicated in behavioral functioning, it is reasonable to believe that peak secretion times could be influential in predicting certain behaviors. The association of depression with increased secretion of melatonin during darkness hours has already been discussed. External manipulation of the light–dark cycle and removal of external time cues often have beneficial effects on mood disorders.

Symptoms that occur in the premenstrual cycle have been linked to disruptions in biological rhythms. A number of the symptoms associated with premenstrual dysphoric disorder (PMDD) strongly resemble those attributed to depression, and hormonal changes have been implicated in the etiology. Some of these changes include progesterone–estrogen imbalance, increase in prolactin and mineralocorticoids, high level of prostaglandins, decrease in endogenous opiates, changes in metabolism of biogenic amines (serotonin, dopamine, norepinephrine, acetylcholine), and variations in secretion of glucocorticoids or melatonin.

Because the sleep–wakefulness cycle is probably the most fundamental of biological rhythms, and sleep disturbances are common in both depression and PMDD, it will be discussed in greater detail. A representation of bodily functions affected by 24-hour biological rhythms is presented in Figure 3–7.

Sleep

The sleep–wakefulness cycle is genetically determined rather than learned and is established some time after birth. Even when environmental cues such as the ability to detect light and darkness are removed, the human sleep–wakefulness cycle generally develops about a 25-hour periodicity, which is close to the 24-hour normal circadian rhythm.

Sleep can be measured by the types of brain waves that occur during various stages of sleep activity. Dreaming episodes are characterized by rapid eye movement (REM) and are called REM sleep. The sleep–wakefulness cycle is represented by six distinct stages.

Stage 0—Alpha rhythm: This stage of the sleep–wakefulness cycle is characterized by a relaxed, waking state with eyes closed. The alpha brain wave rhythm has a frequency of 8 to 12 cycles per second.

FIGURE 3–7   Circadian biological rhythms.
* ▼ indicates low point and ▲ indicates peak time of these biological factors within a 24-hour circadian rhythm.
** The female hormones are presented on a monthly rhythm because of their influence on the reproductive cycle. Daily rhythms of female gonadotropins are difficult to assay and are probably less significant than monthly.

Stage 1—Beta rhythm: Stage 1 characterizes the transition into sleep, a period of dozing in which thoughts wander and the person drifts in and out of sleep. Beta brain wave rhythm has a frequency of 18 to 25 cycles per second.

Stage 2—Theta rhythm: This stage comprises about half of time spent sleeping. Eye movement and muscular activity are minimal. Theta brain wave rhythm has a frequency of 4 to 7 cycles per second.

Stage 3—Delta rhythm: This is a period of deep and restful sleep. Muscles are relaxed, heart rate and blood pressure fall, and breathing slows. No eye movement occurs. Delta brain wave rhythm has a frequency of 1.5 to 3 cycles per second.

Stage 4—Delta rhythm: This is the stage of deepest sleep. Individuals who suffer from insomnia or other sleep disorders often do not experience this stage of sleep. Eye movement and muscular activity are minimal. Delta waves predominate.

REM sleep—Beta rhythm: The dream cycle occurs during REM sleep. Eyes dart about beneath closed eyelids, moving more rapidly than when awake.

The brain wave pattern is similar to that of stage 1 sleep. Heart and respiration rates increase, and blood pressure may increase or decrease. Muscles are hypotonic during REM sleep.

Stages 2 through REM repeat themselves throughout the cycle of sleep. One is more likely to experience longer periods of stages 3 and 4 sleep early in the cycle and longer periods of REM sleep later in the sleep cycle. Most people experience REM sleep about four to five times during the night. The amount of REM sleep and deep sleep decreases with age, and the time spent in drowsy wakefulness and dozing increases.

Neurochemical Influences

A number of neurochemicals have been shown to influence the sleep–wakefulness cycle. Several studies have revealed information about the sleep-inducing characteristics of serotonin. L-Tryptophan, the amino acid precursor to serotonin, has been used for many years as an effective sedative-hypnotic to induce sleep in individuals with sleep-onset disorder. Serotonin and norepinephrine both appear to be most active during non-REM sleep, whereas the neurotransmitter acetylcholine is activated during REM sleep (Skudaev, 2009). The exact role of GABA in sleep facilitation is unclear, although the sedative effects of drugs that enhance GABA transmission, such as benzodiazepines, suggest that this neurotransmitter plays an important role in regulation of sleep and arousal. Some studies have suggested that acetylcholine induces and prolongs REM sleep, whereas histamine appears to have an inhibitory effect. Neuroendocrine mechanisms seem to be more closely tied to circadian rhythms than to the sleep–wakefulness cycle. One exception is growth hormone secretion, which increases during the stage 3 sleep period and may be associated with slow-wave sleep (Van Cauter & Plat, 1996).

CORE CONCEPT

Genetics

The study of the biological transmission of certain physical and/or behavioral characteristics from parent to offspring.

Genetics

Human behavioral genetics seeks to understand both the genetic and environmental contributions to individual variations in human behavior. This type of study is complicated by the fact that behaviors, like all complex traits, involve *multiple genes.*

The term **genotype** refers to the total set of genes present in an individual and coded in the DNA at the time of conception. The physical manifestations of a

particular genotype are designated by characteristics that specify a **phenotype.** Examples of phenotypes include eye color, height, blood type, sound of voice, and hair type. As evident by the examples presented, phenotypes are not *only* genetic but may also be acquired (i.e., influenced by the environment) or a combination of both. It is likely that many psychiatric disorders are the result of a combination of genetics and environmental influences.

Investigators who study the etiological implications for psychiatric illness may explore several risk factors. Studies to determine if an illness is *familial* compare the percentage of family members with the illness to those in the general population or within a control group of unrelated individuals. These studies estimate the prevalence of psychopathology among relatives and make predictions about the predisposition to an illness based on familial risk factors. Schizophrenia, bipolar disorder, major depressive disorder, anorexia nervosa, panic disorder, somatic symptom disorder, antisocial personality disorder, and alcoholism are examples of psychiatric illness in which familial tendencies have been indicated.

Studies that are purely genetic search for a specific gene that causes a particular illness. A number of disorders exist in which the mutation of a specific gene or change in the number or structure of chromosomes has been associated with the etiology. Examples include Huntington's disease, cystic fibrosis, phenylketonuria, Duchenne's muscular dystrophy, and Down syndrome.

The search for pure genetic links to certain psychiatric disorders continues. Risk factors for early-onset Alzheimer's disease have been linked to mutations on chromosomes 21, 14, and 1 (National Institute on Aging, 2015). Other studies have linked a gene in the region of chromosome 19 that produces apolipoprotein E (ApoE) with late-onset Alzheimer's disease. One large study (National Institute of Mental Health, 2013) found similar genetic variations in patients with five mental disorders that were previously considered completely distinct. Autism, attention-deficit/hyperactivity disorder (ADHD), bipolar disorder, major depression, and schizophrenia all showed some common gene variations, including differences in two genes that regulate the flow of calcium into cells. Although these findings are intriguing, they do not clearly explain all the genetic risks for mental illness, the nongenetic risks, or the interaction between the two. Future research will continue to search for answers with the ultimate goal of improving diagnosis and treatment and perhaps uncovering keys to prevention of mental illness. In addition to familial and purely genetic investigations, other types of studies have been conducted to estimate the existence and degree of genetic and environmental contributions to the etiology of certain psychiatric disorders. Twin

studies and adoption studies have been successfully employed for this purpose.

Twin studies examine the frequency of a disorder in monozygotic (genetically identical) and dizygotic (not genetically identical) twins. Twins are called *concordant* when both members suffer from the disorder in question. Concordance in monozygotic twins is considered stronger evidence of genetic involvement than it is in dizygotic (fraternal) twins. Twin studies have supported genetic vulnerability in the etiology of several mental illnesses, including adjustment disorders, PTSD, substance abuse, schizophrenia, bipolar disorder, major depression, obsessive compulsive disorder, risk for suicide, and others (Sadock et al., 2015).

Adoption studies allow researchers to compare the influence of genetics versus environment on the development of a psychiatric disorder. Knowles (2003) describes the four types of adoption studies that have been conducted:

1. The study of adopted children whose biological parent(s) had a psychiatric disorder but whose adoptive parent(s) did not.
2. The study of adopted children whose adoptive parent(s) had a psychiatric disorder but whose biological parent(s) did not.
3. The study of adoptive and biological relatives of adopted children who developed a psychiatric disorder.
4. The study of monozygotic twins reared apart by different adoptive parents.

Disorders in which adoption studies have suggested a possible genetic link include alcoholism, schizophrenia, major depression, bipolar disorder, suicide risk, ADHD, and antisocial personality disorder (Sadock et al., 2015).

A summary of various psychiatric disorders and the possible biological influences discussed in this chapter is presented in Table 3–4. Various diagnostic procedures used to detect alteration in biological functioning that may contribute to psychiatric disorders are presented in Table 3–5.

CORE CONCEPT

Psychoneuroimmunology

The study of the relationship between the immune system, the nervous system, and psychological processes such as thinking and behavior.

TABLE 3–4 Biological Implications of Psychiatric Disorders

ANATOMICAL BRAIN STRUCTURES INVOLVED	NEUROTRANSMITTER HYPOTHESIS	POSSIBLE ENDOCRINE CORRELATION	IMPLICATIONS OF CIRCADIAN RHYTHMS	POSSIBLE GENETIC LINK
SCHIZOPHRENIA Frontal cortex, temporal lobes, limbic system	Dopamine hyperactivity; decreased glutamate	Decreased prolactin levels	May correlate antipsychotic medication administration to times of lowest level	Twin, familial, and adoption studies suggest genetic link
DEPRESSIVE DISORDERS Frontal lobes, limbic system, temporal lobes	Decreased levels of norepinephrine, dopamine, and serotonin; increased glutamate	Increased cortisol levels; thyroid hormone hyposecretion; increased melatonin	DST* used to predict effectiveness of antidepressants; melatonin linked to depression during periods of darkness	Twin, familial, and adoption studies suggest a genetic link
BIPOLAR DISORDER Frontal lobes, limbic system, temporal lobes	Increased levels of norepinephrine and dopamine in acute mania	Some indication of elevated thyroid hormones in acute mania	Abnormal circadian rhythms have been associated with bipolar disorder	Twin, familial, and adoption studies suggest a genetic link
PANIC DISORDER Limbic system, midbrain	Increased levels of norepinephrine; decreased GABA activity	Elevated levels of thyroid hormones	May have some application for times of medication administration	Twin and familial studies suggest a genetic link

TABLE 3–4 Biological Implications of Psychiatric Disorders—cont'd

ANATOMICAL BRAIN STRUCTURES INVOLVED	NEUROTRANSMITTER HYPOTHESIS	POSSIBLE ENDOCRINE CORRELATION	IMPLICATIONS OF CIRCADIAN RHYTHMS	POSSIBLE GENETIC LINK
ANOREXIA NERVOSA Limbic system, particularly the hypothalamus	Decreased levels of norepinephrine, serotonin, and dopamine	Decreased levels of gonadotropins and growth hormone; increased cortisol levels	DST often shows same results as in depression	Twin and familial studies suggest a genetic link
OBSESSIVE-COMPULSIVE DISORDER Limbic system, basal ganglia (specifically caudate nucleus)	Decreased levels of serotonin	Increased cortisol levels	DST often shows same results as in depression	Twin studies suggest a possible genetic link
ALZHEIMER'S DISEASE Temporal, parietal, and occipital regions of cerebral cortex; hippocampus	Decreased levels of acetylcholine, norepinephrine, serotonin, and somatostatin	Decreased corticotropin-releasing hormone	Decreased levels of acetylcholine and serotonin may inhibit hypothalamic-pituitary axis and interfere with hormonal releasing factors	Familial studies suggest a genetic predisposition; late-onset disorder linked to marker on chromosome 19; early-onset to chromosomes 21, 14, and 1

*DST, dexamethasone suppression test. Dexamethasone is a synthetic glucocorticoid that suppresses cortisol secretion via the feedback mechanism. In this test, 1 mg of dexamethasone is administered at 11:30 p.m., and blood samples are drawn at 8:00 a.m., 4:00 p.m., and 11:00 p.m. on the following day. A plasma value greater than 5 mcg/dL suggests that the individual is not suppressing cortisol in response to the dose of dexamethasone. This is a positive result for depression and may have implications for other disorders as well.
GABA, gamma-aminobutyric acid.

TABLE 3–5 Diagnostic Procedures Used to Detect Altered Brain Functioning

EXAMINATION	TECHNIQUE USED	PURPOSE AND POSSIBLE FINDINGS
Electroencephalography (EEG)	Electrodes are placed on the scalp in a standardized position. Amplitude and frequency of beta, alpha, theta, and delta brain waves are graphically recorded on paper by ink markers for multiple areas of the brain surface.	Measures brain electrical activity; identifies dysrhythmias, asymmetries, or suppression of brain rhythms; used in the diagnosis of epilepsy, neoplasm, stroke, metabolic, or degenerative disease.
Computerized EEG mapping	EEG tracings are summarized by computer-assisted systems in which various regions of the brain are identified and functioning is interpreted by color coding or gray shading.	Measures brain electrical activity; used largely in research to represent statistical relationships between individuals and groups or between two populations of subjects (e.g., patients with schizophrenia vs. control subjects).
Computed tomographic (CT) scan	CT scan may be used with or without contrast medium. X-rays are taken of various transverse planes of the brain while a computerized analysis produces a precise reconstructed image of each segment.	Measures accuracy of brain structure to detect possible lesions, abscesses, areas of infarction, or aneurysm. CT has also identified various anatomical differences in patients with schizophrenia, organic mental disorders, and bipolar disorder.

Continued

TABLE 3–5 **Diagnostic Procedures Used to Detect Altered Brain Functioning—cont'd**		
EXAMINATION	TECHNIQUE USED	PURPOSE AND POSSIBLE FINDINGS
Magnetic resonance imaging (MRI)	Within a strong magnetic field, the nuclei of hydrogen atoms absorb and reemit electromagnetic energy that is computerized and transformed into image information. No radiation or contrast medium is used.	Measures anatomical and biochemical status of various segments of the brain; detects brain edema, ischemia, infection, neoplasm, trauma, and other changes such as demyelination. Morphological differences have been noted in brains of patients with schizophrenia as compared with control subjects.
Positron emission tomography (PET)	The patient receives an intravenous (IV) injection of a radioactive substance (type depends on brain activity to be visualized). The head is surrounded by detectors that relay data to a computer that interprets the signals and produces the image.	Measures specific brain functioning, such as glucose metabolism, oxygen utilization, blood flow, and, of particular interest in psychiatry, neurotransmitter-receptor interaction.
Single photon emission computed tomography (SPECT)	The technique is similar to PET, but longer-acting radioactive substance must be used to allow time for a gamma-camera to rotate about the head and gather the data, which are then computer assembled into a brain image.	Measures various aspects of brain functioning, as with PET; has also been used to image activity of cerebrospinal fluid circulation.

Psychoneuroimmunology

Normal Immune Response

Cells responsible for *nonspecific* immune reactions include neutrophils, monocytes, and macrophages. They work to destroy the invasive organism and initiate and facilitate the healing of damaged tissue. If these cells do not accomplish a satisfactory healing response, *specific* immune mechanisms take over.

Cytokines are one such mechanism. These molecules, which regulate immune and inflammatory responses, become active when an individual is fighting an infection and the resultant inflammatory processes. Recent research has also demonstrated that cytokines are active in mood disorders such as depression and bipolar disorder. Current research focuses on the impact of cytokines as part of an essential and complex system of responses that are crucial for reducing inflammation and bolstering the immune response. Studies are also attempting to identify what happens when inflammation is not resolved and cytokines remain active or cross the blood-brain barrier. There is evidence that these maladaptations may be implicated in a multitude of illnesses (Ratnayake et al., 2013).

Implications of the Immune System in Psychiatric Illness

Studies of the biological response to stress have hypothesized that individuals become more susceptible to physical illness following exposure to a stressful stimulus or life event (see Chapter 1). This response is thought to be caused by increased glucocorticoid release from the adrenal cortex following stimulation from the hypothalamic-pituitary-adrenal axis during stressful situations. The result is a suppression in lymphocyte proliferation and function.

Studies have shown that nerve endings exist in tissues of the immune system. The CNS has connections in both bone marrow and the thymus, where immune system cells are produced, and in the spleen and lymph nodes, where those cells are stored.

GH, which may be released in response to certain stressors, may enhance immune functioning, whereas testosterone is thought to inhibit immune functioning. Increased production of epinephrine and norepinephrine occurs in response to stress and may decrease immunity. Serotonin has been described as an immunomodulator because it has demonstrated both enhancing and inhibitory effects on inflammation and immunity (Arreola et al., 2015).

Studies have correlated a decrease in lymphocyte function with periods of grief, bereavement, and depression, associating the degree of altered immunity with severity of the depression. A number of research studies have attempted to correlate the onset of schizophrenia to abnormalities of the immune system. These studies have considered autoimmune responses, viral infections, and immunogenetics (Sadock et al., 2015). The role of these factors in the onset and course of schizophrenia remains unclear. Attempts to identify a neurotoxic virus that triggers the manifestations of schizophrenia have not been successful; however, there is clear evidence of higher incidence of schizophrenia following viral epidemics.

Immunological abnormalities have also been investigated in a number of other psychiatric illnesses, including alcoholism, autism spectrum disorder, and neurocognitive disorder.

Evidence exists to support a correlation between psychosocial stress and the onset of illness. Research is still required to determine the specific processes involved in stress-induced modulation of the immune system.

Psychopharmacology and the Brain

Understanding the brain and the biological processes involved in thoughts, feelings, and behavior has positive ramifications beyond better understanding of psychopharmacological treatment options. As mentioned earlier, future research may continue to demonstrate the impact of psychological interventions on brain activity and neurotransmitters, which would open opportunities to hone psychological treatments and avoid the troubling side effects that accompany many medications. Furthermore, continued research in areas such as psychoneuroimmunology may reveal causes of mental illness, which would provide the opportunity for primary prevention.

In spite of these opportunities, psychopharmacology remains a primary treatment modality for mental disorders. Understanding, as best we can with current evidence, the biological mechanisms at work in psychoactive drugs is essential to nursing practice. Figure 3–8 shows the biological mechanism of psychoactive drugs at the neural synapse. Psychopharmacology, the classes of psychoactive drugs, and relevant nursing implications are discussed in detail in Chapter 4.

Implications for Nursing

The discipline of psychiatric-mental health nursing has always championed its role in holistic health care, but historical review reveals that emphasis has been placed on treatment approaches that focus on psychological and social factors. Psychiatric nurses must integrate knowledge of the biological sciences into their practices if they are to ensure safe and effective care to people with mental illness. In the hallmark Surgeon General's Report on Mental Health (U.S. Department of Health and Human Services, 1999), Dr. David Satcher wrote:

> The mental health field is far from a complete understanding of the biological, psychological, and sociocultural bases of development, but development clearly involves interplay among these influences. Understanding the process of development requires knowledge, ranging from the most fundamental level—that of gene expression and interactions between molecules and cells—all the way up to the highest levels of cognition, memory, emotion, and language. The challenge requires integration of concepts from many different disciplines. A fuller understanding of development is not only important in its own right, but it is expected to pave the way for our ultimate understanding of mental health and mental illness and how different factors shape their expression at different stages of the life span. (pp. 61–62)

To ensure a smooth transition from a strictly psychosocial focus to one of *bio*psychosocial emphasis, nurses must have a clear understanding of the following:

- **Neuroanatomy and neurophysiology:** The structure and functioning of the various parts of the brain and their correlation to human behavior and psychopathology
- **Neuronal processes:** The various functions of the nerve cells, including the role of neurotransmitters, receptors, synaptic activity, and information pathways
- **Neuroendocrinology:** The interaction of the endocrine and nervous systems and the role that the endocrine glands and their respective hormones play in behavioral functioning
- **Circadian rhythms:** The regulation of biochemical functioning over periods of rhythmic cycles and its influence in predicting certain behaviors
- **Genetic influences:** The hereditary factors that predispose individuals to certain psychiatric disorders
- **Psychoneuroimmunology:** The influence of stress on the immune system and its role in the susceptibility to illness
- **Psychopharmacology:** The increasing use of psychotropic drugs in the treatment of mental illness, demanding greater knowledge of psychopharmacological principles and nursing interventions necessary for safe and effective management
- **Diagnostic technology:** The importance of keeping informed about the latest in technological procedures for diagnosing alterations in brain structure and function

Why are these concepts important to the practice of psychiatric-mental health nursing? The interrelationship between psychosocial adaptation and physical functioning has been established. Integrating biological and behavioral concepts into psychiatric nursing practice is essential for nurses to meet the complex needs of clients with mental illness. Psychobiological perspectives must be incorporated into nursing practice, education, and research to attain the evidence-based outcomes necessary for the delivery of competent care.
FIGURE 3–8 Area of synaptic transmission that is altered by drugs.

The transmission of electrical impulses from the axon terminal of one neuron to the dendrite of another is achieved by the controlled release of neurotransmitters into the synaptic cleft. Neurotransmitters include serotonin, norepinephrine, acetylcholine, dopamine, glutamate, gamma-aminobutyric acid (GABA), and histamine, among others. Prior to its release, the neurotransmitter is concentrated into specialized synaptic vesicles. Once fired, the neurotransmitter is released into the synaptic cleft where it encounters receptors on the postsynaptic membrane. Each neurotransmitter has receptors specific to it alone. Some neurotransmitters are considered to be *excitatory,* whereas others are *inhibitory,* a feature that determines whether another action potential will occur. In the synaptic cleft, the neurotransmitter rapidly diffuses, is catabolized by enzymatic action, or is taken up by the neurotransmitter transporters and returned to vesicles inside the axon terminal to await another action potential.

Psychotropic medications exert their effects in various ways in this area of synaptic transmission. Reuptake inhibitors block *reuptake* of the neurotransmitters by the transporter proteins, resulting in elevated levels of extracellular neurotransmitter. Drugs that inhibit catabolic enzymes promote excess buildup of the neurotransmitter at the synaptic site.

Some drugs cause *receptor blockade,* resulting in a reduction in transmission and decreased neurotransmitter activity. These drugs are called *antagonists.* Drugs that increase neurotransmitter activity by *direct stimulation* of the specific receptors are called *agonists.*

Summary and Key Points

- It is important for nurses to understand the interaction between biological and behavioral factors in the development and management of mental illness.
- Psychobiology is the study of the biological foundations of cognitive, emotional, and behavioral processes.
- The limbic system has been called the "emotional brain." It is associated with feelings of fear and anxiety; anger, rage, and aggression; love, joy, and hope; and with sexuality and social behavior.

- The three classes of neurons include afferent (sensory), efferent (motor), and interneurons. The junction between two neurons is called a *synapse.*
- Neurotransmitters are chemicals that convey information across synaptic clefts to neighboring target cells. Many neurotransmitters have implications in the etiology of emotional disorders and in the pharmacological treatment of those disorders.
- Major categories of neurotransmitters include cholinergics, monoamines, amino acids, and neuropeptides.

■ The endocrine system plays an important role in human behavior through the hypothalamic-pituitary axis.

■ Hormones and their circadian rhythms of regulation significantly influence a number of physiological and psychological life cycle phenomena, such as moods, sleep and arousal, stress response, appetite, libido, and fertility.

■ Research continues to validate the role of genetics in psychiatric illness.

■ Familial, twin, and adoption studies suggest that genetics may be implicated in the etiology of schizophrenia, bipolar disorder, depressive disorder, panic disorder, anorexia nervosa, alcoholism, and obsessive-compulsive disorder. Genetic studies, however, fail to entirely explain the complex factors involved in the development of these illnesses.

■ Psychoneuroimmunology examines the relationship between psychological factors, the immune system, and the nervous system.

■ Evidence exists to support a link between psychosocial stressors and suppression of the immune response.

■ Technologies such as magnetic resonance imagery, computed tomographic scan, positron emission tomography, and electroencephalography are used as diagnostic tools for detecting alterations in psychobiological functioning.

■ Psychotropic medications act at the neural synapse to affect neurotransmitter activity and have been associated with improvement in symptoms of many mental disorders.

■ Integrating knowledge of the expanding biological focus into psychiatric nursing is essential if nurses are to meet the changing needs of today's psychiatric clients.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions:

1. Which of the following parts of the brain is associated with multiple feelings and behaviors and is sometimes referred to as the "emotional brain"?
   a. Frontal lobe
   b. Thalamus
   c. Hypothalamus
   d. Limbic system

2. Which of the following parts of the brain is concerned with visual reception and interpretation?
   a. Frontal lobe
   b. Parietal lobe
   c. Temporal lobe
   d. Occipital lobe

3. Which of the following parts of the brain is associated with voluntary body movement, thinking and judgment, and expression of feeling?
   a. Frontal lobe
   b. Parietal lobe
   c. Temporal lobe
   d. Occipital lobe

4. Which of the following parts of the brain integrates all sensory input (except smell) on the way to the cortex?
   a. Temporal lobe
   b. Thalamus
   c. Limbic system
   d. Hypothalamus

Review Questions—cont'd
Self-Examination/Learning Exercise

5. Which of the following parts of the brain deals with sensory perception and interpretation?
   a. Hypothalamus
   b. Cerebellum
   c. Parietal lobe
   d. Hippocampus

6. Which of the following parts of the brain is concerned with hearing, short-term memory, and sense of smell?
   a. Temporal lobe
   b. Parietal lobe
   c. Cerebellum
   d. Hypothalamus

7. Which of the following parts of the brain has control over the pituitary gland and autonomic nervous system, as well as regulation of appetite and temperature?
   a. Temporal lobe
   b. Parietal lobe
   c. Cerebellum
   d. Hypothalamus

8. At a synapse, the determination of further impulse transmission is accomplished by means of which of the following?
   a. Potassium ions
   b. Interneurons
   c. Neurotransmitters
   d. The myelin sheath

9. A decrease in which of the following neurotransmitters has been implicated in depression?
   a. Gamma-aminobutyric acid, acetylcholine, and aspartate
   b. Norepinephrine, serotonin, and dopamine
   c. Somatostatin, substance P, and glycine
   d. Glutamate, histamine, and opioid peptides

10. Which of the following hormones has been implicated in the etiology of mood disorder with seasonal pattern?
   a. Increased levels of melatonin
   b. Decreased levels of oxytocin
   c. Decreased levels of prolactin
   d. Increased levels of thyrotropin

11. Psychotropic medications may act at the neural synapse to accomplish which of the following? (Select all that apply)
   a. Inhibit the reuptake of certain neurotransmitters, creating more availability
   b. Inhibit catabolic enzymes, promoting more availability of a neurotransmitter
   c. Block receptors, resulting in less neurotransmitter activity
   d. Add synthetic neurotransmitters found in the drug

12. Psychoneuroimmunology is a branch of science that involves which of the following? (Select all that apply.)
   a. The impact of psychoactive medications at the neural synapse
   b. The relationships between the immune system, the nervous system, and psychological processes including mental illness
   c. The correlation between psychosocial stress and the onset of illness
   d. The potential role of viruses in the onset of schizophrenia
   e. The genetic factors that influence prevention of mental illness

4 Psychopharmacology

KEY TERMS

agranulocytosis	extrapyramidal symptoms	oculogyric crisis
akathisia	gynecomastia	priapism
akinesia	hypertensive crisis	retrograde ejaculation
amenorrhea	neuroleptic malignant syndrome	serotonin syndrome
dystonia		tardive dyskinesia

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss historical perspectives related to psychopharmacology.
2. Describe indications, actions, contraindications, precautions, side effects, and nursing implications for the following classifications of drugs:
   a. Antianxiety agents
   b. Antidepressants
   c. Mood-stabilizing agents
   d. Antipsychotics
   e. Antiparkinsonian agents
   f. Sedative-hypnotics
   g. Agents for attention-deficit/hyperactivity disorder
3. Apply the steps of the nursing process to the administration of psychotropic medications.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Identify three priority safety concerns for each class of psychotropic medications.
2. Differentiate primary actions and side effects for traditional versus atypical antipsychotics.
3. Differentiate primary actions and side effects for tricyclic versus SSRI antidepressants.

The middle of the 20th century identifies a pivotal period in the treatment of individuals with mental illness with the introduction of the phenothiazine class of antipsychotics in the United States. They were previously used in France as preoperative medications.

As Dr. Henri Laborit (1914–1995) of the Hospital Boucicaut in Paris stated,

> It was our aim to decrease the anxiety of the patients to prepare them in advance for their postoperative recovery. With these new drugs, the phenothiazines,

we were seeing a profound psychic and physical relaxation . . . a real indifference to the environment and to the upcoming operation. It seemed to me these drugs must have an application in psychiatry. (Sage, 1984)

As Laborit foresaw, phenothiazines have had a significant application in psychiatry. Not only have they helped many individuals to function effectively, but they have also provided researchers and clinicians with information to study the origins and etiologies of mental illness. Knowledge gained from learning how these drugs work has promoted advancement in understanding how behavioral disorders develop. Dr. Arnold Scheibel, director of the UCLA Brain Research Institute, stated,

[When these drugs came out] there was a sense of disbelief that we could actually do something substantive for the patients . . . see them for the first time as sick individuals and not as something bizarre that we could literally not talk to. (Sage, 1984)

This chapter explores historical perspectives in the use of psychotropic medications in the treatment of mental illness. Seven classifications of medications are discussed, and their implications for psychiatric nursing are presented in the context of the steps of the nursing process.

CORE CONCEPT

Psychotropic Medication
Medication that affects psychic function, behavior, or experience.

Historical Perspectives

Historically, reaction to and treatment of individuals with mental illness ranged from benign involvement to interventions that some would consider inhumane. Individuals with mental illness were feared because of common beliefs associating them with demons or the supernatural. They were looked upon as loathsome and often were mistreated.

Beginning in the late 18th century, a type of moral reform in the treatment of persons with mental illness began to occur. Community and state hospitals concerned with the needs of persons with mental illness were established. Considered a breakthrough in the humanization of care, these institutions, however well intentioned, fostered the concept of custodial care. Clients were ensured food and shelter but received little or no hope of change for the future. As they became increasingly dependent on the institution to fulfill their needs, the likelihood of their return to the family or community diminished.

The early part of the 20th century saw the advent of the somatic therapies in psychiatry. Individuals with mental illness were treated with insulin shock therapy, wet sheet packs, ice baths, electroconvulsive therapy, and psychosurgery. Before 1950, sedatives and amphetamines were the only significant psychotropic medications available. Even these drugs had limited use because of their toxicity and addictive effects. Since the 1950s, the development of psychopharmacology has expanded to include widespread use of antipsychotic, antidepressant, antianxiety, and mood-stabilizer medications. Research into how these drugs work has provided an understanding of the biochemical influences in many psychiatric disorders.

Psychotropic medications are not a cure for mental illness. Most mental health practitioners who prescribe these medications for their clients use them as an adjunct to individual or group psychotherapy. Although their contribution to psychiatric care cannot be minimized, it must be emphasized that psychotropic medications relieve some physical and behavioral symptoms. They do not eliminate mental disorders.

The Role of the Nurse in Psychopharmacology

Ethical and Legal Implications

Nurses must understand the ethical and legal implications associated with the administration of psychotropic medications. Laws differ from state to state, but most adhere to the client's right to refuse treatment. Exceptions exist in emergency situations when it has been determined that clients are likely to harm themselves or others. Many states have adopted laws that allow courts to order outpatient treatment, which may include medication, in circumstances where an individual is not seeking treatment and has a history of violent, aggressive behavior. The original law, called Kendra's law, was enacted after a young woman named Kendra Webdale was pushed in front of a New York City subway train by a man who lived in the community but was not seeking treatment for his mental illness (New York State Office of Mental Health, 2006). This law is perhaps more developed than those in other states but also includes a medication grant clause that provides uninterrupted medication for those transitioning from hospitals or correctional facilities. Some states do not have similar laws, so nurses must be informed about local, state, and federal laws when working in any health-care setting or correctional facility and providing care to a client with a psychiatric disorder.

Assessment

A thorough baseline assessment must be conducted before a client is placed on a regimen of psychopharmacological therapy. A nursing history and assessment (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing), an ethnocultural assessment (see Table 4–1 for some ethnocultural considerations and Chapter 6, Cultural and Spiritual Concepts Relevant to Psychiatric-Mental Health Nursing for detailed information), and a comprehensive medication assessment (see Box 4–1) are all essential components of this database.

Medication Administration and Evaluation

The nurse is the key health-care professional in direct contact with individuals receiving psychotropic medication in inpatient settings, in partial hospitalization programs, day treatment centers, home health care, and other settings. Medication administration is followed by a careful evaluation, which includes continuous monitoring for side effects and adverse reactions. The nurse also evaluates the therapeutic effectiveness of the medication. It is essential for the nurse to have a thorough knowledge of psychotropic medications to be able to anticipate potential problems and outcomes associated with their administration.

Client Education

The information associated with psychotropic medications is copious and complex. An important role of the nurse is to translate that complex information into terms that can be easily understood by the client. Clients must understand why the medication has been prescribed, when it should be taken, and what they may expect in terms of side effects and possible adverse reactions. They must know whom to contact when they have a question and when it is important to report to their physician. Medication education encourages client cooperation and promotes accurate and effective management of the treatment regimen.

CORE CONCEPTS

Neurotransmitter
A chemical that is stored in the axon terminals of the presynaptic neuron. An electrical impulse through the neuron stimulates the release of the neurotransmitter into the synaptic cleft, which in turn determines whether another electrical impulse is generated.

Receptors
Molecules situated on the cell membrane that are binding sites for neurotransmitters.

TABLE 4–1	**Ethnocultural Considerations in the Assessment and Safe Administration of Psychotropic Medications**
African Americans	■ Metabolize alcohol, psychotropic drugs, beta blockers, antihypertensives, and caffeine differently than European Americans ■ Higher incidence of extrapyramidal side effects with haloperidol decanoate than European Americans ■ Show higher blood levels and faster therapeutic response to tricyclic antidepressants ■ Experience more toxic side effects and are more prone to tricyclic antidepressant delirium
Arabs	■ Some individuals have difficulty metabolizing antidepressants, neuroleptics, and opioid agents
Chinese	■ Increased response to antidepressants and neuroleptics at lower doses ■ Increased sensitivity to the effects of alcohol
Japanese	■ Many are poor metabolizers of mephenytoin (an anticonvulsant) and related medications ■ May be more sensitive to the effects of many psychotropic drugs, alcohol, and some beta blockers ■ Opiates may be less effective and produce more gastrointestinal side effects than among white populations
Hispanic (Cuban and Mexican)	■ May require lower doses of antidepressants and experience more intense side effects than non-Hispanic white populations
Koreans	■ May require lower doses of psychotropic medications
Vietnamese	■ Increased sensitivity to sedative effects of benzodiazepines ■ May require lower doses of tricyclic antidepressants ■ More sensitive to gastrointestinal side effects of analgesics ■ Generally consider American medicine more concentrated than Asian medicine and may be inclined to reduce the dose from that which is prescribed

How Do Psychotropics Work?

Most psychotropic medications affect the neuronal synapse, producing changes in neurotransmitter release and the receptors to which they bind (see Figure 4–1). Researchers hypothesize that most antidepressants work by blocking the reuptake of neurotransmitters, specifically, serotonin and norepinephrine. *Reuptake* is the process of neurotransmitter inactivation by which the neurotransmitter is reabsorbed into the presynaptic neuron from which it was released. Blocking the reuptake process allows more of the neurotransmitter to be available for neuronal transmission. This mechanism of action may also result in undesirable side effects (see Table 4–2). Some antidepressants also block receptor sites that are unrelated to their mechanisms of action. These include α-adrenergic, histaminergic, and muscarinic cholinergic receptors. Blocking these receptors is associated with the development of certain side effects; for example, this explains why individuals treated with tricyclic antidepressants are at risk for developing postural hypotension. The specific type of receptor that medications bind to is also relevant to its level of antianxiety, antidepressant, and sedative properties (see Table 4–2).

Antipsychotic medications block dopamine receptors, and some affect muscarinic cholinergic, histaminergic, and α-adrenergic receptors. The *atypical* (or novel) antipsychotics focus primarily on blocking specific serotonin receptors. Benzodiazepines facilitate the transmission of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA). Psychostimulants work by increasing norepinephrine, serotonin, and dopamine release.

Although each psychotropic medication affects neurotransmission, the specific drugs within each class have varying neuronal effects. Their exact mechanisms of action are unknown. Many neuronal effects occur rapidly; however, therapeutic effects of some medications, such as antidepressants and atypical antipsychotics, may take weeks. Acute alterations in neuronal function do not fully explain how these medications work. Long-term neuropharmacological reactions to increased norepinephrine and serotonin levels may better explain their mechanisms of action. Recent research suggests that the therapeutic effects are related to the nervous system's adaptation to increased levels of neurotransmitters. These adaptive changes result from a homeostatic mechanism, much like a thermostat, that regulates the cell and maintains equilibrium.

Applying the Nursing Process in Psychopharmacological Therapy

An assessment tool for obtaining a drug history is provided in Box 4–1. This tool may be adapted for use by staff nurses admitting clients to the hospital or by nurse practitioners with prescriptive privileges.
FIGURE 4–1   Area of synaptic transmission that is altered by drugs.

Labels: Neurotransmitter transporter; Mitochondria; Neurotransmitter in vesicles; Neurotransmitter transporter; Receptors; Neurotransmitter in the synaptic cleft

TABLE 4–2 Effects of Psychotropic Medications on Neurotransmitters

EXAMPLE OF MEDICATION	ACTION ON NEUROTRANSMITTER AND/OR RECEPTOR	DESIRED EFFECTS	SIDE EFFECTS
SSRIs	Inhibit reuptake of serotonin (5-HT)	Reduce depression Control anxiety Control obsessions	Nausea, agitation, headache, sexual dysfunction
Tricyclic antidepressants	Inhibit reuptake of serotonin (5-HT) Inhibit reuptake of NE Block NE (α_1) receptor Block ACh receptor Block histamine (H_1) receptor	Reduce depression Relieve severe pain Prevent panic attacks	Sexual dysfunction (NE & 5-HT) Sedation, weight gain (H_1) Dry mouth, constipation, blurred vision, urinary retention (ACh) Postural hypotension and tachycardia (α_1)
MAOIs	Increase NE and 5-HT by inhibiting the enzyme that degrades them (MAO-A)	Reduce depression Control anxiety	Sedation, dizziness Sexual dysfunction Hypertensive crisis (interaction with tyramine)
Trazodone and nefazodone	5-HT reuptake block 5-HT$_2$ receptor antagonism Adrenergic receptor blockade	Reduce depression Reduce anxiety	Nausea (5-HT) Sedation (5-HT$_2$) Orthostasis (α_1) Priapism (α_2)
SNRIs: venlafaxine, desvenlafaxine, duloxetine, and levomilnacipran	Potent inhibitors of serotonin and norepinephrine reuptake Weak inhibitors of dopamine reuptake	Reduce depression Relieve pain of neuropathy (duloxetine) Relieve anxiety (venlafaxine)	Nausea (5-HT) ↑ Sweating (NE) Insomnia (NE) Tremors (NE) Sexual dysfunction (5-HT)
Bupropion	Inhibits reuptake of NE and D	Reduces depression Aids in smoking cessation Reduces symptoms of ADHD	Insomnia, dry mouth, tremor, seizures
Antipsychotics: phenothiazines and haloperidol	Strong D$_2$ receptor blockades Weaker blockades of ACh, H$_1$, α_1-adrenergic, and 5-HT$_2$ receptors	Relieve psychosis Relieve anxiety (Some) provide relief from nausea and vomiting and intractable hiccoughs	Blurred vision, dry mouth, ↓ sweating, constipation, urinary retention, tachycardia (ACh) EPS (D$_2$) ↑ Plasma prolactin (D$_2$) Sedation; weight gain (H$_1$) Ejaculatory difficulty (5-HT$_2$) Postural hypotension (α; H$_1$)
Antipsychotics (novel): aripiprazole, asenapine, brexpiprazole, cariprazine, clozapine, iloperidone, lurasidone, olanzapine, paliperidone, quetiapine, risperidone, ziprasidone	Receptor antagonism of 5-HT$_1$ and 5-HT$_2$ D$_1$–D$_5$ (varies with drug) H$_1$,α_1-adrenergic muscarinic (ACh)	Relieve psychosis (with minimal or no EPS) Relieve anxiety Relieve acute mania	Potential with some of the drugs for mild EPS (D$_2$) Sedation, weight gain (H$_1$) Orthostasis and dizziness (α-adrenergic) Blurred vision, dry mouth, ↓ sweating, constipation, urinary retention, tachycardia (ACh)
Antianxiety: benzodiazepines	Bind to BZ receptor sites on the GABA$_A$ receptor complex; increase receptor affinity for GABA	Relieve anxiety Produce sedation	Dependence (with long-term use) Confusion, memory impairment, motor incoordination

TABLE 4–2 Effects of Psychotropic Medications on Neurotransmitters–cont'd

EXAMPLE OF MEDICATION	ACTION ON NEUROTRANSMITTER AND/OR RECEPTOR	DESIRED EFFECTS	SIDE EFFECTS
Antianxiety: buspirone	5-HT$_{1A}$ agonist D$_2$ agonist D$_2$ antagonist	Relieves anxiety	Nausea, headache, dizziness Restlessness

5-HT, 5-hydroxytryptamine (serotonin); ACh, acetylcholine; ADHD, attention deficit-hyperactivity disorder; BZ, benzodiazepine; D, dopamine; EPS, extrapyramidal symptoms; GABA, gamma-aminobutyric acid; H, histamine; MAO, monoamine oxidase; MAO-A, monoamine oxidase A; MAOI, monoamine oxidase inhibitor; NE, norepinephrine; SNRI, serotonin-norepinephrine reuptake inhibitor; SSRI, selective serotonin reuptake inhibitor.

One of the Quality and Safety Education for Nurses (QSEN) criteria culminating from the Institute of Medicine (IOM) (2003) report on essential competencies for health care professionals stresses that the patient must be at the center of decisions about treatment (patient-centered care), and this type of assessment tool provides an opportunity to actively engage the patient in describing what medications have been effective or ineffective and identifying side effects that may impact willingness to adhere to a medication regimen.

Antianxiety Agents

Background Assessment Data

Indications

Antianxiety drugs are also called *anxiolytics* and historically were referred to as *minor tranquilizers*. They are used in the treatment of anxiety disorders, anxiety symptoms, acute alcohol withdrawal, skeletal muscle spasms, convulsive disorders, status epilepticus, and preoperative sedation. They are most appropriate for

---

the treatment of acute anxiety states rather than long-term treatment, as their use and efficacy for longer than 4 months has not been evaluated. For long-term management of anxiety disorders, antidepressants are often used as the first line of treatment because they are not addictive. (A table of current FDA-approved antianxiety agents, pregnancy categories, half-life, and daily dosage ranges can be found online at Davis*Plus* and in Chapter 27, Anxiety, Obsessive-Compulsive, and Related Disorders.)

Action

Antianxiety drugs depress subcortical levels of the central nervous system (CNS), particularly the limbic system and reticular formation. They may potentiate the effects of the powerful inhibitory neurotransmitter GABA in the brain, thereby producing a calming effect. All levels of CNS depression can be affected, from mild sedation to hypnosis to coma. The most commonly prescribed antianxiety agents are benzodiazepines, including clonazepam (Klonopin), diazepam (Valium), and alprazolam (Xanax). Benzodiazepines are much like alcohol in their effects on GABA receptors, which explains why benzodiazepines may be used for the management of alcohol withdrawal. Buspirone (BuSpar) is an antianxiety agent but not a benzodiazepine and does not depress the CNS. Although its action is unknown, the drug is believed to produce

the desired effects through interactions with serotonin, dopamine, and other neurotransmitter receptors. Clients should be instructed that buspirone has a lag period of 7 to 10 days before full therapeutic benefits are achieved. It does not have the addiction potential of the other antianxiety agents and therefore may be a better option for clients with anxiety disorders who have also struggled with substance use disorders.

Interactions

■ Increased effects of antianxiety agents can occur when they are taken concomitantly with alcohol, barbiturates, narcotics, antipsychotics, antidepressants, antihistamines, neuromuscular blocking agents, cimetidine, or disulfiram.

■ Increased effects can also occur with herbal depressants (e.g., kava, valerian, lemon verbena, L-tryptophan, melatonin, and chamomile).

■ Decreased effects can be noted with cigarette smoking and caffeine consumption.

Diagnosis

The following nursing diagnoses may be considered for clients receiving therapy with antianxiety agents:

■ Risk for injury related to seizures, panic anxiety, acute agitation from alcohol withdrawal (indications), abrupt withdrawal from the medication

after long-term use, or effects of medication intoxication or overdose

- Anxiety (specify) related to threat to physical integrity or self-concept
- Risk for activity intolerance related to side effects of sedation, confusion, and/or lethargy
- Disturbed sleep pattern related to situational crises, physical condition, or severe level of anxiety

Safety Issues in Planning and Implementing Care

The IOM (2003) identifies *ensuring safety* as a core competency for nursing. Table 4–3 notes some of the significant safety issues to be considered for clients taking antianxiety agents. Nursing interventions related to each side effect are noted in the right-hand column.

Outcome Criteria and Evaluation

The following criteria may be used for evaluating the effectiveness of therapy with antianxiety agents.

The client:

- Demonstrates a reduction in anxiety, tension, and restless activity

- Experiences no seizure activity
- Experiences no physical injury
- Is able to tolerate usual activities without excessive sedation
- Exhibits no evidence of confusion
- Tolerates the medication without gastrointestinal distress
- Verbalizes understanding of the need for, side effects of, and regimen for self-administration
- Verbalizes possible consequences of abrupt withdrawal from the medication

Antidepressants

Sorting out information on antidepressant medications can be particularly confusing because there are several types of antidepressant medications, some of which are also prescribed to treat anxiety disorders. The first "antidepressant" drug was a monoamine oxidase inhibitor (MAOI), isoniazid, which was used to treat tuberculosis. When patients began describing their increased feelings of well-being on these drugs, MAOIs were developed specifically for the treatment of depression. Unfortunately, they were also potentially deadly for anyone who ate foods

TABLE 4–3 Safety Issues and Nursing Interventions for Patients Taking Antianxiety Agents	
SAFETY ISSUES	**NURSING INTERVENTIONS**
Tolerance and physical dependence may develop. **Abrupt withdrawal can be life threatening** (except with buspirone); signs include sweating, agitation, tremors, nausea and vomiting, delirium, seizures.	Instruct client not to stop taking the drug abruptly. Assess the client for signs of developing tolerance (requiring higher doses of medication to achieve effects). Educate the client about symptoms of withdrawal. Contact the doctor immediately if symptoms of withdrawal are assessed.
Drowsiness, confusion, and lethargy are the most common side effects.	Instruct client not to drive or operate dangerous machinery while taking this medication.
Effects of other CNS depressants are increased.	Instruct the client not to drink alcohol or take other CNS depressants, antihistamines, cimetidine, antidepressants, neuromuscular blocking agents, or disulfiram while taking these drugs.
Antianxiety agents may **aggravate symptoms of depression.**	Assess the client's mood and assess for suicide risk.
Orthostatic hypotension may occur.	Instruct the client to rise slowly from a sitting to standing position to minimize risk for falls. Monitor lying and standing blood pressures to assess for orthostatic hypotension.
Paradoxical excitement (opposite from the desired effect) may occur. Especially the elderly may be at higher risk for agitation and increased anxiety.	Hold the medication and notify the doctor.
Blood dyscrasias, although rare, can be serious or life threatening.	Assess for sore throat, fever, bruising, or unusual bleeding. Hold medication and report these symptoms immediately to the doctor.
Congenital malformations have been associated with use of these drugs during the first trimester of pregnancy.	Instruct the female client who is pregnant or anticipating pregnancy while on these drugs to explore alternative treatment options with her physician.

high in tyramine while taking these drugs, and several serious interactions occurred with other drugs. Because MAOIs increase the availability of norepinephrine, researchers focused on developing drugs that impacted norepinephrine without the need for food restrictions, leading to introduction of the *tricyclic antidepressants.*

Tricyclics were the first line of treatment for depression for many years but were effective for only about 70 percent of those treated. In addition, because all neurotransmitters bind to various receptor sites, increasing the availability of norepinephrine with tricyclics also has anticholinergic effects and increases the potential for postural hypotension. This created limitations for the elderly and those with cardiovascular problems.

In the late 1980s and early 1990s, *serotonin reuptake inhibitors* (SSRIs) and *serotonin-norepinephrine reuptake inhibitors* (SNRIs) were developed in response to research indicating that serotonin, an antianxiety hormone and neurotransmitter, could promote improvement in depression and anxiety without significant anticholinergic side effects. SSRIs and SNRIs became the preferred first line of treatment for depression.

The most recent additions to the pharmacological treatments for depression and anxiety are actually atypical antipsychotics that increase the availability of serotonin and dopamine. These medications are promoted as adjunctive to antidepressant therapy. The most popular example is aripiprazole (Abilify). In a recent large study sponsored by the National Institute of Mental Health, the combination of Abilify with venlafaxine demonstrated a 44 percent improvement in elderly adults who were not responding to antidepressants alone. This finding is important for treatment of elderly clients because more than half of older adults with clinical depression do not respond to antidepressants alone (Lenze et al., 2015).

Despite these developments and client-subjective reports of improvement with antidepressant medications, our understanding of the exact mechanisms of action remains theoretical because, currently, the levels of neurotransmitters in the brain cannot be measured. Further, a large study funded by the National Institute of Mental Health (STAR*D) found that two-thirds of patients with at least moderate depression on antidepressant medication did not experience full recovery after initial treatment with an SSRI (NIMH, 2006).

Research continues with the goal of identifying more broadly effective antidepressant therapies. Several of the newest drugs on the market for treatment of depression are not significantly different from existing products. For example, a "new" antidepressant approved by the FDA in 2016, Oleptro, is a reformulation of trazodone. But new mechanisms are being explored, and some are in clinical trials. Drugs that impact specific types of glutamate receptors (*N*-methyl-D-aspartate (NMDA) receptors) are being studied for potential antidepressant effects, ketamine and midazolam (Versed, a benzodiazepine with transient effects similar to those of ketamine) are being explored as potentially faster-acting treatments, drugs that act on melatonin receptors are currently in clinical trials for use in depression (one is already approved for use in Europe), and a new group of antidepressants called *triple reuptake inhibitors* that simultaneously block reuptake of serotonin, norepinephrine, and dopamine is in preliminary phases of research (Tartakovsky, 2016).

Current research also continues to explore genetic testing to identify factors that may influence whether an individual is more likely to respond to one type of antidepressant than another. If reliability is established, the research will provide a valuable resource for making decisions about which antidepressant to prescribe first.

Background Assessment Data

Indications

In addition to the obvious indications for antidepressant medications in the treatment of major depressive and dysthymic disorders, some atypical drugs, such as the SSRIs, have received FDA approval for the treatment of most anxiety disorders, bulimia nervosa, premenstrual dysphoric disorder, borderline personality disorder, obesity, smoking cessation, and alcoholism A hallmark review of the research on antidepressants (Fournier et al., 2010) found that the benefits of antidepressant therapy for patients with mild to moderate symptoms of depression may be minimal or nonexistent but that, for clients with severe depression, the benefits when compared with placebo effects are substantial. Therefore, these medications are particularly indicated when an individual is identified as having severe depression. (A table of current FDA-approved antidepressants, pregnancy categories, half-life, and daily dosage ranges can be found online at Davis*Plus* and in Chapter 25, Depressive Disorders.)

Action

Antidepressant drugs ultimately work to increase the concentration of norepinephrine, serotonin, and/or dopamine in the body. This is accomplished in the brain by blocking the reuptake of these neurotransmitters by the neurons (tricyclics [TCAs], tetracyclics, SSRIs, and SNRIs). It also occurs when an enzyme, monoamine oxidase (MAO), known to inactivate norepinephrine, serotonin, and dopamine, is *inhibited* at various sites in the nervous system (MAOIs).

Interactions

Tables 4–4, 4–5, 4–6, and 4–7 identify some of the significant, dangerous interactions between antidepressant and other drugs or foods. It is important to recognize that new information about drug interactions is discovered and published frequently. To fully understand safety issues related to medication administration, nurses need to access the most current, evidence-based informatics on drug interaction information.

Other Atypical Antidepressants

Other atypical antidepressants include bupropion (Wellbutrin), mirtazapine (Remeron), and trazodone (Desyrel). Common SNRIs include desvenlafaxine (Pristiq), duloxetine (Cymbalta), levomilnacipran (Fetzima), and venlafaxine (Effexor). Drug interactions vary widely within these groups; following are several examples.

■ Concomitant use with MAOIs results in serious, sometimes fatal, effects resembling **neuroleptic malignant syndrome.** Coadministration is contraindicated.
■ **Serotonin syndrome** may occur when any of the following are used together: St. John's wort, sumatriptan, sibutramine, trazodone, nefazodone, venlafaxine, duloxetine, levomilnacipran, SSRIs, 5-HT-receptor agonists (triptans).

TABLE 4–4 Drug Interactions With SSRIs

INTERACTING DRUGS	ADVERSE EFFECTS
Buspirone (BuSpar), tricyclic antidepressants (especially clomipramine), selegiline (Eldepryl), St. John's wort	Serotonin syndrome*
Monoamine oxidase inhibitors	Hypertensive crisis
Warfarin, NSAIDs	Increased risk of bleeding
Alcohol, benzodiazepines	Increased sedation
Antiepileptics	Lowered seizure threshold

*Serotonin syndrome is a potentially fatal syndrome of serotonin overstimulation with rapid onset that progresses from diarrhea, restlessness, agitation, hyperreflexia, fluctuations in vital signs to later symptoms of myoclonus, seizures, hyperthermia, uncontrolled shivering, muscle rigidity, and ultimately can lead to delirium, coma, status epilepticus, cardiovascular collapse, and death. Immediate cessation of offending drugs and comprehensive supportive intervention is essential (Sadock, Sadock, & Ruiz, 2015).

TABLE 4–5 Drug Interactions With Tricyclic Antidepressants (TCAs)

INTERACTING DRUGS	ADVERSE EFFECTS
Monoamine oxidase inhibitors	High fever, convulsions, death
St. John's wort, tramadol (Ultram)	Seizures, serotonin syndrome
Clonidine (Catapres), epinephrine	Severe hypertension
Acetylcholine blockers	Paralytic ileus
Alcohol and carbamazepine (Tegretol)	Blocks antidepressant action, increases sedation
Cimetidine (Tagamet), bupropion (BuSpar)	Increased TCA blood levels and increased side effects

TABLE 4–6 Drug Interactions With Monoamine Oxidase Inhibitors (MAOIs)

INTERACTING DRUGS	ADVERSE EFFECTS
Selective serotonin reuptake inhibitor, tricyclic antidepressants, atomoxetine (Strattera), duloxetine (Cymbalta), dextromethorphan (an ingredient in many cough syrups), venlafaxine (Effexor), St. John's wort, ginkgo biloba	Serotonin syndrome
Morphine and other narcotic pain relievers, antihypertensives	Hypotension
All other antidepressants, pseudoephedrine, amphetamines, cocaine cyclobenzaprine (Flexeril), dopamine, methyldopa, levodopa, epinephrine, buspirone (BuSpar)	Hypertensive crisis (these side effects can occur even if taken within 2 weeks of stopping MAOIs)
Buspirone	Psychosis, agitation, seizures
Antidiabetics	Hypoglycemia
Tegretol	Fever, hypertension, seizures

■ Increased effects of haloperidol, clozapine, and desipramine may occur with concomitant use of venlafaxine.
■ Increased effects of levomilnacipran may occur with concomitant use of CYP3A4 inhibitors.
■ Increased effects of venlafaxine may occur with concomitant use of cimetidine.

TABLE 4–7 Diet Restrictions for Clients on MAOI Therapy
FOODS CONTAINING TYRAMINE

HIGH TYRAMINE CONTENT (AVOID WHILE ON MAOI THERAPY)	**MODERATE TYRAMINE CONTENT (MAY EAT OCCASIONALLY WHILE ON MAOI THERAPY)**	**LOW TYRAMINE CONTENT (LIMITED QUANTITIES PERMISSIBLE WHILE ON MAOI THERAPY)**
Aged cheeses (cheddar, Swiss, Camembert, blue cheese, parmesan, provolone, Romano, brie)	Gouda cheese, processed American cheese, mozzarella	Pasteurized cheeses (cream cheese, cottage cheese, ricotta)
Raisins, fava beans, flat Italian beans, Chinese pea pods	Yogurt, sour cream	Figs
Red wines (chianti, burgundy, cabernet sauvignon)	Avocados, bananas	Distilled spirits (in moderation)
Liqueurs	Beer, white wine, coffee, colas, tea, hot chocolate	
Smoked and processed meats (salami, bologna, pepperoni, summer sausage)	Meat extracts, such as bouillon	
Caviar, pickled herring, corned beef, chicken or beef liver	Chocolate	
Soy sauce, brewer's yeast, meat tenderizer (MSG)		
Sauerkraut		

SOURCE: Sadock, B.J., Sadock, V.A., & Ruiz, P. (2015). *Synopsis of psychiatry: Behavioral sciences/clinical psychiatry* (11th ed.). Philadelphia: Lippincott Williams & Wilkins; Vallerand, A.H., Sanoski, C.A., & Deglin, J.H. (2016). *Davis drug guide for nurses* (15th ed.). Philadelphia: F.A. Davis.

■ Increased effects of duloxetine may occur with concomitant use of CYP1A2 inhibitors (e.g., fluvoxamine, quinolone antibiotics) or CYP2D6 inhibitors (e.g., fluoxetine, quinidine, paroxetine).

■ Risk of liver injury is increased with concomitant use of alcohol and duloxetine.

■ Risk of toxicity or adverse effects from drugs extensively metabolized by CYP2D6 (e.g., flecainide, phenothiazines, propafenone, tricyclic antidepressants, thioridazine) is increased when these drugs are used concomitantly with duloxetine or bupropion.

■ Decreased effects of bupropion and trazodone may occur with concomitant use of carbamazepine.

■ The anticoagulant effect of warfarin may be altered with concomitant use of bupropion, venlafaxine, desvenlafaxine, duloxetine, levomilnacipran, or trazodone.

■ Risk of seizures is increased when bupropion is coadministered with drugs that lower the seizure threshold (e.g., antidepressants, antipsychotics, systemic steroids, theophylline, tramadol).

■ Effects of midazolam are decreased with concomitant use of desvenlafaxine.

■ Effects of desvenlafaxine and levomilnacipran are increased with concomitant use of potent CYP3A4 inhibitors (e.g., ketoconazole).

Diagnosis

The following nursing diagnoses may be considered for clients receiving therapy with antidepressant medications:

■ Risk for suicide related to depressed mood

■ Risk for injury related to side effects of sedation, lowered seizure threshold, orthostatic hypotension, **priapism,** photosensitivity, arrhythmias, **hypertensive crisis,** or serotonin syndrome

■ Social isolation related to depressed mood

■ Risk for constipation related to side effects of the medication

■ Insomnia related to depressed mood and elevated level of anxiety

Safety Issues in Planning and Implementing Care

Some of the common but manageable side effects of antidepressant medications include dry mouth, sedation, and nausea. General nursing interventions such as offering hard candies, ice, and frequent sips of water are helpful in alleviating dry mouth. Clients may find that sedation is less bothersome if they take the daily dose of antidepressant at bedtime; they should be encouraged to discuss the time of day that their medication should be taken with the prescribing physician or nurse practitioner. Taking antidepressant medication with food may help minimize nausea.

Some patients taking SSRIs or SNRIs complain of sexual dysfunction. Men may report abnormal ejaculation or impotence, and women may report loss of orgasm. This side effect sometimes results in clients stopping the medication abruptly, which may put them at risk for discontinuation syndrome and worsen symptoms of depression. Nurses must develop an open attitude regarding discussion and assessment of client sexual concerns, and clients who are particularly troubled by this side effect can be encouraged to explore alternative medication with their physician or nurse practitioner.

Other side effects or adverse reactions may be dangerous or even fatal. Many of these are related to

drug–drug or drug–food interactions, as discussed previously. Because there is so much information and new drug development is ongoing, practicing nurses should assure that they are accessing evidence-based informatics to keep up to date on side effects as well. Many health-care organizations provide online medication resources to employees, and mobile device applications provide a readily available resource for updated drug information. Some important safety issues and nursing interventions are listed in Table 4–8.

TABLE 4–8 Safety Issues and Nursing Interventions for Patients Taking Antidepressants	
SAFETY ISSUES	NURSING INTERVENTIONS
Drug interactions (multiple, as discussed in the text)	Instruct clients to inform their physician or nurse practitioner of *all* medications they are taking, including herbal preparations, over-the-counter drugs, and any medications they have stopped taking within the previous 2 weeks. 　Notify the physician immediately when any symptoms of serotonin syndrome are assessed. Do not administer the offending agent. ■ Monitor vital signs. ■ Protect from injury secondary to muscle rigidity or change in mental status. ■ Provide cooling blankets for temperature regulation. ■ Monitor intake and output. 　The condition usually resolves when the offending agent is promptly discontinued but can be fatal without intervention (Cooper & Sejnowski, 2013).
Increased risk for suicide	Assess frequently for presence or worsening of suicide ideation. 　Initiate suicide precautions as needed. 　Monitor clients' use of medication as prescribed, since these medications can be lethal in overdose.
Sedation	Instruct clients not to drive or operate dangerous machinery when experiencing sedation.
Discontinuation syndrome: SSRIs—dizziness, lethargy, headache, nausea TCAs—hypomania, akathisia, cardiac arrhythmias, gastrointestinal upset, panic attacks MAOIs—flu-like symptoms, confusion, hypomania	Instruct clients that all antidepressants have some potential for discontinuation syndrome and should not be stopped abruptly but rather tapered off (Schatzberg, Cole, & DeBattista, 2010).
Photosensitivity	Instruct clients of their vulnerability to severe sunburn and recommend sunscreen.
Orthostatic hypotension (TCAs)	Instruct clients to rise slowly from sitting to standing. 　Monitor blood pressure to assess for symptoms.
Tachycardia, arrhythmias (TCAs)	Monitor vital signs, especially in elderly with preexisting cardiovascular disorders.
Hyponatremia (SSRIs) especially among the elderly (potentially life threatening)	Instruct clients to report any symptoms of nausea, malaise, lethargy, muscle cramps. 　Assess for disorientation or restlessness. 　Monitor sodium levels: ■ <120 mEq/L risk for seizure, coma, respiratory arrest ■ Withhold medication, contact physician, restrict water intake (Jacob & Spinier, 2006)
Blurred vision (TCAs and atypicals)	Instruct clients to avoid driving, and reassure them that this side effect usually resolves within 3 weeks. Monitor blood pressure to rule out symptoms of hypertension.
Constipation	Recommend a high-fiber diet and regular exercise, and instruct clients to report any symptoms of ongoing difficulty with bowel movements.

MAOI, monoamine oxidase inhibitor; SSRI, selective serotonin reuptake inhibitor; TCA, tricyclic antidepressant.

Outcome Criteria and Evaluation

The following criteria may be used for evaluating the effectiveness of therapy with antidepressant medications.

The client:

- Has not harmed self
- Has not experienced injury caused by side effects
- Exhibits vital signs within normal limits
- Manifests symptoms of improvement in mood (presents brighter affect, interacts with others, demonstrates improved hygiene, expresses clear thought, conveys hopefulness, shows improved ability to make decisions)
- Willingly participates in activities and interacts appropriately with others

Mood-Stabilizing Agents

Background Assessment Data

For many years, the drug of choice for treatment and management of bipolar mania was lithium carbonate. In recent years, several other medications have demonstrated effectiveness either alone or in combination with lithium. Most notably are drugs in the class of anticonvulsant medications, which are now FDA approved for mood stabilization. Some second-generation atypical antipsychotics have also demonstrated benefits for management of this disorder.

Bipolar disorder is characterized by cycles of depression and manic episodes, which may manifest as grandiose thinking and behavior, rapid thoughts, hyperactivity, and/or impulsive agitation. The effective medication treatment for this disorder is one that reduces the rollercoaster of "ups and downs" often described by clients; thus, the name "mood stabilizer" is an apt description of their purpose. Lithium was first identified as an antimanic but was also recognized as successful for stabilizing the mood swings of bipolar disorder.

Lithium is a salt present in mineral springs and added to spa baths. Although it was also used for other medicinal purposes, in 1949, Australian physician John Cade reported using lithium to treat manic excitement. He found it so successful that some of his patients became symptom free and were able to be discharged after years of institutionalization (Shorter, 2009). It remains true that people who respond to lithium and remain on the medication may show no evidence of bipolar mood swings. While it is not a cure, it is often described as "like insulin to a diabetic" in that proper use and response can reduce or eliminate symptoms. Unfortunately, not everyone responds with the same degree of success, and too much lithium can be fatal. Today, however, we are able to measure the blood levels of lithium and be confident of its safety when maintained within the specified therapeutic range (0.6–1.2 mEq/L). The exact mechanism of action remains unknown, but it is believed to have an impact on the same neurotransmitters (serotonin, norepinephrine, glutamate, GABA, and dopamine) as previously discussed.

In 1995, the FDA approved valproate (Depakote) as a mood stabilizer; since then, a great shift toward this group of anticonvulsant mood stabilizers (including carbamazepine, clonazepam, topiramate, and lamotrigine) and away from lithium has occurred (Shorter, 2009). The mechanism of action for these drugs as well as for lithium is unclear. Impact on cellular sodium transport, GABA modulation, and raising of the seizure threshold have all been advanced as possible explanations for their effectiveness. Both first-generation and second-generation antipsychotics have been used alone or as adjuncts to other medication treatment for bipolar mania. Since lithium has a lag period of 7 to 10 days, first-generation antipsychotics such as haloperidol may be helpful in that their sedative effects are more immediate and may bring relief from manic symptoms before lithium reaches therapeutic levels. They also increase the effects of lithium, so monitoring blood serum levels is especially important in the initial phase of treatment when these two drugs are used in combination. (A table of current FDA-approved mood-stabilizer medications, pregnancy categories, half-life, and daily dosage ranges can be found online at Davis*Plus* and in Chapter 26, Bipolar and Related Disorders.)

Interactions

One of the interesting things about drug interactions with mood stabilizers is that many drugs either increase or decrease their effectiveness, as shown in Table 4–9. Understanding that lithium is a salt is relevant in explaining some of these interactions. Because lithium is an imperfect substitute for sodium, anything that depletes sodium will make more receptor sites available to lithium and increase the risk for lithium toxicity. This is also the rationale behind maintenance of regular dietary sodium and fluid intake, because major fluctuations impact lithium levels. For example, significant increases in dietary sodium intake may reduce the effectiveness of lithium because sodium will bind at more receptor sites and lithium will be excreted. Other drugs that increase serum sodium levels also have an impact on lithium levels.

TABLE 4–9 Drug Interactions With Mood-Stabilizing Agents

THE EFFECTS OF:	ARE INCREASED BY:	ARE DECREASED BY:	CONCURRENT USE MAY RESULT IN:
ANTIMANIC: Lithium	Carbamazepine, fluoxetine, haloperidol, loop diuretics, methyldopa, NSAIDs, and thiazide diuretics	Acetazolamide, osmotic diuretics, theophylline, and urinary alkalinizers	Increased effects of neuromuscular blocking agents and tricyclic antidepressants; decreased pressor sensitivity of sympathomimetics; neurotoxicity may occur with phenothiazines or calcium channel blockers
ANTICONVULSANTS: Clonazepam	CNS depressants, cimetidine, hormonal contraceptives, disulfiram, fluoxetine, isoniazid, ketoconazole, metoprolol, propranolol, valproic acid, probenecid	Rifampin, theophylline (↓ sedative effects), phenytoin	Increased phenytoin levels; decreased efficacy of levodopa
Carbamazepine	Verapamil, diltiazem, propoxyphene, erythromycin, clarithromycin, SSRIs, tricyclic antidepressants, cimetidine, isoniazid, danazol, lamotrigine, niacin, acetazolamide, dalfopristin, valproate, nefazodone	Cisplatin, doxorubicin, felbamate, rifampin, barbiturates, hydantoins, primidone, theophylline	Decreased levels of corticosteroids, doxycycline, quinidine, warfarin, estrogen-containing contraceptives, cyclosporine, benzodiazepines, theophylline, lamotrigine, valproic acid, bupropion, haloperidol, olanzapine, tiagabine, topiramate, voriconazole, ziprasidone, felbamate, levothyroxine, or antidepressants; increased levels of lithium; life-threatening hypertensive reaction with MAOIs
Valproic acid	Chlorpromazine, cimetidine, erythromycin, felbamate, salicylates	Rifampin, carbamazepine, cholestyramine, lamotrigine, phenobarbital, ethosuximide, hydantoins	Increased effects of tricyclic antidepressants, carbamazepine, CNS depressants, ethosuximide, lamotrigine, phenobarbital, warfarin, zidovudine, hydantoins
Lamotrigine	Valproic acid	Primidone, phenobarbital, phenytoin, rifamycin, succinimides, oral contraceptives, oxcarbazepine, carbamazepine, acetaminophen	Decreased levels of valproic acid; increased levels of carbamazepine and topiramate
Topiramate	Metformin, hydrochlorothiazide	Phenytoin, carbamazepine, valproic acid, lamotrigine	Increased risk of CNS depression with alcohol or other CNS depressants; increased risk of kidney stones with carbonic anhydrase inhibitors; increased effects of phenytoin, metformin, amitriptyline; decreased effects of oral contraceptives, digoxin, lithium, risperidone, and valproic acid
Oxcarbazepine		Carbamazepine, phenobarbital, phenytoin, valproic acid, verapamil	Increased concentrations of phenobarbital and phenytoin; decreased effects of oral contraceptives, felodipine, and lamotrigine

Continued

TABLE 4–9 Drug Interactions With Mood-Stabilizing Agents—cont'd			
THE EFFECTS OF:	**ARE INCREASED BY:**	**ARE DECREASED BY:**	**CONCURRENT USE MAY RESULT IN:**
CALCIUM CHANNEL BLOCKER: Verapamil	Amiodarone, beta blockers, cimetidine, ranitidine, and grapefruit juice	Barbiturates, calcium salts, hydantoins, rifampin, and antineoplastics	Increased effects of beta blockers, disopyramide, flecainide, doxorubicin, benzodiazepines, buspirone, carbamazepine, digoxin, dofetilide, ethanol, imipramine, nondepolarizing muscle relaxants, prazosin, quinidine, sirolimus, tacrolimus, and theophylline; altered serum lithium levels
ANTIPSYCHOTICS: Olanzapine	Fluvoxamine and other CYP1A2 inhibitors, fluoxetine	Carbamazepine and other CYP1A2 inducers, omeprazole, rifampin	Decreased effects of levodopa and dopamine agonists; increased hypotension with antihypertensives; increased CNS depression with alcohol or other CNS depressants
Aripiprazole	Ketoconazole and other CYP3A4 inhibitors; quinidine, fluoxetine, paroxetine, or other potential CYP2D6 inhibitors	Carbamazepine, famotidine, valproate	Increased CNS depression with alcohol or other CNS depressants; increased hypotension with antihypertensives
Chlorpromazine	Beta blockers, paroxetine	Centrally acting anticholinergics	Increased effects of beta blockers; excessive sedation and hypotension with meperidine; decreased hypotensive effect of guanethidine; decreased effect of oral anticoagulants; decreased or increased phenytoin levels; increased orthostatic hypotension with thiazide diuretics; increased CNS depression with alcohol or other CNS depressants; increased hypotension with antihypertensives; increased anticholinergic effects with anticholinergic agents
Quetiapine	Cimetidine; ketoconazole, itraconazole, fluconazole, erythromycin, or other CYP3A4 inhibitors	Phenytoin, thioridazine	Decreased effects of levodopa and dopamine agonists; increased CNS depression with alcohol or other CNS depressants; increased hypotension with antihypertensives
Risperidone	Clozapine, fluoxetine, paroxetine, or ritonavir	Carbamazepine	Decreased effects of levodopa and dopamine agonists; increased effects of clozapine and valproate; increased CNS depression with alcohol or other CNS depressants; increased hypotension with antihypertensives
Ziprasidone	Ketoconazole and other CYP3A4 inhibitors	Carbamazepine	Life-threatening prolongation of QT interval with quinidine, dofetilide, other class Ia and III antiarrhythmics, pimozide, sotalol, thioridazine, chlorpromazine, pentamidine, arsenic trioxide, mefloquine, dolasetron, tacrolimus, droperidol, gatifloxacin, or moxifloxacin; decreased effects of levodopa and dopamine agonists; increased CNS depression with alcohol or other CNS depressants; increased hypotension with antihypertensives

TABLE 4–9 **Drug Interactions With Mood-Stabilizing Agents—cont'd**			
THE EFFECTS OF:	ARE INCREASED BY:	ARE DECREASED BY:	CONCURRENT USE MAY RESULT IN:
Asenapine	Fluvoxamine, imipramine, valproate	Carbamazepine, cimetidine, paroxetine	Increased effects of paroxetine and dextromethorphan; increased CNS depression with alcohol or other CNS depressants; increased hypotension with antihypertensives; additive effects of QT interval prolongation with quinidine, dofetilide, other class Ia and III antiarrhythmics, pimozide, sotalol, thioridazine, chlorpromazine, pentamidine, arsenic trioxide, mefloquine, dolasetron, tacrolimus, droperidol, gatifloxacin, or moxifloxacin

CNS, central nervous system; MAOI, monoamine oxidase inhibitor; SSRI, selective serotonin reuptake inhibitor.

Diagnosis

The following nursing diagnoses may be considered for clients receiving therapy with mood-stabilizing agents:

- Risk for injury related to manic hyperactivity
- Risk for self-directed or other-directed violence related to unresolved anger turned inward on the self or outward on the environment
- Risk for injury related to lithium toxicity
- Risk for injury related to adverse effects of mood-stabilizing drugs
- Risk for activity intolerance related to side effects of drowsiness and dizziness

Planning and Implementing Care

One of the primary safety issues with lithium is its narrow therapeutic range. A description of lithium toxicity, other safety concerns with mood-stabilizing agents, and relevant nursing interventions are discussed in Table 4–10.

Lithium Maintenance

Clients who respond to lithium typically remain on the medication indefinitely. To assure safe maintenance and prevent lithium toxicity, client education and regular monitoring are essential. Monitoring includes but

TABLE 4–10 **Safety Issues and Nursing Interventions for Clients Taking Mood Stabilizers**	
SAFETY ISSUES	NURSING INTERVENTIONS

Lithium toxicity (blood levels >1.2 mEq/L) or <1.2 in elderly or debilitated but most common at 1.5 mEq/L
- Early signs: vomiting, diarrhea
- Over 2 mEq/L: tremors, sedation, confusion
- Levels over 3.5 mEq/L: delirium, seizures, coma, cardiovascular collapse, death
  Chlorpromazine (Thorazine) may mask early signs of lithium toxicity
  (Vallerand, Sanoski, & Deglin, 2016)
	Instruct clients to report all medications, herbals, and caffeine use to physician or nurse practitioner to evaluate for drug interactions.
	Encourage clients to maintain fluid intake at 2,000–3,000 ml/day and avoid activities in which excessive sweating and fluid loss are a risk, since inadequate fluid intake can impact lithium levels.
	Instruct clients about the importance of regular monitoring of serum lithium levels.
	Blood levels should be drawn 12 hours after the last dose.

Increased risk of suicide for all antiepileptics (FDA, 2008)	Assess for suicide risk regularly and inform clients of risks associated with anticonvulsants.
Hyponatremia (lithium, carbamazepine)	Instruct clients to maintain usual dietary intake of sodium. Assess for and educate clients to report any episodes of nausea, vomiting, headache, muscle weakness, confusion, seizures, since these may be signs of hyponatremia.
Stevens-Johnson syndrome (especially with lamotrigine and carbamazepine) This toxic skin necrolysis can be life threatening	Assess for and educate clients to report any signs of rash or unusual skin breakdown.

Continued

TABLE 4–10 Safety Issues and Nursing Interventions for Clients Taking Mood Stabilizers—cont'd	
SAFETY ISSUES	**NURSING INTERVENTIONS**
Hypotension, arrhythmias (lithium)	Monitor vital signs and instruct clients to report any symptoms of dizziness or palpitations.
Blood dyscrasias (valproic acid, carbamazepine)	Educate clients to report infections or other illness while on these medications. Ensure that platelet counts and bleeding time are determined before initiation of therapy. Monitor for spontaneous bleeding or bruising.
Increased risk of birth defects (anticonvulsant mood stabilizers)	Inform female clients of the risks of birth defects and provide education about contraception as desired.
Drowsiness (lithium and all anticonvulsants)	Instruct clients to avoid driving or operating dangerous machinery when experiencing this side effect. Assess clients' mental status for level of alertness.

is not limited to evaluating serum lithium levels to assure that they remain within the therapeutic range. The usual ranges of therapeutic serum concentrations differ for initiation of treatment in an acute manic state and maintenance (Facts and Comparisons [Firm], 2014; Schatzberg, Cole, & DeBattista, 2010):

- For acute mania: 1.0 to 1.5 mEq/L
- For maintenance: 0.6 to 1.2 mEq/L

Serum lithium levels should be monitored once or twice a week after initial treatment until dosage and serum levels are stable and then monthly during maintenance therapy. Blood samples should be drawn 12 hours after the last dose is taken.

At times, clients complain that they miss the "high" feeling of being in a manic or hypomanic state once they begin mood-stabilizer medications. They may be at risk for self-adjusting medication or discontinuing it all together. Open discussion and exploring the benefits versus disadvantages of medication treatment promotes patient-centered care and enables the nurse to troubleshoot with the client ways to minimize risks.

Another generally undesirable side effect of lithium is weight gain. Clients should be educated about this potential, and weight should be monitored at regular intervals. It may be helpful to discuss low-calorie diets while stressing the importance of not making large changes in sodium intake because of its impact on serum blood levels of lithium.

CLINICAL PEARL The U.S. Food and Drug Administration requires that all antiepileptic (anticonvulsant) drugs carry a warning label indicating that use of the drugs increases risk for suicidal thoughts and behaviors. Patients treated with these medications should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, or any unusual changes in mood or behavior.

Outcome Criteria and Evaluation

The following criteria may be used for evaluating the effectiveness of therapy with mood stabilizing agents.

The client:

- Is maintaining stability of mood
- Has not harmed self or others
- Has experienced no injury from hyperactivity
- Is able to participate in activities without excessive sedation or dizziness
- Is maintaining appropriate weight
- Exhibits no signs of lithium toxicity
- Verbalizes importance of taking medication regularly and reporting for regular laboratory blood tests

Antipsychotic Agents

Background Assessment Data

Antipsychotic medications are also called *neuroleptics*. Historically, they have been referred to as major tranquilizers and clearly have sedative effects. The term *antipsychotics* is most descriptive because the primary benefit over time is the alleviation of psychotic symptoms such as hallucinations and delusions. Antipsychotic agents were introduced into the United States in the 1950s with the phenothiazines. Other drugs in this classification soon followed. Unfortunately, this group of medications was found to have the potential for side effects that interfere with normal movements, including acute **dystonias** (muscle spasms) that can be life threatening, Parkinson-like symptoms, and **tardive dyskinesia** (later-onset involuntary movement disorders primarily in the tongue, lips, and jaw that may also involve other movement disturbances). Some of these side effects can be permanent, continuing even after the drug is discontinued. Since that discovery, a second generation of medications has been developed with less potential for extrapyramidal

side effects (EPS) such as those mentioned above. These drugs have become the first line of treatment for clients with psychotic disorders such as schizophrenia. This group of drugs may also be effective for treating negative symptoms of schizophrenia and alleviating positive symptoms like hallucinations, delusions, and agitation. More recently, aripiprazole (Abilify), an atypical antipsychotic, has been described as a third-generation antipsychotic because of its unique functional profile with dopamine receptors and minimal risk for EPS (Brust et al., 2015). The typical antipsychotics include the phenothiazines, haloperidol, loxapine, pimozide, and thiothixene. The atypical antipsychotics include aripiprazole, asenapine, clozapine, olanzapine, quetiapine, risperidone, paliperidone, iloperidone, lurasidone, ziprasidone, brexpiprazole (Rexulti), cariprazine (Vraylar), and pimavanserin (Nuplazid) indicated for hallucinatins and delusions associated with Parkinson's disease psychosis.

Indications

Antipsychotics are used in the treatment of schizophrenia and other psychotic disorders. Selected agents are used in the treatment of bipolar mania (see previous section, "Mood-Stabilizing Agents"). Others are used as antiemetics (chlorpromazine, perphenazine, prochlorperazine), in the treatment of intractable hiccoughs (chlorpromazine), and for the control of tics and vocal utterances in Tourette's disorder (haloperidol, pimozide). Selected atypical antipsychotics, including aripiprazole (Abilify), are being identified as adjuncts to the treatment of major depressive disorders. (A table of current FDA-approved antipsychotics, pregnancy categories, half-life, and daily dosage ranges, as well as antiparkinsonian agents used to treat extrapyramidal side effects of antipsychotic medication, can be found online at Davis*Plus* and in Chapter 24, Schizophrenia Spectrum and Other Psychotic Disorders.)

Action

Typical antipsychotics work by blocking postsynaptic dopamine receptors in the basal ganglia, hypothalamus, limbic system, brainstem, and medulla. They also demonstrate varying affinity for cholinergic, alpha$_1$-adrenergic, and histaminic receptors. Antipsychotic effects may be related to inhibition of dopamine-mediated transmission of neural impulses at the synapses.

Atypical antipsychotics are weaker dopamine receptor antagonists than conventional antipsychotics but are more potent antagonists of the serotonin type 2A (5HT$_{2A}$) receptors. They also exhibit antagonism for cholinergic, histaminic, and adrenergic receptors. As mentioned previously, aripiprazole (Abilify) is a dopamine receptor antagonist but seems to have

a unique way of accomplishing its action and thus has a minimal risk of extrapyramidal side effects.

Contraindications and Precautions

Certain individuals may be at greater risk for experiencing side effects associated with antipsychotic agents. The elderly have been identified as an at-risk population because of accounts of stroke and sudden death while taking antipsychotic medication. Studies have indicated that elderly patients with psychosis related to neurocognitive disorder (NCD) who are treated with antipsychotic drugs are at increased risk of death compared with those taking a placebo (Steinberg & Lyketsos, 2012). Causes of death are most commonly related to infections or cardiovascular problems. All antipsychotic drugs now carry black-box warnings to this effect. They are not approved for treatment of elderly patients with NCD-related psychosis.

Typical antipsychotics are contraindicated in clients with known hypersensitivity (cross-sensitivity may exist among phenothiazines). They should not be used in comatose states or when CNS depression is evident; when blood dyscrasias exist; in clients with Parkinson's disease or narrow-angle glaucoma; for those with liver, renal, or cardiac insufficiency; in individuals with poorly controlled seizure disorders; or in elderly clients with dementia-related psychosis. Caution should be taken in administering these drugs to clients who are elderly, severely ill, or debilitated and to clients with diabetes or with respiratory insufficiency, prostatic hypertrophy, or intestinal obstruction.

Atypical antipsychotics are contraindicated in hypersensitivity, comatose or severely depressed patients, elderly patients with dementia-related psychosis, and lactation. Ziprasidone, risperidone, paliperidone, asenapine, and iloperidone are contraindicated in patients with a history of QT prolongation or cardiac arrhythmias, recent myocardial infarction (MI), uncompensated heart failure, and concurrent use with other drugs that prolong the QT interval. Clozapine is contraindicated in patients with myeloproliferative disorders, with a history of clozapine-induced **agranulocytosis** or severe granulocytopenia, and in uncontrolled epilepsy. Lurasidone is contraindicated in concomitant use with strong inhibitors of cytochrome P450 isozyme 3A4 (CYP3A4) (e.g., ketoconazole, an antifungal) and strong CYP3A4 inducers (e.g., rifampin, an antitubercular).

Caution should be taken in administering these drugs to elderly or debilitated patients; patients with cardiac, hepatic, or renal insufficiency; those with a history of seizures; patients with diabetes or risk factors for diabetes; clients exposed to temperature extremes; pregnant clients and children (safety

not established); and under conditions that cause hypotension (dehydration, hypovolemia, treatment with antihypertensive medication). The risk for metabolic disturbances such as weight gain can be particularly dangerous in the elderly.

Interactions

Table 4–11 highlights some drug interactions that warrant monitoring and assessment by nurses.

Diagnosis

The following nursing diagnoses may be considered for clients receiving antipsychotic therapy:

- Risk for other-directed violence related to panic anxiety and mistrust of others
- Risk for injury related to medication side effects of sedation, photosensitivity, reduction of seizure threshold, agranulocytosis, **extrapyramidal symptoms,** tardive dyskinesia, neuroleptic malignant syndrome, and/or QT prolongation
- Risk for activity intolerance related to medication side effects of sedation, blurred vision, and/or weakness
- Noncompliance with medication regimen related to suspiciousness and mistrust of others

Safety Issues in Planning and Implementing Care

Table 4–12 discusses some significant safety issues to consider and relevant nursing interventions for clients taking antipsychotic medication.

TABLE 4–11 Drug Interactions With Antipsychotic Medications	
DRUG INTERACTION	ADVERSE EFFECT
Antihypertensives, CNS depressants Epinephrine or dopamine in combination with haloperidol or phenothiazines	Additive and potentially severe hypotension
Oral anticoagulants with phenothiazines	Less effective anticoagulant effects
Drugs that prolong QT intervals	Additive effects
Drugs that trigger orthostatic hypotension	Additive hypotension
Drugs with anticholinergic effects, prescription and OTC drugs	Additive anticholinergic effects, including anticholinergic toxicity, signs of which are ■ Flushing ■ Dry mouth ■ Mydriasis ■ Altered mental status ■ Tachycardia ■ Urinary retention ■ Tremulousness ■ Hypertension (Ramnarine & Ahmed, 2015)

TABLE 4–12 Safety Issues and Nursing Interventions for Clients Taking Antipsychotic Medication	
SAFETY ISSUES	NURSING INTERVENTIONS
Extrapyramidal side effects[a] (see Table 4–13 for relative risk among specific medications)	Instruct client to report any signs of muscle stiffness or spasms. Hold the medication if this occurs. Administer antiparkinsonian agents as ordered and immediately when signs of acute dystonia are present. Assess the patient for abnormal involuntary movements (see Box 4–2). (See "Additional Issues for Client Education" for further discussion.)
Hyperglycemia, weight gain, and diabetes (more common with atypical antipsychotic agents)	Assess for history of diabetes. Evaluate blood sugars. Instruct the client in these risks and the importance of diet and exercise. Assess for signs of hyperglycemia including polydipsia, polyphagia, polyuria, and weakness.
Hypotension	Educate the client about risk for hypotension. Monitor blood pressure.
Orthostatic hypotension (see Table 4–13 for level of risk by specific medications)	Instruct client to rise slowly from sitting to standing. Monitor blood pressure lying and then standing to assess for postural changes.
Lower seizure threshold (especially with clozapine)	Assess client for history of seizure disorder. Monitor client for evidence of seizure activity and report to prescribing physician or nurse practitioner.

TABLE 4–12 Safety Issues and Nursing Interventions for Clients Taking Antipsychotic Medication–cont'd	
SAFETY ISSUES	NURSING INTERVENTIONS
Prolonged QT interval[b] especially ziprasidone, thioridazine, pimozide, haloperidol, paliperidone, iloperidone, asenapine, and clozapine.	Assess for history of arrhythmias, recent MI, heart failure, and report to prescribing physician or nurse practitioner because these events are contraindications. Assess for other medications the client is taking that prolong QT interval (there are many; online resources such as www.crediblemeds.org provide a composite list for comparison), but note that erythromycin and clarithromycin are two that are commonly prescribed. Instruct client to reported any rapid heartbeat, dizziness, or fainting. Check baseline EKG before beginning treatment.
Anticholinergic effects (see Table 4–13 for relative risk among medications)	Instruct client about additive effects of other anticholinergic drugs in combination with antipsychotics, and to report any other medications taken including over-the-counter and herbal remedies. For minor symptoms such as dry mouth, recommend hard candies, sips of water. Instruct client regarding the importance of good oral hygiene. Instruct client to report and assess for any evidence of urinary retention, tachycardia, tremulousness, or hypertension, which may be signs of anticholinergic toxicity.
Sedation	Educate client about this side effect and instruct client not to drive or operate dangerous machinery if experiencing sedation.
Photosensitivity	Instruct client to use sunblock and sunglasses and to wear protective clothing when in the sun because of the increased risk for severe sunburn while on these medications.
Agranulocytosis (more common with typical antipsychotics but especially with the atypical antipsychotic agent clozapine)	Instruct the client receiving clozapine that regular monitoring of white blood cell and absolute neutrophil counts is essential. Instruct the client to report any signs of sore throat, fever, or malaise. (See additional guidelines in the section on Issues in Antipsychotic Maintenance Therapy.)
Neuroleptic malignant syndrome (NMS)[c]	Instruct client to report immediately any fever, muscle rigidity, diaphoresis, tachycardia. Assess vital signs regularly, including temperature. Assess for deteriorating mental status or any other sign of NMS. Presence of any of these signs requires holding the medication and contacting the prescribing physician or nurse practitioner immediately, as well as monitoring vital signs and intake and output.

[a]Acute dystonias can be life threatening (more common with typical antipsychotic agents).
[b]Potentially life-threatening.
[c]Rare but potentially life-threatening side effect characterized by muscle rigidity, severe hyperthermia, and cardiac effects that can progress rapidly over 24–72 hours.

Additional Issues for Client Education

A comparison of side effects among antipsychotic agents is presented in Table 4–13. Clients should be apprised of health risks, including the following:

- Smoking increases the metabolism of antipsychotics, requiring an adjustment in dosage to achieve a therapeutic effect. Encourage clients to discuss this issue with the prescribing physician or nurse practitioner.
- Body temperature is harder to maintain with this medication, so clients should be encouraged to dress warmly in cold weather and avoid extended exposure to very high or low temperatures.
- Alcohol and antipsychotic drugs potentiate each other's effects, so clients should be advised to avoid drinking alcohol while on antipsychotic therapy.

- Many medications contain substances that interact with antipsychotics in a way that may be harmful. Clients should avoid taking other medications, including over-the-counter products, without the physician's approval.
- A significant number of clients on clozapine report excessive salivation. Sugar-free gum and medications (anticholinergic or alpha$_2$-adrenoceptor agonists) may alleviate symptoms. Encourage clients to discuss these options with the prescribing physician or nurse practitioner.
- Safe use of antipsychotics during pregnancy has not been established. Antipsychotics are thought to readily cross the placental barrier; if so, a fetus could experience adverse effects of the drug. Clients should

TABLE 4–13 Comparison of Side Effects Among Antipsychotic Agents						
CLASS	GENERIC (TRADE) NAME	EPS	SEDATION	ANTICHOLINERGIC	ORTHOSTATIC HYPOTENSION	WEIGHT GAIN

be aware of the possible risks and should inform the physician immediately if pregnancy occurs, is suspected, or is planned.

Issues in Antipsychotic Maintenance Therapy

The nurse must understand the management of side effects associated with antipsychotic medication in order to conduct a thorough assessment and minimize risks. In addition, some of these side effects can be difficult for clients to manage or understand, particularly when they are struggling with impaired mental status including psychosis and cognitive deficits. Three of these are discussed below.

Clozaril and the Risk for Agranulocytosis Agranulocytosis is a potentially fatal blood disorder in which the client's white blood cell (WBC) count can drop to extremely low levels. A baseline WBC count and absolute neutrophil count (ANC) must be taken before initiation of treatment with clozapine and weekly for the first 6 months of treatment. Only a 1-week supply of medication is dispensed at one time. If the counts remain within the acceptable levels (i.e., WBC count at least 3,500/mm³ and ANC at least 2,000/mm³) during the 6-month period, blood counts may be monitored biweekly and a 2-week supply of medication may be dispensed. If the counts remain within the acceptable level for the biweekly period (6 months),

counts may then be monitored every 4 weeks. When the medication is discontinued, weekly WBC counts are continued for an additional 4 weeks.

While the benefits of clozapine can be profound, this medication is typically used when clients fail to respond to other antipsychotics because of the strict protocols for adherence. If the client agrees to this option, the nurse can be a vital link in assuring that support services, both professional and personal (such as family members or peers), are engaged to assist the client with follow-through as needed.

Extrapyramidal Side Effects (See Table 4–13 for differences between typical and atypical antipsychotics.) To conduct a thorough assessment, the nurse must be familiar with the several distinct types of extrapyramidal side effects:

■ **Pseudoparkinsonism:** Symptoms of pseudoparkinsonism—tremor, shuffling gait, drooling, rigidity—may appear 1 to 5 days following initiation of antipsychotic medication. This side effect occurs most often in women, the elderly, and dehydrated clients.

■ **Akinesia:** Absence or impairment in voluntary movement.

■ **Akathisia:** Continuous restlessness and fidgeting, or **akathisia,** occurs most often in women and

may manifest 50 to 60 days after therapy begins. Combining second generation antipsychotics has demonstrated a three-fold risk for developing akathisia as compared to monotherapy with a single second generation antipsychotic (Berna et al., 2015)

■ **Dystonia:** This side effect—involuntary muscle spasms in the face, arms, legs, and neck—occurs most often in men and those younger than age 25. **Dystonia** should be treated as an emergency situation because laryngospasm follows these symptoms and can be fatal. The physician should be contacted, and intravenous or intramuscular benztropine mesylate (Cogentin) is commonly administered (see Table 4–13 for a list of antiparkinsonian agents used to treat extrapyramidal symptoms). Stay with the client and offer reassurance and support during this frightening time.

■ **Oculogyric crisis:** Uncontrolled rolling back of the eyes, or **oculogyric crisis,** is a symptom of acute dystonia and can be mistaken for seizure activity. As with other symptoms of acute dystonia, this side effect should be treated as a medical emergency.

■ **Tardive dyskinesia:** This extrapyramidal side effect involves bizarre face and tongue movements, stiff neck, and difficulty swallowing. It may occur with all classifications but most commonly takes place with typical antipsychotics. All clients receiving antipsychotic therapy for months or years are at risk. Symptoms are potentially irreversible. Nurses should immediately report to the prescribing physician or nurse practitioner earliest signs of **tardive dyskinesia** (usually vermiform movements of the tongue) as the drug is often discontinued, changed to a different antipsychotic, or the dosage is altered. In 2017 the FDA approved the first drug for treating tardive dyskinesia; valbenazine (Ingrezza). It is hoped that this novel drug will effectively reduce this troubling condition and its sometimes stigmatizing effects (FDA, 2017). The involuntary movements associated with tardive dyskinesia can be measured by the Abnormal Involuntary Movement Scale (AIMS), developed in the 1970s by the National Institute of Mental Health. AIMS aids in early detection of movement disorders and provides means for ongoing surveillance. AIMS is featured in Box 4–2.

BOX 4–2 Abnormal Involuntary Movement Scale (AIMS)

NAME _____ **RATER NAME** _____ **DATE** _____

INSTRUCTIONS: Complete the examination procedure before making ratings. For movement ratings, circle the highest severity observed. Rate movements that occur upon activation one less than those observed spontaneously. Circle movement as well as code number that applies.

Code: 0 = None
1 = Minimal, may be normal
2 = Mild
3 = Moderate
4 = Severe

Facial and Oral Movements	1. Muscles of Facial Expression (e.g., movements of forehead, eyebrows, periorbital area, cheeks, including frowning, blinking, smiling, grimacing)	0 1 2 3 4
	2. Lips and Perioral Area (e.g., puckering, pouting, smacking)	0 1 2 3 4
	3. Jaw (e.g., biting, clenching, chewing, mouth opening, lateral movement)	0 1 2 3 4
	4. Tongue (Rate only increases in movement both in and out of mouth. NOT inability to sustain movement. Darting in and out of mouth.)	0 1 2 3 4
Extremity Movements	5. Upper (arms, wrists, hands, fingers) Include choreic movements (i.e., rapid, objectively purposeless, irregular, spontaneous) and athetoid movements (i.e., slow, irregular, complex serpentine). *Do not include tremor* (i.e., repetitive, regular, rhythmic)	0 1 2 3 4
	6. Lower (legs, knees, ankles, toes) (e.g., lateral knee movement, foot tapping, heel dropping, foot squirming, inversion and eversion of foot)	0 1 2 3 4
Trunk Movements	7. Neck, shoulders, hips (e.g., rocking, twisting, squirming, pelvic gyrations)	0 1 2 3 4
Global Judgments	8. Severity of abnormal movements overall	0 1 2 3 4
	9. Incapacitation due to abnormal movements	0 1 2 3 4

Continued

BOX 4–2 Abnormal Involuntary Movement Scale (AIMS)–cont'd

	10. Patient's awareness of abnormal movements (Rate only the client's report)	
	No awareness	0
	Aware, no distress	1
	Aware, mild distress	2
	Aware, moderate distress	3
	Aware, severe distress	4
Dental Status	11. Current problems with teeth and/or dentures?	No Yes
	12. Are dentures usually worn?	No Yes
	13. Edentia?	No Yes
	14. Do movements disappear in sleep?	No Yes

AIMS EXAMINATION PROCEDURE

Either before or after completing the Examination Procedure, observe the client unobtrusively, at rest (e.g., in waiting room). The chair to be used in this examination should be a hard, firm one without arms.

1. Ask client to remove shoes and socks.
2. Ask client whether there is anything in his/her mouth (i.e., gum, candy, etc.), and if there is, to remove it.
3. Ask client about the current condition of his/her teeth. Ask client if he/she wears dentures. Do teeth or dentures bother client now?
4. Ask client whether he/she notices any movements in mouth, face, hands, or feet. If yes, ask to describe and to what extent they currently bother client or interfere with his/her activities.
5. Have client sit in chair with both hands on knees, legs slightly apart, and feet flat on floor. (Look at entire body for movements while in this position.)
6. Ask client to sit with hands hanging unsupported. If male, between legs, if female and wearing a dress, hanging over knees. (Observe hands and other body areas.)
7. Ask client to open mouth. (Observe tongue at rest within mouth.) Do this twice.
8. Ask client to protrude tongue. (Observe abnormalities of tongue movement.) Do this twice.
9. Ask client to tap thumb with each finger as rapidly as possible for 10 to 15 seconds; separately with right hand, then with left hand. (Observe facial and leg movements.)
10. Flex and extend client's left and right arms (one at a time). (Note any rigidity.)
11. Ask client to stand up. (Observe in profile. Observe all body areas again, hips included.)
12. Ask client to extend both arms outstretched in front with palms down. (Observe trunk, legs, and mouth.)
13. Have client walk a few paces, turn, and walk back to chair. (Observe hands and gait.) Do this twice.

INTERPRETATION OF AIMS SCORE

Add client scores and note areas of difficulty.
Score of:

• 0 to 1 = Low risk
• 2 in only ONE of the areas assessed = borderline/observe closely
• 2 in TWO or more of the areas assessed **or** 3 to 4 in ONLY ONE area = indicative of TD

From U.S. Department of Health and Human Services. Available for use in the public domain.

Some extrapyramidal side effects can be life-threatening, and those that are not can sometimes be permanent. The abnormal movements in the tongue and lips are sometimes very visible and severe enough to interfere with a person's ability to speak or swallow.

The nurse's empathic approach in listening to the client's wishes with regard to medication and advocating for exploring other options for management of symptoms is one way to promote patient-centered care, an essential nursing competency, (IOM, 2003) and to promote a recovery model that empowers the client to make decisions about management of the illness. There is evidence that remaining on antipsychotic medication can reduce the frequency of hospitalization, so educating the client about this fact is important in assisting him or her to make an informed decision about medication treatment.

Hormonal Side Effects These may occur with all classifications but are more common with typical antipsychotics. Sexual side effects that may accompany these medications include decreased libido, **retrograde ejaculation,** and **gynecomastia** in men and

amenorrhea in women. These side effects can be troubling for anyone, but for a client struggling with thought disturbances, they can become the foundation for delusions. A male client with gynecomastia, for example, might begin to believe that external forces are taking over his body and turning him into a woman. An amenorrheic woman may begin to believe that she has been divinely impregnated. It is important for the nurse to be clear that these are side effects of the medication and offer reassurance that they are reversible. Women with amenorrhea should be instructed that this side effect does not indicate cessation of ovulation, so contraception use should continue as usual. Clients should be encouraged to explore alternative treatment if these side effects are deemed intolerable.

Current Developments in Psychopharmacological Treatment of Schizophrenia

One of the identified limitations of medication treatments available for schizophrenia is the cognitive deficits that are core symptoms of this illness, including deficits in working memory and long-term memory, reduced processing speed, limited verbal fluency, and impaired executive functions. Some atypical antipsychotics have demonstrated efficacy in lessening cognitive deficits but do not eliminate residual effects.

A drug recently approved by the FDA, *cariprazine* (Vraylor), has demonstrated efficacy in treating the negative symptoms of schizophrenia, including flat affect, social withdrawal, and apathy (Harrison, 2015). Although the atypical antipsychotics have been identified as better than typical antipsychotics in treating these symptoms, no drugs have yet been shown to eliminate them. Ongoing evaluation is needed to determine the effectiveness of cariprazine in this regard.

Outcome Criteria and Evaluation

The following criteria may be used for evaluating the effectiveness of therapy with antipsychotic medications.

The client:

- Has not harmed self or others
- Has not experienced injury caused by side effects of lowered seizure threshold or photosensitivity
- Maintains a WBC count within normal limits
- Exhibits no symptoms of extrapyramidal side effects, tardive dyskinesia, neuroleptic malignant syndrome, or hyperglycemia
- Maintains weight within normal limits
- Tolerates activity unaltered by the effects of sedation or weakness
- Takes medication willingly
- Verbalizes understanding of medication regimen and the importance of regular administration

Sedative-Hypnotics

Background Assessment Data

Indications

Sedative-hypnotics are used in the short-term management of various anxiety states and to treat insomnia. Selected agents are used as anticonvulsants (pentobarbital, phenobarbital) and preoperative sedatives (pentobarbital, secobarbital) and to reduce anxiety associated with alcohol withdrawal (chloral hydrate). (A table of current FDA-approved sedative-hypnotics, pregnancy categories, half-life, and daily dosage ranges can be found online at Davis*Plus*.) Examples of commonly used sedative-hypnotics are presented in Table 4–14.

Action

Sedative-hypnotics cause generalized CNS depression. They may produce tolerance with chronic use and have the potential for psychological or physical dependence.

> **EXCEPTION:** Ramelteon (Rozerem) is not a controlled substance. It does not produce tolerance or physical dependence. Sleep-promoting properties are the result of ramelteon's agonist activity on selective melatonin receptors.

Contraindications and Precautions

Sedative-hypnotics are contraindicated in individuals with hypersensitivity to the drug or to any drug within the chemical class; in pregnancy (exceptions may be made in certain cases based on benefit-to-risk ratio); during lactation; in severe hepatic, cardiac, respiratory, or renal disease; and in children younger than age 15 for flurazepam and those younger than age 18 for estazolam, quazepam, temazepam, triazolam. Triazolam is contraindicated in concurrent use with ketoconazole, itraconazole, or nefazodone, medications that impair the metabolism of triazolam by cytochrome P4503A (CYP3A). Ramelteon is contraindicated in concurrent use with fluvoxamine. Zolpidem, zaleplon, eszopiclone, and ramelteon are contraindicated in children. Chloral hydrate is contraindicated in persons with esophagitis, gastritis, or peptic ulcer disease and in those with hepatic, renal, or cardiac impairment.

Caution should be used in administering these drugs to clients with cardiac, hepatic, renal, or respiratory insufficiency. They should be used with caution in clients who may be suicidal or who previously may have been addicted to drugs. Hypnotic use should be short term. Elderly clients may be more sensitive to CNS depressant effects, and dosage reduction may be required. Chloral hydrate should be used with caution in clients susceptible to acute intermittent porphyria.

TABLE 4–14 Sedative-Hypnotic Agents

CHEMICAL CLASS	GENERIC (TRADE) NAME	CONTROLLED CATEGORIES	PREGNANCY CATEGORIES/ HALF-LIFE (hr)	DAILY DOSAGE RANGE (mg)
Barbiturates	Amobarbital	CII	D/16–40	60–200
	Butabarbital (Butisol)	CIII	D/66–140	45–120
	Pentobarbital (Nembutal)	CII	D/15–50	150–200
	Phenobarbital (Luminal; Solfoton)	CIV	D/53–118	30–200
	Secobarbital (Seconal)	CII	D/15–40	100 (hypnotic) 200–300 (preoperative sedation)
Benzodiazepines	Estazolam	CIV	X/8–28	1–2
	Flurazepam	CIV	X/2–3 (active metabolite: 47–100)	15–30
	Quazepam (Doral)	CIV	X/39 (active metabolite: 73)	7.5–15 mg
	Temazepam (Restoril)	CIV	X/9–15	15–30 mg
	Triazolam (Halcion)	CIV	X/1.5–5.5	0.125–0.5
Miscellaneous	Chloral hydrate	CIV	C/7–10	500–1,000
	Eszopiclone (Lunesta)	CIV	C/6	1–3
	Ramelteon (Rozerem)		C/1–2.6	8
	Zaleplon (Sonata)	CIV	C/1	5–20
	Zolpidem (Ambien)	CIV	C/2–3	5–10 (immediate release), 12.5 (extended release)

Interactions

Barbiturates The effects of barbiturates are increased with concomitant use of alcohol, other CNS depressants, MAOIs, or valproic acid. The effects of barbiturates may be decreased with rifampin. Possible decreased effects of the following drugs may occur when used concomitantly with barbiturates: anticoagulants, beta blockers, carbamazepine, clonazepam, oral contraceptives, corticosteroids, digitoxin, doxorubicin, doxycycline, felodipine, fenoprofen, griseofulvin, metronidazole, phenylbutazone, quinidine, theophylline, or verapamil. Concomitant use with methoxyflurane may enhance renal toxicity.

Benzodiazepines The effects of the benzodiazepine hypnotics are increased with concomitant use of alcohol or other CNS depressants, cimetidine, oral contraceptives, disulfiram, isoniazid, or probenecid. The effects of the benzodiazepine hypnotics are decreased with concomitant use of rifampin, theophylline, carbamazepine, or St. John's wort and with cigarette smoking. The effects of digoxin or phenytoin are increased when used concomitantly with benzodiazepines. Bioavailability of triazolam is increased with concurrent use of macrolides.

Eszopiclone Additive effects of eszopiclone occur with alcohol or other CNS depressants. Decreased effects of eszopiclone occur with CYP3A4 inducers (e.g., rifampin, phenytoin, carbamazepine, phenobarbital), with lorazepam, or following a high-fat or heavy meal. Increased effects of eszopiclone occur with CYP3A4 inhibitors (e.g., ketoconazole, clarithromycin, nefazodone, ritonavir). There are decreased effects of lorazepam with concomitant use.

Zaleplon Additive effects of zaleplon occur with alcohol or other CNS depressants. Decreased effects of zaleplon occur with CYP3A4 inducers (e.g., rifampin, phenytoin, carbamazepine, phenobarbital) or following a high-fat or heavy meal. There are increased effects of zaleplon with cimetidine.

Zolpidem Increased effects of zolpidem occur with alcohol or other CNS depressants, azole antifungals, ritonavir, or SSRIs. Decreased effects of zolpidem occur with flumazenil, rifampin, and with food. There is a risk of life-threatening cardiac arrhythmias with concomitant use of amiodarone.

Ramelteon Increased effects of ramelteon occur with alcohol, ketoconazole (and other CYP3A4 inhibitors), or fluvoxamine (and other CYP1A2 inhibitors). Decreased effects of ramelteon occur with rifampin (and other CYP3A4 inducers) and following a heavy or high-fat meal.

Diagnosis

The following nursing diagnoses may be considered for clients receiving therapy with sedative hypnotics:

■ Risk for injury related to abrupt withdrawal from long-term use or decreased mental alertness caused by residual sedation

■ Disturbed sleep pattern and/or insomnia related to situational crises, physical condition, or severe level of anxiety

■ Risk for activity intolerance related to side effects of lethargy, drowsiness, and dizziness

■ Risk for acute confusion related to action of the medication on the CNS

Safety Issues in Planning and Implementing Care

Refer to the earlier discussion of safety issues in the section "Antianxiety Agents." In addition to the side effects listed in that section, abnormal thinking and behavioral changes, including aggressiveness, hallucinations, and suicidal ideation, have also been noted in some individuals taking sedative-hypnotics. Certain complex behaviors, such as sleep-driving, preparing and eating food, and making phone calls, with amnesia for the behavior, have occurred. Although a direct correlation to the behavior with the use of sedative-hypnotics cannot be made, the emergence of any new behavioral sign or symptom of concern requires careful and immediate evaluation.

Outcome Criteria and Evaluation

The following criteria may be used for evaluating the effectiveness of therapy with sedative-hypnotic medications.

The client:

■ Demonstrates a reduction in anxiety, tension, and restless activity

■ Falls asleep within 30 minutes of taking the medication and remains asleep for 6 to 8 hours without interruption

■ Is able to participate in usual activities without residual sedation

■ Experiences no physical injury

■ Exhibits no evidence of confusion

■ Verbalizes understanding of taking the medication on a short-term basis

■ Verbalizes understanding of potential for development of tolerance and dependence with long-term use

Agents for Attention-Deficit/Hyperactivity Disorder (ADHD)

Background Assessment Data

Indications

The medications in this section are used for ADHD in children and adults. Amphetamines are also used in the treatment of narcolepsy and exogenous obesity. Bupropion is used in the treatment of major depression and for smoking cessation (Zyban only). Clonidine and guanfacine are used to treat hypertension. (A table of current FDA-approved agents for ADHD, pregnancy categories, half-life, and daily dosage ranges can be found online at DavisPlus and in Chapter 33, Children and Adolescents.)

Action

CNS stimulants increase levels of neurotransmitters (probably norepinephrine, dopamine, and serotonin) in the CNS. They produce CNS and respiratory stimulation, dilated pupils, increased motor activity and mental alertness, diminished sense of fatigue, and brighter spirits. The CNS stimulants discussed in this section include dextroamphetamine sulfate, methamphetamine, lisdexamfetamine, amphetamine mixtures, methylphenidate, and dexmethylphenidate. Action in the treatment of ADHD is unclear. However, recent research indicates that their effectiveness in the treatment of hyperactivity disorders is based on the activation of dopamine D_4 receptors in the basal ganglia and thalamus, which depress rather than enhance motor activity (Erlij et al., 2012).

Atomoxetine inhibits the reuptake of norepinephrine, and bupropion blocks the neuronal uptake of serotonin, norepinephrine, and dopamine. Clonidine and guanfacine stimulate central alpha-adrenergic receptors in the brain, resulting in reduced sympathetic outflow from the CNS. The exact mechanism by which these nonstimulant drugs produce the therapeutic effect in ADHD is unclear.

Contraindications and Precautions

CNS stimulants are contraindicated in individuals with hypersensitivity to sympathomimetic amines. They should not be used in patients with advanced arteriosclerosis, cardiovascular disease, hypertension, hyperthyroidism, glaucoma, or agitated or hyperexcitability states; in clients with a history of drug abuse; during or within 14 days of receiving therapy with MAOIs; in children younger than age 3; or in pregnancy and lactation. Atomoxetine and bupropion are contraindicated in clients with hypersensitivity to the drugs or their components, in lactation, and in concomitant use with or within 2 weeks of using MAOIs. Atomoxetine is contraindicated in clients with narrow-angle glaucoma. Bupropion is contraindicated in individuals with known or suspected seizure disorder, in the acute phase of MI, and in clients with bulimia or anorexia nervosa. Alpha agonists are contraindicated in clients with known hypersensitivity to the drugs.

Caution is advised in using CNS stimulants in children with psychosis; in Tourette's disorder; in clients with anorexia or insomnia; in elderly, debilitated, or asthenic clients; and in clients with a history of suicidal or homicidal tendencies. Prolonged use may result in tolerance and physical or psychological dependence. Use atomoxetine and bupropion cautiously in clients

with urinary retention, hypertension, or hepatic, renal, or cardiovascular disease; in suicidal clients; during pregnancy; and in elderly and debilitated clients. Alpha agonists should be used with caution in clients with coronary insufficiency, recent MI, or cerebrovascular disease; in chronic renal or hepatic failure; in the elderly; and in pregnancy and lactation.

Interactions

CNS Stimulants (Amphetamines) Effects of amphetamines are increased with furazolidone or urinary alkalinizers. Hypertensive crisis may occur with concomitant use of (and up to several weeks after discontinuing) MAOIs. Increased risk of serotonin syndrome occurs with coadministration of SSRIs. Decreased effects of amphetamines occur with urinary acidifiers, and decreased hypotensive effects of guanethidine occur with amphetamines.

Dexmethylphenidate and Methylphenidate Effects of antihypertensive agents and pressor agents (e.g., dopamine, epinephrine, phenylephrine) are decreased with concomitant use of the methylphenidates. Effects of coumarin anticoagulants, anticonvulsants (e.g., phenobarbital, phenytoin, primidone), tricyclic antidepressants, and SSRIs are increased with the methylphenidates. Hypertensive crisis may occur with coadministration of MAOIs.

Atomoxetine Effects of atomoxetine are increased with concomitant use of CYP2D6 inhibitors (e.g., paroxetine, fluoxetine, quinidine). Potentially fatal reactions may occur with concurrent use of (or within 2 weeks of discontinuation of) MAOIs. Risk of cardiovascular effects is increased with concomitant use of albuterol or vasopressors.

Bupropion Effects of bupropion are increased with amantadine, levodopa, or ritonavir. Effects of bupropion are decreased with carbamazepine. There is increased risk of acute toxicity with MAOIs. Increased risk of hypertension may occur with nicotine replacement agents, and adverse neuropsychiatric events may occur with alcohol. Increased anticoagulant effects of warfarin and increased effects of drugs metabolized by CYP2D6 (e.g., nortriptyline, imipramine, desipramine, paroxetine, fluoxetine, sertraline, haloperidol, risperidone, thioridazine, metoprolol, propafenone, and flecainide) occur with concomitant use.

Alpha Agonists Synergistic pharmacologic and toxic effects, possibly causing atrioventricular block, bradycardia, and severe hypotension, may occur with concomitant use of calcium channel blockers or beta-blockers. Additive sedation occurs with CNS depressants, including alcohol, antihistamines, opioid analgesics, and sedative-hypnotics. Effects of clonidine may be decreased with concomitant use of tricyclic antidepressants and prazosin. Decreased effects of levodopa may occur with clonidine, and effects of guanfacine are decreased with barbiturates or phenytoin.

Diagnosis

The following nursing diagnoses may be considered for clients receiving therapy with agents for ADHD:

■ Risk for injury related to overstimulation and hyperactivity (CNS stimulants) or seizures (possible side effect of bupropion)
■ Risk for suicide secondary to major depression related to abrupt withdrawal after extended use (CNS stimulants)
■ Risk for suicide (children and adolescents) as a side effect of atomoxetine and bupropion (black-box warning)
■ Imbalanced nutrition, less than body requirements, related to side effects of anorexia and weight loss (CNS stimulants)
■ Insomnia related to side effects of overstimulation
■ Nausea related to side effects of atomoxetine or bupropion
■ Pain related to side effect of abdominal pain (atomoxetine, bupropion) or headache (all agents)
■ Risk for activity intolerance related to side effects of sedation and dizziness with atomoxetine or bupropion

Planning and Implementation

The plan of care should include monitoring for the following side effects from agents for ADHD. Nursing implications related to each side effect are designated by an asterisk (*).

■ Overstimulation, restlessness, insomnia (CNS stimulants)
  *Assess mental status for changes in mood, level of activity, degree of stimulation, and aggressiveness.
  *Ensure that the client is protected from injury.
  *Keep stimuli low and environment as quiet as possible to discourage overstimulation.
  *To prevent insomnia, administer the last dose at least 6 hours before bedtime. Administer sustained-release forms in the morning.
■ Palpitations, tachycardia (CNS stimulants, atomoxetine, bupropion, clonidine), or bradycardia (clonidine, guanfacine)
  *Monitor and record vital signs at regular intervals (two or three times a day) throughout therapy. Report significant changes to the physician immediately.

  NOTE: The FDA has issued warnings associated with CNS stimulants and atomoxetine of the risk for sudden death in patients who have

cardiovascular disease. A careful personal and family history of heart disease, heart defects, or hypertension should be obtained before these medications are prescribed. Careful monitoring of cardiovascular function during administration must be ongoing.

■ Anorexia, weight loss (CNS stimulants, atomoxetine, bupropion)
  *To reduce anorexia, the medication may be administered immediately after meals.
  *The client should be weighed regularly (at least weekly) when receiving therapy with CNS stimulants, atomoxetine, or bupropion because of the potential for anorexia and weight loss and temporary interruption of growth and development.
■ Tolerance, physical and psychological dependence (CNS stimulants)
  *In children with ADHD, a drug "holiday" should be attempted periodically under direction of the physician to determine the effectiveness of the medication and the need for continuation.
  *The drug should not be withdrawn abruptly. To do so could initiate a syndrome of symptoms with nausea, vomiting, abdominal cramping, headache, fatigue, weakness, mental depression, suicidal ideation, increased dreaming, and psychotic behavior.
■ Nausea and vomiting (atomoxetine and bupropion)
  *Recommend taking medication with food to minimize gastrointestinal upset.
■ Constipation (atomoxetine, bupropion, clonidine, guanfacine)
  *Recommend increasing fiber and fluid in diet if not contraindicated.
■ Dry mouth (clonidine and guanfacine)
  *Offer the client sugarless candy, ice, frequent sips of water.
  *Strict oral hygiene is very important.
■ Sedation (clonidine and guanfacine)
  *Warn the client that this effect is increased by concomitant use of alcohol and other CNS drugs.
  *Warn the client to refrain from driving or performing hazardous tasks until response has been established.
■ Potential for seizures (bupropion)
  *Protect the client from injury if seizure should occur.
  *Instruct family and significant others of clients on bupropion therapy how to protect the client during a seizure if one should occur.
  *Ensure that doses of the immediate-release medication are administered at least 4 to 6 hours apart and doses of the sustained-release medication at least 8 hours apart.

■ Severe liver damage (with atomoxetine)
  *Monitor for the following side effects and report to physician immediately: itching, dark urine, right upper quadrant pain, yellow skin or eyes, sore throat, fever, malaise.
■ New or worsened psychiatric symptoms (with CNS stimulants and atomoxetine)
  *Monitor for psychotic symptoms (e.g., hearing voices, paranoid behaviors, delusions).
  *Monitor for manic symptoms, including aggressive and hostile behaviors.
■ Rebound syndrome (with clonidine and guanfacine)
  *The client should be instructed not to discontinue therapy abruptly. To do so may result in symptoms of nervousness, agitation, headache, tremor, and a rapid rise in blood pressure. In addition, sudden withdrawal from stimulants may increase the risk for depression and suicide.

Dosage should be tapered gradually under the supervision of the physician.

Client and Family Education

Instruct the client and/or family that the client should:

■ Use caution when driving or operating dangerous machinery. Drowsiness, dizziness, and blurred vision can occur.
■ Not stop taking CNS stimulants abruptly. To do so could produce serious withdrawal symptoms.
■ Avoid taking CNS stimulants late in the day to prevent insomnia. Take medication no later than 6 hours before bedtime.
■ Not take other medications (including over-the-counter drugs) without physician's approval. Many medications contain substances that, in combination with agents for ADHD, can be harmful.
■ Monitor blood sugar two or three times a day or as instructed by the physician if the client is diabetic. Be aware of the need for possible alteration in insulin requirements because of changes in food intake, weight, and activity.
■ Avoid consumption of large amounts of caffeinated products (coffee, tea, colas, chocolate), as they may enhance the CNS stimulant effect.
■ Notify physician if restlessness, insomnia, anorexia, or dry mouth becomes severe or if rapid, pounding heartbeat becomes evident.
■ Report any of the following side effects to the physician immediately: shortness of breath, chest pain, jaw/left arm pain, fainting, seizures, sudden vision changes, weakness on one side of the body, slurred speech, confusion, itching, dark urine, right-upper quadrant pain, yellow skin or eyes, sore throat, fever, malaise, increased hyperactivity, believing things that are not true, or hearing voices.

■ Be aware of possible risks of taking agents for ADHD during pregnancy. Safe use during pregnancy and lactation has not been established. Inform the physician immediately if pregnancy is suspected or planned.

■ Be aware of potential side effects of agents for ADHD. Refer to written materials furnished by health-care providers for safe self-administration.

■ Carry a card or other identification at all times describing medications being taken.

Outcome Criteria and Evaluation

The following criteria may be used for evaluating the effectiveness of therapy with agents for ADHD.

The client:

■ Does not exhibit excessive hyperactivity
■ Has not experienced injury
■ Is maintaining expected parameters of growth and development
■ Verbalizes understanding of safe self-administration and the importance of not withdrawing medication abruptly

Summary and Key Points

■ Psychotropic medications are intended to be used as adjunctive therapy to individual or group psychotherapy.

■ *Antianxiety agents* are used in the treatment of anxiety disorders and to alleviate acute anxiety symptoms. Benzodiazepines are the most commonly used group. They are CNS depressants and have a potential for physical and psychological dependence. They should not be discontinued abruptly following long-term use because they can produce a life-threatening withdrawal syndrome. The most common side effects are drowsiness, confusion, and lethargy.

■ *Antidepressants* elevate mood and alleviate other symptoms associated with moderate-to-severe depression. These drugs work to increase the concentration of norepinephrine and serotonin in the body.

■ The tricyclics and related drugs accomplish their effect by blocking the reuptake of norepinephrine by the neurons.

■ Another group of antidepressants inhibits MAO, an enzyme that is known to inactivate norepinephrine and serotonin. They are called MAOIs.

■ A third category of drugs blocks neuronal reuptake of serotonin and has minimal or no effect on reuptake of norepinephrine or dopamine. SSRIs.

■ Antidepressant medications may take up to 2 weeks before desired effects are noticed and may take up to 4 weeks to produce full therapeutic benefits.

The most common side effects are anticholinergic effects, sedation, and orthostatic hypotension. They can also reduce the seizure threshold. MAOIs can cause hypertensive crisis if products containing tyramine are consumed while taking these medications.

■ Lithium carbonate is widely used as a *mood-stabilizing agent.* Its mechanism of action is not fully understood, but it is thought to enhance the reuptake of norepinephrine and serotonin in the brain, thereby lowering the levels in the body, resulting in decreased hyperactivity. The most common side effects are dry mouth, gastrointestinal upset, polyuria, and weight gain.

■ There is a very narrow margin between the therapeutic and toxic levels of lithium. Serum levels must be drawn regularly to monitor for toxicity. Symptoms of lithium toxicity begin to appear at serum levels of approximately 1.5 mEq/L. If left untreated, lithium toxicity can be life threatening.

■ Several other medications are used as mood-stabilizing agents. Two groups, anticonvulsants (carbamazepine, clonazepam, valproic acid, lamotrigine, oxcarbazepine, and topiramate) and the calcium channel blocker verapamil, have been used with some effectiveness. Their action in the treatment of bipolar mania is not well understood.

■ Most recently, several atypical antipsychotic medications have been used with success in the treatment of bipolar mania. These include olanzapine, aripiprazole, quetiapine, risperidone, asenapine, and ziprasidone. The phenothiazine chlorpromazine has also been used effectively. The action of antipsychotics in the treatment of bipolar mania is not understood.

■ *Antipsychotic drugs* are used in the treatment of acute and chronic psychoses. The action of phenothiazines is caused by blocking postsynaptic dopamine receptors in the basal ganglia. Their most common side effects include anticholinergic effects, sedation, weight gain, reduction in seizure threshold, photosensitivity, and extrapyramidal symptoms. A newer generation of antipsychotic medications, which includes clozapine, risperidone, paliperidone, olanzapine, quetiapine, aripiprazole, asenapine, iloperidone, lurasidone, and ziprasidone, may have an effect on dopamine, serotonin, and other neurotransmitters. They show promise of greater efficacy with fewer side effects.

■ *Antiparkinsonian agents* are used to counteract the extrapyramidal symptoms associated with antipsychotic medications. Antiparkinsonian drugs work to restore the natural balance of acetylcholine and dopamine in the brain. The most common side effects of these drugs are the anticholinergic effects. They may also cause sedation and orthostatic hypotension.

■ *Sedative-hypnotics* are used in the management of anxiety states and to treat insomnia. These CNS depressants (except ramelteon) have the potential for physical and psychological dependence. They are indicated for short-term use only. Side effects and nursing implications are similar to those described for antianxiety medications.

■ Several medications have been designated as *agents for treatment of ADHD.* These include CNS stimulants, which have the potential for physical and psychological dependence. Tolerance develops quickly with CNS stimulants, and they should not be withdrawn abruptly because they can produce serious withdrawal symptoms. The most common side effects are restlessness, anorexia, and insomnia. Other medications that have shown to be effective with ADHD include atomoxetine, bupropion, and the α-adrenergic agonists clonidine and guanfacine. Their mechanism of action in the treatment of ADHD is not clear.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. How do antianxiety medications, such as benzodiazepines, produce a calming effect?
   a. Depressing the CNS
   b. Decreasing levels of norepinephrine and serotonin in the brain
   c. Decreasing levels of dopamine in the brain
   d. Inhibiting production of the enzyme MAO

2. Tam has a new diagnosis of panic disorder. Dr. S has written a prn order for alprazolam (Xanax) for when Tam is feeling anxious. She says to the nurse, "Dr. S prescribed buspirone for my friend's anxiety. Why did he order something different for me?" The nurse's answer is based on which of the following?
   a. Buspirone is not an antianxiety medication.
   b. Alprazolam and buspirone are essentially the same medication, so either one is appropriate.
   c. Buspirone has delayed onset of action and cannot be used on a prn basis.
   d. Alprazolam is the only medication that really works for panic disorder.

3. Education for the client who is taking MAOIs should include which of the following?
   a. Fluid and sodium replacement when appropriate, frequent drug blood levels, signs and symptoms of toxicity
   b. Lifetime of continuous use, possible tardive dyskinesia, advantages of an injection every 2 to 4 weeks
   c. Short-term use, possible tolerance to beneficial effects, careful tapering of the drug at end of treatment
   d. Tyramine-restricted diet, prohibitive concurrent use of over-the-counter medications without physician notification

4. There is a very narrow margin between the therapeutic and toxic levels of lithium carbonate. Symptoms of toxicity are most likely to appear if the serum levels exceed:
   a. 0.15 mEq/L
   b. 1.5 mEq/L
   c. 15.0 mEq/L
   d. 150 mEq/L

5. Initial symptoms of lithium toxicity include:
   a. Constipation, dry mouth
   b. Dizziness, thirst
   c. Vomiting, diarrhea
   d. Anuria, arrhythmias

Review Questions—cont'd
Self-Examination/Learning Exercise

6. Antipsychotic medications are thought to decrease psychotic symptoms by:
   a. Blocking reuptake of norepinephrine and serotonin
   b. Blocking the action of dopamine in the brain
   c. Inhibiting production of the enzyme MAO
   d. Depressing the CNS

7. Part of the nurse's continual assessment of the client taking antipsychotic medications is to observe for extrapyramidal symptoms. Which of the following are examples of extrapyramidal symptoms?
   a. Muscular weakness, rigidity, tremors, facial spasms
   b. Dry mouth, blurred vision, urinary retention, orthostatic hypotension
   c. Amenorrhea, gynecomastia, retrograde ejaculation
   d. Elevated blood pressure, severe occipital headache, stiff neck

8. If the foregoing extrapyramidal symptoms should occur, which of the following would be a priority nursing intervention?
   a. Notify the physician immediately.
   b. Administer prn trihexyphenidyl (Artane).
   c. Withhold the next dose of antipsychotic medication.
   d. Explain to the client that these symptoms are only temporary and will disappear shortly.

9. A concern with children on long-term therapy with CNS stimulants for ADHD is:
   a. Addiction
   b. Weight gain
   c. Substance abuse
   d. Growth suppression

10. Doses of bupropion should be administered at least 4 to 6 hours apart and never doubled when a dose is missed in order to prevent:
    a. Orthostatic hypotension
    b. Seizures
    c. Hypertensive crisis
    d. Extrapyramidal symptoms

OBJECTIVES
After reading this chapter, the student will be able to:

1. Differentiate among *ethics, morals, values,* and *rights*.
2. Discuss ethical theories, including *utilitarianism, Kantianism, Christian ethics, natural law theories,* and *ethical egoism.*
3. Define *ethical dilemma.*
4. Discuss the ethical principles of *autonomy, beneficence, nonmaleficence, justice,* and *veracity.*
5. Use an ethical decision-making model to make an ethical decision.
6. Describe ethical issues relevant to psychiatric-mental health nursing.
7. Define *statutory law* and *common law.*
8. Differentiate between *civil law* and *criminal law.*
9. Discuss legal issues relevant to psychiatric-mental health nursing.
10. Differentiate between *malpractice* and *negligence*.
11. Identify behaviors relevant to the psychiatric-mental health setting for which specific malpractice action could be taken.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Malpractice and negligence are examples of what kind of law?
2. What charges may be brought against a nurse for confining a client against his or her wishes (outside of an emergency situation)?
3. Which ethical theory espouses that what is right and good is what is best for the individual making the decision?
4. Name the three major elements of informed consent.

Nurses are constantly faced with the challenge of making difficult decisions regarding good and evil or life and death. Complex situations frequently arise in caring for individuals with mental illness, and nurses are held to the highest level of legal and ethical accountability in their professional practice. This chapter presents basic ethical and legal concepts and their relationship to psychiatric-mental health nursing. A discussion of ethical theory is presented as a foundation upon which ethical decisions may be made. The American Nurses Association (ANA) (2015) has established a code of ethics for nurses to use as a framework within which to make ethical choices and decisions (Box 5–1). These recently revised provisions and interpretive guidelines have been expanded to address some of the complexities of the current health-care environment and include ethical principles regarding the nurse's duty not only to the patient but also to himself or herself and all people with whom he or she interacts. All relationships should be conducted within a culture of respect and civility.

The ANA Code of Ethics interpretive guidelines include a discussion of the importance of teamwork and collaboration, which is consistent with one of the recommendations of the Institute of Medicine (IOM) (2003) for improving the future of health care and has become one of the Quality and Safety in Education for Nurses (QSEN) standards.

The ANA, in cooperation with the American Psychiatric Nurses Association and the International Society of Psychiatric-Mental Health Nurses (2014), has published a scope and standards of practice manual specifically for psychiatric-mental health nursing. It maintains consistency with the ANA code of ethics and applies those provisions to psychiatric-mental health nursing issues. Knowledge about the *Code of Ethics for Nurses* (ANA, 2015) and *Psychiatric-Mental Health Nursing: Scope and Standards of Practice* (ANA et al., 2014) are essential for guiding practice because they clarify the accepted expectations of the nurse in this field.

Because legislation determines what is *right* or *good* within a society, legal issues pertaining to psychiatric-mental health nursing are also discussed in this chapter. Definitions are presented along with rights of psychiatric clients of which nurses must be aware. Nursing competency and client care accountability are compromised when the nurse has inadequate knowledge about the laws that regulate the practice of nursing.

Knowledge of the legal and ethical concepts presented in this chapter will enhance the quality of care the nurse provides in his or her psychiatric-mental

BOX 5–1 American Nurses Association Code of Ethics for Nurses

1. The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.
2. The nurse's primary commitment is to the patient whether an individual, family, group, community, or population.
3. The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
4. The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.
5. The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.
6. The nurse, through individual and collective effort, establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.
7. The nurse, in all roles and settings, advances the profession through research and scholarly inquiry, professional standards development, and the generation of both nursing and health policy.
8. The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.
9. The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession and integrate principles of social justice into nursing and health policy.

health nursing practice and will also protect the nurse within the parameters of legal accountability. The right to practice nursing carries with it the responsibility to maintain a specific level of competency and to practice in accordance with certain ethical and legal standards of care.

CORE CONCEPTS

Ethics is a branch of philosophy that deals with systematic approaches to distinguishing right from wrong behavior (Butts & Rich, 2016). **Bioethics** is the term applied to these principles when they refer to concepts within the scope of medicine, nursing, and allied health.

Moral behavior is conduct that results from serious critical thinking about how individuals ought to treat others. Moral behavior reflects the way a person interprets basic respect for other persons, such as the respect for autonomy, freedom, justice, honesty, and confidentiality.

Values are personal beliefs about what is important and desirable (Butts & Rich, 2016). Values clarification is a process of self-exploration through which individuals identify and rank their own personal values. This process increases awareness about why individuals behave in certain ways. Values clarification is important in nursing to increase understanding about why certain choices and decisions are made over others and how values affect nursing outcomes.

A right is "a valid, legally recognized claim or entitlement, encompassing both freedom from government interference or discriminatory treatment and an entitlement to a benefit or service" (Levy & Rubenstein, 1996). A right is *absolute* when there is no restriction whatsoever on the individual's entitlement. A *legal right* is one on which the society has agreed and formalized into law. Both the National League for Nursing (NLN) and the American Hospital Association (AHA) have established guidelines of patients' rights. Although these are not considered legal documents, nurses and hospitals are responsible for upholding these patients' rights.

Ethical Considerations

Theoretical Perspectives

An *ethical theory* is a moral principle or a set of moral principles that can be used in assessing what is morally right or morally wrong (Ellis & Hartley, 2012). These principles provide frameworks for ethical decision-making.

Utilitarianism

The basis of **utilitarianism** is the "greatest-happiness principle." This principle holds that actions are right to the degree that they tend to promote happiness and are wrong as they tend to produce the reverse of happiness. Thus, the good is happiness and the right is that which promotes the good. Conversely, the wrongness of an action is determined by its tendency to bring about unhappiness. An ethical decision based on the utilitarian view looks at the end results of the decision. Action is taken on the basis of the end results that will produce the most good (happiness) for the most people.

Kantianism

Named for philosopher Immanuel Kant, **Kantianism** is directly opposed to utilitarianism. Kant argued that it is not the consequences or end results that make an action right or wrong; rather it is the principle or motivation on which the action is based that is the morally decisive factor. Kantianism suggests that our actions are bound by a sense of duty. This theory is often called *deontology* (from the Greek word *deon,* which means "that which is binding; duty"). Kantian-directed ethical decisions are made out of respect for moral law. For example, "I make this choice because it is morally right and my duty to do so" (not because of consideration for a possible outcome).

Christian Ethics

This approach to ethical decision-making is focused on the way of life and teachings of Jesus Christ. It advances the importance of virtues such as love, forgiveness, and honesty. One basic principle often associated with Christian ethics is known as the golden rule: "Do unto others as you would have them do unto you." The imperative demand of **Christian ethics** is that all decisions about right and wrong should be centered in love for God and in treating others with the same respect and dignity with which we would expect to be treated.

Natural Law Theory

Natural law theory is based on the writings of St. Thomas Aquinas. It advances the idea that decisions about right versus wrong are self-evident and determined by human nature. The theory espouses that, as rational human beings, we inherently know the difference between good and evil (believed to be knowledge that is given to man from God), and this knowledge directs our decision-making.

Ethical Egoism

Ethical egoism espouses that what is right and good is what is best for the individual making the decision. An individual's actions are determined by what is to his or her own advantage. The action may not be best for anyone else involved, but consideration is only for the individual making the decision.

Ethical Dilemmas

An **ethical dilemma** in nursing is a situation that requires the nurse to make a choice between two equally unfavorable alternatives (Catalano, 2015). Evidence exists to support both moral "rightness" and moral "wrongness" related to a certain action. The individual who must make the choice experiences conscious conflict regarding the decision.

Not all ethical issues are dilemmas. An ethical dilemma arises when there is no clear reason to choose one action over another. Ethical dilemmas generally create a great deal of emotion. Often, the reasons supporting each side of the argument for

action are logical and appropriate. The actions associated with both sides are desirable in some respects and undesirable in others. In most situations, taking no action is considered an action taken. For example, consider a patient who refuses to take a prescribed cardiac medication, claiming that he does not believe it is necessary. Although each patient has the right to refuse medication under ordinary circumstances, if the same patient is known to be depressed and suicidal, might he be intending self-harm by his refusal to take such a medication? And, if so, what is the best course of action? Many health-care settings have established guidelines for how to proceed should an ethical question or dilemma arise. Hospitals typically have a formal committee to explore and analyze ethical issues from several vantage points. Nurses can improve their critical-thinking and clinical judgment skills by identifying such issues and seeking clarification through collaborative exploration with others and through ethics committee involvement.

Ethical Principles

Ethical principles are fundamental guidelines that influence decision-making. The ethical principles of autonomy, beneficence, nonmaleficence, veracity, and justice are helpful and are used frequently by health-care workers to assist with ethical decision-making.

Autonomy

The principle of **autonomy** arises from the Kantian view of persons as autonomous moral agents whose right to determine their destinies should always be respected. This presumes that individuals are always capable of making their own independent choices. Health-care workers know this is not always the case. Children, comatose individuals, and people with serious mental illness are incapable of making informed choices. In these instances, a representative of the individual is usually asked to intervene and give consent. However, health-care workers must ensure that respect for an individual's autonomy is not disregarded in favor of what another person may view as best for the client.

Beneficence

Beneficence refers to one's duty to benefit or promote the good of others. Health-care workers who act in their clients' interests are beneficent, provided their actions really do serve the client's best interest. In fact, some duties do take preference over other duties. For example, the duty to respect the autonomy of an individual may be overridden when that individual has been deemed harmful to self or others. "Doing good" for the patient should not be confused with "doing whatever the patient wants" (What do I

do now?, 2013). Good care must include a holistic focus that considers the patient's beliefs, feelings, and wishes; the wishes of the family and significant others; and considerations about competent nursing care (Catalano, 2015). Despite the above-mentioned guidelines, it is not always clear which action *is* in the best interest of the client. When such dilemmas occur, nurses should reach out to available resources, such as an ethics committee or a supervisor, to build confidence that their decisions have explored the necessary vantage points.

Peplau (1991) recognized client **advocacy** as an essential role for the psychiatric nurse. The term *advocacy* means acting in another's behalf as a supporter or defender. Being a client advocate in psychiatric nursing means helping clients fulfill needs that, without assistance and because of their illness, may go unfulfilled. Individuals with mental illness are not always able to speak for themselves. Nurses serve in this manner to protect clients' rights and interests. Strategies include educating clients and their families about their legal rights, ensuring that clients have sufficient information to make informed decisions or to give informed consent, assisting clients to consider alternatives, and supporting them in the decisions they make. Additionally, nurses may act as advocates by speaking on behalf of individuals with mental illness to secure essential mental health services.

Nonmaleficence

Nonmaleficence is the requirement that health-care providers do no harm to their clients, either intentionally or unintentionally. Some philosophers suggest that this principle is more important than beneficence; that is, they support the notion that it is more important to avoid doing harm than it is to do good. In any event, ethical dilemmas arise when a conflict exists between an individual's rights and what is thought to best represent the welfare of the individual. An example of this conflict might occur when a psychiatric client refuses antipsychotic medication (consistent with his or her rights), and the nurse must then decide how to maintain client safety while psychotic symptoms continue.

Justice

The principle of **justice** has been referred to as the "justice as fairness" principle. It is sometimes called *distributive justice,* and its basic premise lies with the right of individuals to be treated equally and fairly regardless of race, gender, marital status, medical diagnosis, social standing, economic level, or religious belief (Catalano, 2015). When applied to health care, the principle of justice suggests that all resources (including health-care services) ought to

be distributed equally to all people. Thus, according to this principle, the vast disparity in the quality of care dispensed to the various socioeconomic classes within our society would be considered unjust. *Retribution* or *restorative justice* refers to the rules for responding when expectations for fairness are violated. *Social justice* can be summarized as the principle that rules for both distribution and rules for retribution should be fair and people should play by the rules (Maiese, 2013). It is important for nurses to recognize that in the latest revision of the *Code of Ethics for Nurses* (ANA, 2015), a new focus in one of the provisions states that nursing should integrate principles of social justice both in practice and in developing health policy.

Veracity

The principle of **veracity** refers to one's duty to always be truthful. Catalano (2015) states that veracity "requires the health-care provider to tell the truth and not intentionally deceive or mislead clients" (p. 126). There are times when limitations must be placed on this principle, such as when the truth would knowingly produce harm or interfere with the recovery process. Being honest is not always easy, but rarely is lying justified. Clients have the right to know about their diagnosis, treatment, and prognosis.

A Model for Making Ethical Decisions

The following steps may be used in making an ethical decision. These steps closely resemble the steps of the nursing process.

1. **Assessment:** Gather the subjective and objective data about a situation. Consider personal values as well as values of others involved in the ethical dilemma.
2. **Problem identification:** Identify the conflict between two or more alternative actions.
3. **Planning:**
   a. Explore the benefits and consequences of each alternative.
   b. Consider principles of ethical theories.
   c. Select an alternative.
4. **Implementation:** Act on the decision made, and communicate the decision to others.
5. **Evaluation:** Evaluate outcomes.

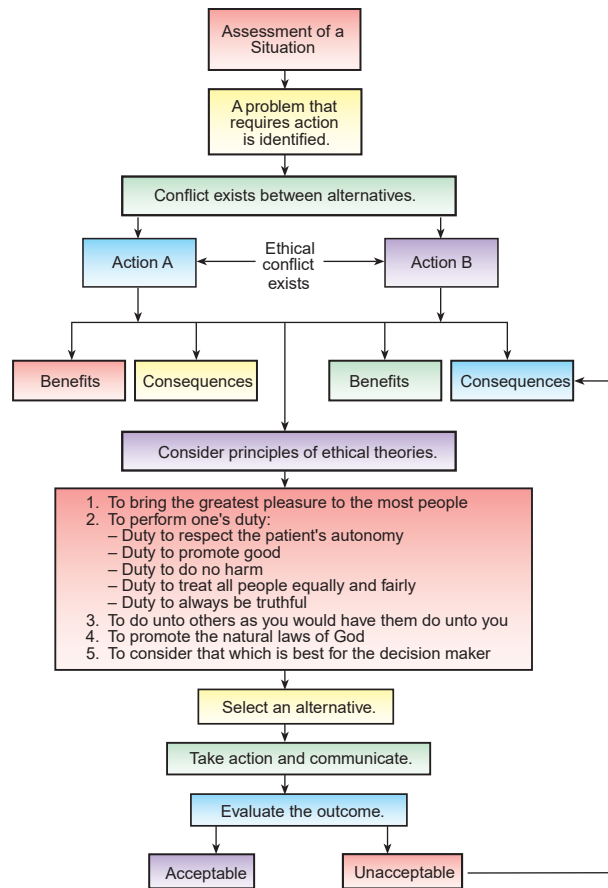
A schematic of this model is presented in Figure 5–1. A case study using this decision-making model is presented in Box 5–2. If the outcome is acceptable, action continues in the manner selected. If the outcome is unacceptable, benefits and consequences of the remaining alternatives are reexamined, and steps 3 through 7 in Box 5–2 are repeated.


FIGURE 5–1 Ethical decision-making model.

Ethical and Legal Issues in Psychiatric-Mental Health Nursing

The Right to Treatment

Anyone who is admitted to the hospital has the right to treatment. Consequently, a psychiatric patient cannot legally be hospitalized and then denied appropriate treatment. The American Hospital Association (AHA) has also identified the rights of hospitalized patients. The AHA patient bill of rights was originally written with an emphasis on protecting the patient from a breach of reasonable standards while hospitalized. These guidelines were revised in 2003 to create an emphasis on the importance of the collaborative relationship between the client and the hospital health-care team. Titled "The Patient Care Partnership," this document informs patients of their rights to high-quality care while hospitalized, to a clean and safe environment, to be involved in their own care, to have their privacy protected, to get help when leaving the hospital, and to get help with their billing claims (AHA, 2003). Nurses practicing in hospital settings need to be aware of and adhere to legal statutes,

BOX 5–2 Ethical Decision-Making–A Case Study

STEP 1. ASSESSMENT

Tonja is a 17-year-old girl who is currently on the psychiatric unit with a diagnosis of conduct disorder. Tonja reports that she has been sexually active since she was 14. She had an abortion when she was 15 and a second one just 6 weeks ago. She states that her mother told her she has "had her last abortion" and that she has to start taking birth control pills. She asks her nurse, Kimberly, to give her some information about the pills and to tell her how to go about getting some. Kimberly believes Tonja desperately needs information about birth control pills and other types of contraceptives, but the psychiatric unit is part of a Catholic hospital, and hospital policy prohibits distributing this type of information.

STEP 2. PROBLEM IDENTIFICATION

A conflict exists between the client's need for information, the nurse's desire to provide that information, and the institution's policy prohibiting the provision of that information.

STEP 3. ALTERNATIVES—BENEFITS AND CONSEQUENCES

Alternative 1: Give the client information and risk losing job.

Alternative 2: Do not give client information and compromise own values of holistic nursing.

Alternative 3: Refer client to another source outside the hospital and risk reprimand from supervisor.

STEP 4. CONSIDER PRINCIPLES OF ETHICAL THEORIES

Alternative 1: Giving the client information would certainly respect the client's autonomy and would benefit the client by decreasing her chances of becoming pregnant again. It would not be to the best advantage of Kimberly in that she would likely lose her job. According to the beliefs of the Catholic hospital, the natural laws of God would be violated.

Alternative 2: Withholding information restricts the client's autonomy. It has the potential for doing harm in that without the use of contraceptives, the client may become pregnant again (and she implies that this is not what she wants). Kimberly's Christian ethic is violated in that this action is not what she would want "done unto her."

Alternative 3: A referral would respect the client's autonomy, would promote good, would do no harm (except perhaps to Kimberly's ego from the possible reprimand), and would comply with Kimberly's Christian ethic.

STEP 5. SELECT AN ALTERNATIVE

Alternative 3 is selected on the basis of the ethical theories of utilitarianism (does the most good for the greatest number of people), Christian ethics (Kimberly's belief of "Do unto others as you would have others do unto you"), and Kantianism (to perform one's duty) and on the basis of the ethical principles of autonomy, beneficence, and non-maleficence. The success of this decision depends on the client's follow-through with the referral and compliance with use of the contraceptives.

STEP 6. TAKE ACTION AND COMMUNICATE

Taking action involves providing information in writing for Tonja or perhaps making a phone call to set up an appointment for her with Planned Parenthood. Communicating suggests sharing the information with Tonja's mother. The referral should be documented in the client's chart.

STEP 7. EVALUATE THE OUTCOME

An acceptable outcome might indicate that Tonja kept her appointment at Planned Parenthood and is complying with the prescribed contraceptive regimen. It might also include Kimberly's input into the change process in her institution to implement these types of referrals to other clients who request them.

An unacceptable outcome might be indicated by Tonja's lack of follow-through with the appointment at Planned Parenthood or lack of compliance in using the contraceptives, resulting in another pregnancy. Kimberly may also view a reprimand from her supervisor as an unacceptable outcome, particularly if she is told that she must select other alternatives should this situation arise in the future. Kimberly's disagreement with the institution's policy may motivate her to make another decision—that of seeking employment in an institution that supports a philosophy more consistent with her own.

---

accepted standards of practice, and organizational policies with regard to a client's rights during hospital treatment.

The Right to Refuse Treatment (Including Medication)

Legally, patients have the right to refuse treatment unless immediate intervention is required to prevent death or serious harm to the patient or another person (Sadock, Sadock, & Ruiz, 2015). The U.S. Constitution and several of its amendments affirm this right (e.g., the First Amendment, which addresses the rights of speech, thought, and expression; the Eighth Amendment, which grants the right to freedom from cruel and unusual punishment; and the Fifth and Fourteenth Amendments, which grant due process of law and equal protection for all). In psychiatry, however, both ethical and legal issues must be considered. Sometimes patients are involuntarily hospitalized because they are at risk of harm to themselves or others and do not recognize

the severity of their symptoms. In emergency cases, sedative medication may be administered without the patients' consent in order to protect them from harming themselves or others. Because laws vary from state to state, nurses must know the laws that pertain in their local jurisdictions. Organizational policies in the nurse's practice setting should also guide decision-making.

Although many courts support a client's right to refuse medications in the psychiatric area, exceptions do exist. Regarding decision-making about forced medication, Weiss-Kaffie and Purtell (2001) stated:

> The treatment team must determine that three criteria be met to force medication without client consent. The client must exhibit behavior that is dangerous to self or others; the medication ordered by the physician must have a reasonable chance of providing help to the client; and clients who refuse medication must be judged incompetent to evaluate the benefits of the treatment in question. (p. 361)

More recently, some states have adopted laws that allow a court to mandate outpatient treatment for people with mental illness who have a history of violent behavior. In New York City, this law, known as *Kendra's law,* also includes a provision for ordering an individual to take medication as part of the treatment plan.

The Right to the Least-Restrictive Treatment Alternative

The right to the least-restrictive treatment alternative means that clients who can be adequately treated in an outpatient setting should not be hospitalized, and if they are hospitalized, they should not be sedated, restrained, or secluded unless less restrictive measures were unsuccessful. In other words, the client has a right to whatever level of treatment is effective and least restricts his or her freedom. The restrictiveness of psychiatric therapy can be described in the context of a continuum based on severity of illness. Clients may be treated on an outpatient basis, in day hospitals, or through voluntary or involuntary hospitalization. Symptoms may be treated with verbal rehabilitative techniques and move successively to behavioral techniques, chemical interventions, mechanical restraints, or electroconvulsive therapy. However, ethical issues arise in selecting the least-restrictive means among involuntary chemical intervention, seclusion, and mechanical restraints. Sadock and associates (2015) state:

> Distinguishing among these interventions on the basis of restrictiveness proves to be a purely subjective exercise fraught with personal bias. Moreover, each of these three interventions is both more and less restrictive than each of the other two. Nevertheless, the effort should be made to think in terms of restrictiveness when deciding how to treat patients. (p. 1386)

While the right to the least restrictive treatment may seem reasonable and expected, it is important to recognize that clients with mental illness have historically been hospitalized against their will simply because they had a mental illness. In the case of *O'Connor v. Donaldson* (1976), the Supreme Court ruled that harmless mentally ill individuals cannot be confined against their will if they are able to remain safe outside of a hospital setting. They must be considered dangerous to themselves or others or be so unable to care for themselves that their safety and survival are at risk. In 1981, the case of *Roger v. Oken* culminated in the ruling that all patients, even those involuntarily hospitalized, are competent to refuse treatment, but a legal guardian may authorize treatment (Sadock et al., 2015). These laws and policies have better attempted to protect the rights of clients with mental illness while still recognizing that, at times, an individual with acute mental illness may be unable to make decisions in the interest of his or her safety and survival.

Ideally, a person recognizes his or her need for treatment and agrees voluntarily to be hospitalized if this measure is recommended by the health-care provider. The client who is voluntarily hospitalized typically signs a consent to treatment upon admission, but it remains the client's right as a voluntary patient to revoke that consent and to be discharged from the hospital if he or she so choose.

Legal Considerations

The Patient Self-Determination Act, as part of the Omnibus Budget Reconciliation Act of 1990, went into effect on December 1, 1991. Cady (2010) states:

> The Patient Self-determination Act requires health-care facilities to provide clear written information for every patient concerning his/her legal rights to make healthcare decisions, including the right to accept or refuse treatment. (p. 118)

Box 5–3 lists the rights of patients affirmed by this law.

Nurse Practice Acts

The legal parameters of professional and practical nursing are defined within each state by the state's nurse practice act. These documents are passed by the state legislature and in general are concerned with provisions such as

■ The definition of important terms, including nursing itself and the various types of nurses.

BOX 5–3 Patient Self-Determination Act–Patient Rights

1. The right to appropriate treatment and related services in a setting and under conditions that are the most supportive of such person's personal liability and that restrict such liberty only to the extent necessary consistent with such person's treatment needs, applicable requirements of law, and applicable judicial orders.
2. The right to an individualized, written treatment or service plan (such plan to be developed promptly after admission of such person), the right to treatment based on such plan, the right to periodic review and reassessment of treatment and related service needs, and the right to appropriate revision of such plan, including any revision necessary to provide a description of mental health services that may be needed after such person is discharged from such program or facility.
3. The right to ongoing participation, in a manner appropriate to a person's capabilities, in the planning of mental health services to be provided (including the right to participate in the development and periodic revision of the plan).
4. The right to be provided, in terms and language appropriate to a person's condition and ability to understand, a reasonable explanation of the person's general mental and physical (if appropriate) condition, the objectives of treatment, the nature and significant possible adverse effects of recommended treatment, the reasons a particular treatment is considered appropriate, the reasons access to certain visitors may not be appropriate, and any appropriate and available alternative treatments, services, and types of providers of mental health services.
5. The right not to receive a mode or course of treatment in the absence of informed, voluntary, written consent to treatment except during an emergency situation or as permitted by law when the person is being treated as a result of a court order.
6. The right not to participate in experimentation in the absence of informed, voluntary, written consent (includes human subject protection).
7. The right to freedom from restraint or seclusion, other than as a mode or course of treatment or restraint or seclusion during an emergency situation with a written order by a responsible mental health professional.
8. The right to a humane treatment environment that affords reasonable protection from harm and appropriate privacy with regard to personal needs.
9. The right to access, on request, to such person's mental health-care records.
10. The right, in the case of a person admitted on a residential or inpatient care basis, to converse with others privately, to have convenient and reasonable access to the telephone and mail, and to see visitors during regularly scheduled hours. (For treatment purposes, specific individuals may be excluded.)
11. The right to be informed promptly and in writing at the time of admission of these rights.
12. The right to assert grievances with respect to infringement of these rights.
13. The right to exercise these rights without reprisal.
14. The right of referral to other providers upon discharge.

Adapted from the U.S. Code, Title 42, Section 10841, The Public Health and Welfare, 1991.

■ A statement of the education and other training or requirements for licensure and reciprocity.
■ Broad statements that describe the scope of practice for various levels of nursing (APN, RN, LPN).
■ Conditions under which a nurse's license may be suspended or revoked and instructions for appeal.
■ The general authority and powers of the state board of nursing.

Most nurse practice acts are general in their terminology and do not provide specific guidelines for practice. Nurses must understand the scope of practice protected by their license and should seek assistance from legal counsel if they are unsure about the proper interpretation of a nurse practice act.

Types of Law

The two general categories of law that are of most concern to nurses are statutory law and common law. These laws are identified by their source or origin.

Statutory Law

A **statutory law** is a law that has been enacted by a legislative body, such as a county or city council, state legislature, or the U.S. Congress. An example of statutory law is the nurse practice acts.

Common Law

Common laws are derived from decisions made in previous cases. These laws apply to a body of principles that evolve from court decisions resolving various controversies. Because common law in the United States has been developed on a state basis, the law on specific subjects may differ from state to state. An example of a common law might be how different states deal with a nurse's refusal to provide care for a specific client.

Classifications Within Statutory and Common Law

Broadly speaking, there are two kinds of unlawful acts: civil and criminal. Both statutory law and common law have civil and criminal components.

Civil Law

Civil law protects the private and property rights of individuals and businesses. Private individuals or

groups may bring a legal action to court for breach of civil law. These legal actions are of two basic types: torts and contracts.

Torts

A **tort** is a violation of a civil law in which an individual has been wronged. In a tort action, one party asserts that wrongful conduct on the part of the other has caused harm and seeks compensation. A tort may be *intentional* or *unintentional*. Examples of unintentional torts are malpractice and negligence actions. An example of an intentional tort is the touching of another person without that person's consent. Intentional touching (e.g., a medical treatment) without the client's consent can result in a charge of battery, an intentional tort.

Contracts

In a contract action, one party asserts that the other party, in failing to fulfill an obligation, has breached the contract, and either compensation or performance of the obligation is sought as remedy. An example is an action by a mental health professional whose clinical privileges have been reduced or terminated in violation of an implied contract between the professional and a hospital.

Criminal Law

Criminal law provides protection from conduct deemed injurious to the public welfare. It provides for punishment of those found to have engaged in such conduct, which commonly includes imprisonment, parole conditions, a loss of privilege (such as a license), a fine, or any combination of these (Ellis & Hartley, 2012). An example of a violation of criminal law is the theft by a hospital employee of supplies or drugs.

Legal Issues in Psychiatric-Mental Health Nursing

Confidentiality and Right to Privacy

The Fourth, Fifth, and Fourteenth Amendments to the U.S. Constitution protect an individual's privacy. Most states have statutes protecting the confidentiality of client records and communications. Nurses must recognize that the only individuals who have a right to observe a client or have access to medical information are those involved in the client's medical care. The client must provide written consent for health-care information to be shared with anyone outside the current treatment team.

HIPAA

Until 1996, client confidentiality in medical records was not protected by federal law. In August 1996, President Clinton signed the Health Insurance Portability and Accountability Act (HIPAA) into law. This federal privacy rule pertains to data that is called *protected health information* (PHI) and applies to most individuals and institutions involved in health care. PHI is individually identifiable health information indicators that "relate to past, present, or future physical or mental health or condition of the individual, or the past, present, or future payment for the provision of health care to an individual; and (1) that identifies the individual; or (2) with respect to which there is a reasonable basis to believe the information can be used to identify the individual" (U.S. Department of Health and Human Services, 2003). These specific identifiers are listed in Box 5–4.

Under HIPAA, individuals have the rights to access their medical records, to have corrections made to their medical records, and to decide with whom their medical information may be shared. The actual document belongs to the facility or the therapist, but the information contained therein belongs to the client. The passage of HIPAA increased the level of control clients have over the information maintained in their

---

BOX 5–4 Protected Health Information (PHI): Individually Identifiable Indicators

1. Names
2. Postal address information (except state), including street address, city, county, precinct, and zip code
3. All elements of dates (except year) for dates directly related to an individual, including birth date, admission date, discharge date, date of death; and all ages over 89 and all elements of dates (including year) indicative of such age, except that such ages and elements may be aggregated into a single category of age 90 or older
4. Telephone numbers
5. Fax numbers
6. Electronic mail addresses
7. Social Security numbers
8. Medical record numbers
9. Health plan beneficiary numbers
10. Account numbers
11. Certificate/license numbers
12. Vehicle identifiers and serial numbers, including license plate numbers
13. Device identifiers and serial numbers
14. Web Universal Resource Locators (URLs)
15. Internet protocol (IP) address numbers
16. Biometric identifiers, including finger and voice prints
17. Full face photographic images and any comparable images
18. Any other unique identifying number, characteristic, or code

From U.S. Department of Health and Human Services (HHS). (2003). Standards for privacy of individually identifiable health information. Washington, DC: HHS.

medical records. Notice of privacy policies must be provided to clients upon entry into the health-care system.

In 2013, HIPAA privacy and security rules were again expanded to afford more rights to patients with regard to their medical information and to assure greater security of a person's health information. In some cases, such as when paying out of pocket for care, patients can tell a provider that they do not want treatment information shared with their health insurance plan (U.S. Department of Health &Human Services, 2013). Nurses in any practice setting need to be aware of these HIPAA laws and any new provisions in law that will impact the conduct of their practice.

Pertinent medical information may be released without consent in a life-threatening situation. If information is released in an emergency, the following information must be recorded in the client's record: date of disclosure, person to whom information was disclosed, reason for disclosure, reason written consent could not be obtained, and the specific information disclosed.

Most states have statutes that pertain to the doctrine of **privileged communication.** Although the codes differ markedly from state to state, most grant certain professionals privileges under which they may refuse to reveal information about and communications with clients. In most states, the doctrine of privileged communication applies to psychiatrists and attorneys; in some instances, psychologists, clergy, and nurses are also included.

In certain instances, nurses may be called on to testify in cases in which the medical record is used as evidence. In most states, the right to privacy of these records is exempted in civil or criminal proceedings. Therefore, it is important that nurses document with these possibilities in mind. Strict recordkeeping using objective and nonjudgmental statements, care plans that are specific in their prescriptive interventions, and documentation that describes those interventions and their subsequent evaluation, all serve the best interests of the client, the nurse, and the institution should questions regarding care arise. Documentation very often weighs heavily in malpractice case decisions.

The right to confidentiality is a basic one, especially in psychiatry. Although societal attitudes are improving, individuals have experienced discrimination in the past for no other reason than a history of mental illness. Nurses working in psychiatric-mental health nursing must guard the privacy of their clients with great diligence.

Exception: A Duty to Warn (Protection of a Third Party)

There are exceptions to the laws of privacy and confidentiality. One of these exceptions stems from the 1974 case of *Tarasoff v. Regents of the University of California.* The incident from which this case evolved came about in the late 1960s. A young man from Bengal, India (Mr. P.), who was a graduate student at the University of California (UC), Berkeley, fell in love with another university student (Ms. Tarasoff). Because she was not interested in an exclusive relationship with Mr. P., he became resentful and angry. He began to stalk her and record some of their conversations in an effort to determine why she did not love him. He soon became very depressed and neglected his health, appearance, and studies.

Ms. Tarasoff spent the summer of 1969 in South America. During this time, Mr. P. entered therapy with a psychologist at UC. He confided in the psychologist that he intended to kill his former girlfriend (identifying Ms. Tarasoff by name) when she returned from vacation. The psychologist recommended civil commitment for Mr. P., claiming he was suffering from acute and severe paranoid schizophrenia. Mr. P. was picked up by the campus police but released a short time later because he appeared rational and promised to stay away from Ms. Tarasoff. Neither Ms. Tarasoff nor her parents received any warning of Mr. P.'s stated intention to kill her.

When Ms. Tarasoff returned to campus in October 1969, Mr. P. resumed his stalking behavior and eventually stabbed her to death. Ms. Tarasoff's parents sued the psychologist, several psychiatrists, and the university for failure to warn the family of the danger. The case was referred to the California Supreme Court, which ruled that a mental health professional has a duty not only to a client but also to individuals who are being threatened by that client. The Court stated:

> Once a therapist does in fact determine, or under applicable professional standards should have determined, that a patient poses a serious danger of violence to others, he bears a duty to exercise reasonable care to protect the foreseeable victim of that danger. While the discharge of this duty of due care will necessarily vary with the facts of each case, in each instance the adequacy of the therapist's conduct must be measured against the traditional negligence standard of reasonable care under the circumstances. (*Tarasoff v. Regents of University of California,* 1974a)

The defendants argued that warning the woman or her family would have breached professional ethics and violated the client's right to privacy. But the court ruled that "the confidential character of patient-psychotherapist communications must yield to the extent that disclosure is essential to avert danger to others. The protective privilege ends where the public peril begins" (*Tarasoff v. Regents of University of California,* 1974b).

In 1976, the California Supreme Court expanded the original case ruling (now referred to as *Tarasoff I*). The second ruling (known as *Tarasoff II*) broadened the ruling of "duty to warn" to include "duty to protect." It stated that under certain circumstances, a therapist might be required to warn an individual, notify police, or take whatever steps are necessary to protect the intended victim from harm. This duty to protect can also occur in instances when patients must be protected by health-care providers because they are vulnerable due to their inability to identify harmful situations (Guido, 2014).

The *Tarasoff* rulings created a great deal of controversy in the psychiatric community regarding breach of confidentiality and the subsequent negative impact on the client-therapist relationship. However, most states now recognize that therapists have ethical and legal obligations to prevent their clients from harming themselves or others. Many states have passed their own variations on the original "protect and warn" legislation, but in most cases, courts have outlined the following guidelines for therapists to follow in determining their obligation to take protective measures:

1. Assessment of a threat of violence by a client toward another individual
2. Identification of the intended victim
3. Ability to intervene in a feasible, meaningful way to protect the intended victim

When these guidelines apply to a specific situation, it is reasonable for the therapist to notify the victim, law enforcement authorities, and/or relatives of the intended victim. They may also consider initiating voluntary or involuntary commitment of the client in an effort to prevent potential violence.

Implications for Nursing While the original decision in the *Tarasoff* ruling was directed toward psychotherapists, it has since been more broadly applied. Not all states identify registered nurses as having a duty to warn, but other statutes include a duty to warn for nurses at all levels, from licensed practical nurses to advanced practice nurses. As of 2015, three states (Maine, Nevada, and North Dakota) have not yet addressed the issue of duty to warn. One state (North Carolina) does not recognize the duty to warn (National Conference of State Legislatures, 2016). But even in states that do not recognize a duty to warn, practitioners still need to make a decision about warning a potential victim. Every nurse, not just those practicing in psychiatric nursing, should be informed about the laws in his or her state regarding duty to warn. As Henderson (2015) notes, emergency nurses are often the frontline health-care workers and thus are in a position to identify persons at risk for violence and to protect

the safety of the patient and others. In psychiatric-mental health nursing practice, if a client confides in the nurse about the potential for harm to an intended victim, it is the nurse's duty to report this information to the psychiatrist and to other team members. This is not a breach of confidentiality, and the nurse may be considered negligent for failure to report. All members of the treatment team must be made aware of the potential danger that the client poses to self or others. Detailed written documentation of the situation is also required.

Exception: Suspected Child or Elder Abuse

Every state requires that health-care professionals—and in many jurisdictions, every citizen—report suspicion of child abuse to legal authorities (Hartsell & Bernstein, 2013). Many jurisdictions also have statutes requiring that suspected elder abuse or neglect be reported. At times, health-care professionals may be reluctant to report, fearing that they may be liable for false allegations, but reporting statutes generally grant immunity to anyone making a good faith report about a reasonable suspicion. In addition, in some jurisdictions, it is a criminal act *not* to report, "so declining to report should not be considered an option" (Hartsell& Bernstein, 2013, p. 170).

Implications for Nursing There is often an element of clinical judgment about whether a patient's communication raises a reasonable suspicion of abuse. For example, when a person is experiencing hallucinations or delusions, his or her perception about events may be distorted. The nurse has a responsibility to explore all patient perceptions of abuse or mistreatment and discuss these with other health-care team members to identify the most appropriate decision with consideration of all legal, ethical, and clinical factors.

Informed Consent

According to law, all individuals have the right to decide whether to accept or reject medical treatment. A health-care provider can be charged with assault and battery for providing life-sustaining treatment to a client when the client has not agreed to the treatment. The rationale for the doctrine of **informed consent** is the preservation and protection of individual autonomy in determining what will and will not happen to a person's body (Guido, 2014).

Informed consent is permission granted by a client for a physician to perform a therapeutic procedure. Before the procedure, the client is presented written information about the treatment and given adequate time to consider the pros and cons. The client should receive information such as what treatment alternatives are available; why the physician believes this treatment is most appropriate; the possible outcomes, risks, and adverse effects; the possible outcome

should the client select another treatment alternative; and the possible outcome should the client choose to decline all treatment. An example of a psychiatric treatment that requires informed consent is electroconvulsive therapy.

Under some conditions, treatment may be performed without obtaining informed consent. A client's refusal to accept treatment may be challenged under the following circumstances (Guido, 2014; Levy & Rubenstein, 1996):

1. When a client is mentally incompetent to make a decision and treatment is necessary to preserve life or avoid serious harm
2. When refusing treatment endangers the life or health of another
3. During an emergency in which a client is in no condition to exercise judgment
4. When the client is a child (consent is obtained from parent or surrogate)
5. In the case of therapeutic privilege, information about a treatment may be withheld if the physician can show that full disclosure would
   a. hinder or complicate necessary treatment,
   b. cause severe psychological harm, or
   c. be so upsetting as to render a rational decision by the client impossible

Although most clients in psychiatric-mental health facilities are competent and capable of giving informed consent, those with severe psychiatric illness do not possess the cognitive ability to do so. If an individual has been legally determined mentally incompetent, consent is obtained from the legal guardian. Difficulty arises when no legal determination has been made, but the individual's current mental state prohibits informed decision-making (e.g., a person who is psychotic, unconscious, or inebriated). In these instances, informed consent is usually obtained from the individual's nearest relative, or if none exist and time permits, the physician may ask the court to appoint a conservator or guardian. When time does not permit court intervention, permission may be sought from the hospital administrator.

A client or guardian always has the right to withdraw consent after it has been given. When this occurs, the physician should inform (or reinform) the client about the consequences of refusing treatment. If treatment has already been initiated, the physician should terminate treatment in a way least likely to cause injury to the client and inform the client or guardian of the risks associated with interrupted treatment (Guido, 2014).

The nurse's role in obtaining informed consent is usually defined by agency policy. A nurse may sign the consent form as witness for the client's signature. However, legal liability for informed consent lies with the physician. The nurse acts as client advocate, ensuring that the following three major elements of informed consent have been addressed:

1. **Knowledge:** The client has received adequate information on which to base his or her decision.
2. **Competency:** The individual's cognition is not impaired to an extent that would interfere with decision-making, or he or she has a legal representative.
3. **Free will:** The individual has given consent voluntarily without pressure or coercion from others.

Restraints and Seclusion

An individual's privacy and personal security are protected by the Patient Self-Determination Act of 1991. This legislation includes a set of patient rights, including an individual's right to freedom from restraint or seclusion except in an emergency. The use of seclusion and restraint as a therapeutic intervention for psychiatric patients has long been controversial. Many efforts have been made through federal and state regulations and through standards set forth by accrediting bodies to minimize or eliminate the use of this type of intervention.

In addition, there is an element of moral decision-making when any kind of treatment is coerced, as is often the case with seclusion and restraint. Landeweer, Abma, and Widdershoven (2011) point out that although coercion may sometimes be necessary, it can be detrimental to the patient, as it may produce trauma and mistrust. One advantage of using a forum such as a hospital-based ethics committee to guide moral decision-making is that by exploring issues such as the use of seclusion and restraint with a diverse group of people who have different vantage points, alternative treatments can be identified and explored.

Because injuries and deaths have been associated with restraint and seclusion, this treatment requires careful attention whenever it is deemed necessary. Further, the laws, regulations, accreditation standards, and hospital policies are frequently revised, so anyone practicing in inpatient psychiatric settings must be well informed in each of these areas.

In psychiatry, the term *restraints* generally refers to a set of leather straps used to restrain the extremities of an individual whose behavior is out of control and who poses an immediate risk to the physical safety and psychological well-being of himself or herself and others. It is important to note that the currently accepted definition of restraint refers not only to leather restraints but also to any manual method or medication used to restrict a person's freedom of movement. Restraints are never to be used as punishment or for the convenience of staff. Other measures

to decrease agitation, such as "talking down" (verbal intervention) and chemical restraints (tranquilizing medication), are usually tried first. If these interventions are ineffective, mechanical restraints may be instituted (although some controversy exists as to whether chemical restraints are indeed less restrictive than mechanical restraints). *Seclusion* is another type of physical restraint in which the client is confined alone in a room from which he or she is unable to leave. The room is usually minimally furnished with items to promote the client's comfort and safety.

The Joint Commission, an association that accredits health-care organizations, has established standards regarding the use of seclusion and restraint. Some examples of current standards include the following (The Joint Commission, 2015):

1. Seclusion or restraint is discontinued as soon as possible regardless of when the order is scheduled to expire.
2. Unless state law is more restrictive, orders for restraint or seclusion must be renewed every 4 hours for adults ages 18 and older, every 2 hours for children and adolescents ages 9 to 17, and every hour for children younger than 9 years. Orders may be renewed according to these time limits for a maximum of 24 consecutive hours.
3. An in-person evaluation (by a physician, clinical psychologist, or other licensed independent practitioner responsible for the care of the patient) must be conducted within 1 hour of initiating restraint or seclusion. Appropriately trained registered nurses and physician assistants may also conduct this assessment, but they must consult with the physician.
4. Patients who are simultaneously restrained and secluded must be continuously monitored by trained staff, either in person or through audio or video equipment positioned near the patient.
5. Staff who are involved in restraining and secluding patients are trained to monitor the physical and psychological well-being of the patient including but not limited to respiratory and circulatory status, skin integrity, and vital signs.

The laws, regulations, accreditation standards, and hospital policies pertaining to restraint and seclusion share a common priority of maintaining patient safety for a procedure that has the potential to incur injury or death. The importance of close and careful monitoring cannot be overstated.

False imprisonment is the deliberate and unauthorized confinement of a person within fixed limits by the use of verbal or physical means (Ellis & Hartley, 2012). Health-care workers may be charged with false imprisonment for restraining or secluding—against the wishes of the client—anyone admitted to the hospital voluntarily. Should a voluntarily admitted client decompensate to a point that restraint or seclusion for protection of self or others is necessary, court intervention to determine competency and involuntary commitment is required to preserve the client's rights to privacy and freedom.

Hospitalization
Voluntary Admissions

Each year, more than 1 million people are admitted to health-care facilities for psychiatric treatment; of these admissions, approximately two-thirds are considered voluntary. To be admitted voluntarily, an individual makes direct application to the institution for services and may stay as long as treatment is deemed necessary. He or she may sign out of the hospital at any time unless the health-care professional determines that the client may be harmful to self or others following a mental status examination and recommends that admission status be changed from voluntary to involuntary. Even when an admission is considered voluntary, it is important to ensure that the individual comprehends the meaning of his or her actions, has not been coerced in any manner, and is willing to proceed with admission.

Involuntary Commitment

Although the term *involuntary hospitalization* is preferred by some over the term *involuntary commitment,* this process needs to be conducted with respect to state and federal law. Because involuntary hospitalization results in substantial restrictions of the rights of an individual, the admission process is subject to the guarantee of the Fourteenth Amendment to the U.S. Constitution that provides citizens protection against loss of liberty and ensures due process rights (Weiss-Kaffie & Purtell, 2001). Involuntary hospitalizations may be made for various reasons. Most states commonly cite the following criteria:

■ The person is imminently dangerous to himself or herself (i.e., suicidal intent).
■ The person is a danger to others (i.e., physically aggressive, violent, or homicidal).
■ The person is unable to take care of basic personal needs (the "gravely disabled").

Under the Fourth Amendment, individuals are protected from unlawful searches and seizures without probable cause. Therefore, the individual recommending involuntary hospitalization must show probable cause why the client should be hospitalized against his or her wishes; that is, the person must show that there is cause to believe that the client would be dangerous to self or others, is mentally ill and in need of treatment, or is gravely disabled.

Emergency Commitments

Emergency commitments are sought when an individual manifests behavior that is clearly and imminently dangerous to self or others. These admissions are usually instigated by relatives or friends of the individual or by police officers, the court, or health-care professionals. Emergency commitments are time-limited, and a court hearing for the individual is scheduled, usually within 72 hours. At that time, the court may decide that the client may be discharged or, if deemed necessary and voluntary admission is refused by the client, an additional period of involuntary hospitalization may be ordered. In most instances, another hearing is scheduled for a specified time (usually in 7 to 21 days).

The Mentally Ill Person in Need of Treatment

A second type of involuntary commitment is for the observation and treatment of mentally ill persons in need of treatment. These commitments typically last longer than emergency commitments. Most states have established definitions of what constitutes "mentally ill" for purposes of state involuntary admission statutes. Some examples include individuals who, because of severe mental illness, are

■ Unable to make informed decisions concerning treatment.
■ Likely to cause harm to self or others.
■ Unable to fulfill basic personal needs necessary for health and safety.

In determining whether commitment is required, the court looks for substantial evidence of abnormal conduct—evidence that cannot be explained by a physical cause. There must be "clear and convincing evidence" as well as probable cause to substantiate the need for involuntary hospitalization to ensure that an individual's constitutional rights are protected. As mentioned earlier, the U.S. Supreme Court, in *O'Connor v. Donaldson,* held that the existence of mental illness alone does not justify involuntary hospitalization. State standards require a specific impact or consequence caused by mental illness that involves danger or an inability to care for one's own needs. These clients are entitled to court hearings with representation, at which time determination of commitment and length of stay are considered. Legislative statutes governing involuntary commitments vary among states.

Involuntary Outpatient Commitment

Involuntary outpatient commitment (IOC) is a court-ordered mechanism used to compel a person with mental illness to submit to treatment on an outpatient basis. A number of eligibility criteria for commitment to outpatient treatment have been cited (Appelbaum, 2001; Csere, 2013; Maloy, 1996; Torrey & Zdanowicz, 2001). Some of these include

■ A history of repeated decompensation requiring involuntary hospitalization.
■ Likelihood that without treatment the individual will deteriorate to the point of requiring inpatient commitment.
■ Presence of severe and persistent mental illness (e.g., schizophrenia or bipolar disorder) and limited awareness of the illness or need for treatment.
■ The presence of severe and persistent mental illness contributing to a risk of becoming homeless, incarcerated, or violent, or of committing suicide.
■ The existence of an individualized treatment plan likely to be effective and a service provider who has agreed to provide the treatment.
■ A danger to self or others. Although this is also a criterion for inpatient commitment, the American Psychiatric Association recommends outpatient commitment as an option when there is an acceptable treatment plan and access to a community provider (Harvard Health, 2008).
■ The risk for relapse and hospitalization related to noncompliance with treatment.

Most states have already enacted IOC legislation or currently have agenda resolutions that speak to this topic. Most commonly, clients who are committed into the IOC programs are those with severe and persistent mental illness such as schizophrenia. The rationale behind the legislation is to improve preventive care and reduce the number of readmissions and lengths of hospital stays for these clients. The need for this kind of legislation arose after it was recognized that patients with schizophrenia who did not meet criteria for involuntary hospital treatment were in some cases ultimately dangerous to themselves or others. In New York, public attention to this need arose after a man with schizophrenia who had stopped taking his medication pushed a young woman into the path of a subway train. He would not have met criteria for involuntary hospitalization until he was deemed dangerous to others, but advocates for this legislation argued that there should be provisions to prevent violence rather than waiting until it happens. The subsequent law governing IOC in New York became known as Kendra's law in reference to the woman who was pushed to her death. Opponents of this legislation fear that it may violate the individual rights of psychiatric clients without significant improvement in outcomes.

Some research studies have attempted to evaluate whether IOC (sometimes abbreviated as OPC, which refers simply to outpatient commitment) improves care, reduces lengths of stay in the hospital, and/or reduces episodes of violence. Most studies have shown positive outcomes, including a decrease in hospital

readmissions, with IOC (Swartz & Swanson, 2008). Continuing research is required to determine whether IOC will ultimately improve treatment compliance and enhance quality of life in the community for individuals with severe and persistent mental illness.

The Gravely Disabled Client

A number of states have statutes that specifically define the "gravely disabled" client. For those that do not use this label, the description of the individual who is unable to take care of basic personal needs because of mental illness is very similar.

Gravely disabled is generally defined as a condition in which an individual, as a result of mental illness, is in danger of serious physical harm resulting from inability to provide for basic needs such as food, clothing, shelter, medical care, and personal safety. Inability to care for oneself cannot be established by showing that an individual lacks the resources to provide the necessities of life. Rather, it is the inability to make use of available resources.

Should it be determined that an individual is gravely disabled, a guardian, conservator, or committee will be appointed by the court to ensure the management of the person and his or her estate. To legally restore competency requires another court hearing to reverse the previous ruling. The individual whose competency is being determined has the right to be represented by an attorney.

Nursing Liability

Mental health practitioners—psychiatrists, psychologists, psychiatric nurses, and social workers—have a duty to provide appropriate care based on the standards of their professions and the standards set by law. The standards of care for psychiatric-mental health nursing are presented in Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing.

Malpractice and Negligence

The terms **malpractice** and **negligence** are often used interchangeably. Negligence has been defined as

> the failure to exercise the standard of care that a reasonably prudent person would have exercised in a similar situation; any conduct that falls below the legal standard established to protect others against unreasonable risk of harm, except for conduct that is intentionally, wantonly, or willfully disregardful of others' rights. (Garner, 2014)

Any person may be negligent. In contrast, malpractice is a specialized form of negligence caused only by professionals. *Black's Law Dictionary* defines malpractice as

> an instance of negligence or incompetence on the part of a professional. To succeed in a malpractice

claim, a plaintiff must also prove proximate cause and damages. (Garner, 2014)

In the absence of state statutes, common law is the basis of liability for injuries to clients caused by acts of malpractice and negligence by individual practitioners. In other words, most decisions of negligence in the professional setting are based on legal precedent (decisions that have been made previously about similar cases) rather than on any specific action taken by the legislature.

To summarize, when a breach of duty is characterized as malpractice, the action is weighed against the professional standard. When it is brought forth as negligence, the action is contrasted with what a reasonably prudent professional would have done in the same or similar circumstances.

Austin (2011) cites the following basic elements of a nursing malpractice lawsuit:

1. A duty to the patient existed, based on the recognized standard of care.
2. A breach of duty occurred, meaning that the care rendered was not consistent with the recognized standard of care.
3. The client was injured.
4. The injury was directly caused by the breach of a standard of care.

For the client to prevail in a malpractice claim, each of these elements must be proven. Jury decisions are generally based on the testimony of expert witnesses because members of the jury are laypeople who cannot be expected to know what nursing interventions should have taken place. Without the testimony of expert witnesses, a favorable verdict usually goes to the defendant nurse.

Types of Lawsuits That Occur in Psychiatric Nursing

Most malpractice suits against nurses are civil actions, which means they are considered breach of conduct actions on the part of the professional for which compensation is sought. The nurse in a psychiatric setting should be aware of the types of behavior that may result in malpractice charges.

The hospitalized psychiatric client has a basic right to confidentiality and privacy. A nurse may be charged with *breach of confidentiality* for revealing aspects about a client's case or even for revealing that an individual has been hospitalized if the client can show that making this information known resulted in harm.

When shared information is detrimental to the client's reputation, the person sharing the information may be liable for **defamation of character.** When the information is in writing, the action is called **libel.** Oral defamation is called **slander.** Defamation of character involves communication that is malicious and false (Ellis & Hartley, 2012). Occasionally, libel

arises out of critical, judgmental statements written in the client's medical record. Nurses need to be very objective in their charting, backing up all statements with factual evidence.

Invasion of privacy is a charge that may result when a client is searched without probable cause. Many institutions conduct body searches on clients with mental illness as a routine intervention. In these cases, there should be a physician's order and written rationale showing probable cause for the intervention. Many institutions are reexamining their policies regarding this procedure.

Assault is an act that results in a person's genuine fear and apprehension that he or she will be touched without consent. **Battery** is the unconsented touching of another person. These charges can result when a treatment is administered to a client against his or her wishes and outside of an emergency situation. Harm or injury need not have occurred for these charges to be legitimate.

For confining a client against his or her wishes outside of an emergency situation, the nurse may be charged with false imprisonment. Examples of actions that may invoke these charges include locking an individual in a room, taking a client's clothes for purposes of detainment against his or her will, and restraining a competent voluntary client who demands to be released.

Avoiding Liability

Catalano (2015) suggests the following proactive nursing actions in an effort to avoid nursing malpractice and the risk of lawsuits:

1. *Effective communication* with patients and other caregivers. The SBAR model of reporting information, which stands for situation, background, assessment, and recommendations, has been identified as a useful tool for effective communication with caregivers. Establishing rapport with clients encourages open and honest communication.
2. *Accurate and complete documentation in the medical record.*

   The electronic health record (EHR) has been identified as the best way to document and share this information. The use of best informatics sources is identified as an essential nursing competency (Institute of Medicine, 2003) and an important standard for quality and safety in nursing education (QSEN Institute, 2013).
3. *Complying with standards of care,* including those established within the profession (such as ANA standards) and those identified by specific hospital policies.
4. *Knowing the client,* which includes helping the client become involved in his or her care as well as understanding and responding to aspects of care in which the client is dissatisfied.
5. *Practicing within the nurse's level of competence and scope of practice,* which includes not only adhering to professional standards (those of the ANA and state boards of nursing) but also keeping knowledge and nursing skills current through evidence-based literature, in-services, and continuing education.

Some clients appear to be more "suit prone" than others. Suit-prone clients are often very critical, complaining, uncooperative, and even hostile. A natural staff response to these clients is to become defensive or withdrawn. Either of these behaviors increases the likelihood of a lawsuit should an unfavorable event occur (Ellis & Hartley, 2012). No matter how high the nurse's technical competence and skill, his or her insensitivity to a client's complaints and failure to meet the client's emotional needs often influence whether or not a lawsuit is generated. A great deal depends on the psychosocial skills of the health-care professional.

CLINICAL PEARLS
- Always put the client's rights and welfare first.
- Develop and maintain a good interpersonal relationship with each client and his or her family.

Summary and Key Points

- *Ethics* is a branch of philosophy that addresses methods for determining the rightness or wrongness of one's actions.
- *Bioethics* is the term applied to these principles when they refer to concepts within the scopes of medicine, nursing, and allied health.
- *Moral behavior* is conduct that results from serious critical thinking about how individuals ought to treat others.
- *Values* are personal beliefs about what is important or desirable
- A *right* is "a valid, legally recognized claim or entitlement, encompassing both freedom from government interference or discriminatory treatment and an entitlement to a benefit or service" (Levy & Rubenstein, 1996).
- The ethical theory of utilitarianism is based on the premise that what is right and good is that which produces the most happiness for the most people.
- The ethical theory of Kantianism suggests that actions are bound by a sense of duty and that ethical decisions are made out of respect for moral law.
- The code of Christian ethics is that all decisions about right and wrong should be centered in love for God and in treating others with the same respect and dignity with which we would expect to be treated.

■ The moral precept of the natural law theory is "do good and avoid evil." Good is viewed as that which is inscribed by God into the nature of things. Evil acts are never condoned, even if they are intended to advance the noblest of ends.

■ Ethical egoism espouses that what is right and good is what is best for the individual making the decision.

■ Ethical principles include autonomy, beneficence, nonmaleficence, veracity, and justice.

■ An ethical dilemma is a situation that requires an individual to make a choice between two equally unfavorable alternatives.

■ Ethical issues may arise in psychiatric-mental health nursing around the client's right to refuse medication and right to the least-restrictive treatment alternative.

■ Statutory laws are those that have been enacted by legislative bodies, and common laws are derived from decisions made in previous cases. Both types of laws have civil and criminal components.

■ Civil law protects the private and property rights of individuals and businesses, and criminal law provides protection from conduct deemed injurious to the public welfare.

■ Legal issues in psychiatric-mental health nursing center around confidentiality and the right to privacy, informed consent, restraints and seclusion, and commitment issues.

■ Nurses are accountable for their own actions in relation to legal issues, and violation can result in malpractice lawsuits against the physician, the hospital, and the nurse.

■ Developing and maintaining a good interpersonal relationship with the client and his or her family appears to be a positive factor when the question of malpractice is being considered.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. The nurse decides to go against family wishes and tell the client of his terminal status because that is what she would want if she were the client. Which of the following ethical theories is considered in this decision?
   a. Kantianism
   b. Christian ethics
   c. Natural law theories
   d. Ethical egoism

2. The nurse decides to respect family wishes and not tell the client of his terminal status because that would bring the most happiness to the most people. Which of the following ethical theories is considered in this decision?
   a. Utilitarianism
   b. Kantianism
   c. Christian ethics
   d. Ethical egoism

3. The nurse decides to tell the client of his terminal status because she believes it is her duty to do so. Which of the following ethical theories is considered in this decision?
   a. Natural law theories
   b. Ethical egoism
   c. Kantianism
   d. Utilitarianism

4. The nurse assists the physician with electroconvulsive therapy on a client who has refused to give consent. With which of the following legal actions might the nurse be charged because of this nursing action?
   a. Assault
   b. Battery
   c. False imprisonment
   d. Breach of confidentiality

Review Questions—cont'd
Self-Examination/Learning Exercise

5. A competent, voluntary client has stated he wants to leave the hospital. The nurse hides his clothes in an effort to keep him from leaving. With which of the following legal actions might the nurse be charged because of this nursing action?
   a. Assault
   b. Battery
   c. False imprisonment
   d. Breach of confidentiality

6. Joe is very restless and is pacing the room. The nurse says to Joe, "If you don't sit down in the chair and be still, I'm going to put you in restraints!" With which of the following legal actions might the nurse be charged because of this nursing action?
   a. Defamation of character
   b. Battery
   c. Breach of confidentiality
   d. Assault

7. An individual may be considered *gravely disabled* for which of the following reasons? (Select all that apply.)
   a. A person, because of mental illness, cannot fulfill basic needs.
   b. A mentally ill person is in danger of physical harm based on inability to care for himself or herself.
   c. A mentally ill person lacks the resources to provide the necessities of life.
   d. A mentally ill person is unable to make use of available resources to meet daily living requirements.

8. Which of the following statements is correct regarding the use of restraints? (Select all that apply.)
   a. Restraints may never be initiated without a physician's order.
   b. Orders for restraints must be reissued by a physician every 2 hours for children and adolescents.
   c. Clients in restraints must be observed and assessed every hour for issues regarding circulation, nutrition, respiration, hydration, and elimination.
   d. An in-person evaluation must be conducted within 1 hour of initiating restraints.

9. Guidelines relating to "duty to warn" state that a therapist should consider taking action to warn a third party when his or her client does which of the following? (Select all that apply.)
   a. Threatens violence toward another individual
   b. Identifies a specific intended victim
   c. Is having command hallucinations
   d. Reveals paranoid delusions about another individual

10. Attempting to calm an angry client by using "talk therapy" is an example of which of the following clients' rights?
    a. The right to privacy
    b. The right to refuse medication
    c. The right to the least-restrictive treatment alternative
    d. The right to confidentiality

11. The Quality and Safety Education for Nurses guidelines identify that student nurses need to be well schooled on informatics. This most directly refers to which of the following?
    a. Learning how to effectively communicate information using electronic health records
    b. Learning the SBAR method of reporting information
    c. Learning guidelines for preventing lawsuits
    d. Learning information about new treatments to keep nursing skills current

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define and differentiate between *culture, race,* and *ethnicity.*
2. Identify cultural differences based on six characteristic phenomena.
3. Describe cultural variances, based on the six phenomena, for the following:
   a. Northern European Americans
   b. African Americans
   c. American Indian and Alaska Natives
   d. Asian and Pacific Islander Americans
   e. Latino Americans

   f. Western European Americans
   g. Arab Americans
   h. Jewish Americans
4. Apply the nursing process in the care of individuals from various cultural groups.
5. Define and differentiate between *spirituality* and *religion.*
6. Identify clients' spiritual and religious needs.
7. Apply the six steps of the nursing process to individuals with spiritual and religious needs.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions.

1. Which cultural group may use a medicine man (or woman) called a *shaman*?
2. Restoring a balance between opposite forces is a fundamental concept of Asian health practices. What is this called?
3. Name five types of human spiritual needs.
4. What is the largest ethnic minority group in the United States?
5. What is the perception of mental illness in the Arab culture?

Cultural Concepts

What is culture? What is race? How does it differ from ethnicity? Why are these questions important? The answers lie in the changing face of America. Immigration is not new in the United States. Most U.S. citizens are either immigrants or descendants of immigrants, and the number of foreign-born residents in this country continues to grow each year. This pattern persists because of the many individuals who want to take advantage of the technological growth and upward mobility that exists in this country.

> ## CORE CONCEPTS
>
> **Culture** describes a particular society's entire way of living, encompassing shared patterns of belief, feeling, and knowledge that guide people's conduct and are passed down from generation to generation. **Ethnicity** relates to groups of people who identify with each other because of a shared social and cultural heritage passed on to each successive generation (Giger, 2017). **Race** may be understood as a more biological term, describing a group of people who share similar inherited characteristics such as skin color, facial features, and blood groups.

Knowledge related to culture and ethnicity is important because these influences affect human behavior, its interpretation, and the response to it. Therefore, it is essential for nurses to understand the effects of cultural influences if they are to work effectively with the diverse population. Generalizations about a cultural group in this context can be beneficial. As Sue and Sue (2016) state, "Generalizations are necessary for us; without them we would become inefficient creatures. However, they are guidelines for our behaviors, to be tentatively applied in new situations, and they should be open to change and challenge" (p. 245). Caution must be taken, however, not to assume that all individuals who share a culture or ethnic group are identical or exhibit behaviors perceived as characteristic of the group. Such assumptions constitute **stereotyping** and must be avoided.

Many variations and subcultures occur within a culture. These differences may be related to status, ethnic background, residence, religion, education, or other factors. People of many different cultures reside in the United States. Some maintain traditional cultural practices, whereas others **acculturate** to dominant cultural practices (give up cultural practices or values as a result of contact with another group) and **assimilate** by incorporating practices and values of the dominant culture. Every individual must be appreciated for his or her uniqueness and assessed carefully to identify his

or her preferences with regard to cultural and spiritual practices.

Race is a controversial term because of its association with racism or prejudicial views about a group of people based on their appearance. Some scientists argue that no group of individuals is genetically pure enough to define race as a set of biological distinctions. Other scientists argue the benefit of understanding racial differences in determining response to treatments such as medications (see Chapter 4, Psychopharmacology, for a discussion of this topic). The U.S. Census Bureau collects data on racial demographics, and they clarify that the data is based on self-reported, self-identified affiliations (U.S. Census Bureau, 2013). In 2000, the Census Bureau also began including a category that allows for individuals to identify with two or more races. A breakdown of these demographics is presented in Figure 6–1.

This chapter explores the ways in which various cultures differ. The nursing process is applied to the delivery of psychiatric-mental health nursing care for individuals from the following cultural groups: Northern European Americans, African Americans, American Indian and Alaska Natives, Asian and Pacific Islander Americans, Latino Americans, Arab Americans, and Jewish Americans.

How Do Cultures Differ?

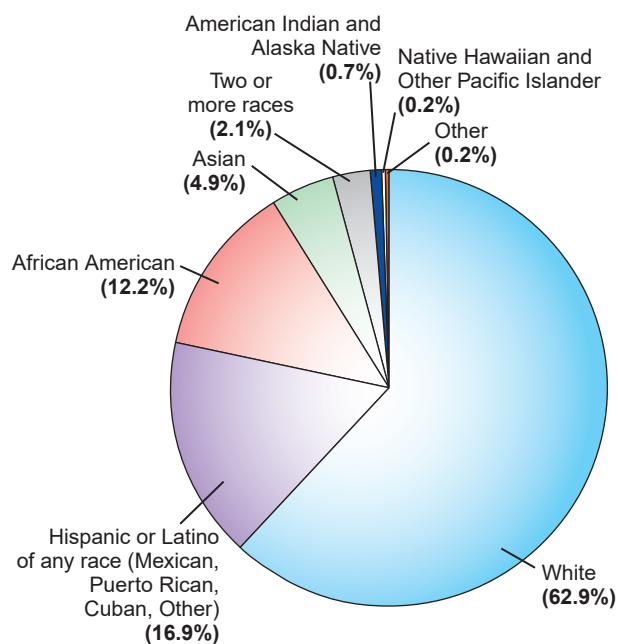
It is difficult to generalize about any specific group in a country that is known for its heterogeneity. Within


FIGURE 6–1 U.S. Census Bureau report on racial demographics. (From U.S. Census Bureau, 2010–2014 American Community Survey 5-Year estimates [2016].)

our American "melting pot," any or all characteristics could apply to individuals within any or all of the cultural groups represented. As these differences continue to be integrated, one American culture will eventually emerge. This integration is already evident in some regions of the country today, particularly in the urban coastal areas. However, some differences still exist, and it is important for nurses to be aware of cultural influences that may affect individuals' behaviors and beliefs, particularly as they apply to health care.

Giger (2017) describes six cultural phenomena that vary with application and use yet are evidenced among all cultural groups: (1) communication, (2) space, (3) social organization, (4) time, (5) environmental control, and (6) biological variations.

Communication

All verbal and nonverbal behavior in connection with another individual is communication. Therapeutic communication has always been considered an essential part of the nursing process and represents a critical element in most nursing school curricula. Communication has its roots in culture. Cultural mores, norms, ideas, and customs provide the basis for our way of thinking. Cultural values are learned and differ from society to society. Communication is expressed through language (the spoken and written word), paralanguage (the voice quality, intonation, rhythm, and speed of the spoken word), and gestures (touch, facial expression, eye movements, body posture, and physical appearance). The nurse who is planning care must have an understanding of the client's needs and expectations as they are being communicated. As a third party, an interpreter often complicates matters but may be necessary when the client does not speak the same language as the nurse. Interpreting is a very complex process, however, that requires a keen sensitivity to cultural nuances and not just translating words into another language. Technology has facilitated access to interpreters through such devices as telephone services, video remote interpretation, and Internet document translation, but these technologies do not negate the importance of culturally sensitive, respectful nursing care. Tips for facilitating the communication process when using an interpreter are presented in Box 6–1.

Space

Spatial determinants relate to the place where the communication occurs and encompass the concepts of *territoriality, density,* and *distance.* **Territoriality** is the innate tendency to own space. The need for territoriality is met only if the individual has control of a

---

BOX 6–1 Using an Interpreter

When using an interpreter, keep the following points in mind:

- Whenever possible, use a certified interpreter with a background in health care. Avoid using relatives or children as interpreters because they may not be objective or may have difficulty relaying information about sensitive topics.
- Address the client directly and maintain eye contact with the client (rather than the interpreter) to engage the client in interaction with the health-care provider.
- Do not interrupt or rush the client and the interpreter. Allow time for interpretation and response before asking another question.
- Ask the interpreter to give you verbatim translations so that you can assess and document exactly what the client has stated in response to questions.
- Avoid using medical jargon or colloquialisms that the interpreter or client may not understand.
- Avoid talking separately with the interpreter at length; the client may feel left out and distrustful.
- Always ask permission to discuss emotional or sensitive topics first, and prepare the interpreter for the content of the interview.
- When possible, allow the client and the interpreter to meet each other before the interview, and if possible, try to use the same interpreter for all subsequent interviews with the client.
- If possible, request an interpreter of the same gender as the client and of similar age or older.
- Discuss the interview questions with the interpreter ahead of time to facilitate flow of the interview.

---

space, can establish rules for that space, and is able to defend the space against invasion or misuse by others. **Density,** which refers to the number of people within a given environmental space, can influence interpersonal interaction. **Distance** is the means by which various cultures use space to communicate. Hall (1966) identified three primary dimensions of space in interpersonal interactions in the Western culture: the intimate zone (0 to 18 inches), the personal zone (18 inches to 3 feet), and the social zone (3 to 6 feet).

Social Organization

Cultural behavior is socially acquired through a process called **enculturation,** also called *socialization,* which involves acquiring knowledge and internalizing values of the group (Giger, 2017). Children are enculturated by observing adults within their social organizations. Social organizations include, among others, families, religious groups, and ethnic groups.

Time

An awareness of the concept of time is a gradual learning process. Some cultures place great importance on values measured by clock time. Punctuality and efficiency are highly valued in the United States, whereas some cultures are actually scornful of clock time. For example, some rural people in Algeria label the clock as the "devil's mill" and therefore have no notion of scheduled appointment times or meal times (Giger, 2017). They are indifferent to the passage of clock time and despise haste in all human endeavors. Other cultural implications regarding time have to do with perception of time orientation. Whether individuals are present oriented or future oriented in their perception of time influences many aspects of their lives.

Environmental Control

The variable of environmental control has to do with the degree to which individuals perceive that they have control over their environments. Cultural beliefs and practices influence how an individual responds to his or her environment during periods of wellness and illness. To provide culturally appropriate care, the nurse should not only respect the individual's unique beliefs, but also have an understanding of how these beliefs can be used to promote optimal health in the client's environment.

Biological Variations

Biological differences exist among people in various racial groups. These differences include body structure (both size and shape), skin color, physiological responses to medication, electrocardiographic patterns, susceptibility to disease, and nutritional preferences and deficiencies. Giger (2017) suggests that nurses who provide care for diverse cultural groups need to be aware of basic biological differences to give nonharmful, competent, and culturally appropriate care.

Application of the Nursing Process

Background Assessment Data

A cultural assessment tool for gathering information related to culture and ethnicity that is important in the planning of client care is provided in Box 6–2.

Northern European Americans

Northern European Americans include people who originate from England, Ireland, Iceland, Wales, Finland, Sweden, Norway, Denmark, and the Baltic states of Estonia, Latvia, and Lithuania. English is the primary language for those living in the United States. Their language may also include words and phrases that reflect the influence of the languages spoken in the countries of their heritages. The descendants of these immigrants comprise the dominant cultural

BOX 6–2 Cultural Assessment Tool

Client's name _____   Ethnic origin _____
Address _____   Birthdate _____
Name of significant other _____   Relationship _____
Primary language spoken _____   Second language spoken _____
How does client usually communicate with people who speak a different language? _____
Is an interpreter required? _____   Available? _____
Highest level of education achieved: _____   Occupation: _____
Presenting problem: _____
Has this problem ever occurred before? _____
If so, in what manner was it handled previously? _____
What is the client's usual manner of coping with stress? _____
Who is (are) the client's main support system(s)? _____
Describe the family living arrangements: _____
Who is the major decision maker in the family? _____
Describe client's/family members' roles within the family. _____
_____
Describe religious beliefs and practices: _____
    Are there any religious requirements or restrictions that place limitations on the client's care? _____
    If so, describe: _____
Who in the family takes responsibility for health concerns? _____
Describe any special health beliefs and practices: _____
_____
From whom does family usually seek help in addressing health care concerns when needed? _____

BOX 6–2 Cultural Assessment Tool–cont'd

Describe client's usual emotional/behavioral response to:
  Anxiety: _____
  Anger: _____
  Loss/change/failure: _____
  Pain: _____
  Fear: _____
Describe any topics that are particularly sensitive or that the client is unwilling to discuss (because of cultural taboos):
_____
Describe any activities in which the client is unwilling to participate (because of cultural customs or taboos):
_____
What are the client's personal feelings regarding touch? _____
What are the client's personal feelings regarding eye contact? _____
What is the client's personal orientation to time? (past, present, future) _____
What are the client's practices regarding punctuality and scheduled appointment times? _____
_____
Describe any particular illnesses to which the client may be biologically susceptible (e.g., hypertension and sickle cell anemia in African Americans):
_____
Describe any nutritional deficiencies to which the client may be biologically susceptible (e.g., lactose intolerance in Native and Asian Americans) _____
Describe client's favorite foods: _____
Are there any foods the client requests or refuses because of cultural beliefs related to this illness (e.g., "hot" and "cold" foods for Latino Americans and Asian Americans)? If so, please describe: _____
_____
What does the client typically do to balance his or her diet? _____
Describe client's perception of the problem and expectations of health care: _____
_____
_____

group in the United States today. Specific dialects and rate of speech are common to various regions of the country. All cultures can be described on a continuum from individualistic to collectivistic, which describes, in part, the degree of focus on self versus group. **Individualistic cultures** stress independence, self-reliance, and freedom, and traditional European American culture in the United States is a highly individualistic culture (Purnell, 2013). Northern European Americans value territory. Personal space preference is about 18 inches to 3 feet.

Data collected on the U.S. population can be revealing about cultural values and trends, which influence perceptions about American culture both within and outside the country. Data on marriage and divorce in the United States show that about half of first marriages end in divorce (Centers for Disease Control and Prevention [CDC], 2015a). The CDC also identifies that the marriage rate has steadily declined over the past 14 years, from 8.2 per 1000 population in 2000 to 6.9 per 1000 in 2014.

The value that was once placed on religion and the organized church also seems to be diminishing in the American culture. According to Gallup polls, over the last four decades there has been a steady decline in Americans' confidence in religion. The organized church reached an all-time low confidence rating of 42 percent in 2015 (Gallup, 2015). A 2012 Pew Research poll noted that church attendance has also shown a similar decline but that some individuals still report a religious affiliation even though they do not attend church. Among the variables cited for lack of church attendance were disagreements with the church and being too busy (Lipka, 2013). Although the majority of Americans still identify as affiliated with some branch of Christianity, the percentage declined from 78.4 percent in 2014 to 70.6 percent in 2014. The number of Americans identifying as agnostic, atheist, or "nothing in particular" increased from 16.1 percent to 22.8 percent over the same time period (Pew Research Center, 2015). These findings suggest that while a majority of Americans may still value faith and worship, their mechanisms for expressing those values are undergoing cultural change.

Northern European Americans, particularly those who achieve middle-class socioeconomic status, value preventive medicine and primary health care. This value follows with the socioeconomic group's

educational level, successful achievement, and financial capability to maintain a healthy lifestyle. Most recognize the importance of regular physical exercise. Punctuality and efficiency are valued aspects of mainstream American work ethic, and in general, individual needs are considered subservient to the needs of the organization (Purnell, 2013). However, as Purnell points out, in the current postmodern movement with its lack of adherence to truths as "absolute" and an emphasis on worldviews based on perception and social context, the face of mainstream American culture is changing.

A typical diet for many Northern European Americans is high in fats and cholesterol and low in fiber. Americans, in general, are learning about the health benefits of reducing fats and increasing nutrients in their diet. However, they still enjoy fast food, which conforms to their fast-paced lifestyles.

Changing Trends in Dominant American Culture and Nurse Self-Awareness

Nurses who identify with the dominant culture will benefit from reflecting on the values and practices considered important within this context. Much attention is placed on understanding values and practices of people of different cultures, but self-awareness is vitally important as well. Asking clients to describe their expectations for health-care provision and the role of the nurse can begin to lay the groundwork for discussing differences in cultural values and interacting as individuals within a culturally sensitive context. For example, a nurse who identifies with the dominant, individualistic culture may have the belief that people should take responsibility for themselves and do what they want to do independent of the opinions of family and community. If the nurse communicates this expectation to someone from a collectivist cultural framework, the nurse and client may encounter difficulty establishing a working relationship because their basic values are at odds with one another.

The United States, viewed as a melting pot of multiple worldwide ethnic groups, has its own unique blended culture that impacts the health and care of individuals. It is important that the nurse is aware—and self-aware of these conscious and unconscious attitudes and values within the U.S. culture when caring for clients and understands how these characteristics can impact mental health and mental illness. Characteristics common to the U.S. culture are presented in Box 6–3.

African Americans

The African American or black population in the United States numbers 46.3 million according to the most recent US Census data. Of those, 2.2 million are

---

BOX 6–3 American Culture

General: The United States is the third-largest country and one of the most culturally diverse. The vast majority of Americans speak and understand at least some English. The majority (83%) identify as being of the Christian faith, and the second-largest group (13%) identifies as having no religious affiliation. Judaism is the second-largest religion (1.7%), and Islam is the third (0.6%). Football and baseball are identified as favorite pastimes. Marketing products to people in their homes and other countries now constitutes one of the biggest industries.

Work and economy: Equality and economic mobility are valued, and several laws protect equality rights, but there is still evidence of stratification and segregation (e.g., urban versus suburban neighborhoods). Most Americans are not opposed to social security benefits, but welfare for the poor is controversial. Work and competition are valued; being "on the go" is more valued than idle time.

Time and orientation: Making the best use of time is important and may be connected to work ethics (e.g., "time is money"). Being on time for meetings is expected. Most Americans are future oriented; from a young age, children are taught to focus on what they "want to be" when they grow up.

Individuality: Developing one's own goals and not relying too heavily on others is valued. Independent achievements are rewarded.

Privacy: Privacy and having some "alone time" are valued. Personal thoughts and feelings are considered by most to be private. It is often considered rude to ask about someone's finances or their age.

Informality: Casual lifestyle is common. Greetings and farewells are usually short and friendly but superficial; friendships are often casual (e.g., easily developed and easily ended).

Social: Personal restraint of one's body is common; physical distance is common in interaction, especially among men. Breastfeeding, yawning, and expelling gas in public are considered rude.

Death: Most Americans are uncomfortable with their own mortality. Death is considered difficult to talk about, and funerals are typically sad and solemn occasions.

---

military veterans, and 84.7% over the age of 25 hold a high school diploma or higher level of education. Despite these favorable statistics, the US Census also reports that 25.4% of the US black population remains below the poverty level.

Despite decades of civil rights advances, patterns of discrimination against African Americans continue, and evidence of segregation still exists, usually in the form of predominantly black neighborhoods, churches, and schools, which are still visible in most U.S. cities. Some African Americans find it difficult to assimilate into the mainstream culture and choose to remain within their own social organization.

The most recent survey by the U.S. Census Bureau revealed that 40.4 percent of African American family households were headed by a woman (U.S. Census Bureau, 2015). Social support systems may be large and include sisters, brothers, aunts, uncles, cousins, boyfriends, girlfriends, neighbors, and friends. Many African Americans have a strong religious orientation, with the vast majority practicing some form of Protestantism. However, the declining rate of those who identify themselves as Christians and the concurrent rise in numbers who identify themselves as having no affiliation with organized religion is similar among many demographic groups, including African Americans (Pew Research Center, 2015).

African Americans who have assimilated into the dominant culture are likely to be well educated, professional, and future oriented. Some who have not become assimilated may believe that planning for the future is hopeless, a belief based on their previous experiences and encounters with racism and discrimination (Cherry & Giger, 2013). Among this group, some may be unemployed or have low-paying jobs with little expectation for improvement.

Some African Americans, particularly those from lower socio-economic groups, may have limited access to primary care services, and may be more receptive to folk medicine practices as an alternative. Incorporated into the system of **folk medicine** is the belief that health is a gift from God, whereas illness is a punishment from God or a retribution for sin and evil. Historically, African Americans have sometimes pursued folk medicine remedies because the cost of mainstream medical treatment was prohibitive, or because of the insensitive treatment by caregivers in the health-care delivery system.

Hypertension occurs more frequently and sickle cell disease occurs predominantly in African Americans. Hypertension carries a strong hereditary risk factor, and sickle cell disease is genetically derived. Alcoholism is a serious problem among members of the black community, leading to a high incidence of alcohol-related illness and death (Cherry & Giger, 2013).

American Indian and Alaska Natives

The federal government currently recognizes 566 American Indian (AI) tribes and Alaska Native (AN) groups. Approximately 200 tribal languages are still spoken, some by only a few individuals and others by many (Bureau of Indian Affairs, 2016). Fewer than half of these individuals still live on reservations, but many return regularly to participate in family and tribal life and sometimes to retire. American Indians and Alaska Natives are often grouped together in statistical reporting about Native Americans, but they are a diverse group, and some Alaska Natives prefer not to be referred to as Native Americans (Purnell, 2014). The AI/AN group is described as a *collectivist culture,* which stresses their close dependence on and interconnectedness with family and tribe.

Touch is an aspect of communication that is not the same among AI/AN groups as in the dominant American culture. Some AI/AN groups view the traditional handshake as somewhat aggressive. Instead, if a hand is offered to another, it may be accepted with a light touch or just a passing of hands. Some AI/AN groups will not touch a dead person (Hanley, 2017).

American Indians and Alaska Natives may appear silent and reserved. They may be uncomfortable expressing emotions because the culture encourages keeping private thoughts to oneself. In conversation, most prefer a distance of greater than 2 feet, and for some it may be up to 6 feet, so it is important to pay attention to cues from the client (Purnell, 2014).

The concept of space is very concrete to AI/AN culture. Living space is often crowded with members of both nuclear and extended families. A large network of kin is very important to American Indians and Alaska Natives. However, a need for extended space exists, as demonstrated by a distance of many miles between individual homes or camps.

The primary social organizations of AI/AN groups are the family and the tribe. From infancy, AI/AN children are taught the importance of these units. Traditions are passed down by the elders, and children are taught to respect tradition and to honor wisdom.

Most AI/AN individuals are present-time oriented. The concept of time is very casual, and tasks are accomplished not with the notion of a particular time in mind but in a present-oriented time frame. AI/AN individuals typically are not ruled by the clock, and some do not even own clocks.

Religion and health practices are intertwined in the AI/AN culture. The medicine man (or woman), generally called the shaman (although some tribes prefer different terms) may use a variety of methods in his or her practice. Some use crystals to diagnose illness, some sing and perform healing ceremonies, and some use herbs and other plants or roots to create remedies with healing properties. The American Indian healers

and U.S. Indian Health Service have worked together with mutual respect for many years. Hanley (2017) relates that an AI/AN healer may confer with a physician regarding the care of a client in the hospital. Research studies have continued to show the importance of each of these health-care approaches and collaborative practice in the overall wellness of AI/AN client (Hanley, 2017).

The risks of illness and premature death from alcoholism, diabetes, tuberculosis, heart disease, accidents, homicide, suicide, pneumonia, and influenza are dramatically higher for American Indians and Alaska Natives than for the U.S. population as a whole. The Indian Health Service (2015) reports that American Indians and Alaska Natives are "more likely to report past-year alcohol and substance use disorders than any other race, and suicide rates are 1.7 times higher than the U.S. all-races rate." Domestic violence, too, is a significant behavioral health concern in this group, with 39 percent of women experiencing intimate partner violence. Nutritional deficiencies are not uncommon among tribal AI/AN populations. Fruits and green vegetables are often scarce in many of the federally defined Indian geographical regions. Meat and corn products are identified as preferred foods. Fiber intake is relatively low, while fat intake is often of the saturated variety. Approximately 276 of the tribes recognized by the federal or state government receive commodity foods supplied by the U.S. Department of Agriculture's food distribution program (U.S. Department of Agriculture, 2015).

Asian Pacific Islander Americans

Asian Americans comprise 4.9 percent of the U.S. population. The Asian American culture includes peoples (and their descendants) from Japan, China, Vietnam, the Philippines, Thailand, Cambodia, Korea, Laos, India, and the Pacific Islands. Although this discussion relates to this population as a single culture, it is important to keep in mind that a multiplicity of differences regarding attitudes, beliefs, values, religious practices, and language exist among these subcultures.

Many Asian Americans, particularly Japanese, are third- and even fourth-generation Americans. These individuals are likely to be acculturated to the U.S. culture. Kuo and Roysircar-Sodowsky (2000) describe three patterns common to Asian Americans in their attempt to adjust to the American culture. Some older-generation Asians tend to hold on to the traditional values and practices of their native culture. They have strong, internalized Asian values. Primary allegiance is to their biological family. Frequently,

members of the younger generation may reject the traditional values of their ancestral culture, and totally embrace Western culture. Finally, some Asian Americans strike a balance, incorporating traditional values and beliefs with Western values and beliefs. They are—or become—integrated into the American culture while maintaining a connection with their ancestral culture.

The languages and dialects of Asian Americans are very diverse. In general, they share a similar belief in harmonious interaction. To raise one's voice is likely to be interpreted as a sign of loss of control. The English language is very difficult to master, and even bilingual Asian Americans who are recent immigrants may encounter communication problems because of the differences in meaning assigned to nonverbal cues such as facial gestures, verbal intonation and speed, and body movements. In Asian cultures, touching during communication has historically been considered unacceptable. However, with the advent of Western acculturation, younger generations of Asian Americans accept touching as more appropriate than did their ancestors. Acceptable personal and social spaces are larger than in the dominant American culture. Some Asian Americans have a great deal of difficulty expressing emotions. Because of their reserved public demeanor, Asian Americans may be misperceived as shy, cold, or uninterested.

The family is the ultimate social organization in traditional Asian American culture, and loyalty to family is emphasized above all else. Children are expected to obey and honor their parents. Misbehavior is perceived as bringing dishonor to the entire family. Filial piety (one's social obligation or duty to one's parents) is held in high regard. Failure to fulfill these obligations can create a great deal of guilt and shame in an individual. A chronological hierarchy exists with the elderly maintaining positions of authority. Several generations or even extended families may share a single household.

Although education is highly valued among traditional Asian Americans, many remain undereducated. Religious beliefs and practices are diverse and exhibit influences of Taoism, Buddhism, Confucianism, Islam, Hinduism, and Christianity.

Many Asian Americans value both a past and a present orientation. Emphasis is placed on the wishes of one's ancestors while adjusting to demands of the present. Prompt adherence to schedules or rigid standards of activities may or may not be valued.

Restoring the balance of **yin and yang** is the fundamental concept of Asian health practices. Yin and yang represent opposite forces of energy, such as

negative/positive, dark/light, cold/hot, hard/soft, and feminine/masculine. The belief is that illness occurs when there is a disruption in the balance of these energy forces. In medicine, the opposites are expressed as "hot" and "cold," and health is the result of a balance between hot and cold elements (Chang, 2017). Food, medicines, and herbs are classified according to their hot and cold properties and are used to restore balance between yin and yang (cold and hot), thereby restoring health.

Rice, vegetables, and fish were the traditional main staple foods of many Asian diets. Milk is seldom consumed because a large majority of Asian Americans experience lactose intolerance. With Western acculturation, their diet is changing, and unfortunately, the percentage of fat in the diet is increasing as more meat is consumed.

Some Asian cultures believe that psychiatric illness is merely behavior that is out of control. They view this as a great shame to the individual and the family. They often attempt to manage the ill person on their own until they can no longer handle the situation. It is not uncommon for Asian Americans to somaticize. Expressing mental distress through various physical ailments may be viewed as more acceptable than expressing true emotions.

The incidence of alcohol dependence is low among Asians. This may be a result of a possible genetic intolerance of the substance. Some Asians develop unpleasant symptoms, such as flushing, headaches, and palpitations, from drinking alcohol. Research indicates that this is due to an isoenzyme variant that quickly converts alcohol to acetaldehyde and the absence of an isoenzyme that is needed to oxidize acetaldehyde. This results in a rapid accumulation of acetaldehyde that produces the unpleasant symptoms (Wall et al., 1997).

Latino Americans

Latino Americans are the fastest-growing group of people in the United States, comprising 16.9 percent of the population (U.S. Census Bureau, 2016). They represent the largest ethnic minority group. Recent presidential debates highlighted public confusion about the correct terminology to describe different groups (Garcia-Navarro, 2015). The U.S. Census Bureau clarifies that Latino or Hispanic peoples comprise many different races. It would not be correct, for example, to refer to someone as a member of the Latin race, since there are a variety of races among Latin American countries. Latin Americans are those who currently reside in Latin American countries. Latino Americans are those who come from Latin American countries but currently reside in the United States. *Latino American* is often shortened to *Latino,* but individual preferences about this term vary. The term *Hispanic* is used to refer to people who share the common language of Spanish. Brazilian people, for example, would be offended by being referred to as Hispanic, since their primary language is Portuguese (Garcia-Navarro, 2015). Preferences as to what constitutes appropriate descriptive terms can vary depending on geographic location. Asking clients how *they* would describe their cultural identity is in the interest of averting an unintentional insult and demonstrates cultural sensitivity.

Latino Americans trace their ancestry to countries such as Mexico, Spain, Puerto Rico, Cuba, and other countries of Central and South America. Touch is a common form of communication among Latinos; however, they can also be very modest and are likely to withdraw from any infringement on their modesty.

Traditional Latino Americans, as a collectivist culture, are very group oriented and often interact with large groups of relatives. Touching and embracing are common modes of communication. The family is the primary social organization and includes nuclear family members as well as numerous extended family members. The traditional nuclear family is male dominated, and the father possesses ultimate authority.

Latino Americans tend to be focused on the present time. The concept of being punctual and giving attention to activities that concern the future are perceived as less important than activities in the present.

Roman Catholicism is the predominant religion among Latino Americans. Most Latinos identify with the Roman Catholic Church, even if they do not attend services. Religious beliefs and practices are likely to be strong influences in their lives. Especially in times of crisis, such as in cases of illness and hospitalization, Latino Americans rely on priests and the family to carry out important religious rituals, such as promise making, offering candles, visiting shrines, and offering prayers (Spector, 2013).

Folk beliefs regarding health are a combination of elements incorporating views of Roman Catholicism and Indian and Spanish beliefs. The folk healer is called a **curandero** (male) or **curandera** (female). Among traditional Latino Americans, the *curandero* is believed to have a gift from God for healing the sick and is often the first contact made when illness is encountered. Treatments used include massage, diet, rest, suggestions, practical advice, indigenous herbs, prayers, magic, and supernatural rituals (McMurry et al., 2017). Many Latino Americans still subscribe to the "hot and cold theory" of disease. This concept is

similar to the Asian perception of yin and yang discussed earlier in this chapter. Diseases and the foods and medicines used to treat them are classified as "hot" or "cold," and the intention is to restore the body to a balanced state.

National studies have revealed that the lifetime prevalence for selected psychiatric disorders is higher for U.S.-born Latinos (52.5%) than for Latino immigrants (30.9%), suggesting that there may be a protective context associated with living in their country of origin before immigrating (Alegria et al., 2008; Alegria et al., 2007). This has been referred to as the "immigration paradox" (Alegria et al., 2008), since the stresses of immigration might seem to confer more risk of mental disorders, while the reverse is actually true. The contributing factors are not well understood, and there is variation among some Latino subgroups. Among Mexicans, the immigration paradox holds true for mood, anxiety, and substance disorders, but among Cubans and other Latino subgroups, it holds true only for substance disorders. This paradox does not hold true for migrant versus U.S.-born Puerto Ricans (Alegria et al., 2008). In general, Latino Americans have demonstrated a lower lifetime prevalence of mental disorders than their non-Hispanic white counterparts, but it should be noted that the CDC (2015b) reports that the risk for suicide attempts among teenage girls is higher among Latino girls (15.1%) than non-Hispanic white teenage girls (9.8%). As this cultural group, and particularly U.S.-born Latino Americans, continues to grow in number, mental health professionals will need to develop awareness of risks for illness and sensitivity to the cultural values that may impact seeking treatment.

Arab Americans*

Arab Americans trace their ancestry and traditions to the nomadic desert tribes of the Arabian Peninsula. The Arab countries include Algeria, Bahrain, Comoros, Djibouti, Egypt, Iraq, Jordan, Kuwait, Lebanon, Libya, Mauritania, Morocco, Oman, Palestine, Qatar, Saudi Arabia, Somalia, Sudan, Syria, Tunisia, United Arab Emirates, and Yemen.

First-wave immigrants, primarily Christians, came to the United States between 1887 and 1913 seeking economic opportunity. These immigrants and their descendants typically resided in urban centers of the

*This section on Arab Americans is adapted from Kulwicki, A.D., & Ballout, S. (2013). People of Arab heritage. In L.D. Purnell (Ed.), *Transcultural health care: A culturally competent approach* (4th ed.). © F.A. Davis. Used with permission.

Northeast. Second-wave immigrants entered the United States after World War II. Most are refugees from nations beset by war and political instability. This group includes a large number of professionals and individuals seeking educational degrees who have subsequently remained in the United States. Most are Muslims and favor professional occupations.

Arabic is the official language of the Arab world. Although English is a common second language, language and communication can pose formidable problems in health-care settings. Communication is highly contextual, where unspoken expectations are more important than the actual spoken words. While conversing, individuals stand close together, maintain steady eye contact, and touch (only between members of the same gender) the other's hand or shoulder.

Speech may be loud and expressive and characterized by repetition and gesturing, particularly when in serious discussion. Observers witnessing impassioned communication may incorrectly assume that members of this culture are argumentative, confrontational, or aggressive. Privacy is valued, and many resist disclosure of personal information to strangers, especially when it relates to familial disease conditions. Among friends and relatives, Arabs express feelings freely. Devout Muslim men may not shake hands with women. When an Arab man is introduced to an Arab woman, the man may wait for the woman to extend her hand.

Gender roles are often clearly defined. The man is traditionally the head of the household, and women are subordinate to men. Men are traditionally breadwinners, protectors, and decision makers, and women traditionally are responsible for the care and education of children and for the maintenance of a successful marriage by tending to their husbands' needs.

The family is the primary social organization, and children are loved and indulged. The father is the disciplinarian, and the mother is an ally and mediator. Loyalty to one's family takes precedence over personal needs. Sons are responsible for supporting elderly parents.

Women value modesty, especially devout Muslims, for whom modesty is expressed with attire. Many Muslim women view the practice of *hijab,* covering the body except for one's face and hands, offering them protection in situations in which the genders mix.

Sickle cell disease and the thalassemias (a type of inherited blood disorder) are common in the eastern Mediterranean. Sedentary lifestyle and high fat intake among Arab Americans place them at higher risk for cardiovascular diseases. The rates of cholesterol testing, colorectal cancer screening, and uterine cancer

screening are low; however, in recent years, the rate of mammography screening has increased.

Arab cooking shares many general characteristics. Spices and herbs include cinnamon, allspice, cloves, ginger, cumin, mint, parsley, bay leaves, garlic, and onions. Bread accompanies every meal and is viewed as a gift from God. Lamb and chicken are the most popular meats. Muslims are prohibited from eating pork and pork products. Food is eaten with the right hand because it is regarded as clean. Eating and drinking at the same time is viewed as unhealthy. Eating properly, consuming nutritious foods, and fasting are believed to cure disease. Gastrointestinal complaints are the most frequent reason for seeking health care. Lactose intolerance is common.

Most Arabs are Muslims. Islam is the religion of most Arab countries, and in Islam there is no separation of church and state; a certain amount of religious participation is obligatory. Many Muslims believe in combining spiritual medicine, performing daily prayers, and reading or listening to the Qur'an with conventional medical treatment. The devout client may request that his or her chair or bed be turned to face Mecca and that a basin of water be provided for ritual washing or ablution before praying. Sometimes illness is considered punishment for one's sins.

Mental illness is a major social stigma. Psychiatric symptoms may be denied or attributed to "bad nerves" or evil spirits. When individuals suffering from mental distress seek medical care, they are likely to present with a variety of vague complaints such as abdominal pain, lassitude, anorexia, and shortness of breath. Clients often expect and may insist on somatic treatment, often vitamins and tonics. When mental illness is accepted as a diagnosis, treatment with medications rather than counseling is preferred.

Jewish Americans

To be Jewish is to belong to a specific group of people and a specific religion. The term *Jewish* does not refer to a race. The Jewish people came to the United States mostly from Spain, Portugal, Germany, and Eastern Europe (Bralock & Padgham, 2017). More than 5 million Jewish Americans live in the United States, primarily in the larger urban areas.

Four main Jewish religious groups exist today: Orthodox, Reform, Conservative, and Reconstructionist. Orthodox Jews adhere to strict interpretation and application of Jewish laws and ethics. They believe that the laws outlined in the Torah (the five books of Moses) are divine, eternal, and unalterable.

Reform Judaism is the largest Jewish religious group in the United States. The Reform group believes in the autonomy of the individual in interpreting the Jewish code of law, and a more liberal interpretation is followed. Conservative Jews also accept a less strict interpretation. They believe that the code of laws come from God, but they accept flexibility and adaptation of those laws to absorb aspects of the culture while remaining true to Judaism's values. The Reconstructionists have modern views that generally override traditional Jewish laws. They do not believe that Jews are God's chosen people and reject the notion of divine intervention. Reconstructionists are generally accepting of interfaith marriage.

The primary language of Jewish Americans is English. Hebrew, the official language of Israel and the Torah, is used for prayers and taught in Jewish religious education. Early Jewish immigrants spoke a Judeo-German dialect called Yiddish, and some of those words have become part of American English (e.g., *klutz, kosher, tush, chutzpah, mazel tov*).

Although traditional Jewish law is clearly male oriented, with acculturation, little difference is seen today with regard to gender roles. Formal education is a highly respected value among the Jewish people. Over one-third of Jewish Americans hold advanced degrees and are employed as professionals (e.g., science, medicine, law, education), more than any other group within the U.S. white population.

Although most Jewish people live for today and plan for and worry about tomorrow, they are raised with stories of their past, especially of the Holocaust. They are warned to "never forget" lest history be repeated. Therefore, their time orientation is simultaneously to the past, the present, and the future (Selekman, 2013).

Children are considered blessings and valued treasures, treated with respect, and deeply loved. They play an active role in most holiday celebrations and services. Respecting and honoring one's parents is one of the Ten Commandments. Children are expected to be forever grateful to their parents for giving them the gift of life (Selekman, 2013). The rite of passage into adulthood occurs during a religious ceremony called a *bar* or *bat mitzvah* (son or daughter of the commandment) and is usually commemorated by a family celebration.

Because of the respect afforded physicians and the emphasis on keeping the body and mind healthy, Jewish Americans tend to be health conscious. In general, they practice preventive health care, with routine physical, dental, and vision screening. Circumcision for male infants is both a medical procedure and a

religious rite and is performed on the eighth day of life. The procedure is usually performed at home and is considered a family festivity.

A number of genetic diseases are more common in the Jewish than among other populations, including Tay-Sachs disease, Gaucher's disease, and familial dysautonomia. Other conditions that occur with increased incidence in the Jewish population include inflammatory bowel disease (ulcerative colitis and Crohn's disease), colorectal cancer, and breast and ovarian cancer. Jewish people have a higher rate of side effects from the antipsychotic clozapine. About 20 percent develop agranulocytosis, the cause of which has been attributed to a specific genetic haplotype (Selekman, 2013).

Alcohol, especially wine, is an essential part of religious holidays and festive occasions. It is viewed as appropriate and acceptable as long as it is used in moderation. For Jewish people who follow the dietary laws, a tremendous amount of attention is given to the slaughter of livestock and the preparation and consumption of food. Religious laws dictate which foods are permissible. The term *kosher* means "fit to eat," and following these guidelines is considered a commandment of God. Meat may be eaten only if the permitted animal has been slaughtered, cooked, and served following kosher guidelines. Pigs are considered unclean, and pork and pork products are forbidden. Dairy products and meat may not be mixed together in cooking, serving, or eating.

Judaism opposes discrimination against people with physical, mental, and developmental conditions. The maintenance of one's mental health is considered just as important as the maintenance of one's physical health. Mental incapacity has always been recognized as grounds for exemption from all obligations under Jewish law (Selekman, 2013).

A summary of information related to the six cultural phenomena as they apply to the cultural groups discussed here is presented in Table 6–1.

Cultural Syndromes

Cultural syndromes are those that are specific to a cultural group and do not share an exact correlation to any diagnostic categories listed in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (Sue & Sue, 2016). These syndromes have historically been described as culture-bound syndromes, but as Sadock, Sadock, and Ruiz (2015) point out, "The clear implication was that Western psychiatric categories were not culture bound . . . [when in fact] culture suffuses all forms of psychological distress,

the familiar as well as the unfamiliar" (p. 145). It is important for nurses to understand the physical and behavioral manifestations of these cultural syndromes. Ataques de nervios (attack of nerves), a Latin American cultural syndrome, may sound similar to the *DSM-5* category of panic attacks, but it is a distinct syndrome with distinct treatment implications (Sue & Sue, 2016). Examples of cultural syndromes are presented in Table 6–2.

Diagnosis and Outcome Identification

Nursing diagnoses are selected on the basis of information gathered during the assessment process. With background knowledge of cultural variables and information uniquely related to the individual, the following nursing diagnoses may be appropriate:

■ Impaired verbal communication related to cultural differences, evidenced by inability to speak the dominant language
■ Anxiety (moderate to severe) related to entry into an unfamiliar health-care system and separation from support systems, evidenced by apprehension and suspicion, restlessness, and trembling
■ Imbalanced nutrition, less than body requirements, related to refusal to eat unfamiliar foods provided in the health-care setting, evidenced by loss of weight
■ Spiritual distress related to inability to participate in usual religious practices because of hospitalization, evidenced by alterations in mood (e.g., anger, crying, withdrawal, preoccupation, anxiety, hostility, apathy)

Outcome criteria related to these nursing diagnoses may include the following:

The client:

1. Has all basic needs fulfilled
2. Communicates with staff through an interpreter
3. Maintains anxiety at a manageable level by having family members stay with him or her during hospitalization
4. Maintains weight by eating foods that he or she likes brought to the hospital by family members
5. Has restored spiritual strength through use of cultural rituals and beliefs and visits from a spiritual leader

Planning and Implementation

The following interventions have special cultural implications for nursing:

■ Use an interpreter, if necessary, to ensure that there are no barriers to communication. Be careful with nonverbal communication because it may be

TABLE 6–1 Summary of Six Cultural Phenomena in Comparison of Various Cultural Groups

CULTURAL GROUP AND COUNTRIES OF ORIGIN	COMMUNICATION	SPACE	SOCIAL ORGANIZATION	TIME	ENVIRONMENTAL CONTROL	BIOLOGICAL VARIATIONS
Northern European Americans (England, Ireland, and others)	National languages (although many learn English very quickly) Dialects (often regional) English More verbal than nonverbal	Territory valued Personal space: 18 inches to 3 feet Uncomfortable with personal contact and touch	Families: Nuclear and extended Religions: Jewish and Christian Organizations: Social community	Future oriented	Most value preventive medicine and primary health care through traditional health-care delivery system Alternative methods on the increase	Health concerns: Cardiovascular disease Cancer Diabetes mellitus
African Americans (Largely descendants of Africans brought forcibly to America as slaves). There are cultural differences between long-standing African Americans and those recently immigrating form Africa.	National languages Primary language is English Highly verbal and nonverbal	Close personal space Comfortable with touch	Large, extended families Many female-headed households Traditionally strong religious orientation, mostly Protestant Community social organizations	Present-time oriented	Traditional health-care delivery system Some individuals prefer to use folk practitioner Home remedies	Health concerns: Cardiovascular disease Hypertension Sickle cell disease Diabetes mellitus Lactose intolerance
American Indians and Alaska Natives (North America, Alaska, Aleutian Islands)	200 tribal languages recognized Comfortable with silence	Large, extended space important Uncomfortable with touch	Families: Nuclear and extended Children taught importance of tradition Social organizations: Tribe and family most important	Present-time oriented	Religion and health practices intertwined Nontraditional healer (shaman) uses folk practices to heal Shaman may work with modern medical practitioner	Health concerns: Alcoholism Tuberculosis Accidents Diabetes mellitus Heart disease
Asian/Pacific Islander Americans (Japan, China, Korea, Vietnam, Philippines, Thailand, Cambodia, Laos, Pacific Islands, others)	More than 30 different languages spoken Comfortable with silence Nonverbal connotations may be misunderstood	Large personal space Uncomfortable with touch	Families: Nuclear and extended Children taught importance of family loyalty and tradition Many religions: Taoism, Buddhism, Islam, Hinduism, Christianity Community social organizations	Present-time oriented Past is important and valued	Traditional health-care delivery system Some prefer to use folk practices (e.g, yin and yang, herbal medicine, and moxibustion)	Health concerns: Hypertension Cancer Diabetes mellitus Thalassemia Lactose intolerance

TABLE 6–1 Summary of Six Cultural Phenomena in Comparison of Various Cultural Groups—cont'd

CULTURAL GROUP AND COUNTRIES OF ORIGIN	COMMUNICATION	SPACE	SOCIAL ORGANIZATION	TIME	ENVIRONMENTAL CONTROL	BIOLOGICAL VARIATIONS
Latino Americans (Mexico, Spain, Cuba, Puerto Rico, other countries of Central and South America)	Spanish, with many dialects	Close personal space Lots of touching and embracing Very group oriented	Families: Nuclear and large extended families Strong ties to Roman Catholicism Community social organizations	Present-time oriented	Traditional health-care delivery system Some prefer to use folk practitioner, called *curandero* or *curandera* Folk practices include hot and cold herbal remedies	Health concerns: Heart disease Cancer Diabetes mellitus Accidents Lactose intolerance
Arab Americans (Algeria, Bahrain, Comoros, Djibouti, Egypt, Iraq, Jordan, Kuwait, Lebanon, Libya, Mauritania, Morocco, Oman, Palestine, Qatar, Saudi Arabia, Somalia, Sudan, Syria, Tunisia, United Arab Emirates, Yemen)	Arabic English	Large personal space between members of the opposite gender outside of the family Touching common between members of same gender	Families: Nuclear and extended Religion: Muslim and Christianity	Past and present-time oriented	Traditional health-care delivery system Authority of physician is seldom challenged or questioned Adverse outcomes are attributed to God's will Mental illness may be viewed as a social stigma	Health concerns: Sickle cell disease Thalassemia Cardiovascular disease Cancer
Jewish Americans (Spain, Portugal, Germany, Eastern Europe)	English, Hebrew, Yiddish	Touch forbidden between opposite genders in the Orthodox tradition Closer personal space common among non-Orthodox Jews	Families: Nuclear and extended Community social organizations	Past, present-time, and future oriented	Great respect for physicians Emphasis on keeping body and mind healthy Practice preventive health care	Health concerns: Tay-Sachs disease Gaucher's disease Familial dysautonomia Ulcerative colitis Crohn's disease Colorectal cancer Breast cancer Ovarian cancer

TABLE 6–2 **Examples of Cultural Syndromes**		
SYNDROME	CULTURE	SYMPTOMS
Amok	Malaysia, Laos, Philippines, Polynesia, Papua New Guinea, Puerto Rico, and among the Navajo (may be precipitated by the perception that they have been insulted in some way)	A state of depression followed by violent or homicidal behavior and ending with a period of exhaustion, somnolence, and amnesia; persecutory ideas are also common
Ataque de nervios	Latin America, Latin Caribbean, and Mediterranean (often occurs in response to a stressful family event such as death or divorce)	Uncontrollable shouting, crying, trembling, verbal or physical aggression, sometimes accompanied by dissociative experiences, seizure-like or fainting episodes, and suicidal gestures
Brain fag	West Africa (usually occurring in high school or university students during periods of academic stress)	Difficulty concentrating, poor memory retention, pain and pressure around head and neck, blurred vision; students often complain of "brain fatigue"
Ghost sickness	American Indian tribes	Preoccupation with death and the deceased; symptoms include anxiety, confusion, weakness, feelings of danger, anorexia, and bad dreams; sometimes associated with witchcraft
Hwa-byung	Korea (often attributed to suppression of anger)	Symptoms closely related to those of depression, including insomnia, fatigue, indigestion, dysphoria, anorexia, bodily aches, and loss of interest
Koro	Southern and Eastern Asia	Intense anxiety associated with fear that the penis (in males) or the vulva and nipples (in females) will retract into the body and cause the person to die
Pibloktoq	Eskimo cultures	Sometimes called *arctic hysteria,* an abrupt episode of extreme excitement, preceded by withdrawal or mild irritability, and followed by seizure activity and coma. During the attack the individual engages in aberrant and bizarre verbal and motor behavior; afterward, usually reports complete amnesia for the attack
Shenjing Shuairuo (neurasthenia)	China	Weakness, emotional excitement, nervous symptoms, and sleep disturbances; this condition is featured in the *Chinese Classification of Mental Disorders* under a section called "other neuroses"
Shen-k'uei or Shenkui	Taiwan, China	Panic anxiety and somatic symptoms; sexual dysfunctions are common but without identified physical cause. Attributed to fear of excessive semen loss related to frequent sexual activity; semen is considered part of one's vital essence
Susto	Latin America	Appetite and sleep disturbances, sadness, pains, headache, stomachache, and diarrhea. The soul is thought to leave the body (during dreams or following a traumatic event), resulting in unhappiness and illness
Taijin kyofusho	Japan	Intense anxiety and fear about possibly offending others, particularly with their body functions, appearance, or odor

interpreted differently by different cultures (e.g., Asians and American Indians may be uncomfortable with touch, whereas Latinos and Western Europeans perceive touch as a sign of caring).

■ Make allowances for individuals from other cultures to have family members around them and even to participate in their care. Large numbers of extended family members are very important to African Americans, American Indians, Asian Americans, Latino Americans, and Western European Americans. To deny access to these family support systems could interfere with the healing process.

■ Ensure that the individual's spiritual needs are being met. Religion is an important source of support for many individuals, and the nurse must be tolerant of various rituals that may be connected with different cultural beliefs about health and illness.

■ Be aware of the differences in concept of time among the various cultures. Most members of the dominant American culture are future oriented and place a high value on punctuality and efficiency. Other cultures may be more present-time oriented. Nurses must be aware that such individuals may not share the value of punctuality. They may be late to appointments and appear to be indifferent to some aspects of their therapy. Nurses must be accepting of these differences and refrain from allowing existing attitudes to interfere with delivery of care.

■ Be aware of different beliefs about health care among the various cultures, and recognize the importance of these beliefs to the healing process. If an individual from another culture has been receiving health care from a spiritualist, curandero, or other nontraditional healer, it is important for the nurse to listen to what has been done in the past and even to consult with these cultural healers about the care being given to the client.

■ Follow the health-care practices the client views as essential, provided they do no harm and do not interfere with the healing process. For example, the concepts of yin and yang and the hot and cold theory of disease are very important to the well-being of some Asians and Latinos, respectively. Try to ensure that a balance of these foods are included in the diet as an important reinforcement for traditional medical care.

■ Be aware of favorite foods of individuals from different cultures. The health-care setting may seem strange and somewhat isolated, and for some individuals, it feels good to have anything around them that is familiar. They may even refuse to eat unfamiliar foods. If it does not interfere with his or her care, allow family members to provide favorite foods for the client.

■ The nurse working in psychiatry must realize that psychiatric illness is stigmatized in some cultures. Individuals who believe that expressing emotions is unacceptable will present unique problems as clients in a psychiatric setting. Nurses must have patience and work slowly to establish trust in order to provide these individuals with the assistance they require.

Evaluation

Evaluation of nursing actions is directed at achievement of the established outcomes. Part of the evaluation process is continuous reassessment to ensure that the selected actions are appropriate and the goals and outcomes are realistic. Including the family and extended support systems in the evaluation process is essential if cultural implications of nursing care are to be measured. Modifications to the plan of care are made as the need is determined.

Spiritual Concepts

CORE CONCEPT

Spirituality

The human quality that gives meaning and sense of purpose to an individual's existence. Spirituality exists within each individual regardless of belief system and serves as a force for interconnectedness between the self and others, the environment, and a higher power.

Spirituality is difficult to describe. Historically, it has had distinctly religious connections, with a spiritual person being described as "someone with whom the Spirit of God dwelt." Koenig (2012) describes spirituality as distinguished by its connection to that which is considered sacred and transcendent. He identifies spirituality as connected to the supernatural, the mystical, and to organized religion but extending beyond and beginning before organized religion. In other words, spirituality may be considered a quest for the transcendent that might lead to staunch belief or nonbelief.

In the treatment of mental illness, some of the earliest practices focused on spiritual treatment because insanity was considered a disruption of mind and spirit (Reeves & Reynolds, 2009). However, Freud (often described as a forefather of psychiatric treatment) believed that religion had a negative effect on mental health and that it was linked to a host of psychiatric symptoms. Thus, religion and spiritually have been avoided rather than embraced as a valuable aspect of treatment. More recently, the focus is changing once again. Reeves and Reynolds (2009) note that the large volume of contemporary research

(more than 60 studies) demonstrating the value of spirituality for both medical and psychiatric patients is influencing this change. Nursing has embraced this new focus by the inclusion of nursing responsibility for spiritual care in the International Council of Nurses *Code of Ethics* and in the American Holistic Nurses Association *Standards for Holistic Nursing Practice*. The inclusion of spiritual care is also evidenced by two current NANDA International nursing diagnoses: Spiritual distress and Readiness for enhanced spiritual well-being (Herdman & Kamitsuru, 2014).

Smucker (2001) stated:

> Spirituality is the recognition or experience of a dimension of life that is invisible, and both within us and yet beyond our material world, providing a sense of connectedness and interrelatedness with the universe. (p. 5)

Smucker (2001) identified the following five factors as types of spiritual needs associated with human beings:

1. Meaning and purpose in life
2. Faith or trust in someone or something beyond ourselves
3. Hope
4. Love
5. Forgiveness

Spiritual Needs

Meaning and Purpose in Life

Humans by nature appreciate order and structure in their lives. Having a purpose in life gives one a sense of control and the feeling that life is worth living. Each nurse's exploration of his or her own spirituality and efforts to grow spiritually are foundational to being responsive to those needs in others. Walsh (1999) describes seven perennial practices that he believes promote enlightenment, aid in transformation, and encourage spiritual growth:

1. **Transform your motivation:** Reduce craving and find your soul's desire.
2. **Cultivate emotional wisdom:** Heal your heart and learn to love.
3. **Live ethically:** Feel good by doing good.
4. **Concentrate and calm your mind:** Accept the challenge of mastering attention and mindfulness.
5. **Awaken your spiritual vision:** See clearly and recognize the sacred in all things.
6. **Cultivate spiritual intelligence:** Develop wisdom and understand life.
7. **Express spirit in action:** Embrace generosity and the joy of service. (p. 14)

In the final analysis, each individual must determine his or her own perception of what is important and what gives meaning to life. Throughout one's existence, the meaning of life will undoubtedly be challenged many times. A solid spiritual foundation may help an individual confront the challenges that result from life's experiences.

Faith

Faith is often thought of as the acceptance of a belief in the absence of physical or empirical evidence. Smucker (2001) stated:

> For all people, faith is an important concept. From childhood on, our psychological health depends on having faith or trust in something or someone to help meet our needs. (p. 7)

Having faith requires that individuals rise above that which they can experience only through the five senses. Faith transcends the appearance of the physical world. An increasing amount of medical and scientific research is showing that what individuals believe exists can have as powerful an impact as what actually exists. Karren and associates (2010) stated:

> [There is a] growing appreciation of the healing power of faith among members of the medical community. Belief strongly impacts health outcomes, and belief of a large majority of Americans is connected to their religious commitments. Seventy-five percent of Americans say that their religious faith forms the foundation for their approach to life. Seventy-three percent of Americans say that prayer is an important part of their daily life. Religious belief provides power for an individual. With such beliefs so prevalent, it is no surprise that religious faith plays a significant role in healing. (p. 360)

Evidence suggests that faith, combined with conventional treatment and an optimistic attitude, can be a very powerful element in the healing process.

Hope

Hope has been defined as a special kind of positive expectation (Karren, Smith, & Gordon, 2013). With hope, individuals look at a situation, and no matter how negative, find something positive on which to focus. Hope functions as an energizing force. In addition, research indicates that hope may promote healing, facilitate coping, and enhance quality of life (Enayati, 2013; Nekolaichuk, Jevne, & Maguire, 1999).

Kübler-Ross (1969), in her classic study of dying patients, stressed the importance of hope. She suggested that even though these patients could not hope for a cure, they could hope for additional time to live, to be with loved ones, for freedom from pain, or for a peaceful death with dignity. She found hope to be a satisfaction unto itself, whether or not it was fulfilled. She stated, "If a patient stops expressing hope, it is usually a sign of imminent death" (p. 140).

Researchers in the field of psychoneuroimmunology have found that the attitudes we have and the emotions we experience have a definite effect on the body. An optimistic feeling of hope is not just a mental state. Hope and optimism produce positive physical changes in the body that can influence the immune system and the functioning of specific body organs. The medical literature abounds with countless examples of individuals with terminal conditions who suddenly improve when they find something to live for. Conversely, there are many accounts of patients whose conditions deteriorate when they lose hope.

Love

Love may be identified as a projection of one's own good feelings onto others. To love others, one must first experience love of self and then be able and willing to project that warmth and affectionate concern for others (Karren et al., 2013).

Smucker (2001) stated:

> Love, in its purest unconditional form, is probably life's most powerful force and our greatest spiritual need. Not only is it important to receive love, but equally important to give love to others. Thinking about and caring for the needs of others keeps us from being too absorbed with ourselves and our needs to the exclusion of others. We all have experienced the good feelings that come from caring for and loving others. (p. 10)

Love may be a very important key in the healing process. Thaik, a cardiologist, states that love, as one of many strong human emotions, releases a cascade of hundreds or thousands of neuropeptides and hormones that can affect physical and mental health (2013). Among the beneficial effects, Thaik reports:

1. Love counteracts the fight-or-flight syndrome and decreases production of the stress hormone cortisol.
2. Love encourages the production of oxytocin, the "feel good" hormone, which can reduce cardiovascular stress and improve the immune system.
3. Love increases the production of norepinephrine and dopamine and may stave off depression.
4. Love decreases inflammation, which affects immune function and pain relief.

Some researchers suggest that love has a positive effect on the immune system. This has been shown to be true in adults and children and also in animals (Fox & Fox, 1988; Ornish, 1998; Pace et al., 2009). The giving and receiving of love may also result in higher levels of endorphins, thereby contributing to a sense of euphoria and helping to reduce pain.

In a classic long-term study, researchers Werner and Smith (1992) studied children who were reared in impoverished environments. Their homes were troubled by discord, desertion, or divorce or were marred by parental alcoholism or mental illness. The participants were studied at birth, childhood, adolescence, and adulthood. Two out of three of these high-risk children had developed serious learning and/or behavioral problems by age 10 or had a record of delinquencies, mental health problems, or pregnancies by age 18. A quarter of them had developed "very serious" physical and psychosocial problems. By the time they reached adulthood, more than three-fourths of them suffered from profound psychological and behavioral problems, and even more were in poor physical health. But of particular interest to the researchers were the 15 to 20 percent who remained resilient and well despite their impoverished and difficult existence. These children had experienced a warm and loving relationship with another person during their first year of life, whereas the children who developed serious psychological and physical problems did not. This research indicates that the earlier people have the benefit of a strong, loving relationship, the better they seem able to resist the effects of a deleterious lifestyle.

Forgiveness

Forgiveness has been defined as the letting go of resentments and thoughts of revenge (Mayo Clinic, 2014). Feelings of bitterness and resentment take a physical toll on an individual by generating stress hormones, which, when maintained for long periods, can have a detrimental effect on health. Forgiveness enables a person to cast off resentment and begin the pathway to healing. Owen, as cited by Harrison (2011), conducted research with patients who were HIV positive to study the effects of forgiveness on the immune system and found that forgiveness was correlated with improvements in immune function.

Forgiveness is not easy. Individuals often have great difficulty when called upon to forgive others and even greater difficulty in attempting to forgive themselves. Many people carry throughout their lives a sense of guilt for having committed a mistake for which they do not believe they have been forgiven or for which they have not forgiven themselves.

To forgive is not necessarily to condone or excuse one's own or someone else's inappropriate behavior. Karren and associates (2013) suggest that forgiveness is an attitude of owning responsibility for one's own perceptions in order to move beyond the perception of being a helpless victim to the perception of being empowered in choosing one's own responses to hurts and offenses.

Holding on to grievances causes pain, suffering, and conflict. Forgiveness (of self and others) is a gift to oneself. It offers freedom and peace of mind.

Current research supports that spiritual issues such as love and forgiveness are important to address not only because of their impact on psychological and spiritual healing but also because they are deeply connected to neuroendocrine and immune system healing.

It is important for nurses to be able to assess the spiritual needs of their clients. Nurses need not serve the role of professional counselor or spiritual guide, but because of the closeness of their relationship with clients, nurses may be the part of the health-care team to whom clients may reveal the most intimate details of their lives. Smucker (2001) stated:

> Just as answering a patient's question honestly and with accurate information and responding to his needs in a timely and sensitive manner communicates caring, so also does high-quality professional nursing care reach beyond the physical body or the illness to that part of the person where identity, self-worth, and spirit lie. In this sense, good nursing care is also good spiritual care. (pp. 11–12)

Religion

Religion is one way an individual's spirituality may be expressed. There are more than 6500 religions in the world (Bronson, 2005). Some individuals seek out various religions in an attempt to find answers to fundamental questions that they have about life and, indeed, about their very existence. Others, although they may regard themselves as spiritual, choose not to affiliate with an organized religious group. In either situation, however, it is inevitable that questions related to life and the human condition arise during the progression of spiritual maturation.

Brodd (2015) suggested that all religious traditions manifest seven dimensions: experiential, mythic, doctrinal, ethical, ritual, social, and material. He explains that these seven dimensions are intertwined and complementary. Depending on the particular religion, certain dimensions are emphasized more than others. For example, Zen Buddhism has a strong experiential dimension but says little about doctrines. Roman Catholicism is strong in both ritual and doctrine. The social dimension is a significant aspect of religion, as it provides a sense of community from belonging to a group such as a parish or a congregation, which is empowering for some individuals.

CORE CONCEPT

Religion

A set of beliefs, values, rites, and rituals adopted by a group of people. The practices are usually grounded in the teachings of a spiritual leader.

Evidence supports that affiliation with a religious group is a health-enhancing endeavor (Karren et al., 2013). A number of studies indicate a correlation between religious faith/church attendance and increased chance of survival following serious illness, fewer instances of depression and mental illness, longer life, and overall better physical and mental health. In an extensive review of the literature, Levin (2010) concludes that the weight of the evidence across studies suggests that religious involvement is a generally protective factor for mental illness and psychological distress.

It is unknown how religious participation protects health and promotes well-being. Some churches actively promote healthy lifestyles and discourage behavior that would be harmful to health or would interfere with treatment of disease. Graham and Crown (2014) conducted a study to identify what aspects of religion most contributed to happiness and a sense of well-being. They found that those who sought religion for social purpose (as opposed to social interaction) were happiest regardless of religious affiliation or service attendance. Certainly, participation in religious activities also provides opportunities for social interaction. Despite these findings, confidence in organized religion and church attendance, as previously discussed, has been showing a steady decline in American society.

Addressing Spiritual and Religious Needs Through the Nursing Process

Assessment

It is important for nurses to consider spiritual and religious needs when planning care for their clients. The Joint Commission requires that nurses address the psychosocial, spiritual, and cultural variables that influence the perception of illness. Dossey (1998) has developed a spiritual assessment tool (Box 6–4) about which she stated,

> The Spiritual Assessment Tool provides reflective questions for assessing, evaluating, and increasing awareness of spirituality in patients and their significant others. The tool's reflective questions can facilitate healing because they stimulate spontaneous, independent, meaningful initiatives to improve the patient's capacity for recovery and healing. (p. 45)

Assessing the spiritual needs of a client with a psychotic disorder can pose some additional challenges. Approximately 25 percent of people with schizophrenia and 15 to 22 percent of people with bipolar disorder have religious delusions (Koenig, 2012). Sometimes these delusions can be difficult to differentiate from general religious or cultural beliefs, but nonpsychotic religious activity may actually

BOX 6–4 Spiritual Assessment Tool

The following reflective questions may assist you in assessing, evaluating, and increasing awareness of spirituality in yourself and others.

MEANING AND PURPOSE

These questions assess a person's ability to seek meaning and fulfillment in life, manifest hope, and accept ambiguity and uncertainty.

- What gives your life meaning?
- Describe your sense of purpose in life.
- How does your illness affect your life goals?
- How hopeful are you about obtaining a better degree of health?
- How would you describe your role in maintaining your health?
- What kind of changes will you be able to make in your life to maintain your health?
- Describe your level of motivation to get well.
- What is the most important or powerful thing in your life?

INNER STRENGTHS

These questions assess a person's ability to manifest joy and recognize strengths, choices, goals, and faith.

- What brings you joy and peace in your life?
- What can you do to feel alive and full of spirit?
- What traits do you like about yourself?
- What are your personal strengths?
- What choices are available to you to enhance your healing?
- What life goals have you set for yourself?
- What do you think is the role of stress, if any, in your illness?
- How aware were you of your body before you became sick?
- What do you believe in?
- How has your illness influenced your faith?
- How important is faith in your overall health and sense of well-being?

INTERCONNECTIONS

These questions assess a person's positive self-concept, self-esteem, and sense of self; sense of belonging in the world with others; capacity to pursue personal interests; and ability to demonstrate love of self and self-forgiveness.

- How do you feel about yourself right now?
- How do you feel when you have a true sense of yourself?
- Describe any activities of personal interest that you pursue.
- What do you do to show love for yourself?
- Can you forgive yourself?
- What do you do to heal your spirit?

RELATIONSHIPS

These questions assess a person's ability to connect in life-giving ways with family, friends, and social groups and to engage in the forgiveness of others.

- Who are the significant people in your life?
- Who are your readily available, nearby, support people?
- Who are the people to whom you are closest?
- Describe any groups in which you are an active participant.
- How comfortable are you with asking people for help when you need it?
- How comfortable are you with sharing your feelings with others?
- What are some of the most loving things that others have done for you?
- What are the loving things that you do for other people?
- What are your thoughts about forgiving others?

BEHAVIOR AND ACTIVITIES

These questions assess a person's capacity for finding meaning in worship or religious activities and a connectedness with a divinity.

- How important is worship to you?
- What do you consider the most significant act of worship in your life?
- Describe any religious activities in which you are an active participant.
- Describe any spiritual activities, if any, that you find meaningful.
- Do you find prayer meaningful?
- To whom do you turn for support?
- Describe any activities in which you engage for coping and support.
- Describe any activities in which you have previously engaged and have not found helpful.

ENVIRONMENT

These questions assess a person's ability to experience a sense of connection with life and nature, an awareness of the effects of the environment on life and well-being, and a capacity or concern for the health of the environment.

- How does your environment have an impact on your state of well-being?
- What are your environmental stressors at work and at home?
- What strategies reduce your environmental stressors?
- Do you have any concerns for the state of your immediate environment?
- Are you involved with environmental issues such as recycling environmental resources at home, work, or in your community?
- Are you concerned about the survival of the planet?

(1995). *Holistic nursing: A handbook for practice (2nd ed.).* Gaithersburg, MD: Aspen. From Dossey, B.M. (1998). *Holistic modalities and healing moments,* American Journal of Nursing, 98*(6)*, 44-47, with permission.

improve long-term prognosis in patients with psychotic disorders (Koenig, 2012). Engaging family members and significant others in the assessment process can be a great help in determining which religious beliefs and activities have been beneficial to the patient and which have been detrimental to their progress.

Diagnoses and Outcome Identification

Nursing diagnoses that may be used when addressing spiritual and religious needs of clients include the following:

■ Risk for spiritual distress
■ Spiritual distress
■ Readiness for enhanced spiritual well-being
■ Risk for impaired religiosity
■ Impaired religiosity
■ Readiness for enhanced religiosity

The following outcomes may be used as guidelines for care and to evaluate effectiveness of the nursing interventions.

The client:

■ Identifies meaning and purpose in life that reinforce hope, peace, and contentment
■ Verbalizes acceptance of self as a worthwhile human being
■ Accepts and incorporates change into life in a healthy manner
■ Expresses understanding of relationship between difficulties in current life situation and interruption in previous religious beliefs and activities
■ Discusses beliefs and values about spiritual and religious issues
■ Expresses desire and ability to participate in beliefs and activities of desired religion

Planning and Implementation

NANDA International information related to the diagnoses Risk for spiritual distress and Risk for impaired religiosity is provided in the subsections that follow.

Risk for Spiritual Distress

Definition "Vulnerable to an impaired ability to experience and integrate meaning and purpose in life through connectedness within self, literature, nature, and/or a power greater than oneself which may compromise health" (Herdman & Kamitsuru, 2014, p. 374).

Risk factors

Physical: Physical/chronic illness; substance abuse
Psychosocial: Low self-esteem; depression; anxiety; stress; poor relationships; separate from support systems; blocks to experiencing love; inability to forgive; loss; racial or cultural conflict; change in religious rituals; change in spiritual practices
Developmental: Life changes
Environmental: Environmental changes; natural disasters

Risk for Impaired Religiosity

Definition "Vulnerable to impaired ability to exercise reliance on religious beliefs and/or participate in rituals of a particular faith tradition which may compromise health" (Herdman & Kamitsuru, 2014, p. 371).

Risk factors

Physical: Illness/hospitalization; pain
Psychological: Ineffective support, coping, caregiving; depression; lack of security
Sociocultural: Lack of social interaction; cultural barrier to practicing religion; social isolation
Spiritual: Suffering
Environmental: Lack of transportation; environmental barriers to practicing religion
Developmental: Life transitions
A plan of care addressing client's spiritual and/or religious needs is presented in Table 6–3. Selected nursing diagnoses are presented along with appropriate nursing interventions and rationales for each.

Evaluation

Evaluation of nursing actions is directed at achievement of the established outcomes. Part of the evaluation process is continuous reassessment to ensure that the selected actions are appropriate and the goals and outcomes are realistic. Including the family and extended support systems in the evaluation process is essential if spiritual and religious implications of nursing care are to be measured. Modifications to the plan of care are made as the need is determined.

Table 6–3 | CARE PLAN FOR THE CLIENT WITH SPIRITUAL AND RELIGIOUS NEEDS*

NURSING DIAGNOSIS: RISK FOR SPIRITUAL DISTRESS

RELATED TO: Life changes; environmental changes; stress; anxiety; depression

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client identifies meaning and purpose in life that reinforce hope, peace, contentment, and self-satisfaction.	1. Assess current situation.	1–8. Thorough assessment is necessary to develop an accurate care plan for the client.
	2. Listen to client's expressions of anger, concern, self-blame.	
	3. Note reason for living and whether it is directly related to situation.	
	4. Determine client's religious and/or spiritual orientation, current involvement, and presence of conflicts, especially in current circumstances.	
	5. Assess sense of self-concept, worth, ability to enter into loving relationships.	
	6. Observe behavior indicative of poor relationships with others.	
	7. Determine support systems available to and used by client and significant others.	
	8. Assess substance use/abuse.	
	9. Establish an environment that promotes free expression of feelings and concerns.	9. Trust is the basis of a therapeutic nurse-client relationship.
	10. Have client identify and prioritize current/immediate needs.	10. Helps client focus on what needs to be done and identify manageable steps to take.
	11. Discuss philosophical issues related to impact of current situation on spiritual beliefs and values.	11. Helps client to understand that certain life experiences can cause individuals to question personal values and that this response is not uncommon.
	12. Use therapeutic communication skills of reflection and active listening.	12. Helps client find own solutions to concerns.
	13. Review coping skills used and their effectiveness in current situation.	13. Identifies strengths to incorporate into plan and techniques that need revision.
	14. Provide a role model (e.g., nurse, individual experiencing similar situation).	14. Sharing of experiences and hope assists client to deal with reality.

Table 6–3 | CARE PLAN FOR THE CLIENT WITH SPIRITUAL AND RELIGIOUS NEEDS*–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	15. Suggest use of journaling.	15. Journaling can assist in clarifying beliefs and values and in recognizing and resolving feelings about current life situation.
	16. Discuss client's interest in the arts, music, literature.	16. Provides insight into meaning of these issues and how they are integrated into an individual's life.
	17. Role-play new coping techniques. Discuss possibilities of taking classes, becoming involved in discussion groups, cultural activities of client's choice.	17. These activities will help to enhance integration of new skills and necessary changes in client's lifestyle.
	18. Refer client to appropriate resources for help.	18. Client may require additional assistance with an individual who specializes in these types of concerns.

NURSING DIAGNOSIS: RISK FOR IMPAIRED RELIGIOSITY

RELATED TO: Suffering; depression; illness; life transitions

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client expresses achievement of support and personal satisfaction from spiritual and/or religious practices.	1. Assess current situation (e.g., illness, hospitalization, prognosis of death, presence of support systems, financial concerns).	1. This information identifies problems client is dealing with in the moment that is affecting desire to be involved with religious activities.
	2. Listen nonjudgmentally to client's expressions of anger and possible belief that illness or condition may be a result of lack of faith.	2. Individuals often blame themselves for what has happened and reject previous religious beliefs and/or God.
	3. Determine client's usual religious and/or spiritual beliefs, current involvement in specific church activities.	3. This information is important background for establishing a database.
	4. Note quality of relationships with significant others and friends.	4. Individual may withdraw from others in relation to the stress of illness, pain, and suffering.
	5. Assess substance use/abuse.	5. When in distress, individuals often turn to use of various substances, which can affect the ability to deal with problems in a positive manner.
	6. Develop nurse-client relationship in which individual can express feelings and concerns freely.	6. Trust is the basis for a therapeutic nurse-client relationship.
	7. Use therapeutic communication skills of active listening, reflection, and "I" messages.	7. Helps client to find own solutions to problems and concerns and promotes sense of control.

Table 6–3 | CARE PLAN FOR THE CLIENT WITH SPIRITUAL AND RELIGIOUS NEEDS*–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	8. Be accepting and nonjudgmental when client expresses anger and bitterness toward God. Stay with the client.	8. The nurse's presence and non-judgmental attitude increase the client's feelings of self-worth and promote trust in the relationship.
	9. Encourage client to discuss previous religious practices and how these practices provided support in the past.	9. A nonjudgmental discussion of previous sources of support may help the client work through current rejection of them as potential sources of support.
	10. Allow the client to take the lead in initiating participation in religious activities, such as prayer.	10. Client may be vulnerable in current situation and needs to be allowed to decide own resumption of these actions.
	11. Contact spiritual leader of client's choice, if he or she requests.	11. These individuals serve to provide relief from spiritual distress and often can do so when other support persons cannot.

*The interventions for this care plan were adapted from Doenges, M.E., Moorhouse, M.F., & Murr, A.C. (2013). *Nursing diagnosis manual: Planning, individualizing, and documenting client care* (4th ed.). Philadelphia: F.A. Davis.

Summary and Key Points

- Culture encompasses shared patterns of belief, feeling, and knowledge that guide people's conduct and are passed down from generation to generation.
- Some cultures, such as the dominant culture in the United States, are described as **individualistic cultures** and value independence, personal responsibility, and freedom.
- Cultures such as Latin American, Asian, and AI/AN groups can be described as **collectivistic** cultures in that they place a high value on interconnectedness and interreliance on family, community, and/or tribal affiliation.
- Ethnic groups are tied together by a shared heritage.
- Cultural groups differ in terms of communication, space, social organization, time, environmental control, and biological variations.
- America is often described as the melting pot of cultural diversity. People of many different cultures reside in the United States; some maintain traditional cultural practices, whereas others acculturate to dominant cultural practices (give up cultural practices or values as a result of contact with another group) and assimilate by incorporating practices and values of the dominant culture.

- Northern European Americans are the descendants of the first immigrants to the United States and make up the current dominant cultural group. They value punctuality, work responsibility, and a healthy lifestyle.
- Some African Americans trace their roots in the United States to the days of slavery. Most have large support systems and a strong religious orientation. Many have assimilated into and have many of the same characteristics as the dominant culture.
- Many American Indians and Alaska Natives still live on reservations. They speak many different languages and dialects. They often appear silent and reserved, and many are uncomfortable with touch and expressing emotions. Health care may be delivered by a healer called a *shaman*.
- Asian American languages are very diverse. Touching during communication has historically been considered unacceptable. Asian Americans may have difficulty expressing emotions and appear cold and aloof. Family loyalty is emphasized. Psychiatric illness is viewed as behavior that is out of control and brings shame on the family.
- Latino Americans are those who have origins in Latin American countries but now reside in the United States. Many can be referred to as Hispanic,

which implies their primary language is Spanish. Large family groups are important, and touch is a common form of communication. The predominant religion is Roman Catholicism, and the church is often a source of strength in times of crisis. Health care may be delivered by a folk healer called a *curandero* or a *curandera,* who uses various forms of treatment to restore the body to a balanced state.

■ Arab Americans trace their ancestry and traditions to the nomadic desert tribes of the Arabian Peninsula. Arabic is the official language of the Arab world, and the dominant religion is Islam. Mental illness is considered a social stigma, and symptoms are often somaticized.

■ The Jewish people came to the United States predominantly from Spain, Portugal, Germany, and Eastern Europe. Four main Jewish religious groups exist today: Orthodox, Reform, Conservative, and Reconstructionist. The primary language is English. A high value is placed on education. Jewish Americans are very health conscious and practice preventive health care. The maintenance of one's mental health is considered just as important as the maintenance of one's physical health.

■ Cultural syndromes are clusters of physical and behavioral symptoms considered as illnesses or "afflictions" by specific cultures that do not readily fit into the Western conventional diagnostic categories.

■ Spirituality is the human quality that gives meaning and sense of purpose to an individual's existence.

■ Individuals possess a number of spiritual needs that include meaning and purpose in life, faith or trust in someone or something beyond themselves, hope, love, and forgiveness.

■ Religion is a set of beliefs, values, rites, and rituals adopted by a group of people.

■ Religion is one way in which an individual's spirituality may be expressed.

■ Affiliation with a religious group has been shown to be a health-enhancing endeavor.

■ Nurses must consider cultural, spiritual, and religious needs when planning care for their clients.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Miss Lee is an Asian American on the psychiatric unit. She tells the nurse, "I must have the hot ginger root for my headache. It is the only thing that will help." What cultural belief is likely associated with Miss Lee's request?
   a. She is being obstinate and wants control over her care.
   b. She believes that ginger root has magical qualities.
   c. She subscribes to the restoration of health through the balance of yin and yang.
   d. Asian Americans refuse to take traditional medicine for pain.

2. Miss Lee, an Asian American on the psychiatric unit, says she is afraid that no one from her family will visit her. On what belief does Miss Lee base her statement?
   a. Many Asian Americans do not believe in hospitals.
   b. Many Asian Americans do not have close family support systems.
   c. Many Asian Americans believe the body will heal itself if left alone.
   d. Many Asian Americans view psychiatric problems as bringing shame to the family.

3. Joe, an American Indian, appears at the community health clinic with an oozing stasis ulcer on his lower right leg. It is obviously infected, and he tells the nurse that the shaman has been treating it with herbs. The nurse determines that Joe needs emergency care, but Joe states he will not go to the emergency department (ED) unless the shaman is allowed to help treat him. How should the nurse handle this situation?
   a. Contact the shaman and have him meet them at the ED to consult with the attending physician.
   b. Tell Joe that the shaman is not allowed in the ED.
   c. Explain to Joe that the shaman is at fault for his leg being in the condition it is in now.
   d. Have the shaman try to talk Joe into going to the ED without him.

Review Questions—cont'd
Self-Examination/Learning Exercise

4. Joe, an American Indian, goes to the emergency department (ED) because he has an oozing stasis ulcer on his leg. He is accompanied by the tribal shaman, who has been treating Joe on the reservation. As a greeting, the physician extends his hand to the shaman, who lightly touches the physician's hand, then quickly moves away. What cultural norm among American Indians most likely explains the shaman's behavior?
   a. The shaman is snubbing the physician.
   b. The shaman is angry at Joe for wanting to go to the ED.
   c. The shaman does not believe in traditional medicine.
   d. The shaman does not feel comfortable with touch.

5. Sarah is an African American woman who receives a visit from the psychiatric home health nurse. A referral for a mental health assessment was made by the public health nurse, who noticed that Sarah was becoming exceedingly withdrawn. When the psychiatric nurse arrives, Sarah says to her, "No one can help me. I was an evil person in my youth, and now I must pay." How might the nurse assess this statement?
   a. Sarah is having delusions of persecution.
   b. Some African Americans believe illness is God's punishment for their sins.
   c. Sarah is depressed and just wants to be left alone.
   d. African Americans do not believe in psychiatric help.

6. Frank is a Latino American who has an appointment at the community health center for 1 p.m. The nurse is angry when Frank shows up at 3:30 p.m. stating, "I was visiting with my brother." How must the nurse interpret this behavior?
   a. Frank is being passive-aggressive by showing up late.
   b. This is Frank's way of defying authority.
   c. Frank is a member of a cultural group that is present-time oriented.
   d. Frank is a member of a cultural group that rejects traditional medicine.

7. The nurse must give Frank, a Latino American, a physical examination. She asks him to remove his clothing and put on an examination gown. Frank refuses. What cultural norm among Latino Americans most likely explains Frank's response?
   a. Frank does not believe in taking orders from a woman.
   b. Frank is modest and embarrassed to remove his clothes.
   c. Frank does not understand why he must remove his clothes.
   d. Frank does not think he needs a physical examination.

8. Maria is an Italian American who is in the hospital after having suffered a miscarriage at 5 months' gestation. Her room is filled with relatives who have brought a variety of foods and gifts for Maria. They are all talking, seemingly at the same time, and some, including Maria, are crying. They repeatedly touch and hug Maria and each other. How should the nurse handle this situation?
   a. Explain to the family that Maria needs her rest and they must all leave.
   b. Allow the family to remain and continue their activity as described, as long as they do not disturb other clients.
   c. Explain that Maria will not get over her loss if they keep bringing it up and causing her to cry so much.
   d. Call the family priest to come and take charge of this family situation.

9. Mark, who has come to the mental health clinic with symptoms of depression, says to the nurse, "My father is dying. I have always hated my father. He physically abused me when I was a child. We haven't spoken for many years. He wants to see me now, but I don't know if I want to see him." With which spiritual need is Joe struggling?
   a. Forgiveness
   b. Faith
   c. Hope
   d. Meaning and purpose in life

Review Questions—cont'd
Self-Examination/Learning Exercise

10. As a child, Joe was physically abused by his father. The father is now dying and has expressed a desire to see his son before he dies. Joe is depressed and says to the mental health nurse, "I'm so angry! Why did God have to give me a father like this? I feel cheated of a father! I've always been a good person. I deserved better. I hate God!" From this subjective data, which nursing diagnosis might the nurse apply to Joe?
    a. Readiness for enhanced religiosity
    b. Risk for impaired religiosity
    c. Readiness for enhanced spiritual well-being
    d. Spiritual distress

Therapeutic Approaches in Psychiatric Nursing Care

7

Relationship Development

CHAPTER OUTLINE

KEY TERMS

attitude

belief

concrete thinking

confidentiality

countertransference

empathy

genuineness

rapport

sympathy

transference

unconditional positive regard

values

OBJECTIVES
After reading this chapter, the student will be able to:

1. Describe the relevance of a therapeutic nurse-client relationship.
2. Discuss the dynamics of a therapeutic nurse-client relationship.
3. Discuss the importance of self-awareness in the nurse-client relationship.
4. Identify goals of the nurse-client relationship.
5. Identify and discuss essential conditions for a therapeutic relationship to occur.
6. Describe the phases of relationship development and the tasks associated with each phase.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. When the nurse's verbal and nonverbal interactions are congruent, he or she is thought to be expressing which characteristic of a therapeutic relationship?
2. During which phase of the nurse-client relationship do each of the following occur:
   a. The nurse may become angry and anxious in the presence of the client.
   b. A plan of action for dealing with stress is established.
   c. The nurse examines personal feelings about working with the client.
   d. Nurse and client establish goals of care.
3. What is the goal of using the Johari Window?
4. How do sympathy and empathy differ?
5. Write a one-page journal entry reflecting on patterns you notice in your relationships with others. How might you use this awareness in developing therapeutic relationship skills?

The nurse-client relationship is the foundation on which psychiatric nursing is established. It is a relationship in which both participants must recognize each other as unique and important human beings. It is also a relationship in which mutual learning occurs. In today's health-care environment, patient-centered care is promoted as central to quality and safety, and the therapeutic relationship remains at the foundation of this tenet. Concepts that were advanced over 60 years ago (by Hildegard Peplau in 1952) and have been the core of nursing practice to the present day are now recognized by the larger medical community as not only still relevant but critical to improving quality and safety in the future of health care. Peplau (1991) stated:

> Shall a nurse do things *for* a patient or can participant relationships be emphasized so that a nurse comes to do things *with* a patient as her share of an agenda of work to be accomplished in reaching a goal—health. *It is likely that the nursing process is educative and therapeutic when nurse and patient can come to know and to respect each other, as persons who are alike, and yet, different, as persons who share in the solution of problems.* (p. 9, emphasis in original)

This chapter examines the role of the psychiatric nurse and the use of self as the therapeutic tool in the nursing care of clients with mental illness. Phases of the therapeutic relationship are explored, and conditions essential to the development of a therapeutic relationship are discussed. The importance of values clarification in the development of self-awareness is emphasized.

CORE CONCEPT
Therapeutic Relationship
An interaction between two people (usually a caregiver and a care receiver) in which input from both participants contributes to a climate of healing, growth promotion, and/or illness prevention.

Role of the Psychiatric Nurse

What is a nurse? Undoubtedly, this question would elicit as many different answers as the number of people to whom it was presented. Nursing as a *concept* has probably existed since the beginning of the civilized world, with the provision of "care" for the ill or infirm by anyone in the environment who took the time to administer to those in need. However, the emergence of nursing as a *profession* only began in the late 1800s with the graduation of Linda Richards from the New England Hospital for Women and Children in Boston upon achievement of the diploma in nursing. Since that time, the nurse's role has evolved from that of custodial caregiver and physician's handmaiden to recognition as a unique, independent member of the professional health-care team.

Peplau (1991) identified several subroles within the nursing role:

1. **The stranger:** A nurse is at first a stranger to the client. The client is also a stranger to the nurse. Peplau (1991) stated:

   > Respect and positive interest accorded a stranger is at first nonpersonal and includes the same ordinary courtesies that are accorded to a new guest who has been brought into any situation. This principle implies: (1) accepting the patient as he is; (2) treating the patient as an emotionally able stranger and relating to him on this basis until evidence shows him to be otherwise. (p. 44)

2. **The resource person:** According to Peplau, "A resource person provides specific answers to questions usually formulated with relation to a larger problem" (p. 47). In the role of resource person, the nurse explains, in language that the client can understand, information related to the client's health care.

3. **The teacher:** In this subrole, the nurse identifies learning needs and provides information required by the client or family to improve the health situation.

4. **The leader:** According to Peplau, "Democratic leadership in nursing situations implies that the patient will be permitted to be an active participant in designing nursing plans for him" (p. 49). Autocratic leadership promotes overvaluation of the nurse and clients' substitution of the nurse's goals for their own. Laissez-faire leaders convey a lack of personal interest in the client.

5. **The surrogate:** Outside of their awareness, clients often perceive nurses as symbols of other individuals. They may view the nurse as a mother figure, a sibling, a former teacher, or another nurse who has provided care in the past. This perception occurs when a client is placed in a situation that generates feelings similar to ones he or she has experienced previously. Peplau (1991) explained that the nurse-client relationship progresses along a continuum. When a client is acutely ill, he or she may incur the role of infant or child, while the nurse is perceived as the mother surrogate. Peplau (1991) stated, "Each nurse has the responsibility for exercising her professional skill in aiding the relationship to move forward on the continuum, so that person to person relations compatible with chronological age levels can develop" (p. 55).

6. **The technical expert:** The nurse understands various professional devices and possesses the clinical skills necessary to perform interventions that are in the best interest of the client.

7. **The counselor:** The nurse uses "interpersonal techniques" to assist clients in adapting to difficulties or changes in life experiences. Peplau (1991) stated, "Counseling in nursing has to do with helping the patient to remember and to understand fully what is happening to him in the present situation, so that the experience can be integrated with, rather than dissociated from, other experiences in life" (p. 64).

Peplau (1962) believed that the emphasis in psychiatric nursing is on the counseling subrole. How then does this emphasis influence the role of the nurse in the psychiatric setting? Many sources define the *nurse therapist* as a person with graduate preparation in psychiatric-mental health nursing. He or she has developed skills through intensive, supervised educational experiences to provide helpful individual, group, or family therapy.

Peplau suggested that it is essential for the *staff nurse working in psychiatry* to have a general knowledge of basic counseling techniques. A therapeutic or "helping" relationship is established through use of these interpersonal techniques and is based on a sound knowledge of theories of personality development and human behavior.

Sullivan (1953) believed that emotional problems stem from difficulties with interpersonal relationships. Interpersonal theorists, such as Peplau and Sullivan, emphasize the importance of relationship development in the provision of emotional care. Through establishment of a satisfactory nurse-client relationship, individuals learn to generalize the ability to achieve satisfactory interpersonal relationships to other aspects of their lives.

Dynamics of a Therapeutic Nurse-Client Relationship

Travelbee (1971), who expanded on Peplau's theory of interpersonal relations in nursing, stated that only when each individual in the interaction perceives the other as a unique human being is a relationship possible. She refers not to a nurse-client relationship but rather to a human-to-human relationship, which she describes as a "mutually significant experience." That is, both the nurse and the recipient of care have needs met when each views the other as a unique human being, not as "an illness," as "a room number," or as "all nurses" in general.

Therapeutic relationships are goal oriented. Ideally, the nurse and client decide together what the goal of the relationship will be. Most often, the goal is promotion of learning and growth in an effort to bring about change in the client's life. In general, the goal of a therapeutic relationship may be based on a problem-solving model.

EXAMPLE

Goal

The client will demonstrate more adaptive coping strategies for dealing with (specific life situation).

Interventions

- Identify what is troubling the client at the present time.
- Encourage the client to discuss changes he or she would like to make.
- Discuss with the client which changes are possible and which are not possible.
- Have the client explore feelings about aspects of his or her life that cannot be changed and alternative ways of coping more adaptively.
- Discuss alternative strategies for creating changes the client desires to make.
- Weigh the benefits and consequences of each alternative.
- Assist the client to select an alternative.
- Encourage the client to implement the change.
- Provide positive feedback for the client's attempts to create change.
- Assist the client to evaluate outcomes of the change and make modifications as required.

Therapeutic Use of Self

Travelbee (1971) described the instrument for delivery of interpersonal nursing as the *therapeutic use of self*, which she defined as "the ability to use one's personality consciously and in full awareness in an attempt to establish relatedness and to structure nursing intervention" (p. 19).

Use of the self in a therapeutic manner requires that the nurse have a great deal of self-awareness and self-understanding, having arrived at a philosophical belief about life, death, and the overall human condition. The nurse must understand that the ability to and the extent to which one can effectively help others in time of need is strongly influenced by this internal value system—a combination of intellect and emotions.

Gaining Self-Awareness

Values Clarification

Knowing and understanding oneself enhances the ability to form satisfactory interpersonal relationships. Self-awareness requires that an individual recognize and accept what he or she values and learn to accept the uniqueness of and differences in others. This concept is important in everyday life and in the nursing profession in general, but it is *essential* in psychiatric nursing.

An individual's value system is established very early in life and has its foundations in the value system held by the primary caregivers. It is culturally oriented; consists of beliefs, attitudes, and values; and may change many times over the course of a lifetime. Values clarification is one process by which an individual may gain self-awareness.

Beliefs

A **belief** is an idea that one holds true, and it can take any of several forms:

■ *Rational beliefs* are ideas for which objective evidence exists to substantiate their truth.

EXAMPLE

Alcoholism is a disease.

■ *Irrational beliefs* are ideas that an individual holds as true despite the existence of objective contradictory evidence. Delusions can be a form of irrational beliefs.

EXAMPLE

Once an alcoholic has been through detoxification and rehabilitation, he or she can drink socially if desired.

■ *Faith* (sometimes called *blind beliefs*) is a belief in something or someone that does not require proof.

EXAMPLE

Belief in a higher power can help an alcoholic stop drinking.

■ *Stereotype* is a socially shared belief that describes a concept in an oversimplified or undifferentiated matter.

EXAMPLE

All alcoholics are skid-row bums.

Attitudes

An **attitude** is a frame of reference around which an individual organizes knowledge about his or her world. An attitude also has an emotional component. It can be a prejudgment and may be selective and biased. Attitudes fulfill the need to find meaning in life and to provide clarity and consistency for the individual. The prevailing stigma attached to mental illness is an example of a negative attitude. An associated belief might be that "all people with mental illness are dangerous."

Values

Values are abstract standards, positive or negative, that represent an individual's ideal mode of conduct and ideal goals. Examples of ideal modes of conduct include seeking truth and beauty; being clean and orderly; and behaving with sincerity, justice, reason, compassion, humility, respect, honor, and loyalty. Examples of ideal goals are security, happiness, freedom, equality, ecstasy, fame, and power.

Values differ from attitudes and beliefs in that they are action oriented or action producing. One may hold many attitudes and beliefs without behaving in a way that shows they hold those attitudes and beliefs. For example, a nurse may believe that all clients have the right to be told the truth about their diagnosis; however, he or she may not always act on the belief by telling all clients the complete truth about their conditions. Only when the belief is acted on does it become a value.

Attitudes and beliefs flow out of one's set of values. An individual may have thousands of beliefs and hundreds of attitudes, but his or her values probably number only in the dozens. Values may be viewed as a kind of core concept or basic standard that determines one's attitudes, beliefs, and ultimately, behavior. Raths, Harmin, and Simon (1978) identified a seven-step process of valuing that can be used to help clarify personal values. This process is presented in Table 7–1. The process can be used by applying these seven steps to an attitude or belief that one holds. When an attitude or belief has met each of the seven criteria, it can be considered a value.

TABLE 7–1 **The Process of Values Clarification**			
LEVEL OF OPERATIONS	**CATEGORY**	**CRITERIA**	**EXPLANATION**
Cognitive	Choosing	1. Freely 2. From alternatives 3. After careful consideration of the consequences	"This value is mine. No one forced me to choose it. I understand and accept the consequences of holding this value."
Emotional	Prizing	4. Satisfied; pleased with the choice 5. Making public affirmation of the choice, if necessary	"I am proud that I hold this value, and I am willing to tell others about it."
Behavioral	Acting	6. Taking action to demonstrate the value behaviorally 7. Demonstrating this pattern of behavior consistently and repeatedly	The value is reflected in the individual's behavior for as long as he or she holds it.

The Johari Window

The self arises out of self-appraisal and the appraisal of others. It represents each individual's unique pattern of values, attitudes, beliefs, behaviors, emotions, and needs. Self-awareness is the recognition of these aspects and understanding about their impact on the self and others. The Johari Window, presented in Figure 7–1, is a representation of the self and a tool that can be used to increase self-awareness (Luft, 1970). The Johari Window is divided into four quadrants (four aspects of the self): the open self, the unknowing self, the private self, and the unknown self.

The Open or Public Self

The upper-left quadrant of the window represents the part of the self that is public; that is, aspects of the self about which both the individual and others are aware.

EXAMPLE

Susan, a nurse who is the adult child of an alcoholic, has strong feelings about helping alcoholics to achieve sobriety. She volunteers her time as a support person on call to help recovering alcoholics. She is aware of her feelings and her desire to help others. Members of the Alcoholics Anonymous group in which she volunteers her time are also aware of Susan's feelings, and they feel comfortable calling her when they need help with refraining from drinking.

The Unknowing Self

The upper-right quadrant of the window represents the part of the self that is known to others but remains hidden from the awareness of the individual.

EXAMPLE

When Susan takes care of patients in detoxification, she does so without emotion, tending to the technical aspects of the task in a way that the patients perceive as cold and judgmental. She is unaware that she comes across to patients in this way.

The Private Self

The lower-left quadrant of the window represents the part of the self that is known to the individual but which the individual deliberately and consciously conceals from others.

EXAMPLE

Susan would prefer not to take care of the clients in detoxification because doing so provokes painful memories from her childhood. However, because she does not want the other staff members to know about these feelings, she volunteers to take care of the detoxification clients whenever they are assigned to her unit.

The Unknown Self

The lower-right quadrant of the window represents the part of the self that is unknown to both the individual and to others.

EXAMPLE

Susan felt very powerless as a child growing up with an alcoholic father. She seldom knew in what condition she would find her father or what his behavior would be. She learned over the years to find small ways to maintain control over her life situation, and she left home as soon as she graduated from high school. The need to stay in control has always been very important to Susan, and she is unaware that working with recovering alcoholics helps to fulfill this need. The people she is helping are also unaware that Susan is satisfying an unfulfilled personal need as she provides them with assistance.

The goal of increasing self-awareness by using the Johari Window is to increase the size of the quadrant that represents

|	Known to Self	Unknown to Self
Known to Others	The open or public self	The unknowing self
Unknown to Others	The private self	The unknown self

FIGURE 7–1 The Johari window. (From Luft, J. [1970]. *Group processes: An introduction to group dynamics* [3rd ed.]. Palo Alto, CA: Mayfield Publishing, 1984, with permission.)

the open or public self. The individual who is open to self and others has the ability to be spontaneous and to share emotions and experiences with others. This individual also has a greater understanding of personal behavior and of others' responses to him or her. Increased self-awareness allows an individual to interact comfortably with others, to accept the differences in others, and to observe each person's right to respect and dignity.

Conditions Essential to Development of a Therapeutic Relationship

Several characteristics that enhance the achievement of a therapeutic relationship have been identified. These concepts are highly significant to the use of self as the therapeutic tool in interpersonal relationship development.

Rapport

Getting acquainted and establishing **rapport** is the primary task in relationship development. Rapport implies special feelings on the part of both the client and the nurse based on acceptance, warmth, friendliness, common interest, a sense of trust, and a nonjudgmental attitude. Establishing rapport may be accomplished by discussing non-health-related topics. Travelbee (1971) states:

> [To establish rapport] is to create a sense of harmony based on knowledge and appreciation of each individual's uniqueness. It is the ability to be still and experience the other as a human being—to appreciate the unfolding of each personality one to the other. The ability to truly care for and about others is the core of rapport. (pp. 152; 155)

Trust

To trust another, one must feel confidence in that person's presence, reliability, integrity, veracity, and sincere desire to provide assistance when requested. As discussed in the chapter Theoretical Models of Personality Development (available online at www.davisplus.com), trust is the initial developmental task described by Erikson. If the task has not been achieved, this component of relationship development becomes more difficult. That is not to say that trust cannot be established, but only that additional time and patience may be required on the part of the nurse.

> **CLINICAL PEARL** The nurse must convey an aura of trustworthiness, which requires that he or she possess a sense of self-confidence. Confidence in the self is derived from knowledge gained through achievement of personal and professional goals as well as the ability to integrate these roles and to function as a unified whole.

Trust cannot be presumed; it must be earned. Trustworthiness is demonstrated through nursing interventions that convey a sense of warmth and caring to the client. These interventions are initiated simply and concretely and directed toward activities that address the client's basic needs for physiological and psychological safety and security. Many psychiatric clients experience **concrete thinking,** which focuses their thought processes on specifics rather than generalities and on immediate issues rather than eventual outcomes. Examples of nursing interventions that promote trust in an individual who is thinking concretely include the following:

- Providing a blanket when the client is cold
- Providing food when the client is hungry
- Keeping promises
- Being honest (e.g., saying "I don't know the answer to your question, but I'll try to find out") and then following through
- Simply and clearly providing reasons for certain policies, procedures, and rules
- Providing a written, structured schedule of activities
- Attending activities with the client if he or she is reluctant to go alone
- Being consistent in adhering to unit guidelines
- Listening to the client's preferences, requests, and opinions and making collaborative decisions concerning his or her care whenever possible
- Ensuring **confidentiality;** providing reassurance that what is discussed will not be repeated outside the boundaries of the health-care team

Trust is the basis of a therapeutic relationship. The nurse working in psychiatry must perfect the skills that foster the development of trust. Trust must be established in order for the nurse-client relationship to progress beyond the superficial level of tending to the client's immediate needs.

Respect

To show respect is to believe in the dignity and worth of an individual regardless of his or her unacceptable behavior. The psychologist Carl Rogers called this **unconditional positive regard** (Raskin, Rogers, & Witty, 2014). The attitude is nonjudgmental, and the respect is unconditional in that it does not depend on the behavior of the client to meet certain standards. The nurse, in fact, may not approve of the client's lifestyle or behavior patterns. However, with unconditional positive regard, the client is accepted and respected for no other reason than that he or she is considered to be a worthwhile and unique human being.

Many psychiatric clients have very little self-respect. Sometimes lack of self-respect is related to the low self-esteem that accompanies illnesses such as clinical

depression, and sometimes it is related to rejection and stigmatization by others. Recognition that they are unconditionally accepted and respected as unique, valuable individuals can elevate feelings of self-worth and self-respect. The nurse can convey an attitude of respect by

- Calling the client by name (and title, if he or she prefers).
- Spending time with the client.
- Allowing sufficient time to answer the client's questions and concerns.
- Promoting an atmosphere of privacy during therapeutic interactions with the client and during physical examination or therapy.
- Always being open and honest with the client, even when the truth may be difficult to discuss.
- Listening to the client's ideas, preferences, and opinions and making collaborative decisions concerning his or her care whenever possible.
- Striving to understand the motivation behind the client's behavior regardless of how unacceptable it may seem.

Genuineness

The concept of **genuineness** refers to the nurse's ability to be open, honest, and "real" in interactions with the client. To be real is to be aware of what one is experiencing internally and to allow the quality of this inner experience to be apparent in the therapeutic relationship. When one is genuine, there is *congruence* between what is felt and what is expressed (Raskin et al., 2014). The nurse who is genuine responds to the client with truth and honesty rather than with responses he or she may consider more "professional" or ones that merely reflect the "nursing role."

Genuineness may call for a degree of *self-disclosure* on the part of the nurse. This is not to say that the nurse must disclose to the client *everything* he or she is feeling or *all* personal experiences that relate to what the client is going through. Indeed, care must be taken when using self-disclosure to avoid reversing the roles of nurse and client. For example, when a client tells the nurse, "I just get so upset when someone disrespects me; sometimes you have to smack someone to teach them a lesson," the nurse might respond, "I get upset by that, too. Let's talk about some different ways to respond to your anger rather than hitting someone." In this example, the nurse discloses a common feeling while maintaining a focus on the client's need for problem-solving. When the nurse uses self-disclosure, a quality of "humanness" is revealed to the client, creating a role for the client to model in similar situations. The client may then feel more comfortable revealing personal information to the nurse.

Most individuals have an uncanny ability to detect when others are artificial. When the nurse does not bring genuineness and respect to the relationship, a reality basis for trust cannot be established. These qualities are essential to helping the client actualize his or her potential within the nurse-client relationship and for change and growth to occur (Raskin et al., 2014).

Empathy

Empathy is the ability to see beyond outward behavior and understand the situation from the client's point of view. With empathy, the nurse can accurately perceive and comprehend the meaning and relevance of the client's thoughts and feelings. The nurse must also be able to communicate this perception to the client by attempting to translate words and behaviors into feelings.

It is not uncommon for the concept of empathy to be confused with that of **sympathy.** The major difference is that with *empathy* the nurse "accurately perceives or understands" what the client is feeling and encourages the client to explore these feelings. With *sympathy* the nurse actually "shares" what the client is feeling and experiences a need to alleviate distress. Schuster (2000) stated:

> Empathy means that you remain emotionally separate from the other person, even though you can see the patient's viewpoint clearly. This is different from sympathy. Sympathy implies taking on the other's needs and problems as if they were your own and becoming emotionally involved to the point of losing your objectivity. To empathize rather than sympathize, you must show feelings but not get caught up in feelings or overly identify with the patient's and family's concerns. (p. 102)

Empathy is considered to be one of the most important characteristics of a therapeutic relationship. Accurate empathetic perceptions on the part of the nurse assist the client to identify feelings that may have been suppressed or denied. Positive emotions are generated as the client realizes that he or she is truly understood by another. As the feelings surface and are explored, the client learns aspects about self of which he or she may have been unaware. This contributes to the process of personal identification and the promotion of positive self-concept.

With empathy, while understanding the client's thoughts and feelings, the nurse is able to maintain sufficient objectivity to allow the client to achieve problem resolution with minimal assistance. With sympathy, the nurse actually feels what the client is feeling, objectivity is lost, and the nurse may become focused on relief of personal distress rather than on helping the client resolve the problem at hand. The

following is an example of an empathetic and sympathetic response to the same situation.

EXAMPLE

Situation: BJ is a client on the psychiatric unit with a diagnosis of persistent depressive disorder (dysthymia). She is 5′5½″ tall and weighs 295 pounds. BJ has been overweight all her life. She is single, has no close friends, and has never had an intimate relationship with another person. It is her first day on the unit, and she is refusing to come out of her room. When she appeared for lunch in the dining room following admission, she was embarrassed when several of the other clients laughed out loud and called her "fatso."

Sympathetic response: Nurse: "I can certainly identify with what you are feeling. I've been overweight most of my life, too. I just get so angry when people act like that. They are so insensitive! It's just so typical of skinny people to act that way. You have a right to want to stay away from them. We'll just see how loud they laugh when *you* get to choose what movie is shown on the unit after dinner tonight."

Empathetic response: Nurse: "You feel angry and embarrassed by what happened at lunch today." As tears fill BJ's eyes, the nurse encourages her to cry if she feels like it and to express her anger at the situation. She stays with BJ but does not dwell on her *own* feelings about what happened. Instead, she focuses on BJ and what the client perceives are her most immediate needs at this time.

Rapport, trust, respect, genuineness, and empathy all are essential to forming therapeutic relationships, and they can be assets in social relationships, too. The primary differences between social and therapeutic relationships are that therapeutic relationships always remain focused on the health-care needs of the client, are never for the purpose of addressing the nurse's personal needs, and progress through identified phases of development for the purpose of helping the client solve health-related problems.

Phases of a Therapeutic Nurse-Client Relationship

Psychiatric nurses use interpersonal relationship development as the primary intervention with clients in psychiatric-mental health settings. This is congruent with Peplau's (1962) identification of *counseling* as the major subrole of nursing in psychiatry. Sullivan (1953), from whom Peplau patterned her own interpersonal theory of nursing, strongly believed that many emotional problems were closely related to difficulties with interpersonal relationships. With this concept in mind, this role of the nurse in psychiatry becomes especially meaningful and purposeful—an integral part of the total therapeutic regimen.

The therapeutic interpersonal relationship is the means by which the nursing process is implemented. Through the relationship, problems are identified and resolution is sought. Tasks of the relationship have been categorized into four phases: (1) the preinteraction phase, (2) the orientation (introductory) phase, (3) the working phase, and (4) the termination phase. Although each phase is presented as specific and distinct from the others, there may be some overlap of tasks, particularly when the interaction is limited. The major nursing goals during each phase of the nurse-client relationship are listed in Table 7–2.

The Preinteraction Phase

The preinteraction phase involves preparation for the first encounter with the client. Tasks include

■ Obtaining available information about the client from his or her chart, significant others, or other health-care team members. From this information, the initial assessment begins. The nurse may also become aware of personal responses to knowledge about the client.

■ Examining one's feelings, fears, and anxieties about working with a particular client. For example, the nurse may have been reared in an alcoholic family and have ambivalent feelings about caring for a client who is dependent on alcohol. All individuals bring attitudes and feelings from prior experiences to the clinical setting. The nurse needs to be aware of how these preconceptions may affect his or her ability to care for individual clients.

The Orientation (Introductory) Phase

During the orientation phase, the nurse and client become acquainted. Tasks include

■ Creating an environment for the establishment of trust and rapport.

■ Establishing a contract for intervention that details the expectations and responsibilities of both nurse and client.

TABLE 7–2	Phases of Relationship Development and Major Nursing Goals
PHASE	**GOALS**
1. Preinteraction	Explore self-perceptions
2. Orientation (introductory)	Establish trust Formulate contract for intervention
3. Working	Promote client change
4. Termination	Evaluate goal attainment Ensure therapeutic closure

■ Gathering assessment information to build a strong client database.
■ Identifying the client's strengths and limitations.
■ Formulating nursing diagnoses.
■ Setting goals that are mutually agreeable to the nurse and client.
■ Developing a plan of action that is realistic for meeting the established goals.
■ Exploring feelings of both the client and nurse in terms of the introductory phase.

Introductions are often uncomfortable, and the participants may experience some anxiety until a degree of rapport has been established. Interactions may remain on a superficial level until anxiety subsides. Several interactions may be required to fulfill the tasks associated with this phase.

The Working Phase

The therapeutic work of the relationship is accomplished during this phase. Tasks include

■ Maintaining the trust and rapport established during the orientation phase.
■ Promoting the client's insight and perception of reality.
■ Problem-solving using the model presented earlier in this chapter.
■ Overcoming resistance behaviors on the part of the client as the level of anxiety rises in response to discussion of painful issues.
■ Continuously evaluating progress toward goal attainment.

Transference and Countertransference

Transference and countertransference are common phenomena that often arise during the course of a therapeutic relationship.

Transference

Transference occurs when the client unconsciously displaces (or "transfers") to the nurse feelings formed toward a person from his or her past (Sadock, Sadock, & Ruiz, 2015). These feelings may be triggered by something about the nurse's appearance or personality characteristics that reminds the client of another person. Transference can interfere with the therapeutic interaction when the feelings expressed include anger and hostility. Anger toward the nurse can be manifested by uncooperativeness and resistance to therapy.

Transference can also take the form of overwhelming affection for or excessive dependency on the nurse. The nurse is overvalued, and the client forms unrealistic expectations of the nurse. When the nurse is unable to fulfill those expectations or meet the excessive dependency needs, the client becomes angry and hostile.

Interventions for Transference

Hilz (2013) states:

> In cases of transference, the relationship does not usually need to be terminated, except when the transference poses a serious barrier to therapy or safety. The nurse should work with the patient in sorting out the past from the present, assist the patient into identifying the transference, and reassign a new and more appropriate meaning to the current nurse-patient relationship. The goal is to guide patients toward independence by teaching them to assume responsibility for their own behaviors, feelings, and thoughts, and to assign the correct meanings to their relationships based on present circumstances instead of the past.

Countertransference

Countertransference refers to the nurse's behavioral and emotional responses to the client in which the nurse transfers feelings (often unconscious) about past experiences or people onto the patient. These responses may be related to unresolved feelings toward significant others from the nurse's past, or they may be generated in response to transference feelings on the part of the client. It is not easy to refrain from becoming angry when the client is consistently antagonistic, to feel flattered when showered with affection and attention by the client, or even to feel quite powerful when the client exhibits excessive dependency on the nurse. These feelings can interfere with the therapeutic relationship when they initiate the following types of behaviors:

■ The nurse overidentifies with the client's feelings, as they remind him or her of problems from the nurse's past or present.
■ The nurse and client develop a social or personal relationship.
■ The nurse begins to give advice or attempts to "rescue" the client.
■ The nurse encourages and promotes the client's dependence.
■ The nurse's anger engenders feelings of disgust toward the client.
■ The nurse feels anxious and uneasy in the presence of the client.
■ The nurse is bored and apathetic in sessions with the client.
■ The nurse has difficulty setting limits on the client's behavior.
■ The nurse defends the client's behavior to other staff members.

The nurse may be completely unaware or only minimally aware of the countertransference as it is occurring (Hilz, 2013).

Interventions for Countertransference

Hilz (2013) states:

> The relationship usually should not be terminated in the presence of countertransference. Rather, the nurse or staff member experiencing the countertransference should be supportively assisted by other staff members to identify his or her feelings and behaviors and recognize the occurrence of the phenomenon. It may be helpful to have evaluative sessions with the nurse after his or her encounter with the patient, in which both the nurse and other staff members (who are observing the interactions) discuss and compare the exhibited behaviors in the relationship.

The Termination Phase

Termination of the relationship may occur for a variety of reasons: the mutually agreed-on goals may have been reached, the client may be discharged from the hospital, or, in the case of a student nurse, the clinical rotation ends. Termination can be difficult for both the client and nurse. The main task involves bringing a therapeutic conclusion to the relationship. This occurs when

- Progress has been made toward attainment of mutually set goals.
- A plan for continuing care or for assistance during stressful life experiences is mutually established by the nurse and client.
- Feelings about termination of the relationship are recognized and explored. Both the nurse and client may experience feelings of sadness and loss. The nurse should share his or her feelings with the client. Through these interactions, the client learns that it is acceptable to have these kinds of feelings at a time of separation. With this knowledge, the client experiences growth during the process of termination. This is also a time when both nurse and client may evaluate and summarize the learning that occurred as an outgrowth of their relationship.

> **CLINICAL PEARL** When the client feels sadness and loss, behaviors to delay termination may become evident. If the nurse experiences the same feelings, he or she may allow the client's behaviors to delay termination. For therapeutic closure, the nurse must establish the reality of the separation and resist being manipulated into repeated delays by the client.

Boundaries in the Nurse-Client Relationship

A boundary indicates a border that determines the extent of acceptable limits. Many types of boundaries exist, such as the following:

- **Material boundaries:** These are physical property that can be seen, such as fences that border land.
- **Social boundaries:** These are established within a culture and define how individuals are expected to behave in social situations.
- **Personal boundaries:** These are boundaries that individuals define for themselves. They include *physical distance boundaries,* or just how close individuals will allow others to invade their physical space; and *emotional boundaries,* or how much individuals choose to disclose of their most private and intimate selves to others.
- **Professional boundaries:** These boundaries limit and outline expectations for appropriate professional relationships with clients. "Professional boundaries are the spaces between a nurse's power and the patient's vulnerability" (National Council of State Boards of Nursing [NCSBN], 2014). Nurses must recognize that they have an imbalance of power with their patients by virtue of their role and the patient information to which they have access. They must be consistently conscientious in avoiding any circumstance in which they might achieve personal gain within that relationship. Concerns regarding professional boundaries are commonly related to the following issues:
  - **Self-disclosure:** Self-disclosure on the part of the nurse may be appropriate when the information may therapeutically benefit the client. It should never be undertaken to meet the nurse's needs.
  - **Gift-giving:** Individuals who are receiving care often feel indebted toward health-care providers. Indeed, gift-giving may be part of the therapeutic process for people who receive care (College and Association of Registered Nurses of Alberta, 2011). Cultural beliefs and values may also enter into the decision of whether to accept a gift from a client. In some cultures, failure to do so would be interpreted as an insult (Pies, 2012). Accepting financial gifts is never appropriate, but in some instances nurses may be permitted to suggest instead a donation to a charity of the client's choice. If acceptance of a small gift of gratitude is deemed appropriate, the nurse may choose to share it with other staff members who have been involved in the client's care. In all instances, nurses should exercise professional judgment when deciding whether to accept a gift from a client. Attention should be given to what the gift-giving means to the client, as well as to institutional policy, the American Nurses Association (ANA) *Code of Ethics for Nurses,* and the ANA *Scope and Standards of Practice.*
  - **Touch:** Nursing by its very nature involves touching clients. Touching is required to perform the therapeutic procedures involved in the physical care of clients. Caring touch is the touching of clients when there is no physical need to do so. Touching or hugging can be beneficial when it

is implemented with therapeutic intent and client consent. When using caring touch, make sure it is appropriate, supportive, and welcomed (College of Registered Nurses of British Columbia, 2015). Caring touch may provide comfort or encouragement, but some vulnerable clients may misinterpret its meaning. In certain cultures, such as within Navajo Indian, Chinese, and Japanese heritages, touch is not considered acceptable unless the parties know each other very well (Purnell, 2014). The nurse must be sensitive to these cultural nuances and aware when touch is crossing a personal boundary. Additionally, clients who are experiencing high levels of anxiety or suspicious or psychotic behavior may interpret touch as aggressiveness. These are times when touch should be avoided or considered with extreme caution.

■ **Friendship or romantic association:** When a nurse is acquainted with a client, the relationship must move from a personal nature to professional. If the nurse is unable to accomplish this separation, he or she should withdraw from the nurse-client relationship. Likewise, nurses must guard against personal relationships developing as a result of the nurse-client relationship. Romantic, sexual, or otherwise intimate personal relationships are never appropriate between nurse and client.

Certain warning signs indicate that professional boundaries of the nurse-client relationship may be in jeopardy. These may include (Coltrane & Pugh, 1978)

■ Favoring one client's care over that of another.
■ Keeping secrets with a client.
■ Changing dress style for working with a particular client.
■ Swapping assignments to care for a particular client.
■ Giving special attention or treatment to one client over others.
■ Spending free time with a client.
■ Frequently thinking about the client when away from work.
■ Sharing personal information or work concerns with the client.
■ Receipt of gifts or continued contact or communication with the client after discharge.

Boundary crossing can threaten the integrity of the nurse-client relationship. Nurses must gain self-awareness and insight to recognize when professional integrity is compromised. Although some variables, such as the care setting, community influences, patient needs, and the nature of therapy, affect how boundaries are delineated, "any actions that overstep the established boundaries to meet the needs of the nurse are boundary violations" (NCSBN, 2014).

Summary and Key Points

■ Nurses who work in the psychiatric-mental health field use special skills, or "interpersonal techniques," to assist clients in adapting to difficulties or changes in life experiences. Therapeutic nurse-client relationships are goal oriented, and the problem-solving model is used to try to bring about some type of change in the client's life.
■ The instrument for delivery of the process of interpersonal nursing is the therapeutic use of self, which requires that the nurse possess a strong sense of self-awareness and self-understanding.
■ Hildegard Peplau identified seven subroles within the role of nurse: stranger, resource person, teacher, leader, surrogate, technical expert, and counselor.
■ Characteristics that enhance the achievement of a therapeutic relationship include rapport, trust, respect, genuineness, and empathy.
■ Phases of a therapeutic nurse-client relationship include the preinteraction phase, the orientation (introductory) phase, the working phase, and the termination phase.
■ Transference occurs when the client unconsciously displaces (or "transfers") to the nurse feelings formed toward a person from the past.
■ Countertransference refers to the nurse's behavioral and emotional response to the client in which the nurse transfers feelings (often unconscious) about past experiences or people onto the patient. These responses may be related to unresolved feelings toward significant others from the nurse's past, or they may be generated in response to transference feelings on the part of the client.
■ Types of boundaries include material, social, personal, and professional.
■ Concerns associated with professional boundaries include self-disclosure, gift-giving, touch, and developing a friendship or romantic association.
■ Boundary crossings can threaten the integrity of the nurse-client relationship.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Nurse Mary has been providing care for Tom during his hospital stay. On Tom's day of discharge, his wife brings a bouquet of flowers and box of chocolates to his room. He presents these gifts to Nurse Mary, saying, "Thank you for taking care of me." What is a correct response by the nurse?
   a. "I don't accept gifts from patients."
   b. "Thank you so much! It is so nice to be appreciated."
   c. "Thank you. I will share these with the rest of the staff."
   d. "Hospital policy forbids me to accept gifts from patients."

2. Elisa says to the nurse, "I worked as a secretary to put my husband through college, and as soon as he graduated, he left me. I hate him! I hate all men!" Which of the following is an empathetic response by the nurse?
   a. "You are very angry now. This is a normal response to your loss."
   b. "I know what you mean. Men can be very insensitive."
   c. "I understand completely. My husband divorced me, too."
   d. "You are depressed now, but you will feel better in time."

3. Which of the following behaviors suggest a possible breach of professional boundaries? (Select all that apply.)
   a. The nurse repeatedly requests to be assigned to a specific client.
   b. The nurse shares the details of her divorce with the client.
   c. The nurse makes arrangements to meet the client outside of the therapeutic environment.
   d. The nurse shares how she dealt with a similar difficult situation.

4. Which of the following tasks are associated with the orientation phase of relationship development? (Select all that apply.)
   a. Promoting the client's insight and perception of reality
   b. Creating an environment for the establishment of trust and rapport
   c. Using the problem-solving model toward goal fulfillment
   d. Obtaining available information about the client from various sources
   e. Formulating nursing diagnoses and setting goals

5. Nurse Rosetta, who is the adult child of an alcoholic, is working with John, a client who abuses alcohol. John has experienced a successful detoxification process and is beginning a rehabilitation program. He says to Rosetta, "I'm not going to go to those stupid AA meetings. They don't help anything." Rosetta, whose father died of complications from alcoholism, responds with anger: "Don't you even care what happens to your children?" Rosetta's response is an example of which of the following?
   a. Transference
   b. Countertransference
   c. Self-disclosure
   d. A breach of professional boundaries

6. Nurse Jones is working with Kim, a client in the anger-management program. Which of the following identifies actions associated with the working phase of the therapeutic relationship?
   a. Kim tells Nurse Jones she wants to learn more adaptive ways to handle her anger. Together, they set some goals.
   b. The goals of therapy have been met, but Kim cries and says she has to keep coming to therapy in order to be able to handle her anger appropriately.
   c. Nurse Jones reads Kim's previous medical records. She explores her feelings about working with a woman who has abused her child.
   d. Nurse Jones helps Kim practice various techniques to control her angry outbursts. She gives Kim positive feedback for attempting to improve maladaptive behaviors.

Review Questions—cont'd
Self-Examination/Learning Exercise

7. When there is congruence between what is felt and what is expressed, the nurse is exhibiting which of the following characteristics?
   a. Trust
   b. Respect
   c. Genuineness
   d. Empathy

8. When the nurse shows unconditional acceptance of an individual as a worthwhile and unique human being, he or she is exhibiting which of the following characteristics?
   a. Trust
   b. Respect
   c. Genuineness
   d. Empathy

9. Hildegard Peplau identified seven subroles within the role of the nurse. She believed the emphasis in psychiatric nursing was on which of the subroles?
   a. The resource person
   b. The teacher
   c. The surrogate
   d. The counselor

10. Which of the following behaviors are associated with the phenomenon of *transference?* (Select all that apply.)
   a. The client attributes toward the nurse feelings associated with a person from the client's past.
   b. The nurse attributes toward the client feelings associated with a person from the nurse's past.
   c. The client forms an overwhelming affection for the nurse.
   d. The client becomes excessively dependent on the nurse and forms unrealistic expectations of him or her.

Therapeutic Communication

8

CHAPTER OUTLINE

Objectives

Homework Assignment

What Is Communication?

The Impact of Preexisting Conditions

Nonverbal Communication

Therapeutic Communication Techniques

Nontherapeutic Communication Techniques

Active Listening

Motivational Interviewing

Process Recordings

Feedback

Summary and Key Points

Review Questions

KEY TERMS

density

distance

intimate distance

motivational interviewing

paralanguage

personal distance

public distance

social distance

territoriality

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss the transactional model of communication.
2. Identify types of preexisting conditions that influence the outcome of the communication process.
3. Define *territoriality, density,* and *distance* as components of the environment.
4. Identify components of nonverbal expression.
5. Describe therapeutic and nontherapeutic verbal communication techniques.
6. Describe motivational interviewing as a communication strategy.
7. Describe active listening.
8. Discuss therapeutic feedback.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. A client asks the nurse for advice about a personal situation, and the nurse responds, "What do *you* think you should do?" This is an example of what technique? Is it therapeutic or nontherapeutic?
2. "Just hang in there. Everything will be all right." If the nurse makes this statement to a client, it is an example of what technique? Is it therapeutic or nontherapeutic?
3. Why might it be more appropriate to conduct a client interview in a conference room or interview room rather than in the client's room or nurse's office?
4. Name the five elements of constructive feedback.
5. Write a one-page journal entry reflecting on things that friends or close relatives have told you characterize your style of communicating with others. How can you use this self-awareness to promote the development of therapeutic communication?

Development of the *therapeutic interpersonal relationship* was described in Chapter 7, Relationship Development, as the process by which nurses provide care for clients in need of psychosocial intervention. *Therapeutic use of self* was identified as the instrument for delivery of care. The focus of this chapter is on *techniques*—or, more specifically, *interpersonal communication techniques*—to facilitate the delivery of that care.

In their classic work on therapeutic communication, Hays and Larson (1963) stated, "To relate therapeutically with a patient it is necessary for the nurse to understand his or her role and its relationship to the patient's illness" (p. 1). They describe the role of the nurse as providing the client with the opportunity to accomplish the following:

1. Identify and explore problems in relating to others.
2. Discover healthy ways of meeting emotional needs.
3. Experience a satisfying interpersonal relationship.

These goals are achieved through use of interpersonal communication techniques (both verbal and nonverbal). The nurse must be aware of the therapeutic or nontherapeutic value of the communication techniques used with the client because they are the tools of psychosocial intervention.

CORE CONCEPT

Communication

An interactive process of transmitting information between two or more entities.

What Is Communication?

It has been said that individuals "cannot *not* communicate." Every word spoken, every movement made, and every action taken or not taken gives a message to someone. Interpersonal communication is a *transaction* between the sender and the receiver. In the transactional model of communication, both participants simultaneously perceive each other, listen to each other, and are mutually involved in creating meaning in a relationship. The transactional model is illustrated in Figure 8–1.
FIGURE 8–1   The Transactional Model of Communication.

The Impact of Preexisting Conditions

In all interpersonal transactions, the sender and receiver each bring certain preexisting conditions to the exchange that influence both the intended message and the way in which it is interpreted. Examples of these conditions include one's value system, internalized attitudes and beliefs, culture and religion, social status, gender, background knowledge and experience, and age or developmental level. The type of environment in which the communication takes place may also influence the outcome of the transaction. Figure 8–2 shows how these influencing factors are positioned on the transactional model.

Values, Attitudes, and Beliefs

Values, attitudes, and beliefs are learned ways of thinking. Children generally adopt the value systems and internalize the attitudes and beliefs of their parents. Children may retain this way of thinking into adulthood or develop a different set of attitudes and values as they mature.

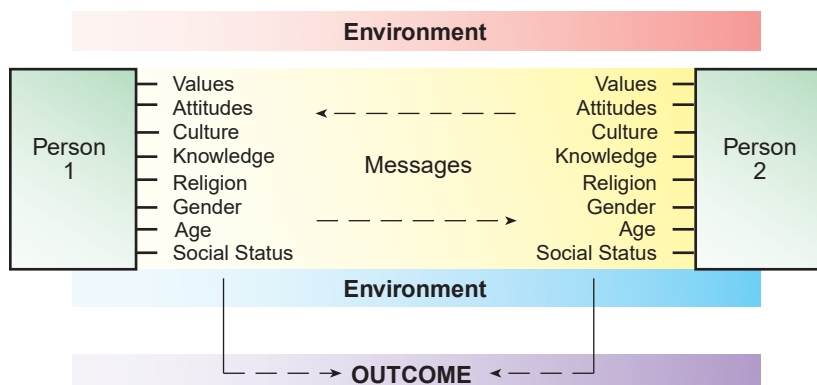
Values, attitudes, and beliefs can influence communication in numerous ways. For example, prejudice is expressed verbally through negative stereotyping.


FIGURE 8–2   Factors influencing the Transactional Model of Communication.

One's value system may be communicated with behaviors that are symbolic in nature. For example, an individual who values youth may dress and behave in a manner that is characteristic of one who is much younger. Persons who value freedom and the American way of life may fly the U.S. flag in front of their homes each day. In each of these situations, a message is being communicated.

Culture and Religion

Communication has its roots in culture. Cultural mores, norms, ideas, and customs provide the basis for our way of thinking. Cultural values are learned and differ from society to society. For example, in some European countries (e.g., Italy, Spain, and France), men may greet each other with hugs and kisses. These behaviors are appropriate in those cultures but may communicate a different message in the United States or England.

Religion can influence communication as well. Priests and ministers who wear clerical collars publicly communicate their mission in life. The collar may also influence the way in which others relate to them, either positively or negatively. Other symbolic gestures, such as wearing a cross around the neck or hanging a crucifix on the wall, communicate an individual's religious beliefs.

Social Status

Studies of nonverbal indicators of social status or power have suggested that high-status persons are associated with gestures that communicate their higher-power position. For example, they use less eye contact, have a more relaxed posture, use louder voice pitch, place hands on hips more frequently, are "power dressers," have greater height, and maintain more distance when communicating with individuals considered to be of lower social status.

Gender

Gender influences the manner in which individuals communicate. Most cultures have *gender signals* that are recognized as either masculine or feminine and provide a basis for distinguishing between members of each gender. Examples include differences in posture, both standing and sitting, between men and women in the United States. Men usually stand with thighs 10 to 15 degrees apart, the pelvis rolled back, and the arms slightly away from the body. Women often stand with legs close together, the pelvis tipped forward, and the arms close to the body. When sitting, men may lean back in the chair with legs apart or may rest the ankle of one leg over the knee of the other. Women tend to sit more upright in the chair with legs together, perhaps crossed at the ankles, or one leg crossed over the other at thigh level.

Roles have historically been identified as either male or female. For example, in the United States masculinity typically was communicated through such roles as husband, father, breadwinner, doctor, lawyer, or engineer. Traditional female roles included those of wife, mother, homemaker, nurse, teacher, or secretary.

Gender signals are changing in U.S. society as sexual roles become less distinct. Behaviors that had been considered typically masculine or feminine in the past may now be generally accepted in members of both genders. Words such as *unisex* communicate a desire by some individuals to diminish the distinction between genders and minimize the discrimination of either. Gender roles are changing as both women and men enter professions that were once dominated by members of the opposite gender.

Age or Developmental Level

Age influences communication, which is never more evident than during adolescence. In their struggle to separate from parental confines and establish their own identity, adolescents generate a unique pattern of communication that changes from generation to generation. Words such as *dude, groovy, clueless, awesome, cool,* and *wasted* have had special meaning for certain generations of adolescents. The technological age has produced a whole new language for today's teenagers. Communication by text messaging includes such acronyms as BRB ("be right back"), BFF ("best friends forever"), and MOS ("mom over shoulder").

Developmental influences on communication may relate to physiological alterations. One example is American Sign Language, the system of unique gestures used by many people who are deaf or hearing impaired. Individuals who are blind at birth never learn the subtle nonverbal gesticulations that accompany language, which can totally change the meaning of the spoken word.

Environment in Which the Transaction Takes Place

The place where communication occurs influences the outcome of the interaction. Some individuals who feel uncomfortable and refuse to speak during a group therapy session may be willing to discuss problems privately on a one-to-one basis with the nurse.

Territoriality, density, and **distance** are aspects of environment that communicate messages. *Territoriality* is the innate tendency to own space. Individuals lay claim to areas around them as their own. This influences communication when an interaction takes place in the territory "owned" by one or the other. Interpersonal communication can be more successful if the interaction takes place in a "neutral" area. For

example, with the concept of territoriality in mind, the nurse may choose to conduct the psychosocial assessment in an interview room rather than in his or her office or in the client's room.

Density refers to the number of people within a given environmental space. It has been shown to influence interpersonal interaction. Some studies indicate that a correlation exists between prolonged high-density situations and certain behaviors, such as aggression, stress, criminal activity, hostility toward others, and a deterioration of mental and physical health.

Distance is the means by which various cultures use space to communicate. Hall (1966) identified four kinds of spatial interaction, or distances, that people maintain from each other in their interpersonal interactions and the kinds of activities in which people engage at these various distances. **Intimate distance** is the closest distance that individuals will allow between themselves and others. In mainstream American culture, this distance, which is restricted to interactions of an intimate nature, is 0 to 18 inches. **Personal distance** is approximately 18 to 40 inches and reserved for interactions that are personal in nature, such as close conversations with friends or colleagues. **Social distance** is about 4 to 12 feet away from the body. Interactions at this distance include conversations with strangers or acquaintances, such as at a cocktail party or in a public building. A **public distance** is one that exceeds 12 feet. Examples include speaking in public or yelling to someone some distance away. This distance is considered public space, and communicants are free to move about in it during the interaction.

Nonverbal Communication

About 70 to 80 percent of all effective communication is nonverbal (Khan, 2014). Some aspects of nonverbal expression were discussed in the previous section on preexisting conditions that influence communication. Other components of nonverbal communication include physical appearance and dress, body movement and posture, touch, facial expressions, eye behavior, and vocal cues or paralanguage. These nonverbal messages vary from culture to culture.

Physical Appearance and Dress

Physical appearance and dress are part of the total nonverbal stimuli that influence interpersonal responses, and under some conditions, they are the primary determinants of such responses. Body coverings—both dress and hair—are manipulated by the wearer in a manner that conveys a distinct message to the receiver. Dress can be formal or casual, stylish or unkempt. Hair can be long or short, and even the presence or absence

of hair conveys a message about the person. Other body adornments that are also considered potential communicative stimuli include tattoos, masks, cosmetics, badges, jewelry, and eyeglasses. Some jewelry worn in specific ways can give special messages (e.g., a gold band or diamond ring worn on the third finger of the left hand, a pin bearing Greek letters worn on the lapel, or the wearing of a ring that is inscribed with the insignia of a college or university). Some individuals convey a specific message with the total absence of any type of body adornment.

Body Movement and Posture

The way in which an individual positions his or her body communicates messages regarding self-esteem, gender identity, status, and interpersonal warmth or coldness. The individual whose posture is slumped, with head and eyes pointed downward, conveys a message of low self-esteem. Specific ways of standing or sitting are considered to be either feminine or masculine within a defined culture. In the United States, to stand straight and tall with head high and hands on hips indicates a superior status over the person being addressed.

Reece and Whitman (1962) identified response behaviors that were used to designate individuals as either "warm" or "cold" persons. Individuals who were perceived as warm responded to others with a shift of posture toward the other person, a smile, direct eye contact, and hands that remained still. Individuals who responded to others with a slumped posture, by looking around the room, drumming fingers on the desk, and not smiling were perceived as cold.

Touch

Touch is a powerful communication tool. It can elicit both negative and positive reactions, depending on the people involved and the circumstances of the interaction. It is a very basic and primitive form of communication, and the appropriateness of its use is culturally determined.

Touch can be categorized according to the message communicated (Knapp & Hall, 2014):

Functional-professional: This type of touch is impersonal and businesslike. It is used to accomplish a task.

EXAMPLE

A tailor measuring a customer for a suit or a physician examining a client

Social-polite: This type of touch is still rather impersonal, but it conveys an affirmation or acceptance of the other person.

EXAMPLE

A handshake

Friendship-warmth: Touch at this level indicates a strong liking for the other person, a feeling that he or she is a friend.

EXAMPLE

Laying one's hand on the shoulder of another

Love-intimacy: This type of touch conveys an emotional attachment or attraction for another person.

EXAMPLE

Engaging in a strong, mutual embrace

Sexual arousal: Touch at this level is an expression of physical attraction only.

EXAMPLE

Touching another in the genital region

Some cultures encourage more touching of various types than do others. "Contact cultures" (e.g., France, Latin America, Italy) use a greater frequency of touch cues than do those in "noncontact cultures" (e.g., Germany, United States, Canada) (Givens, 2013c). The nurse should understand the cultural meaning of touch before using this method of communication in specific situations.

Facial Expressions

Next to human speech, facial expression is the primary source of communication. Facial expressions reveal an individual's emotional state, such as happiness, sadness, anger, surprise, and fear. The face is a complex multimessage system. Facial expressions serve to complement and qualify other communication behaviors and at times even take the place of verbal messages. A summary of feelings associated with various facial expressions is presented in Table 8–1.

Eye Behavior

Eyes have been called the "windows of the soul." It is through eye contact that individuals view and are viewed by others in a revealing way, creating an interpersonal connection. In American culture, eye contact conveys a personal interest in the other person. Eye contact indicates that the communication channel is open, and it is often the initiating factor in verbal interaction between two people.

Eye behavior is regulated by social rules. These rules dictate where, when, for how long, and at whom we can look. Staring is often used to register disapproval of the behavior of another. People are extremely sensitive to being looked at, and if the gazing or staring behavior violates social rules, they often assign meaning to it, such as the following statement implies: "He kept staring at me, and I began to wonder if I was dressed inappropriately or had mustard on my face!"

TABLE 8–1 **Summary of Facial Expressions**	
FACIAL EXPRESSION	**ASSOCIATED FEELINGS**
NOSE	
Nostril flare	Anger; arousal
Wrinkling up	Dislike; disgust
LIPS	
Grin; smile	Happiness; contentment
Grimace	Fear; pain
Compressed	Anger; frustration
Canine-type snarl	Disgust
Pouted; frown	Unhappiness; discontented; disapproval
Pursing	Disagreement
Sneer	Contempt; disdain
BROWS	
Frown	Anger; unhappiness; concentration
Raised	Surprise; enthusiasm
TONGUE	
Stick out	Dislike; disagree
EYES	
Widened	Surprise; excitement
Narrowed; lids squeezed shut	Threat; fear
Stare	Threat
Stare, blink, then look away	Dislike; disinterest
Eyes downcast; lack of eye contact	Submission; low self-esteem
Eye contact (generally intermittent as opposed to a stare)	Self-confidence; interest

SOURCES: Givens, D.B. (2013b). Facial expression. In *The Nonverbal Dictionary of Gestures, Signs, and Body Language Cues.* Retrieved from http://www.nonverbal-dictionary.org/2012/12/facial-expression.html; Hughey, J.D. (1990). *Speech communication.* Stillwater: Oklahoma State University; Simon, M. (2005). *Facial expressions: A visual reference for artists.* New York: Watson-Guptill.

Gazing at another's eyes arouses strong emotions. Thus, eye contact rarely lasts longer than 3 seconds before one or both viewers experience a powerful urge to glance away. Breaking eye contact lowers stress levels (Givens, 2013a).

Vocal Cues or Paralanguage

Paralanguage is the gestural component of the spoken word. It consists of pitch, tone, and loudness of

spoken messages; the rate of speaking; expressively placed pauses; and emphasis assigned to certain words. These vocal cues greatly influence the way individuals interpret verbal messages. A normally soft-spoken individual whose pitch and rate of speaking increases may be perceived as being anxious or tense.

Different vocal emphases can alter interpretation of the message. Three examples follow:

1. "I felt **SURE** you would notice the change."
   Interpretation: I was **SURE** you would, but you didn't.
2. "I felt sure **YOU** would notice the change."
   Interpretation: I thought **YOU** would, even if nobody else did.
3. "I felt sure you would notice the **CHANGE**."
   Interpretation: Even if you didn't notice anything else, I thought you would notice the **CHANGE**.

Verbal cues play a major role in determining responses in human communication situations. *How* a message is verbalized can be as important as *what* is verbalized.

CORE CONCEPT
Therapeutic Communication
Caregiver verbal and nonverbal techniques that focus on the care receiver's needs and advance the promotion of healing and change. Therapeutic communication encourages exploration of feelings and fosters understanding of behavioral motivation. It is nonjudgmental, discourages defensiveness, and promotes trust.

Therapeutic Communication Techniques

Hays and Larson (1963) identified a number of techniques to assist the nurse in interacting more therapeutically with clients. These are important "technical procedures" carried out by the nurse working in psychiatry, and they should serve to enhance development of a therapeutic nurse-client relationship. Table 8–2 includes a list of these techniques, a short explanation of their usefulness, and examples of each.

TABLE 8–2 Therapeutic Communication Techniques

TECHNIQUE	EXPLANATION/RATIONALE	EXAMPLES
Using silence	Silence gives the client the opportunity to collect and organize thoughts, to think through a point, or to consider introducing a topic of greater concern than the one being discussed.	The client pauses midsentence in answering a question. The nurse remains quiet, does not "rescue" the client with prompts or by moving on to another question, and ensures that his or her body language and facial expression project interest in and willingness to wait for the client to answer.
Accepting	Conveys an attitude of reception and regard.	"Yes, I understand what you said." Eye contact; nodding.
Giving recognition	Acknowledging and indicating awareness is better than complimenting, which reflects the nurse's judgment.	"Hello, Mr. J. I notice that you made a ceramic ash tray in OT." "I see you made your bed."
Offering self	Making oneself available on an unconditional basis helps to increase the client's feelings of self-worth.	"I'll stay with you awhile." "We can eat our lunch together." "I'm interested in talking with you."
Giving broad openings	Allowing the client to take the initiative in introducing the topic emphasizes the importance of the client's role in the interaction.	"What would you like to talk about today?" "Tell me what you are thinking."
Offering general leads	General leads, or prompts, offer the client encouragement to continue.	"Yes, I see." "Go on." "And after that?"
Placing the event in time or sequence	Clarifying the relationship of events in time enables the nurse and client to view them in perspective.	"What seemed to lead up to . . . ?" "Was this before or after . . . ?" "When did this happen?"
Making observations	Verbalizing what is observed or perceived encourages the client to recognize specific behaviors and compare perceptions with the nurse.	"You seem tense." "I notice you are pacing a lot." "You seem uncomfortable when you. . . ."

TABLE 8–2 **Therapeutic Communication Techniques–cont'd**		
TECHNIQUE	**EXPLANATION/RATIONALE**	**EXAMPLES**
Encouraging description of perceptions	Asking the client to verbalize what is being perceived is often used with clients experiencing hallucinations.	"Tell me what is happening now." "Are you hearing the voices again?" "What do the voices seem to be saying?"
Encouraging comparison	Asking the client to compare similarities and differences in ideas, experiences, or interpersonal relationships helps the client recognize life experiences that tend to recur as well as those aspects of life that are changeable.	"Was this something like . . . ?" "How does this compare with the time when . . . ?" "What was your response the last time this situation occurred?"
Restating	Repeating the main idea of what the client has said lets the client know whether an expressed statement has been understood and gives him or her the chance to continue or to clarify if necessary.	Cl: "I can't study. My mind keeps wandering." Ns: "You have trouble concentrating." Cl: "I can't take that new job. What if I can't do it?" Ns: "You're afraid you will fail in this new position."
Reflecting	Questions and feelings are referred back to the client so that they may be recognized and accepted and so that the client may recognize that his or her point of view has value—a good technique to use when the client asks the nurse for advice.	Cl: "What do you think I should do about my wife's drinking problem?" Ns: "What do *you* think you should do?" Cl: "My sister won't help a bit with my mother's care. I have to do it all!" Ns: "You feel angry when she doesn't help."
Focusing	Taking notice of a single idea or even a single word works especially well with a client who is moving rapidly from one thought to another. This technique is *not* therapeutic, however, with the client who is very anxious. Focusing should not be pursued until the anxiety level has subsided.	"This point seems worth looking at more closely. Perhaps you and I can discuss it together."
Exploring	Delving further into a subject, idea, experience, or relationship is especially helpful with clients who tend to remain on a superficial level of communication. However, if the client chooses not to disclose further information, the nurse should refrain from pushing or probing in an area that obviously creates discomfort.	"Please explain that situation in more detail." "Tell me more about that particular situation."
Seeking clarification and validation	Striving to explain that which is vague or incomprehensible and searching for mutual understanding of what has been said facilitates and increases understanding for both client and nurse.	"I'm not sure that I understand. Would you please explain?" "Tell me if my understanding agrees with yours." "Do I understand correctly that you said . . . ?"
Presenting reality	When the client has a misperception of the environment, the nurse defines reality or indicates his or her perception of the situation for the client.	"I understand that the voices seem real to you, but I do not hear any voices." "There is no one else in the room but you and me."
Voicing doubt	Expressing uncertainty as to the reality of the client's perceptions is a technique often used with clients experiencing delusional thinking.	"I understand that you believe that to be true, but I see the situation differently." "I find that hard to believe (or accept)." "That seems rather doubtful to me."

Continued

TABLE 8–2	**Therapeutic Communication Techniques—cont'd**	
TECHNIQUE	**EXPLANATION/RATIONALE**	**EXAMPLES**
Verbalizing the implied	Putting into words what the client has only implied or said indirectly is a helpful technique to use with clients who are reticent to speak as well as with clients who are mute or are otherwise experiencing impaired verbal communication. This clarifies that which is *implicit* rather than *explicit.*	Cl: "It's a waste of time to be here. I can't talk to you or anyone." Ns: "Are you feeling that no one understands?" Cl: (Mute) Ns: "It must have been very difficult for you when your husband died in the fire."
Attempting to translate words into feelings	When feelings are expressed indirectly, the nurse tries to "desymbolize" what has been said and to find clues to the underlying true feelings.	Cl: "I'm way out in the ocean." Ns: "You must be feeling very lonely right now."
Formulating a plan of action	When a client has a plan in mind for dealing with what is considered to be a stressful situation, it may serve to prevent anger or anxiety from escalating to an unmanageable level.	"What could you do to let your anger out harmlessly?" "Next time this comes up, what might you do to handle it more appropriately?"

SOURCE: Adapted from Hays, J.S., & Larson, K.H. (1963). *Interacting with patients*. New York: Macmillan.

Nontherapeutic Communication Techniques

Several approaches are considered to be barriers to open communication between the nurse and client. Hays and Larson (1963) identified a number of these techniques, which are presented in Table 8–3. Nurses should recognize and eliminate the use of these patterns in their relationships with clients. Avoiding these communication barriers will maximize the effectiveness of communication and enhance the nurse-client relationship.

Active Listening

To listen actively is to be attentive and really desire to hear and understand what the client is saying, both verbally and nonverbally. Attentive listening creates a climate in which the client can communicate. With active listening, the nurse communicates acceptance and respect for the client, and trust is enhanced. A climate is established within the relationship that promotes openness and honest expression.

TABLE 8–3	**Nontherapeutic Communication Techniques**	
TECHNIQUE	**EXPLANATION/RATIONALE**	**EXAMPLES**
Giving reassurance	Indicating to the client that there is no cause for anxiety devalues the client's feelings and may discourage the client from further expression of feelings if he or she believes they will only be downplayed or ridiculed.	"I wouldn't worry about that if I were you." "Everything will be all right." Better to say: "We will work on that together."
Rejecting	Refusing to consider or showing contempt for the client's ideas or behavior may cause the client to discontinue interaction with the nurse for fear of further rejection.	"Let's not discuss. . . ." "I don't want to hear about. . . ." Better to say: "Let's look at that a little closer."
Approving or disapproving	Sanctioning or denouncing the client's ideas or behavior implies that the nurse has the right to pass judgment on whether the client's ideas or behaviors are "good" or "bad" and that the client is expected to please the nurse. The nurse's acceptance of the client is then seen as conditional depending on the client's behavior.	"That's good. I'm glad that you. . . ." "That's bad. I'd rather you wouldn't. . . ." Better to say: "Let's talk about how your behavior invoked anger in the other clients at dinner."

TABLE 8–3 Nontherapeutic Communication Techniques—cont'd

TECHNIQUE	EXPLANATION/RATIONALE	EXAMPLES
Agreeing or disagreeing	Indicating accord with or opposition to the client's ideas or opinions implies that the nurse has the right to pass judgment on whether the client's ideas or opinions are "right" or "wrong." Agreement prevents the client from later modifying his or her point of view without admitting error. Disagreement implies inaccuracy, provoking the need for defensiveness on the part of the client.	"That's right. I agree." "That's wrong. I disagree." "I don't believe that." Better to say: "Let's discuss what you feel is unfair about the new community rules."
Giving advice	Telling the client what to do or how to behave implies that the nurse knows what is best and that the client is incapable of any self-direction. It nurtures the client in the dependent role by discouraging independent thinking.	"I think you should. . . ." "Why don't you. . . ." Better to say: "What do *you* think you should do?" or "What do *you* think would be the best way to solve this problem?
Probing	Persistent questioning of the client and pushing for answers to issues the client does not wish to discuss causes the client to feel used and valued only for what is shared with the nurse and places the client on the defensive.	"Tell me how your mother abused you when you were a child." "Tell me how you feel toward your mother now that she is dead." "Now tell me about. . . ." Better technique: The nurse should be aware of the client's response and discontinue the interaction at the first sign of discomfort.
Defending	Attempting to protect someone or something from verbal attack, or defending what the client has criticized, implies that he or she has no right to express ideas, opinions, or feelings. Defending does not change the client's feelings and may cause the client to think the nurse is taking sides against the client.	"No one here would lie to you." "You have a very capable physician. I'm sure he has only your best interests in mind." Better to say: "I will try to answer your questions and clarify some issues regarding your treatment."
Requesting an explanation	Asking the client to provide the reasons for thoughts, feelings, behavior, and events— asking "why" a client did something or feels a certain way—can be very intimidating and implies that the client must defend his or her behavior or feelings.	"Why do you think that?" "Why do you feel this way?" "Why did you do that?" Better to say: "Describe what you were feeling just before that happened."
Indicating the existence of an external source of power	Attributing the source of thoughts, feelings, and behavior to others or to outside influences encourages the client to project blame for his or her thoughts or behaviors on others rather than accepting the responsibility personally.	"What makes you say that?" "What made you do that?" "What made you so angry last night?" Better to say: "You became angry when your brother insulted your wife."
Belittling feelings expressed	When the nurse misjudges the degree of the client's discomfort, a lack of empathy and understanding may be conveyed. Telling the client to "perk up" or "snap out of it" causes the client to feel insignificant or unimportant. When one is experiencing discomfort, it is no relief to hear that others are or have been in similar situations.	Cl: "I have nothing to live for. I wish I were dead." Ns: "Everybody gets down in the dumps at times. I feel that way myself sometimes." Better to say: "You must be very upset. Tell me what you are feeling right now."

Continued

TABLE 8–3 Nontherapeutic Communication Techniques—cont'd		
TECHNIQUE	EXPLANATION/RATIONALE	EXAMPLES
Making stereotyped comments	Clichés and trite expressions are meaningless in a nurse-client relationship. When the nurse makes empty conversation, it encourages a like response from the client.	"I'm fine, and how are you?" "Hang in there. It's for your own good." "Keep your chin up." Better to say: "The therapy must be difficult for you at times. How do you feel about your progress at this point?"
Using denial	Denying that a problem exists blocks discussion with the client and precludes helping the client identify and explore areas of difficulty.	Cl: "I'm nothing." Ns: "Of course you're something. Everybody is somebody." Better to say: "You're feeling like no one cares about you right now."
Interpreting	With this technique, the therapist seeks to make conscious that which is unconscious, to tell the client the meaning of his or her experience.	"What you really mean is. . . ." "Unconsciously you're saying. . . ." Better technique: The nurse must leave interpretation of the client's behavior to the psychiatrist. The nurse has not been prepared to perform this technique, and in attempting to do so, may endanger other nursing roles with the client.
Introducing an unrelated topic	Changing the subject causes the nurse to take over the direction of the discussion. This may occur in order to get to something that the nurse wants to discuss with the client or to get away from a topic that he or she prefers not to discuss.	Cl: "I don't have anything to live for." Ns: "Did you have visitors this weekend?" Better technique: The nurse must remain open and free to hear the client and to take in all that is being conveyed, both verbally and nonverbally.

SOURCE: Adapted from Hays, J.S., & Larson, K.H. (1963). *Interacting with patients*. New York: Macmillan.

Several nonverbal behaviors have been designated as facilitative skills for attentive listening. Those listed here can be identified by the acronym SOLER:

S—Sit squarely facing the client. This nonverbal cue gives the message that the nurse is there to listen and is interested in what the client has to say.

O—Observe an open posture. Posture is considered "open" when arms and legs remain uncrossed. This nonverbal cue suggests that the nurse is open to what the client has to say. With a closed position, the nurse can convey a somewhat defensive stance, possibly invoking a similar response in the client.

L—Lean forward toward the client. Leaning forward conveys to the client that the nurse is involved in the interaction, interested in what is being said, and making a sincere effort to be attentive.

E—Establish eye contact. Eye contact, intermittently directed, is another behavior that conveys the nurse's involvement and willingness to listen to what the client has to say. The absence of eye "contact or the constant shifting of eye contact elsewhere in the environment gives the message that the nurse is not really interested in what is being said.

CLINICAL PEARL Ensure that eye contact conveys warmth and is accompanied by smiling and intermittent nodding of the head and does not come across as staring or glaring, which can create intense discomfort in the client.

R—Relax. Whether sitting or standing during the interaction, the nurse should communicate a sense of being relaxed and comfortable with the client. Restlessness and fidgetiness communicate a lack of interest and may convey a feeling of discomfort that is likely to be transferred to the client.

Motivational Interviewing

Patient-centered care has been identified as an important focus in the quest to improve the quality of nurse communication and therapeutic relationships with clients (Institute of Medicine, 2003). **Motivational interviewing** is an evidence-based, patient-centered style of communicating that promotes behavior change by guiding clients to explore their own motivation for change and the advantages and disadvantages of their decisions. This style of communication

incorporates active listening and verbal therapeutic communication techniques, but it is focused on what the client wants rather than on what the nurse thinks *should* be the next steps in behavior change. Motivational interviewing was originally developed for use with clients who were struggling with substance use disorders, primarily because this style of communication may decrease defensive client responses. It has since gained widespread acceptance as a patient-centered communication strategy that promotes behavior change for clients with many different health-care issues. See the "Real People, Real Stories" box for an example of motivational interviewing described in a process recording format.

Process Recordings

Process recordings are written reports of verbal interactions with clients. They are verbatim accounts recorded by the nurse or student as a tool for improving interpersonal communication techniques. Process recording can take many forms but usually includes the verbal and nonverbal communication of both nurse and client. The exercise provides a means for the nurse to analyze both the content and pattern of the interaction. Process recording, which is not considered documentation, is intended to be used as a learning tool for professional development. An example of one type of process recording is presented in Table 8–4.

Real People, Real Stories: A Sample of Motivational Interviewing in a Process Recording Format

The following is part of an interaction with Alan, incorporating motivational interviewing communication strategies in a process recording format. Learn more about Alan's story in the chapter on substance use disorders.

Interaction	Nurse's Thoughts and Feelings	Communication Technique/Evaluation
Karyn: You mentioned that you were at an event and you commented that you "needed a drink." Tell me more about what was happening. (SOLER)	I wasn't sure if Alan was willing to talk about this, but I thought it was important to facilitate his looking at his behavior in response to this experience.	Technique: **Exploring** Evaluation: This approach was effective. Alan talked more about the event and was able to articulate some thoughts and feelings as well.
Alan: (nodding) I was perturbed. I felt like I was stuck at this event. There was supposed to be entertainment but it got cancelled due to rain, and suddenly I noticed people were drinking and smoking. It brought back a lot of memories. (looks down)	I was glad that Alan was open to discussing this experience, but he said so many things in this short statement that I had to be thoughtful about what to follow up on.	
Karyn: So you felt perturbed and stuck. . . . (looking up, not making direct eye contact)	I was thinking that I don't usually explore feelings right off the bat because I believe it's better to help someone fully describe events and thoughts first (or at least it's less threatening), but I've interacted with Alan many times, he's been through rehab, sober for seven years, and he's pretty comfortable talking about feelings	Technique: **Reflecting** Evaluation: This technique was effective. Alan began to process his thoughts about why he might be feeling perturbed and stuck. I think I may have been not making direct eye contact because of my perception that feelings can be a little more threatening for some people to talk about.
Alan: Yeah, but it didn't last long. Maybe it had something to do with the fact that there was nothing else going on and it seemed like the whole thing became about drinking. But then I just blacked it out.	My immediate thought was that I want to tell him to go to an AA meeting or call his sponsor, but I was trying to incorporate a motivational interviewing strategy, and that meant it would be better to help him explore his motivation for how to respond to this experience. I didn't know what he meant by "blacked it out," but I felt uncomfortable when he said that.	

Continued

Real People, Real Stories: A Sample of Motivational Interviewing in a Process Recording Format—cont'd

Interaction	Nurse's Thoughts and Feelings	Communication Technique/Evaluation
Karyn: What do you mean when you say you blacked it out? (SOLER)	I thought this was an important statement to clarify, since it might help him explore how he behaved in response to this event.	Technique: **Clarifying** Evaluation: Asking this question was effective. Alan talked at length about his thoughts and feelings.
Alan: (silent for several seconds) I do need to go back to an AA meeting. I mean, am I different than other people? I know there are other people out there that have to be struggling with the same kind of things. When I was in rehab, my mom and her boyfriend were always there taking me to meetings. My sister went, too. . . . (silent for several more seconds) I know it's important (silence) . . . about 75 percent of the people I went to rehab with are back out there using again.	Alan seemed to be thinking a lot about this and was responding with several different thoughts, so I felt like it was important to just use silence and facilitate his reflection. I thought Alan seemed to be genuinely considering a behavior change.	
Karyn: You said that you need to go back to a meeting and that they are important. Is it more helpful to go to meetings when you just start thinking about needing a drink, or do you think that meetings are only necessary after you actually take a drink?	I knew that Alan had not been going to meetings regularly for the last couple of years, even though he acknowledges their importance, so I wanted to know more about whether he thought behavior change (such as going to AA meetings) was necessary at this point.	Technique: **Restating, focusing** Evaluation: Restatement was effective. The way I chose to focus was probably leading Alan to choose the "right" answer, and that makes it harder to evaluate whether he is just telling me what I want to hear or is really motivated. It might have been better to use the technique of formulating a plan of action.
Alan: Oh no, you've got to go long before you take that first drink. (silence) People told me when I was in rehab that they could tell I was really listening in meetings . . . the meetings were helpful (silence), and I just reconnected with my sponsor on Facebook, so I need to get back to a meeting to see him.	Alan seemed like he was thinking about what is important to him, so I continued to remain silent to facilitate that process.	
Karyn: You've identified three reasons why you believe you need to go to a meeting: because they are helpful to you, because you want to find out if others are struggling with the same kinds of thoughts that you are, and because you need to reconnect with your sponsor. Do you have a plan in mind for how to follow through with that?	I was thinking that he talks about needing to go to AA, and *I* was feeling anxious about wanting him to commit to that, but at the same time, I recognized that the motivation for change and commitment to a plan of action has to come from him.	Technique: **Summarizing, formulating a plan of action** Evaluation: I think the techniques were effective, although Alan may not be ready to formulate an action plan at present.
Alan: Well, I haven't done it yet. I guess I'm still just thinking about it.	I was appreciating his honesty and thinking that this is the challenge of motivational interviewing: accepting where the client is at while continuing to explore and facilitate his or her motivations for behavior change.	

TABLE 8–4 Sample Process Recording

NURSE VERBAL (NONVERBAL)	CLIENT VERBAL (NONVERBAL)	NURSE'S THOUGHTS AND FEELINGS CONCERNING THE INTERACTION	ANALYSIS OF THE INTERACTION
Do you still have thoughts about harming yourself? (Sitting facing the client; looking directly at client.)	Not really. I still feel sad, but I don't want to die. (Looking at hands in lap.)	Felt a little uncomfortable. Always a hard question to ask.	**Therapeutic.** Asking a direct, closed-ended question about suicidal intent to elicit specific information.
Tell me what you were feeling before you took all the pills the other night. (Using SOLER techniques of active listening.)	I was just so angry! To think that my husband wants a divorce now that he has a good job. I worked hard to put him through college. (Fists clenched. Face and neck reddened.)	Beginning to feel more comfortable. Client seems willing to talk, and I think she trusts me.	**Therapeutic.** Exploring. Delving further into client's feelings to help her better understand her experience.
You wanted to hurt him because you felt betrayed. (SOLER)	Yes! If I died, maybe he'd realize that he loved me more than that other woman. (Tears starting to well up in her eyes.)	Starting to feel sorry for her.	**Therapeutic.** Attempting to translate words into feelings to convey active listening.
Seems like a pretty drastic way to get your point across. (Small frown.)	I know. It was a stupid thing to do. (Wiping eyes.)	Trying hard to remain objective.	**Nontherapeutic.** Sounds disapproving. Better to have pursued client's feelings.
How are you feeling about the situation now? (SOLER)	I don't know. I still love him. I want him to come home. I don't want him to marry her. (Starting to cry again)	Wishing there was an easy way to help relieve some of her pain.	**Therapeutic.** Focusing on client's current feelings to assess current mental status.
Yes, I can understand that you would like things to be the way they were before. (Offer client a tissue.)	(Silence. Continues to cry softly.)	I'm starting to feel some anger toward her husband. Sometimes it's so hard to remain objective!	**Therapeutic.** Conveying empathy to support caring and connectedness.
What do you think are the chances of your getting back together? (SOLER)	None. He's refused marriage counseling. He's already moved in with her. He says it's over. (Wipes tears. Looks directly at nurse.)	Relieved to know that she isn't using denial about the reality of the situation.	**Therapeutic.** Reflecting on the client's expressed feelings to encourage client to recognize and clarify their perceptions.
So how are you preparing to deal with this inevitable outcome? (SOLER)	I'm going to do the things we talked about: join a divorced women's support group, increase my job hours to full time, do some volunteer work, and call the suicide hotline if I feel like taking pills again. (Looks directly at nurse. Smiles.)	Positive feeling to know that she remembers what we discussed earlier and plans to follow through.	**Therapeutic.** Formulating a plan of action to set the foundation for problem-solving.
It won't be easy. But you have come a long way, and I feel you have gained strength in your ability to cope. (Standing. Looking at client. Smiling.)	Yes, I know I will have hard times. But I also know I have support, and I want to go on with my life and be happy again. (Standing, smiling at nurse.)	Feeling confident that the session has gone well; hopeful that the client will succeed in what she wants to do with her life.	**Therapeutic.** Presenting reality, making observations, and giving recognition to support client's progress in problem solving.

Feedback

Feedback is a method of communication for helping the client consider behavior modification by providing information about how he or she is perceived by others. Feedback can be useful to the client if presented with objectivity by a trusted individual in a manner that discourages defensiveness.

Characteristics of useful feedback include the following:

■ Feedback is descriptive rather than evaluative and focuses on the behavior rather than on the client. Avoiding evaluative language reduces the need for the client to react defensively. Objective descriptions allow clients to use the information in whatever way they choose. When the focus of feedback is on the client, the nurse makes judgments about the client.

EXAMPLE

Descriptive and focused on behavior	"Jessica was very upset in group today when you called her 'a cow' and laughed at her in front of the others."
Evaluative	"You were very rude and inconsiderate to Jessica in group today."
Focus on client	"You are a very insensitive person."

■ Feedback should be specific rather than general. Information that gives details about the client's behavior is more effective than a generalized description in promoting behavior change.

EXAMPLE

Specific	"You were talking to Joe when we were deciding on the issue. Now you want to argue about the outcome."
General	"You just don't pay attention."

■ Feedback should be directed toward behavior that the client has the capacity to modify. To provide feedback about a characteristic or situation that the client cannot change only provokes frustration.

EXAMPLE

Can modify	"I noticed that you did not want to hold your baby when the nurse brought her to you."
Cannot modify	"Your baby daughter is mentally retarded because you took drugs when you were pregnant."

■ Feedback should impart information rather than offer advice. Giving advice fosters dependence and may convey the message to the client that he or she is not capable of making decisions and solving problems independently. It is the client's right and privilege to be as self-sufficient as possible.

EXAMPLE

Imparting information	"There are various methods of assistance for people who want to lose weight, such as Overeaters Anonymous, Weight Watchers, regular visits to a dietitian, and the Physician's Weight Loss Program. You can decide what is best for you."
Giving advice	"You obviously need to lose a great deal of weight. I think the Physician's Weight Loss Program would be best for you."

■ Feedback should be well-timed. Feedback is most useful when given at the earliest appropriate opportunity following the specific behavior.

EXAMPLE

Prompt response	"I saw you hit the wall with your fist just now when you hung up the phone after talking to your mother."
Delayed response	"You need to learn some more appropriate ways of dealing with your anger. Last week after group I saw you pounding your fist against the wall."

Summary and Key Points

■ Interpersonal communication is a transaction between the sender and the receiver.
■ In all interpersonal transactions, the sender and receiver each bring certain preexisting conditions to the exchange that influence both the intended message and the way in which it is interpreted.
■ Examples of these preexisting conditions include one's value system, internalized attitudes and beliefs, culture and religion, social status, gender, background knowledge and experience, age or developmental level, and the type of environment in which the communication takes place.
■ Nonverbal expression is a primary communication system in which meaning is assigned to various gestures and patterns of behavior.
■ Some components of nonverbal communication include physical appearance and dress, body movement and posture, touch, facial expressions, eye behavior, and vocal cues or paralanguage.
■ Meaning of the nonverbal components of communication is culturally determined.
■ Therapeutic communication is an intentional process that applies both verbal and nonverbal techniques to focus on the care *receiver's* needs and advance the promotion of healing and change.
■ Motivational interviewing is an evidence-based, patient-centered style of therapeutic communication

that facilitates clients' exploration of their own motivations for behavior change and guides the client to explore the advantages and disadvantages of their decisions.

■ Nurses must be aware of and avoid techniques that are considered barriers to effective communication.

■ Active listening is described as attentiveness to what the client is saying through both verbal and nonverbal cues. Skills associated with active listening include sitting squarely facing the client, observing an open posture, leaning forward toward the client, establishing eye contact, and being relaxed.

■ Process recordings are written reports of verbal interactions with clients. They are used as learning tools for professional development.

■ Feedback is a method of communication for helping the client consider a modification of behavior.

■ The nurse must be aware of the therapeutic or nontherapeutic value of the communication techniques used with the client because they are the tools of psychosocial intervention.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. A client states, "I refuse to shower in this room. I must be very cautious. The FBI has placed a camera in here to monitor my every move." Which of the following is the most therapeutic response?
   a. "That's not true."
   b. "I have a hard time believing that is true."
   c. "Surely you don't really believe that."
   d. "I will help you search this room so that you can see there is no camera."

2. Simone, a depressed client who has been unkempt and untidy for weeks, today comes to group therapy wearing makeup and a clean dress with hair washed and combed. Which of the following responses by the nurse is most appropriate?
   a. "Simone, I see you have put on a clean dress and combed your hair."
   b. "Simone, you look wonderful today!"
   c. "Simone, I'm sure everyone will appreciate that you have cleaned up for the group today."
   d. "Now that you see how important it is, I hope you will do this every day."

3. Dorothy was involved in an automobile accident while under the influence of alcohol. She swerved her car into a tree and narrowly missed hitting a child on a bicycle. She is in the hospital with multiple abrasions and contusions. She is talking about the accident with the nurse. Which of the following statements by the nurse is most appropriate?
   a. "Now that you know what can happen when you drink and drive, I'm sure you won't let it happen again."
   b. "You know that was a terrible thing you did. That child could have been killed."
   c. "I'm sure everything is going to be okay now that you understand the possible consequences of such behavior."
   d. "How are you feeling about what happened?"

4. Judy has been in the hospital for 3 weeks. She has used Valium "to settle her nerves" for the past 15 years. She was admitted by her psychiatrist for safe withdrawal from the drug. She has passed the physical symptoms of withdrawal at this time but states to the nurse, "I don't know if I will be able to make it without Valium after I go home. I'm already starting to feel nervous. I have so many personal problems." Which is the most appropriate response by the nurse?
   a. "Why do you think you need drugs to deal with your problems?"
   b. "Everybody has problems, but not everybody uses drugs to deal with them. You'll just have to do the best that you can."
   c. "Let's explore some things you can do to decrease your anxiety without resorting to drugs."
   d. "Just hang in there. I'm sure everything is going to be okay."

Review Questions—cont'd
Self-Examination/Learning Exercise

5. Mrs. S. asks the nurse, "Do you think I should tell my husband about my affair with my boss?" Which is the most appropriate response by the nurse?
   a. "What do you think would be best for you to do?"
   b. "Of course you should. Marriage has to be based on truth."
   c. "Of course not. That would only make things worse."
   d. "I can't tell you what to do. You have to decide for yourself."

6. Abby, an adolescent, just returned from group therapy and is crying. She says to the nurse, "All the other kids laughed at me! I try to fit in, but I always seem to say the wrong thing. I've never had a close friend. I guess I never will." Which is the most appropriate response by the nurse?
   a. "What makes you think you will never have any friends?"
   b. "You're feeling pretty down on yourself right now."
   c. "I'm sure they didn't mean to hurt your feelings."
   d. "Why do you feel this way about yourself?"

7. Walter is angry with his psychiatrist and says to the nurse, "He doesn't know what he is doing. That medication isn't helping a thing!" The nurse responds, "He has been a doctor for many years and has helped many people." This is an example of what nontherapeutic technique?
   a. Rejecting
   b. Disapproving
   c. Probing
   d. Defending

8. The client says to the nurse, "I've been offered a promotion, but I don't know if I can handle it." The nurse replies, "You're afraid you may fail in the new position." This is an example of which therapeutic technique?
   a. Restating
   b. Making observations
   c. Focusing
   d. Verbalizing the implied

9. The environment in which the communication takes place influences the outcome of the interaction. Which of the following are aspects of the environment that influence communication? (Select all that apply.)
   a. Territoriality
   b. Density
   c. Dimension
   d. Distance
   e. Intensity

10. The nurse says to a client, "You are being readmitted to the hospital. Why did you stop taking your medication?" What communication technique does this represent?
    a. Disapproving
    b. Requesting an explanation
    c. Disagreeing
    d. Probing

Review Questions—cont'd
Self-Examination/Learning Exercise

11. Joe has been in rehabilitation for alcohol dependence. When he returns from a visit to his home, he tells the nurse, "We were having a celebration and I did have one drink, but it really wasn't a problem." The nurse notices that his breath smells of alcohol. Which of the following responses by the nurse demonstrates a motivational interviewing style of communication?
    a. "You are obviously not motivated to change, so perhaps we should discuss your discharge from the treatment program."
    b. "You need to abstain from alcohol in order to recover, so let me talk to the doctor about the consequences of your behavior."
    c. "Why would you destroy everything you've worked so hard to achieve?"
    d. "What do you mean when you say, 'It really wasn't a problem'?"

12. Bill, who has been diagnosed with schizophrenia and has been on medication for several months, states, "I'm not taking that stupid medication anymore." Which of the following responses by the nurse demonstrates a motivational interviewing style of communication?
    a. "Don't you know that if you don't take your medication you will never recover?"
    b. "Why won't you cooperate with the treatment your doctor prescribed?"
    c. "Bill, the medication is not stupid."
    d. "Tell me more about why you don't want to take the medication."

9 The Nursing Process in Psychiatric-Mental Health Nursing

KEY TERMS

case management
case manager
concept mapping
critical pathways of care
Focus Charting®
interdisciplinary

managed care
Nursing Interventions
   Classification (NIC)
Nursing Outcomes
   Classification (NOC)
nursing process

PIE charting
problem-oriented recording

OBJECTIVES

After reading this chapter, the student will be able to:

1. Define *nursing process*.
2. Identify six steps of the nursing process, and describe nursing actions associated with each.
3. Describe the benefits of using nursing diagnosis.
4. Discuss the list of nursing diagnoses approved by NANDA International for clinical use and testing.
5. Define and discuss the use of case management and critical pathways of care in the clinical setting.
6. Apply the six steps of the nursing process in caring for a client in the psychiatric setting.
7. Document client care that validates use of the nursing process.

HOMEWORK ASSIGNMENT

Please read the chapter and answer the following questions:

1. Nursing outcomes (sometimes referred to as *goals*) are derived from the nursing diagnosis. Name two essential aspects of an acceptable outcome or goal.
2. Define *managed care.*
3. The American Nurses Association identifies certain interventions that may be performed only by psychiatric nurses in advanced practice. What are they?
4. In Focus Charting®, one item cannot be used as the focus for documentation. What is this item?

For many years, the **nursing process** has provided a systematic framework for the delivery of nursing care. This framework fulfills the requirement for a *scientific methodology* in order for nursing to be considered a profession.

This chapter examines the steps of the nursing process as they are set forth by the American Nurses Association (ANA) in *Nursing: Scope and Standards of Practice* (ANA, 2015). An explanation is provided for the implementation of case management and the critical pathways of care tool used with this methodology. A description of concept mapping is included, and documentation that validates the use of the nursing process is discussed.

The Nursing Process

Definition

The nursing process consists of six steps and uses a problem-solving approach that has come to be accepted as nursing's scientific methodology. It is goal-directed with the objective of quality client care delivery.

The nursing process is dynamic, not static. It is an ongoing process that continues for as long as the nurse and client have interactions directed toward change in the client's physical or behavioral responses. Figure 9–1 presents a schematic of the ongoing nursing process.

Standards of Practice

The ANA, in collaboration with the American Psychiatric Nurses Association (APNA) and the International Society of Psychiatric-Mental Health Nurses

(ISPN) (2014) has delineated a set of standards that psychiatric-mental health nurses are expected to follow as they provide care for their clients. The ANA (2015) describes a standard of practice as an authoritative statement that is defined and promoted by the profession and that provides the foundation for evaluating quality of nursing practice. The nursing process is a critical thinking model that integrates professional standards of practice to assess, diagnose, identify outcomes, plan, implement, and evaluate nursing care.

Following is a discussion of the standards of practice for psychiatric-mental health nurses as set forth by the ANA, APNA, and ISPN (2014). Many of these standards outline the registered nurse's role in each step of the nursing process and apply them to the psychiatric-mental health nurse. Three changes in the current standards of practice reflect issues and trends that have evolved more recently.

First, patients are now referred to as *health-care consumers*. This term reflects the trend toward patient-centered care and conceptualizing that relationship as a collaborative partnership.

Second, counseling interventions (performed by psychiatric-mental health registered nurses) are now differentiated from psychotherapy (performed by psychiatric-mental health *advanced practice* registered nurses). The third change, in Standard 5G. Therapeutic Relationship and Counseling, adds the phrase "assisting healthcare consumers in their individual recovery journeys." This language supports the recovery model of intervention, a current trend toward focus on a collaborative recovery process rather than health-care provider–prescribed treatment alone. (See Chapter 21, The Recovery Model, for more information.)

FIGURE 9–1   The ongoing nursing process.

CORE CONCEPT

Assessment

A systematic, dynamic process by which the registered nurse, through interaction with the patient, family, groups, communities, populations, and healthcare providers, collects and analyzes data. Assessment may include the following dimensions: physical, psychological, sociocultural, spiritual, cognitive, functional abilities, developmental, economic, and lifestyle (ANA et al., 2014, p. 87).

Standard 1. Assessment

The psychiatric-mental health registered nurse collects and synthesizes comprehensive health data that are pertinent to the healthcare consumer's health and/or situation (ANA et al., 2014. p. 44).

In this first step, a database to determine the best possible client care is established. Information for this database is gathered from a variety of sources, including interviews with the client and/or family, observation of the client and his or her environment, consultation with other health team members, review of the client's records, and a nursing physical examination. A biopsychosocial assessment tool based on the stress-adaptation framework is included in Box 9–1.

BOX 9–1 Nursing History and Assessment Tool

I. General Information
   Client name: _____ Allergies: _____
   Room number: _____ Diet: _____
   Doctor: _____ Height/weight: _____
   Age: _____ Vital signs: TPR/BP _____
   Sex: _____ Name and phone no. of significant other: _____
   Race: _____
   Dominant language: _____ City of residence: _____
   Marital status: _____ Diagnosis (admitting & current): _____
   Chief complaint: _____
   _____

   Conditions of admission:
   Date: _____ Time: _____
   Accompanied by: _____
   Route of admission (wheelchair; ambulatory; cart): _____
   Admitted from: _____

II. Predisposing Factors
   A. *Genetic Influences*
   1. Family configuration (use genograms):
            Family of origin: Present family:

      Family dynamics (describe significant relationships between family members): _____
      _____
      _____
      _____
      _____

   2. Medical/psychiatric history: _____
      a. Client: _____
      _____
      _____
      b. Family members: _____
      _____
      _____

   3. Other genetic influences affecting present adaptation. This might include effects specific to gender, race, appearance, such as genetic physical defects, or any other factor related to genetics that is affecting the client's adaptation that has not been mentioned elsewhere in this assessment.
      _____
      _____

   B. *Past Experiences*
   1. Cultural and social history:
      a. Environmental factors (family living arrangements, type of neighborhood, special working conditions):
         _____
         _____
         _____

BOX 9–1 **Nursing History and Assessment Tool–cont'd**

b. Health beliefs and practices (personal responsibility for health; special self-care practices): _____
_____

c. Religious beliefs and practices: _____
_____
_____

d. Educational background: _____
_____
_____

e. Significant losses/changes (include dates): _____
_____
_____

f. Peer/friendship relationships: _____
_____
_____

g. Occupational history: _____
_____
_____

h. Previous pattern of coping with stress: _____
_____
_____

i. Other lifestyle factors contributing to present adaptation: _____
_____
_____

C. *Existing Conditions*
1. Stage of development (Erikson):
   a. Theoretically: _____
   b. Behaviorally: _____
   c. Rationale: _____
   _____
   _____

2. Support systems: _____
_____

3. Economic security: _____
_____

4. Avenues of productivity/contribution:
   a. Current job status: _____
   _____
   b. Role contributions and responsibility for others: _____
   _____

III. Precipitating Event
   Describe the situation or events that precipitated this illness/hospitalization: _____
_____
_____

Continued

BOX 9–1 **Nursing History and Assessment Tool–cont'd**

IV. Client's Perception of the Stressor
   Client's or family member's understanding or description of stressor/illness and expectations of hospitalization:
   _____
   _____
   _____

V. Adaptation Responses
   A. *Psychosocial*
   1. Anxiety level (circle one of the 4 levels and check the behaviors that apply):   Mild   Moderate Severe Panic
      calm _____ friendly _____ passive _____ alert _____ perceives environment correctly _____ cooperative _____
      impaired attention _____ "jittery" _____ unable to concentrate _____ hypervigilant _____ tremors _____ rapid
      speech _____ withdrawn _____ confused _____ disoriented _____ fearful _____ hyperventilating _____ misinterpreting
      the environment (hallucinations or delusions) _____ depersonalization _____ obsessions _____ compulsions _____
      somatic complaints _____ excessive hyperactivity _____ other _____
      _____

   2. Mood/affect (circle as many as apply): happiness   sadness   dejection   despair   elation   euphoria   suspi-
      ciousness   apathy (little emotional tone)   anger/hostility

   3. Ego defense mechanisms (describe how used by client):
      Projection _____
      Suppression _____
      Undoing _____
      Displacement _____
      Intellectualization _____
      Rationalization _____
      Denial _____
      Repression _____
      Isolation _____
      Regression _____
      Reaction Formation _____
      Splitting _____
      Religiosity _____
      Sublimation _____
      Compensation _____

   4. Level of self-esteem (circle one):   low   moderate   high
      Things client likes about self _____
      _____
      Things client would like to change about self _____
      _____
      Objective assessment of self-esteem:
      Eye contact _____
      General appearance _____
      _____
      Personal hygiene _____
      Participation in group activities and interactions with others _____
      _____

   5. Stage and manifestations of grief (circle one):
                  Denial   Anger   Bargaining   Depression   Acceptance
      Describe the client's behaviors that are associated with this stage of grieving in response to loss or change.
      _____
      _____
      _____
      _____

BOX 9–1 **Nursing History and Assessment Tool–cont'd**

6. Thought processes (circle as many as apply):   clear   logical   easy to follow   relevant   confused   blocking   delusional   rapid flow of thoughts   slowness in thought   suspicious
   Recent memory (circle one):   loss   intact   Remote memory (circle one):   loss   intact
   Other: _____
   _____

7. Communication patterns (circle as many as apply):   clear   coherent   slurred speech   incoherent   neologisms   loose associations   flight of ideas   aphasic   perseveration   rumination   tangential speech   loquaciousness   slow, impoverished speech   speech impediment (describe) _____
   Other _____
   _____

8. Interaction patterns (describe client's pattern of interpersonal interactions with staff and peers on the unit, e.g., manipulative, withdrawn, isolated, verbally or physically hostile, argumentative, passive, assertive, aggressive, passive-aggressive, other): _____
   _____
   _____
   _____

9. Reality orientation (check those that apply):
   Oriented to: Time _____   Person _____
                 Place _____   Situation _____

10. Ideas of destruction to self/others?   Yes   No
    If yes, consider plan; available means _____
    _____
    _____
    _____

B. *Physiological*
1. Psychosomatic manifestations (describe any somatic complaints that may be stress-related): _____
   _____
   _____
   _____

2. Drug history and assessment:
   Use of prescribed drugs:

Name	**Dosage**	**Prescribed for**	**Results**

   Use of over-the-counter drugs:

Name	**Dosage**	**Used for**	**Results**

BOX 9–1 **Nursing History and Assessment Tool–cont'd**

Use of street drugs or alcohol:

Name	Amount Used	How Often Used	When Last Used	Effects Produced
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____

3. Pertinent physical assessments:
   a. Respirations: normal _____ labored _____
      Rate _____ Rhythm _____

   b. Skin: warm _____ dry _____ moist _____ cool _____ clammy _____ pink _____
      cyanotic _____ poor turgor _____ edematous _____
      Evidence of: rash _____ bruising _____ needle tracks _____ hirsutism _____
      loss of hair _____ other _____
      _____

   c. Musculoskeletal status: _____ weakness _____ tremors
      Degree of range of motion (describe limitations) _____
      _____

      Pain (describe) _____
      _____

      Skeletal deformities (describe) _____
      Coordination (describe limitations) _____

   d. Neurological status:
      History of (check all that apply): seizures _____ (describe method of control) _____
      _____
      headaches (describe location and frequency) _____
      fainting spells _____ dizziness _____
      tingling/numbness (describe location) _____

   e. Cardiovascular: B/P _____ Pulse _____
      History of (check all that apply):
      hypertension _____ palpitations _____
      heart murmur _____ chest pain _____
      shortness of breath _____ pain in legs _____
      phlebitis _____ ankle/leg edema _____
      numbness/tingling in extremities _____
      varicose veins _____

   f. Gastrointestinal:
      Usual diet pattern: _____
      Food allergies: _____
      Dentures? Upper _____ Lower _____
      Any problems with chewing or swallowing? _____
      Any recent change in weight? _____
      Any problems with:
      Indigestion/heartburn? _____
        Relieved by _____
      Nausea/vomiting? _____
        Relieved by _____
      History of ulcers? _____
      Usual bowel pattern _____
        Constipation? _____ Diarrhea? _____
        Type of self-care assistance provided for either of the above problems _____
      _____

BOX 9–1 **Nursing History and Assessment Tool—cont'd**

g. Genitourinary/Reproductive:
   Usual voiding pattern _____
   Urinary hesitancy? _____ Frequency? _____
   Nocturia? _____ Pain/burning? _____
   Incontinence? _____
   Any genital lesions? _____
     Discharge? _____ Odor? _____
   History of sexually transmitted disease? _____
     If yes, please explain: _____
     _____
   Any concerns about sexuality/sexual activity? _____
     _____
   Method of birth control used _____
   Females:
     Date of last menstrual cycle _____
     Length of cycle _____
     Problems associated with menstruation? _____
     _____
   Breasts: Pain/tenderness? _____
     Swelling? _____ Discharge? _____
     Lumps? _____ Dimpling? _____
   Practice breast self-examination? _____
     Frequency? _____
   Males:
     Penile discharge? _____
     Prostate problems? _____

h. Eyes:

n. Other pertinent physical assessments: _____
_____
_____

VI. Summary of Initial Psychosocial/Physical Assessment:

Knowledge Deficits Identified:

Nursing Diagnoses Indicated:

An example of a simple and quick mental status evaluation is presented in Table 9–1. Sometimes the term *mental status assessment* is used to describe an assessment of the cognitive aspects of functioning, as is the case with tools such as Folstein's Mini-Mental State Evaluation (Folstein, Folstein, & McHugh, 1975). Likewise, the tool in Table 9–1 focuses strictly on a brief assessment of the cognitive aspects of mental functioning. In psychiatry and psychiatric-mental health nursing, mental status assessment assumes a much broader definition and includes assessment of mood, affect, behavior, relationships, speech, perceptual disturbances, insight, and judgment in addition to cognitive function. A comprehensive mental status assessment guide, with explanations and selected sample interview questions, is provided in Appendix C, Mental Status Assessment.

CORE CONCEPT

Nursing Diagnosis

Clinical judgments about individual, family, or community experiences/responses to actual or potential health problems/life processes. A nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse has accountability (NANDA International [NANDA-I], 2015a).

Standard 2. Diagnosis

The psychiatric-mental health registered nurse analyzes the assessment data to determine diagnoses, problems, and areas of focus for care and treatment, including level of risk (ANA et al., 2014, p. 46).

TABLE 9–1 **Brief Mental Status Evaluation**	
AREA OF MENTAL FUNCTION EVALUATED	EVALUATION ACTIVITY
Orientation to time	"What year is it?" "What month is it?" "What day is it?" (3 points)
Orientation to place	"Where are you now?" (1 point)
Attention and immediate recall	"Repeat these words now: bell, book, & candle." (3 points) "Remember these words, and I will ask you to repeat them in a few minutes."
Abstract thinking	"What does this mean: No use crying over spilled milk." (3 points)
Recent memory	"Say the 3 words I asked you to remember earlier." (3 points)
Naming objects	Point to eyeglasses and ask, "What is this?" Repeat with 1 other item (e.g., calendar, watch, pencil). (2 points possible)
Ability to follow simple verbal command	"Tear this piece of paper in half and put it in the trash container." (2 points)
Ability to follow simple written command	Write a command on a piece of paper (e.g., TOUCH YOUR NOSE), give the paper to the client, and say, "Do what it says on this paper." (1 point for correct action)
Ability to use language correctly	Ask the patient to write a sentence. (3 points if sentence has a subject, a verb, and valid meaning)
Ability to concentrate	"Say the months of the year in reverse, starting with December." (1 point each for correct answers from November through August; 4 points possible)
Understanding spatial relationships	Instruct client to draw a clock, put in all the numbers, and set the hands on 3 o'clock. (clock circle = 1 pt; numbers in correct sequence = 1 pt; numbers placed on clock correctly = 1 pt; two hands on the clock = 1 pt; hands set at correct time = 1 pt; 5 points possible)

Scoring: 30–21 = normal; 20–11 = mild cognitive impairment; 10–0 = severe cognitive impairment (scores are not absolute and must be considered within the comprehensive diagnostic assessment).

A short portable mental status questionnaire for the assessment of organic brain deficit in elderly patients. *Journal of the American Geriatric Society, 23*(10), 433-441.

In the second step, data gathered during the assessment are analyzed. Diagnoses and potential problem statements are formulated and prioritized. Diagnoses are congruent with available and accepted classification systems (e.g., *NANDA International Nursing Diagnoses: Definitions and Classification* [see Appendix E, Assigning NANDA International Nursing Diagnoses to Client Behaviors]).

CORE CONCEPT

Outcomes

Client behaviors and responses that are collaboratively agreed upon, measurable, desired results of nursing interventions.

Standard 3. Outcomes Identification

The psychiatric-mental health registered nurse identifies expected outcomes and the healthcare consumer's goals for a plan individualized to the healthcare consumer or to the situation (ANA et al., 2014, p. 48).

Expected outcomes are derived from the diagnosis. They must be measurable and include a time estimate for attainment. They must be realistic for the client's capabilities, and they are most effective when formulated cooperatively by the interdisciplinary team members, the client, and significant others.

Nursing Outcomes Classification

The **Nursing Outcomes Classification (NOC)** is a comprehensive, standardized classification of client outcomes developed to evaluate the effects of nursing

interventions (Moorhead et al., 2013). The outcomes have been linked to NANDA International (NANDA-I) diagnoses and to the **Nursing Interventions Classification (NIC).** NANDA-I, NIC, and NOC represent all domains of nursing and can be used together or separately (Moorhead & Dochterman, 2012). Each of the NOC outcomes has a label name, a definition, a list of indicators to evaluate client status in relation to the outcome, and a five-point Likert scale to measure client status (Moorhead et al., 2013).

Standard 4. Planning

The psychiatric-mental health registered nurse develops a plan that prescribes strategies and alternatives to assist the healthcare consumer in attainment of expected outcomes (ANA et al., 2014, p. 50).

The care plan is individualized to the client's mental health problems, condition, or needs and is developed in collaboration with the client, significant others, and interdisciplinary team members if possible. For each diagnosis identified, the most appropriate interventions are selected on the basis of current psychiatric-mental health nursing practice, standards, relevant statutes, and research evidence. Client education and necessary referrals are included. Priorities for delivery of nursing care are determined on the basis of safety needs and the client's risk for harm to self or others. Elements of the plan should be prioritized with input from the client, the family, and others as appropriate (ANA et al., 2014).

Nursing Interventions Classification

NIC is a comprehensive, standardized language describing treatments that nurses perform in all settings and specialties (Bulechek, Butcher, Dochterman, & Wagner, 2013). NIC includes both physiological and psychosocial interventions as well as those for illness treatment, illness prevention, and health promotion. NIC interventions are comprehensive, based on research, and reflect current clinical practice. They were developed inductively on the basis of existing practice.

Each NIC intervention has a definition and a detailed set of activities that describe what a nurse does to implement the intervention. The use of standardized language is thought to enhance continuity of care and facilitate communication among nurses and between nurses and other providers.

Standard 5. Implementation

The psychiatric-mental health registered nurse implements the identified plan (ANA et al., 2014, p. 52).

Interventions selected during the planning stage are executed, taking into consideration the nurse's level of practice, education, and certification. The care plan serves as a blueprint for delivery of safe, ethical, and appropriate interventions. Documentation

of interventions also occurs at this step in the nursing process.

Several specific interventions are included among the standards of psychiatric-mental health clinical nursing practice (ANA et al., 2014):

Standard 5A. Coordination of Care

The psychiatric-mental health registered nurse coordinates care delivery (ANA et al., 2014, p. 54).

Standard 5B. Health Teaching and Health Promotion

The psychiatric-mental health registered nurse employs strategies to promote health and a safe environment (ANA et al., 2014, p. 55).

Standard 5C. Consultation

The psychiatric-mental health advanced practice registered nurse provides consultation to influence the identified plan, enhance the abilities of other clinicians to provide services for healthcare consumers, and effect change (ANA et al., 2014, p. 57).

Standard 5D. Prescriptive Authority and Treatment

The psychiatric-mental health advanced practice registered nurse uses prescriptive authority, procedures, referrals, treatments, and therapies in accordance with state and federal laws and regulations (ANA et al., 2014, p. 58).

Standard 5E. Pharmacological, Biological, and Integrative Therapies

The psychiatric-mental health registered nurse incorporates knowledge of pharmacological, biological, and complementary interventions with applied clinical skills to restore the healthcare consumer's health and prevent further disability (ANA et al., 2014, p. 59).

Standard 5F. Milieu Therapy

The psychiatric-mental health registered nurse provides, structures, and maintains a safe, therapeutic, recovery-oriented environment in collaboration with healthcare consumers, families, and other healthcare clinicians (ANA et al., 2014, p. 60).

Several models have been developed to identify what constitutes a therapeutic environment. These are discussed further in Chapter 12, Milieu Therapy—The Therapeutic Community. Incorporation of the health-care environment and the community of clients, their families, and health-care providers is a unique aspect of treatment for the client with a psychiatric-mental health disorder.

Standard 5G. Therapeutic Relationship and Counseling

The psychiatric-mental health registered nurse (PMH-RN) uses the therapeutic relationship and counseling interventions

to assist healthcare consumers in their individual recovery journeys by improving and regaining their previous coping abilities, fostering mental health, and preventing mental disorder and disability (ANA et al., 2014, p. 62).

As mentioned previously, therapeutic relationship and counseling interventions are part of the role of registered nurses practicing in psychiatric-mental health settings. These are basic psychoeducational and problem discussion interventions and are differentiated from psychotherapy that requires advanced practice education and competency.

Standard 5H. Psychotherapy

The psychiatric-mental health advanced practice registered nurse conducts individual, couples, group, and family psychotherapy using evidence-based psychotherapeutic frameworks and the nurse-client therapeutic relationship (ANA et al., 2014, p. 63).

CORE CONCEPT

Evaluation

The process of determining the healthcare consumer's progress toward attainment of expected outcomes, and the effectiveness of the registered nurse's care and interventions (ANA et al., 2014, p. 88).

Standard 6. Evaluation

The psychiatric-mental health registered nurse evaluates progress toward attainment of expected outcomes (ANA et al., 2014, p. 65).

During the evaluation step, the nurse measures the success of the interventions in meeting the outcome criteria. The client's response to treatment is documented, validating use of the nursing process in the delivery of care. The diagnoses, outcomes, and plan of care are reviewed and revised as need is determined by the evaluation.

Why Nursing Diagnosis?

The concept of nursing diagnosis is not new. For centuries, nurses have identified specific client responses for which nursing interventions were used in an effort to improve quality of life. Historically, however, the autonomy of practice to which nurses were entitled by virtue of their licensure was lacking in the provision of nursing care. Nurses assisted physicians as required and performed a group of specific tasks that were considered within their scope of responsibility.

The term *diagnosis* in relation to nursing first began to appear in the literature in the early 1950s. The formalized organization of the concept, however,

was initiated in 1973 with the convening of the First Task Force to Name and Classify Nursing Diagnoses. The Task Force of the National Conference Group on the Classification of Nursing Diagnoses was developed during this conference and charged with the task of identifying and classifying nursing diagnoses.

Also in the 1970s, the ANA began to write standards of practice around the steps of the nursing process, of which nursing diagnosis is an inherent part. This format encompassed both the general and specialty standards outlined by the ANA.

From this progression, a policy statement that includes a definition of nursing was published in 1980. The ANA defined nursing as "the diagnosis and treatment of human responses to actual or potential health problems" (ANA, 2010). This definition has been expanded to describe more appropriately nursing's commitment to society and to the profession. The ANA (2017) defines nursing as follows:

> Nursing is the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations.

Nursing diagnosis is an inherent component of both the original and expanded definitions.

Decisions regarding professional negligence are made on the basis of the standards of practice defined by the ANA and the individual state nurse practice acts. A number of states have incorporated the steps of the nursing process, including nursing diagnosis, into the scope of nursing practice described in their nurse practice acts. When this is the case, it is the legal duty of the nurse to show that nursing process and nursing diagnosis were accurately implemented in the delivery of nursing care.

NANDA-I evolved from the original 1973 task force to name and classify nursing diagnoses. The major purpose of NANDA-I is to "to develop, refine and promote terminology that accurately reflects nurses' clinical judgments. NANDA-I will be a global force for the development and use of nursing's standardized terminology to ensure patient safety through evidence-based care, thereby improving the health care of all people" (NANDA-I, 2015b). The list of NANDA-I-approved diagnoses is by no means all-inclusive. In an effort to maintain a common language within nursing and encourage clinical testing, most of the nursing diagnoses used in this text are taken from the 2015–2017 list approved by NANDA-I. However, in a few instances, nursing diagnoses that have been retired by NANDA-I for various reasons will continue to be used because of their

appropriateness and suitability in describing specific behaviors.

The use of nursing diagnosis affords a degree of autonomy that historically has been lacking in the practice of nursing. Nursing diagnosis describes the client's condition, facilitating the prescription of interventions and establishment of parameters for outcome criteria based on unique components of the nursing profession. The ultimate benefit is to the client, who receives effective and consistent nursing care based on knowledge of the problems that he or she is experiencing and of the most beneficial nursing interventions to resolve them.

Nursing Case Management

The concept of **case management** evolved with the advent of diagnosis-related groups (DRGs) and shorter hospital stays. Case management is a model of care delivery that can result in improved client care. In this model, clients are assigned a manager who negotiates with multiple providers to obtain diverse services. This type of health-care delivery process serves to decrease fragmentation of care while striving to contain cost of services.

Case management in the acute care setting aims to organize client care through an episode of illness so that specific clinical and financial outcomes are achieved within an allotted time frame. Commonly, the allotted time frame is determined by the established protocols for length of stay as defined by the DRGs.

Case management has been shown to be an effective method of treatment for individuals with a severe and persistent mental illness. This type of care strives to improve functioning by assisting the individual to solve problems, improve work and socialization skills, promote leisure-time activities, and enhance overall independence.

Ideally, case management incorporates concepts of care at the primary, secondary, and tertiary levels of prevention. Various definitions have emerged and should be clarified, as follows.

Managed care refers to a strategy employed by purchasers of health services who make determinations about various services in order to maintain quality and control costs. In a managed care program, individuals receive health care based on need as assessed by coordinators of the providership. Managed care exists in many settings, including (but not limited to):

■ Insurance-based programs
■ Employer-based medical providerships
■ Social service programs
■ The public health sector

Managed care may exist in virtually any setting in which a private or government-based organization is responsible for payment of health-care services for a group of people. Examples of managed care are health maintenance organizations (HMOs) and preferred provider organizations (PPOs).

Case management, the method used to achieve managed care, is the actual coordination of services required to meet the needs of a client within the fragmented health-care system. Case management strives to help at-risk clients prevent avoidable episodes of illness while controlling health-care costs for the consumer and third-party payers.

Types of clients who benefit from case management include (but are not limited to):

■ The frail elderly
■ Individuals with developmental disabilities
■ Individuals with physical disabilities
■ Individuals with mental disabilities
■ Individuals with long-term, medically complex problems that require multifaceted, costly care (e.g., high-risk infants, those who are HIV positive or who have AIDS, and transplant clients)
■ Individuals who are severely compromised by an acute episode of illness or an acute exacerbation of a severe and persistent illness (e.g., schizophrenia)

The **case manager** is responsible for negotiating with multiple health-care providers to obtain a variety of services for the client. Nurses are exceptionally qualified to serve as case managers. The very nature of nursing, which incorporates knowledge about the biological, psychological, and sociocultural aspects related to human functioning, makes nurses highly appropriate for this role. Several years of experience as a registered nurse is usually required for employment as a case manager. Some case management programs prefer advanced practice registered nurses who have experience working with the specific populations for whom the service will be rendered. The American Nurses Credentialing Center (ANCC) offers an examination for nurses to become board certified in nursing case management.

Critical Pathways of Care

Critical pathways of care (CPCs) may be used as the tools for provision of care in a case management system. A critical pathway is an abbreviated care plan that provides outcome-based guidelines for goal achievement within a designated length of stay. A sample CPC is presented in Table 9–2. Only one nursing diagnosis is used in this sample, but a comprehensive CPC may have nursing diagnoses for several individual problems and incorporates responsibilities of other team members as well.

CPCs are intended to be used by the entire interdisciplinary team, which may include a nurse case

TABLE 9–2 Sample Critical Pathway of Care for Client in Alcohol Withdrawal

Estimated Length of Stay: 7 Days—Variations From Designated Pathway Should Be Documented in Progress Notes

NURSING DIAGNOSES AND CATEGORIES OF CARE	TIME DIMENSION	GOALS AND/OR ACTIONS	TIME DIMENSION	GOALS AND/OR ACTIONS	TIME DIMENSION	DISCHARGE OUTCOME
Risk for injury related to CNS agitation					Day 7	Client shows no evidence of injury obtained during ETOH withdrawal
Referrals	Day 1	Psychiatrist Assess need for: Neurologist Cardiologist Internist			Day 7	Discharge with follow-up appointments as required
Diagnostic studies	Day 1	Blood alcohol level Drug screen (urine and blood) Chemistry profile Urinalysis Chest x-ray ECG	Day 4	Repeat of selected diagnostic studies as necessary		
Additional assessments	Day 1 Day 1–5 Ongoing Ongoing	VS q4h I&O Restraints prn for client safety Assess withdrawal symptoms: tremors, nausea/vomiting, tachycardia, sweating, high blood pressure, seizures, insomnia, hallucinations	Day 2–3 Day 6 Day 4	VS q8h if stable DC I&O Marked decrease in objective withdrawal symptoms	Day 4–7 Day 7	VS bid; remain stable Discharge; absence of objective withdrawal symptoms
Medications	Day 1 Day 2 Day 1–6 Day 1–7	*Librium 200 mg in divided doses Librium 160 mg in divided doses Librium prn Maalox pc & hs *Note: Some physicians may elect to use Serax or Tegretol in the detoxification process	Day 3 Day 4	Librium 120 mg in divided doses Librium 80 mg in divided doses	Day 5 Day 6 Day 7	Librium 40 mg Discontinue Librium Discharge; no withdrawal symptoms
Client education			Day 5	Discuss goals of AA and need for outpatient therapy	Day 7	Discharge with information regarding AA attendance or outpatient treatment

AA, Alcoholics Anonymous; bid, twice a day; DC, discontinue; ECG, electrocardiogram; ETOH, alcohol; hs, bedtime; I&O, intake and output; pc, after meals; prn, as needed; q4h, every 4 hours; q8h, every 8 hours; VS, vital signs.

manager, clinical nurse specialist, social worker, psychiatrist, psychologist, dietitian, occupational therapist, recreational therapist, chaplain, and others. The team decides what categories of care are to be performed, by what date, and by whom. Each member of the team is then expected to carry out his or her functions according to the time line designated on the CPC.

Unlike a nursing care plan, CPCs have the benefit of describing what an episode of care will look like when implemented by team members in collaboration with one another. Clarity about how team members collaborate is important not only for providing efficient patient care but also for improving quality and safety.

As case manager, the nurse is ultimately responsible for ensuring that each assignment is carried out. If variations occur in any of the categories of care, rationale must be documented in the progress notes. For example, with the sample CPC presented in Table 9–2, the nurse case manager may admit the client into the detoxification center. The nurse contacts the psychiatrist to inform him or her of the admission. The psychiatrist performs additional assessments to determine if other consultations are required and writes the orders for the initial diagnostic work-up and medication regimen. Within 24 hours, the interdisciplinary team meets to decide on other categories of care, complete the CPC, and make individual care assignments from the CPC. This particular sample CPC relies heavily on nursing care of the client through the critical withdrawal period. However, other problems for the same client, such as imbalanced nutrition, impaired physical mobility, or spiritual distress, may involve other members of the team to a greater degree. Each member of the team stays in contact with the nurse case manager regarding individual assignments. Ideally, team meetings are held daily or every other day to review progress and modify the plan as required.

CPCs can be standardized, as they are intended to be used with uncomplicated cases. A CPC can be viewed as protocol for clients who have specific problems for which a designated outcome can be predicted.

Applying the Nursing Process in the Psychiatric Setting

Based on the definition of *mental health* set forth in Chapter 2, Mental Health and Mental Illness: Historical and Theoretical Concepts, the nurse's role in psychiatry is to help the client successfully adapt to stressors in the environment. Goals are directed toward changes in thoughts, feelings, and behaviors that are age appropriate and congruent with local and cultural norms.

Therapy in the psychiatric setting is very often team oriented, or **interdisciplinary.** Therefore, it is important to delineate nursing's involvement in the treatment regimen. Nurses are valuable members of the team. Having progressed beyond the role of custodial caregiver in the psychiatric setting, they provide defined services within the scope of nursing practice. Nursing diagnosis is helping to define these nursing boundaries, providing the degree of autonomy and professionalism that has for so long been unrealized.

For example, a newly admitted client with the medical diagnosis of schizophrenia may be demonstrating the following behaviors:

■ Inability to trust others
■ Hearing voices
■ Refusal to interact with staff and peers
■ Fear of failure
■ Poor personal hygiene

From these assessments, the treatment team may determine that the client has the following problems:

■ Paranoid delusions
■ Auditory hallucinations
■ Social withdrawal
■ Developmental regression

Team goals would be directed toward the following:

■ Reducing suspiciousness
■ Terminating auditory hallucinations
■ Increasing feelings of self-worth

From this team treatment plan, nursing may identify the following nursing diagnoses:

■ Disturbed sensory perception, auditory (evidenced by hearing voices)*
■ Disturbed thought processes (evidenced by delusions)*
■ Low self-esteem (evidenced by fear of failure and social withdrawal)
■ Self-care deficit (evidenced by poor personal hygiene)

Nursing diagnoses are prioritized according to life-threatening potential. Maslow's hierarchy of needs is an appropriate model to follow when prioritizing nursing diagnoses. In this instance, Disturbed sensory perception (auditory) is identified as the priority nursing diagnosis because the client may be hearing voices that command him or her to harm self or others. Psychiatric nursing, regardless of the setting—hospital (inpatient or outpatient), office, home, community—is

---

*Disturbed sensory perception and Disturbed thought processes have been removed from the NANDA-I list of approved nursing diagnoses (NANDA-I, 2012). However, they will continue to be used in this textbook because of their appropriateness to certain behaviors.

goal-directed care. The goals (or expected outcomes) are client-oriented, measurable, and focused on problem resolution (if this is realistic) or on a more short-term outcome (if resolution is unrealistic). For example, in the previous situation, expected outcomes for the identified nursing diagnoses might be as follows:

The client:

- Demonstrates trust in one staff member within 3 days
- Verbalizes understanding that the voices are not real (not heard by others) within 5 days
- Completes one simple craft project within 5 days
- Takes responsibility for own self-care and performs activities of daily living independently by time of discharge

Nursing's contribution to the interdisciplinary treatment regimen will focus on establishing trust on a one-to-one basis (thus reducing the level of anxiety that may be promoting hallucinations), giving positive feedback for small day-to-day accomplishments in an effort to build self-esteem, and assisting with and encouraging independent self-care. These interventions describe *independent nursing* actions and goals that are evaluated apart from, while also being directed toward achievement of, the *team's* treatment goals.

In this manner of collaboration with other team members, nursing provides a unique service based on sound knowledge of psychopathology, scope of practice, and legal implications of the role. Although there is no question that implementing physician's orders is an important aspect of nursing care, nursing interventions that enhance achievement of the overall goals of treatment are important contributions as well. The nurse who administers a medication prescribed by the physician to decrease anxiety may also choose to stay with the anxious client and offer reassurance of safety and security, thereby providing an independent nursing action that is distinct from, yet complementary to, the medical treatment.

Concept Mapping*

Concept mapping is a diagrammatic teaching and learning strategy that allows students and faculty to visualize interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. Basically, it is a diagram of client problems and interventions. Compared to the commonly used column format care plans, concept map care plans are more succinct. They primarily serve to enhance critical-thinking skills and clinical reasoning ability by creating a holistic picture of various client problems and their interconnectedness to one another.

---

*Content in this section is adapted from Doenges, Moorhouse, & Murr (2016) and Schuster (2015).

The nursing process is foundational to developing and using the concept map care plan, just as with all types of nursing care plans. Client data are collected and analyzed, nursing diagnoses are formulated, outcome criteria are identified, nursing actions are planned and implemented, and the success of the interventions in meeting the outcome criteria is evaluated.

The concept map care plan may be presented in its entirety on one page, or the assessment data and nursing diagnoses may appear in diagram format on one page, with outcomes, interventions, and evaluation written on a second page. Alternatively, the diagram may appear in circular format, with nursing diagnoses and interventions branching off the "client" in the center of the diagram. Or, it may begin with the "client" at the top of the diagram, with branches emanating in a linear fashion downward.

Whatever format is chosen to visualize the concept map, the diagram should reflect the nursing process in a stepwise fashion, beginning with the client and his or her reason for needing care, nursing diagnoses with subjective and objective clinical evidence for each, nursing interventions, and outcome criteria for evaluation.

Figure 9–2 presents one example of a concept map care plan. It is assembled for the hypothetical client with schizophrenia discussed in the previous section, "Applying the Nursing Process in the Psychiatric Setting." Different colors may be used in the diagram to designate various components of the care plan. Connecting lines are drawn between components to indicate any relationships that exist. For example, there may be a relationship between two nursing diagnoses (e.g., between the nursing diagnoses of Pain or Anxiety and Disturbed sleep pattern). A line between these nursing diagnoses should be drawn to show the relationship.

Concept map care plans permit viewing the "whole picture" without generating a great deal of paperwork. Because they reflect the steps of the nursing process, concept map care plans also are valuable guides for documentation of client care. Doenges, Moorhouse, and Murr (2016) note that traditional care plans fail to clarify how all the client's identified needs are related, so the user may not develop a holistic view. The concept map clarifies those linkages. Whether these care-planning strategies are used for learning or in actual practice, both the concept map and traditional care plan are useful tools for developing and visualizing the critical-thinking process that goes into planning client care.

Documentation of the Nursing Process

Equally as important as using the nursing process in the delivery of care is documenting its use in writing.

Clinical Vignette: Harry has been admitted to the psychiatric unit with a diagnosis of schizophrenia. He is socially isolated and stays in his room unless strongly encouraged by the nurse to come out. He says to the nurse, "You have to be your own boss. You can't trust anybody." He refuses to eat any food from his tray, stating that the voice of his deceased grandfather is telling him it is poisoned. His clothes are dirty, and he has an objectionable body odor. The nurse develops the following concept map care plan for Harry.

Signs and Symptoms
- Delusional thinking
- Suspiciousness

Signs and Symptoms
- Verbalizes hearing voices
- Listening pose

Signs and Symptoms
- Social withdrawal
- Expresses fear of failure

Signs and Symptoms
- Offensive body odor
- Soiled clothing
- Unkempt appearance

Nursing Diagnosis
Disturbed thought processes

Nursing Diagnosis
Disturbed sensory perception (auditory)

Nursing Diagnosis
Low self-esteem

Nursing Diagnosis
Self-care deficit (hygiene)

Nursing Actions
- Do not whisper to others in client's presence.
- Serve food family style.
- Perform mouth checks for meds.
- Be cautious with touch.
- Use same staff.
- Meet client needs and keep promises to promote trust.

Nursing Actions
- Observe for signs of hallucinations.
- Be cautious with touch.
- Use "the voices" instead of "they" when asking for content of hallucinations.
- Use distraction to bring client back to reality.

Nursing Actions
- Spend time with client and develop trust.
- Attend groups with client at first to offer support.
- Encourage simple methods of achievement.
- Teach effective communication techniques.
- Encourage verbalization of fears.

Nursing Actions
- Encourage independence in ADLs, but intervene as needed.
- Offer recognition and positive reinforcement for independent accomplishments.

Medical Rx: Risperidone 2 mg bid

Outcomes
- Demonstrates ability to trust
- Differentiates between delusional thinking and reality

Outcomes
- Discusses content of hallucinations with nurse
- Hallucinations are eliminated

Outcomes
- Attends groups willingly and without being accompanied by nurse
- Interacts appropriately with others

Outcomes
- Performs ADLs independently
- Maintains personal hygiene at an acceptable level

FIGURE 9–2 Example of a concept map care plan for a client with schizophrenia.

Some contemporary nursing leaders advocate that with solid standards of practice and procedures in place within the institution, nurses need only chart when there has been a deviation in the care as outlined by that standard. This method of documentation, known as *charting by exception,* is not widely accepted, as many legal decisions are still based on the precept that "if it was not charted, it was not done."

Because nursing process and diagnosis are mandated by nurse practice acts in some states, documentation of their use is considered evidence in those states when determining certain cases of negligence by nurses. Some health-care organization accrediting agencies also require that nursing process be reflected in the delivery of care.

A variety of documentation methods can be used to reflect use of the nursing process in the delivery of

nursing care. Three examples are presented here: problem-oriented recording (POR); Focus Charting®; and the problem, intervention, evaluation (PIE) system of documentation.

Problem-Oriented Recording

Problem-oriented recording, based on a list of problems, follows the subjective, objective, assessment, plan, implementation, and evaluation (SOAPIE) format. When used in nursing, the problems (nursing diagnoses) are identified on a written plan of care, with appropriate nursing interventions described for each. Documentation written in the SOAPIE format includes the following:

S = Subjective data: Information gathered from what the client, family, or other source has said or reported

O = Objective data: Information gathered through direct observation by the person performing the assessment; may include a physiological measurement such as blood pressure or a behavioral response such as affect

A = Assessment: The nurse's interpretation of the subjective and objective data

P = Plan: The actions or treatments to be carried out (may be omitted in daily charting if the plan is clearly explained in the written nursing care plan and no changes are expected)

I = Intervention: Those nursing actions that were actually carried out

E = Evaluation: Evaluation of the problem following nursing intervention (some nursing interventions cannot be evaluated immediately, so this section may be optional)

Table 9–3 shows how POR corresponds to the steps of the nursing process. Following is an example of a three-column documentation in the POR format.

EXAMPLE

DATE/TIME	PROBLEM	PROGRESS NOTES
9-12-17 1000	Social isolation	**S:** States he does not want to sit with or talk to others; "they frighten me." **O:** Stays in room alone unless strongly encouraged to come out; no group involvement; at times listens to group conversations from a distance but does not interact; some hypervigilance and scanning noted **A:** Inability to trust; panic level of anxiety; delusional thinking **I:** Initiated trusting relationship by spending time alone with the client; discussed his feelings regarding interactions with others; accompanied client to group activities; provided positive feedback for voluntarily participating in assertiveness training

TABLE 9–3 Validation of the Nursing Process With Problem-Oriented Recording

PROBLEM-ORIENTED RECORDING	WHAT IS RECORDED	NURSING PROCESS
S and O (Subjective and Objective data)	Verbal reports to, and direct observation and examination by, the nurse	Assessment
A (Assessment)	Nurse's interpretation of S and O	Diagnosis and outcome identification
P (Plan) (Omitted in charting if written plan describes care to be given)	Description of appropriate nursing actions to resolve the identified problem	Planning
I (Intervention)	Description of nursing actions actually carried out	Implementation
E (Evaluation)	A reassessment of the situation to determine results of nursing actions implemented	Evaluation

Focus Charting

Another type of documentation that reflects use of the nursing process is **Focus Charting®.** Focus Charting differs from POR in that the main perspective has been changed from "problem" to "focus," and a data, action, and response (DAR) format has replaced SOAPIE.

Lampe (1985) suggested that a focus for documentation can be any of the following:

■ Nursing diagnosis
■ Current client concern or behavior
■ Significant change in the client status or behavior
■ Significant event in the client's therapy

The focus cannot be a medical diagnosis. The documentation is organized in the format of DAR. These categories are defined as follows:

D = Data: Information that supports the stated focus or describes pertinent observations about the client

A = Action: Immediate or future nursing actions that address the focus, and evaluation of the present care plan along with any changes required

R = Response: Description of client's responses to any part of the medical or nursing care

Table 9–4 shows how Focus Charting corresponds to the steps of the nursing process. Following is an example of a three-column documentation in the DAR format.

EXAMPLE

DATE/TIME	FOCUS	PROGRESS NOTES
9-12-17 1000	Social isolation related to mistrust, panic anxiety, delusions	**D:** States he does not want to sit with or talk to others; they "frighten" him; stays in room alone unless strongly encouraged to come out; no group involvement; at times listens to group conversations from a distance, but does not interact; some hypervigilance and scanning noted **A:** Initiated trusting relationship by spending time alone with client; discussed his feelings regarding interactions with others; accompanied client to group activities; provided positive feedback for voluntarily participating in assertiveness training **R:** Cooperative with therapy; still acts uncomfortable in the presence of a group of people; accepted positive feedback from nurse

TABLE 9–4 **Validation of the Nursing Process With Focus Charting**		
FOCUS CHARTING	**WHAT IS RECORDED**	**NURSING PROCESS**
D (Data)	Information that supports the stated focus or describes pertinent observations about the client	Assessment
Focus	A nursing diagnosis; current client concern or behavior; significant change in client status; significant event in the client's therapy (*Note:* If outcome appears on written care plan, it need not be repeated in daily documentation unless a change occurs.)	Diagnosis and outcome identification
A (Action)	Immediate or future nursing actions that address the focus; appraisal of the care plan along with any changes required	Plan and implementation
R (Response)	Description of client responses to any part of the medical or nursing care	Evaluation

The PIE Method

The PIE method, or more specifically, "APIE" (assessment, problem, intervention, evaluation), is a systematic approach of documenting to nursing process and nursing diagnosis. A problem-oriented system, **PIE charting** uses accompanying flow sheets that are individualized by each institution. Criteria for documentation are organized in the following manner:

A = Assessment: A complete client assessment is conducted at the beginning of each shift. Results are

documented under this section in the progress notes. Some institutions elect instead to use a daily client assessment sheet designed to meet specific needs of the unit. Explanation of any deviation from the norm is included in the progress notes.

P = Problem: A problem list, or list of nursing diagnoses, is an important part of the APIE method of charting. The name or number of the problem being addressed is documented in this section.

I = Intervention: Nursing actions are performed, directed at resolution of the problem.

E = Evaluation: Outcomes of the implemented interventions are documented, including an evaluation of client responses to determine the effectiveness of nursing interventions and the presence or absence of progress toward resolution of a problem.

Table 9–5 shows how APIE charting corresponds to the steps of the nursing process. Following is an example of a three-column documentation in the APIE format.

EXAMPLE

DATE/TIME	PROBLEM	PROGRESS NOTES
9-12-17 1000	Social isolation	**A:** States he does not want to sit with or talk to others; they "frighten" him; stays in room alone unless strongly encouraged to come out; no group involvement; at times listens to group conversations from a distance but does not interact; some hypervigilance and scanning noted **P:** Social isolation related to inability to trust, panic level of anxiety, and delusional thinking **I:** Initiated trusting relationship by spending time alone with client; discussed his feelings regarding interactions with others; accompanied client to group activities; provided positive feedback for voluntarily participating in assertiveness training **E:** Cooperative with therapy; still uncomfortable in the presence of a group of people; accepted positive feedback from nurse

TABLE 9–5 Validation of the Nursing Process With APIE Method

APIE CHARTING	WHAT IS RECORDED	NURSING PROCESS
A (Assessment)	Subjective and objective data about the client that are gathered at the beginning of each shift	Assessment
P (Problem)	Name (or number) of nursing diagnosis being addressed from written problem list, and identified outcome for that problem (*Note:* If outcome appears on written care plan, it need not be repeated in daily documentation unless a change occurs.)	Diagnosis and outcome identification
I (Intervention)	Nursing actions performed, directed at problem resolution	Plan and implementation
E (Evaluation)	Appraisal of client responses to determine effectiveness of nursing interventions	Evaluation

Electronic Documentation

Most health-care facilities have implemented an electronic health record (EHR) or electronic documentation system. Federal regulations and programs have incentivized the move to EHR systems by requiring health-care organizations to use them in order to receive Medicare and Medicaid reimbursement; as of 2015, progressive reductions in reimbursement have been initiated for health-care providers who are not demonstrating meaningful use of EHRs.

The rationale for this move is that EHR systems have been shown to improve both the quality of client care and the efficiency of the health-care system (U.S. Government Accountability Office, 2010). In 2003, the U.S. Department of Health and Human Services commissioned the Institute of Medicine (IOM) to study the capabilities of an EHR system. The IOM identified a set of eight core functions that EHR systems should perform in the delivery of safer, higher-quality, and more efficient health care (Institute of Medicine, 2003):

1. **Health information and data:** EHRs would provide more rapid access to important patient information (e.g., allergies, laboratory test results, a medication list, demographic information, and clinical narratives), thereby improving care providers' abilities to make sound clinical decisions in a timely manner.
2. **Results management:** Computerized results of all types (e.g., laboratory test results, radiology procedure result reports) can be accessed more easily by the provider at the time and place they are needed.
3. **Order entry and order management:** Computer-based order entries improve workflow processes by

eliminating lost orders and ambiguities caused by illegible handwriting, generating related orders automatically, monitoring for duplicate orders, and improving the speed with which orders are executed.

4. **Decision support:** Computerized decision support systems enhance clinical performance for many aspects of health care. Using reminders and prompts, improvement in regular screenings and other preventive practices can be accomplished. Other aspects of health-care support include identifying possible drug interactions and facilitating diagnosis and treatment.

5. **Electronic communication and connectivity:** Improved communication among care associates, such as medicine, nursing, laboratory, pharmacy, and radiology team members, can enhance client safety and quality of care. Efficient communication among providers improves continuity of care, allows for more timely interventions, and reduces the risk of adverse events.

6. **Patient support:** Computer-based interactive client education, self-testing, and self-monitoring have been shown to improve control of chronic illnesses.

7. **Administrative processes:** Electronic scheduling systems (e.g., for hospital admissions and outpatient procedures) increase the efficiency of health-care organizations and provide more timely service to patients.

8. **Reporting and population health management:** Health-care organizations are required to report health-care data to government and private sectors for patient safety and public health. Uniform electronic data standards facilitate this process at the provider level, reduce the associated costs, and increase the speed and accuracy of the data reported.

Table 9–6 lists some of the advantages and disadvantages of paper records and EHRs.

TABLE 9–6 **Advantages and Disadvantages of Paper Records and EHR Systems**	
PAPER*	EHR SYSTEM
ADVANTAGES	**ADVANTAGES**
■ People know how to use it.	■ Can be accessed by multiple providers from remote sites.
■ It is fast for current practice.	■ Facilitates communication between disciplines.
■ It is portable.	■ Provides reminders about completing information.
■ It is nonbreakable.	■ Provides warnings about incompatibilities of medications or variances from normal standards.
■ It accepts multiple data types, such as graphs, photographs, drawings, and text.	■ Reduces redundancy of information.
■ Legal issues and costs are understood.	■ Requires less storage space and is more difficult to lose.
DISADVANTAGES	■ Easier to research for audits, quality assurance, and epidemiological surveillance.
■ It can be lost.	■ Provides immediate retrieval of information (e.g., test results).
■ It is often illegible and incomplete.	■ Provides links to multiple databases of health-care knowledge, thus providing diagnostic support.
■ It has no remote access.	■ Decreases charting time.
■ It can be accessed by only one person at a time.	■ Reduces errors due to illegible handwriting.
■ It is often disorganized.	■ Facilitates billing and claims procedures.
■ Information is duplicated.	**DISADVANTAGES**
■ It is hard to store.	■ Excessive expense to initiate the system.
■ It is difficult to research, and continuous quality improvement is laborious.	■ Substantial learning curve involved for new users; training and retraining required.
■ Same client has separate records at each facility (physician's office, hospital, home care).	■ Stringent requirements to maintain security and confidentiality.
■ Records are shared only through hard copy.	■ Technical difficulties are possible.
	■ Legal and ethical issues involving privacy and access to client information.
	■ Requires consistent use of standardized terminology to support information sharing across wide networks.

*From Young, K.M., & Catalano, J. T. (2015). Nursing informatics. In J.T. Catalano (Ed.), *Nursing now! Today's issues, tomorrow's trends* (7th ed.). Philadelphia: F.A. Davis. With permission.

Summary and Key Points

■ The nursing process provides a methodology by which nurses may deliver care using a systematic, scientific approach.

■ The focus of the nursing process is goal directed and based on a decision-making or problem-solving model consisting of six steps: assessment, diagnosis, outcome identification, planning, implementation, and evaluation.

■ Assessment is a systematic, dynamic process by which the nurse, through interaction with the client, significant others, and health-care providers, collects and analyzes data about the client.

■ Nursing diagnoses are clinical judgments about individual, family, or community responses to actual or potential health problems and life processes.

■ Outcomes are measurable, expected, patient-focused goals that translate into observable behaviors.

■ Evaluation is the process of determining both the client's progress toward the attainment of expected outcomes and the effectiveness of nursing care.

■ The psychiatric nurse uses the nursing process to assist clients to adapt successfully to stressors within the environment.

■ The nurse serves as a valuable member of the interdisciplinary treatment team, working both independently and cooperatively with other team members.

■ Case management is an innovative model of care delivery that serves to provide quality client care while controlling health-care costs. Critical pathways of care serve as the tools for provision of care in a case management system.

■ Nurses may serve as case managers, who are responsible for negotiating with multiple health-care providers to obtain a variety of services for the client.

■ Concept mapping is a diagrammatic teaching and learning strategy that allows students and faculty to visualize interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. The concept map care plan is an innovative approach to planning and organizing nursing care.

■ Nurses must document that the nursing process has been used in the delivery of care. Three methods of documentation that reflect use of the nursing process are POR, Focus Charting, and the PIE method.

■ Many health-care facilities have implemented the use of EHRs or electronic documentation systems. EHRs have been shown to improve both the quality of client care and the efficiency of the healthcare system.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. The nurse is using nursing process to care for a client who is suicidal. Which of the following nursing actions is a part of the assessment step of the nursing process?
   a. Identifies nursing diagnosis: Risk for suicide
   b. Notes that client's family reports recent suicide attempt
   c. Prioritizes the necessity of maintaining a safe client environment
   d. Obtains a short-term contract from the client to seek out staff if feeling suicidal

2. The nurse is using nursing process to care for a client who is suicidal. Which of the following nursing actions is a part of the diagnosis step of the nursing process?
   a. Identifies nursing diagnosis: Risk for suicide
   b. Notes that client's family reports recent suicide attempt
   c. Prioritizes the necessity for maintaining a safe environment for the client
   d. Obtains a short-term contract from the client to seek out staff if feeling suicidal

Review Questions—cont'd
Self-Examination/Learning Exercise

3. The nurse is using nursing process to care for a client who is suicidal. Which of the following nursing actions is a part of the outcome identification step of the nursing process?
a. Prioritizes the necessity for maintaining a safe environment for the client
b. Determines if nursing interventions have been appropriate to achieve desired results
c. Obtains a short-term contract from the client to seek out staff if feeling suicidal
d. Establishes goal of care: Client will not harm self during hospitalization

4. The nurse is using nursing process to care for a client who is suicidal. Which of the following nursing actions is a part of the planning step of the nursing process?
a. Prioritizes the necessity for maintaining a safe environment for the client
b. Determines if nursing interventions have been appropriate to achieve desired results
c. Obtains a short-term contract from the client to seek out staff if feeling suicidal
d. Establishes goal of care: Client will not harm self during hospitalization

5. The nurse is using nursing process to care for a client who is suicidal. Which of the following nursing actions is a part of the implementation step of the nursing process?
a. Prioritizes the necessity for maintaining a safe environment for the client
b. Determines if nursing interventions have been appropriate to achieve desired results
c. Collaborates with the client to develop a plan for ongoing safety and suicide prevention
d. Establishes goal of care: Client will not harm self during hospitalization

6. The nurse is using nursing process to care for a client who is suicidal. Which of the following nursing actions is a part of the evaluation step of the nursing process?
a. Prioritizes the necessity for maintaining a safe environment for the client
b. Determines if nursing interventions have been appropriate to achieve desired results
c. Obtains a short-term contract from the client to seek out staff if feeling suicidal
d. Establishes goal of care: Client will not harm self during hospitalization

7. S.T. is a 15-year-old girl who has just been admitted to the adolescent psychiatric unit with a diagnosis of anorexia nervosa. She is 5 feet 5 inches tall and weighs 82 pounds. She was selected to join the cheerleading squad for the fall but states that she is not as good as the others on the squad. The treatment team has identified the following problems: refusal to eat, occasional purging, refusing to interact with staff and peers, and fear of failure. Which of the following nursing diagnoses would be appropriate for S.T.? (Select all that apply.)
a. Social isolation
b. Disturbed body image
c. Low self-esteem
d. Imbalanced nutrition: Less than body requirements

8. S.T. is a 15-year-old girl who has just been admitted to the adolescent psychiatric unit with a diagnosis of anorexia nervosa. She is 5 feet 5 inches tall and weighs 82 pounds. She was selected to join the cheerleading squad for the fall but states that she is not as good as the others on the squad. The treatment team has identified the following problems: refusal to eat, occasional purging, refusing to interact with staff and peers, and fear of failure. Which of the following nursing diagnoses would be the priority diagnosis for S.T.?
a. Social isolation
b. Disturbed body image
c. Low self-esteem
d. Imbalanced nutrition: Less than body requirements

9. Nursing diagnoses are prioritized according to which of the following?
a. Degree of potential for resolution
b. Legal implications associated with nursing intervention
c. Life-threatening potential
d. Client and family requests

Review Questions—cont'd
Self-Examination/Learning Exercise

10. Which of the following describe advantages of electronic health records (EHRs)? (Select all that apply.)
   a. They reduce redundancy of information.
   b. They reduce privacy issues.
   c. They decrease charting time.
   d. They facilitate communication between disciplines.

10 Therapeutic Groups

CHAPTER OUTLINE

KEY TERMS

altruism
autocratic
catharsis

democratic
laissez-faire

psychodrama
universality

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define a group.
2. Discuss eight functions of a group.
3. Identify various types of groups.
4. Describe physical conditions that influence groups.
5. Discuss therapeutic factors that occur in groups.
6. Describe the phases of group development.
7. Identify various leadership styles in groups.
8. Identify various roles that members assume within a group.
9. Discuss psychodrama as a specialized form of group therapy.
10. Describe the role of the nurse in group therapy.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What is the difference between therapeutic groups and group therapy?
2. What are the expectations of the leader in the initial or orientation phase of group development?
3. How does an autocratic leadership style affect member enthusiasm and morale?
4. How does size of the group influence group dynamics?

Human beings are complex creatures who share their activities of daily living with various *groups* of people. As Forsyth (2010) stated, "The tendency to join with others in groups is perhaps the single most important characteristic of humans and the processes that unfold within these groups leave an indelible imprint on their members and on society" (p. 1).

Health-care professionals share their personal lives with groups of people and encounter multiple group situations in their professional operations. Team conferences, committee meetings, grand rounds, and

inservice sessions are but a few instances in which this occurs. In psychiatry, work with clients and families often takes the form of groups. With group work, not only does the nurse have the opportunity to reach out to a greater number of people at one time, but those individuals also assist each other by sharing their feelings, opinions, ideas, and behaviors with the group. Clients learn from each other in a group setting.

This chapter explores various types and methods of therapeutic groups that can be used with psychiatric clients and the role of the nurse in group intervention.

CORE CONCEPT

Group

A *group* is a collection of individuals whose association is founded on commonalities of interest, values, norms, or purpose. Membership in a group is generally by chance (born into the group), by choice (voluntary affiliation), or by circumstance (the result of life-cycle events over which an individual may or may not have control).

Functions of a Group

Sampson and Marthas (1990) outlined the following eight functions that groups serve for their members. They contend that groups may serve more than one function and usually serve different functions for different members of the group.

1. **Socialization:** The cultural group into which individuals are born begins the process of teaching social norms. This process is continued throughout their lives by members of other groups with which they become affiliated.
2. **Support:** One's fellow group members are available in time of need. Individuals derive a feeling of security from group involvement.
3. **Task completion:** Group members provide assistance in endeavors that are beyond the capacity of one individual alone or when results can be achieved more effectively as a team.
4. **Camaraderie:** Members of a group provide the joy and pleasure that individuals seek from interactions with significant others.
5. **Information sharing:** Learning takes place within groups. Knowledge is gained when individual members learn how others in the group have resolved situations similar to those with which they are currently struggling.
6. **Normative influence:** This function relates to the ways in which groups enforce the established norms. As group members interact, they influence each other about expected norms for communication and behavior.

7. **Empowerment:** Groups help to bring about improvement in existing conditions by providing support to individual members who seek to bring about change. Groups have power that individuals alone do not.
8. **Governance:** Groups that provide governance functions oversee and direct activities often within the context of a larger group organization. "For example, groups or committees that oversee strategic planning, ensure compliance with quality standards, or establish rules and policies" within a larger organization.

Types of Groups

The functions of a group vary depending on the reason the group was formed. Clark (2009) identified three types of groups in which nurses most often participate: task, teaching, and supportive/therapeutic groups.

Task Groups

The function of a task group is to accomplish a specific outcome or task. The focus is on solving problems and making decisions to achieve this outcome. Often, a deadline is placed on completion of the task, and such importance is placed on a satisfactory outcome that conflict in the group may be smoothed over or ignored in order to focus on the priority at hand.

Teaching Groups

Teaching, or educational, groups exist to convey knowledge and information to a number of individuals. Nurses can be involved in many types of teaching groups, such as medication education, childbirth education, breast self-examination, and effective parenting classes. These groups usually have a set time frame or specified number of meetings. Members learn from each other as well as from the designated instructor. The objective of teaching groups is verbalization or demonstration by the learner of the material presented by the end of the designated period.

Supportive/Therapeutic Groups

Supportive or therapeutic groups are primarily concerned with preventing future upsets by teaching participants effective ways to deal with emotional stress arising from situational or developmental crises.

CORE CONCEPT

Group Therapy

A form of psychosocial treatment in which a number of clients meet together with a therapist for purposes of sharing, gaining personal insight, and improving interpersonal coping strategies.

For the purposes of this text, it is important to differentiate between *therapeutic groups* and *group therapy.* Leaders of group therapy generally have advanced degrees in psychology, social work, nursing, or medicine. They often have additional training or experience in conducting group psychotherapy based on various theoretical frameworks such as psychoanalytic, psychodynamic, interpersonal, or family dynamics, under the supervision of accomplished professionals. Approaches based on these theories are used by group therapy leaders to encourage improvement in group members' abilities to function on an interpersonal level.

Therapeutic groups, on the other hand, are not designed for psychotherapy. They focus instead on group relations, interactions among group members, and the consideration of selected issues. Like group therapists, individuals who lead therapeutic groups must be knowledgeable in *group process;* that is, the *way* in which group members interact with each other. Interruptions, silences, judgments, glares, and scapegoating are examples of group processes (Clark, 2009). These interactions may occur whether or not there is a designated group leader, but nurses acting as group leaders can guide the ways in which members interact to facilitate accomplishing the group's goals or tasks. This is one reason that group leaders are often referred to as *group facilitators.* They must also have thorough knowledge of *group content,* the topic or issue being discussed by the group, and the ability to present the topic in language that can be understood by all members. Many nurses who work in psychiatry lead supportive/therapeutic groups.

Self-Help Groups

Nurses may also be involved in self-help groups, a type of group that has grown in number and in credibility in recent years. They allow clients to talk about their fears and relieve feelings of isolation while receiving comfort and advice from others undergoing similar experiences. Examples of self-help groups for clients and families dealing with disorders such as Alzheimer's disease or anorexia nervosa, Weight Watchers, Alcoholics Anonymous, Reach to Recovery, Parents Without Partners, Overeaters Anonymous, Adult Children of Alcoholics, and many others related to specific needs or illnesses. These groups may or may not have a professional leader or consultant. They are run by the members, and leadership often rotates from member to member.

Nurses may become involved with self-help groups either voluntarily or because their advice or participation has been requested by the members. The nurse may function as a referral agent, resource person, member of an advisory board, or leader of the group. Self-help groups are a valuable source of referral for clients

with specific problems. However, nurses must be knowledgeable about the purposes of the group, membership, leadership, benefits, and problems that might threaten the success of the group before making referrals to their clients for a specific self-help group. The nurse may find it necessary to attend several meetings of a particular group, if possible, to assess its effectiveness of purpose and appropriateness for client referral.

Physical Conditions That Influence Group Dynamics

Seating

When preparing the setting for a group, there should be no barrier between members. For example, a circle of chairs is better than chairs set around a table. Members should be encouraged to sit in different chairs at each meeting. This openness and change creates a feeling of discomfort that encourages anxious and unsettled behaviors that can then be explored within the group.

Size

Various authors have suggested different ranges of size as ideal for group interaction: 5 to 10 (Yalom & Leszcz, 2005), 2 to 15 (Sampson & Marthas, 1990), and 4 to 12 (Clark, 2009). Group size does make a difference in the interaction among members. The larger the group, the less time is available to devote to individual members. In larger groups, more aggressive individuals are most likely to be heard, whereas quieter members may be left out of the discussions altogether. Understanding this dynamic alerts the nurse group leader to this possibility and allows him or her to facilitate interaction that promotes greater involvement for all members. Conversely, larger groups provide more opportunities for individuals to learn from other members. The wider range of life experiences and knowledge provides a greater potential for effective group problem-solving. Studies have indicated that a composition of 7 or 8 members provides a favorable climate for optimal group interaction and relationship development.

Membership

Whether the group is open or closed is another condition that influences the dynamics of group process. Open groups are those in which members leave and others join at any time while the group is active. The continuous movement of members in and out of the group creates the type of discomfort described previously that encourages unsettled behaviors in individual members and fosters the exploration of feelings. These are the most common types of groups held on short-term inpatient units, although they are used in outpatient and long-term care facilities as well. Closed groups

usually have a predetermined, fixed time frame. All members join at the time the group is organized and terminate at the end of the designated time period. Closed groups are often composed of individuals with common issues or problems they wish to address.

Therapeutic Factors

Why are therapeutic groups helpful? Yalom and Leszcz (2005) described 11 therapeutic factors that individuals can achieve through interpersonal interactions within the group, some of which are present in most groups in varying degrees:

1. **Instillation of hope:** By observing the progress of others in the group with similar problems, a group member garners hope that his or her problems can also be resolved.
2. **Universality:** Through **universality,** individuals come to realize that they are not alone in the problems, thoughts, and feelings they are experiencing. Anxiety is relieved by the support and understanding of others in the group who share similar (universal) experiences.
3. **Imparting of information:** Knowledge is gained through formal instruction as well as sharing of advice and suggestions among group members.
4. **Altruism: Altruism** is assimilated by group members through mutual sharing and concern for each other. Providing assistance and support to others creates a positive self-image and promotes self-growth.
5. **Corrective recapitulation of the primary family group:** Group members are able to reexperience early family conflicts that remain unresolved. Attempts at resolution are promoted through feedback and exploration.
6. **Development of socializing techniques:** Through interaction with and feedback from other members within the group, individuals are able to correct maladaptive social behaviors and learn and develop new social skills.
7. **Imitative behavior:** In this setting, one who has mastered a particular psychosocial skill or developmental task can be a valuable role model for others. Individuals may imitate selected behaviors that they wish to develop in themselves.
8. **Interpersonal learning:** The group offers many and varied opportunities for interacting with other people. Insight is gained regarding how one perceives and is being perceived by others.
9. **Group cohesiveness:** Members develop a sense of belonging that separates the individual ("I am") from the group ("we are"). Out of this alliance emerges a common feeling that both individual members and the total group are of value to each other.
10. **Catharsis:** Within the group, members are able to express both positive and negative feelings—perhaps feelings that have never been expressed before—in a nonthreatening atmosphere. This **catharsis,** or open expression of feelings, is beneficial for the individual within the group.
11. **Existential factors:** The group is able to help individual members take direction of their own lives and accept responsibility for the quality of their existence.

It may be helpful for a group leader to explain these therapeutic factors to members. Positive responses are experienced by individuals who understand and are able to recognize therapeutic factors as they occur within the group.

Phases of Group Development

Groups, like individuals, move through phases of life-cycle development. Ideally, groups progress from the phase of infancy to advanced maturity in an effort to fulfill the objectives set forth by the membership. Unfortunately, as with individuals, some groups become fixed in early developmental levels and never progress, or they experience periods of regression in the developmental process. Three phases of group development are discussed here.

Phase I. Initial or Orientation Phase
Group Activities

Leader and members work together to establish the rules that will govern the group (e.g., when and where meetings will occur, the importance of confidentiality, how meetings will be structured). Goals of the group are established. Members are introduced to each other.

Leader Expectations

The leader is expected to orient members to specific group processes, encourage members to participate without disclosing too much too soon, promote an environment of trust, and ensure that rules established by the group do not interfere with fulfillment of the goals.

Member Behaviors

In phase I, members have not yet established trust and will respond to this lack of trust by being overly polite. There is a fear of not being accepted by the group. They may try to "get on the good side" of the leader with compliments and conforming behaviors. A power struggle may ensue as members compete for their position in the "pecking order" of the group.

Phase II. Middle or Working Phase

Group Activities

Ideally, during the working phase, cohesiveness has been established within the group. This phase is when productive work toward completion of the task is undertaken. Problem-solving and decision-making occur within the group. In the mature group, cooperation prevails, and differences and disagreements are confronted and resolved.

Leader Expectations

The leader becomes less of a leader and more of a facilitator during the working phase. Some leadership functions are shared by certain members of the group as they progress toward resolution. The leader helps to resolve conflict and continues to foster cohesiveness among the members while ensuring that they do not deviate from the intended task or purpose for which the group was organized.

Member Behaviors

At this point, trust has been established among the members. They turn more often to each other and less often to the leader for guidance. They accept criticism from each other, using it in a constructive manner to create change. Occasionally, subgroups form in which two or more members conspire with each other to the exclusion of the rest of the group. To maintain group cohesion, these subgroups must be confronted and discussed by the entire membership. Conflict is managed by the group with minimal assistance from the leader.

Phase III. Final or Termination Phase

Group Activities

The longer a group has existed, the more difficult termination is likely to be for the members. Termination should be mentioned from the outset of group formation and be discussed in depth for several meetings prior to the final session. A sense of loss that precipitates the grief process may be evident, particularly in groups that have been successful in their stated purpose.

Leader Expectations

In the termination phase, the leader encourages the group members to reminisce about what has occurred within the group, review the goals and discuss the actual outcomes, and provide feedback to each other about individual progress within the group. The leader encourages members to discuss feelings of loss associated with termination of the group.

Member Behaviors

Members may express surprise over the actual materialization of the end. This represents the grief response of denial, which may then progress to anger. Anger toward other group members or toward the leader may reflect feelings of abandonment (Sampson & Marthas, 1990). These feelings may lead to individual members' discussions of previous losses for which similar emotions were experienced. Successful termination of the group may help members develop the skills needed when losses occur in other dimensions of their lives.

Leadership Styles

Lippitt and White (1958) identified three of the most common group leadership styles: autocratic, democratic, and laissez-faire. Table 10–1 outlines various similarities and differences among the three leadership styles.

Autocratic

Autocratic leaders have personal goals for the group. They withhold information from group members, particularly issues that may interfere with achievement of their own objectives. The message that is conveyed to the group is: "We will do it my way. My way is best." The focus in this style of leadership is on the leader. Members are dependent on the leader for problem-solving, decision-making, and permission to perform. The approach of the autocratic leader is one of persuasion, striving to convince others in the group that his or her ideas and methods are superior. Productivity is high with this type of leadership, but often morale within the group is low because of lack of member input and creativity.

Democratic

The **democratic** leadership style focuses on the members of the group. Information is shared with members in an effort to allow them to make decisions regarding group goals. Members are encouraged to participate fully in solving problems that affect the group, including taking action to effect change. The message that is conveyed to the group is: "Decide what must be done, consider the alternatives, make a selection, and proceed with the actions required to complete the task." The leader provides guidance and expertise as needed. Productivity is lower than it is with autocratic leadership, but morale is much higher because of the extent of input allowed all members of the group and the potential for individual creativity.

Laissez-Faire

This leadership style allows people to do as they please. There is no direction from the leader. In fact, the **laissez-faire** leader's approach is noninvolvement. Goals for the group are undefined. No decisions are made, no problems are solved, and no action is taken.

TABLE 10–1 **Leadership Styles—Similarities and Differences**			
CHARACTERISTICS	AUTOCRATIC	DEMOCRATIC	LAISSEZ-FAIRE
Focus	Leader	Members	Undetermined
Task strategy	Members are persuaded to adopt leader's ideas	Members engage in group problem-solving	No defined strategy exists
Member participation	Limited	Unlimited	Inconsistent
Individual creativity	Stifled	Encouraged	Not addressed
Member enthusiasm and morale	Low	High	Low
Group cohesiveness	Low	High	Low
Productivity	High	High (may not be as high as autocratic)	Low
Individual motivation and commitment	Low (tend to work only when leader is present to urge them to do so)	High (satisfaction derived from personal input and participation)	Low (feelings of frustration from lack of direction or guidance)

Members become frustrated and confused, and productivity and morale are low.

Member Roles

Benne and Sheats (1948) identified three major types of roles that individuals play within the membership of the group. These are roles that serve to

1. Complete the task of the group.
2. Maintain or enhance group processes.
3. Fulfill personal or individual needs.

   Task roles and maintenance roles contribute to the success or effectiveness of the group. Personal roles satisfy needs of the individual members, sometimes to the extent of interfering with the effectiveness of the group.

   Table 10–2 outlines specific roles within these three major types and the behaviors associated with each.

Psychodrama

A specialized type of therapeutic group, called **psychodrama,** was introduced by Jacob L. Moreno, a Viennese psychiatrist. Moreno's method employs a dramatic approach in which clients become "actors" in life-situation scenarios.

   The group leader is called the *director,* group members are the *audience,* and the *set* or *stage* may be specially designed or just a room or area selected for this purpose. Actors are members from the audience who agree to take part in the "drama" by role-playing a situation about which they have been informed by the director. Usually, the situation is an issue with which an individual client has been struggling. The client plays the role of himself or herself and is called the *protagonist.* In this role, he or she is able to express true feelings toward individuals (represented by group members) with whom unresolved conflicts exist.

TABLE 10–2 **Member Roles Within Groups**	
ROLE	BEHAVIORS
TASK ROLES	
Coordinator	Clarifies ideas and suggestions that have been made within the group; brings relationships together to pursue common goals
Evaluator	Examines group plans and performance, measuring against group standards and goals
Elaborator	Explains and expands upon group plans and ideas
Energizer	Encourages and motivates group to perform at its maximum potential
Initiator	Outlines the task at hand for the group and proposes methods for solution
Orienter	Maintains direction within the group

Continued

TABLE 10–2 **Member Roles Within Groups—cont'd**	
ROLE	BEHAVIORS
MAINTENANCE ROLES	
Compromiser	Relieves conflict within the group by assisting members to reach a compromise agreeable to all
Encourager	Offers recognition and acceptance of others' ideas and contributions
Follower	Listens attentively to group interaction; is a passive participant
Gatekeeper	Encourages acceptance of and participation by all members of the group
Harmonizer	Minimizes tension within the group by intervening when disagreements produce conflict
INDIVIDUAL (PERSONAL) ROLES	
Aggressor	Expresses negativism and hostility toward other members; may use sarcasm in effort to degrade the status of others
Blocker	Resists group efforts; demonstrates rigid and sometimes irrational behaviors that impede group progress
Dominator	Manipulates others to gain control; behaves in authoritarian manner
Help-seeker	Uses the group to gain sympathy from others; seeks to increase self-confidence from group feedback; lacks concern for others or for the group as a whole
Monopolizer	Maintains control of the group by dominating the conversation
Mute or silent member	Does not participate verbally; remains silent for a variety of reasons—may feel uncomfortable with self-disclosure or may be seeking attention through silence
Recognition seeker	Talks about personal accomplishments in an effort to gain attention for self
Seducer	Shares intimate details about self with group; is the least reluctant of the group to do so; may frighten others in the group and inhibit group progress with excessive premature self-disclosure

SOURCES: Benne, K.D., & Sheats, P. (1948, Spring). Functional roles of group members. *Journal of Social Issues, 4*(2), 41-49; Hobbs, D.J., & Powers, R.C. (1981). *Group member roles: For group effectiveness.* Ames: Iowa State University, Cooperative Extension Service; Larson, M.L., & Williams, R.A. (1978). How to become a better group leader? Learn to recognize the strange things that happen to some people in groups. *Nursing, 8*(8), 65-72.

In some instances, the group leader may ask for a client to volunteer as protagonist for that session. The client may choose a situation he or she wishes to enact and select the audience members to portray the roles of others in the life situation. The psychodrama setting provides the client with a safer and less-threatening atmosphere than the real situation, facilitating the expression of true feelings and resolution of interpersonal conflicts.

When the drama has been completed, group members from the audience discuss the situation they have observed, offer feedback, express their feelings, and relate their own similar experiences. In this way, all group members benefit from the session, either directly or indirectly.

Nurses often serve as actors or role players in psychodrama sessions. Leaders of psychodrama have graduate degrees in psychology, social work, nursing, or medicine with additional training in group therapy and specialty preparation to become a psychodramatist.

The Role of the Nurse in Therapeutic Groups

Nurses participate in group situations on a daily basis. In health-care settings, nurses serve on or lead task groups that create policy, describe procedures, and plan client care. They are also involved in a variety of other groups aimed at the institutional effort of serving the consumer. Nurses are encouraged to use the steps of the nursing process as a framework for task group leadership.

In psychiatry, nurses may lead various types of therapeutic groups, such as client education, assertiveness training, grief support, parenting, and transition to discharge groups, among others. To function effectively in the leadership capacity for these groups, nurses

must recognize the various processes that occur in groups, such as the phases of group development, the roles that people play within groups, and the motivation behind these behaviors. They also need to be able to select the most appropriate leadership style for the type of group. Generalist nurses may develop these skills as part of their undergraduate educations, or they may pursue additional study while serving and learning as the coleader of a group with a more experienced nurse leader.

Generalist nurses in psychiatry should not serve as leaders of psychotherapy groups. The *Psychiatric-Mental Health Nursing Scope and Standards of Practice* (American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric Nurses, 2014) specifies that nurses who serve as group psychotherapists should have a minimum of a master's degree in psychiatric nursing. Educational preparation in group theory, extended practice as a group coleader or leader under the supervision of an experienced psychotherapist, and participation in group therapy on an experiential level are also recommended. Additional specialist training is required beyond the master's level to prepare nurses to become family therapists or psychodramatists.

Leading therapeutic groups is within the realm of nursing practice. Because group work is such a common therapeutic approach in the discipline of psychiatry, nurses working in this field must continually strive to expand their knowledge and use of group process as a significant psychiatric nursing intervention.

> **CLINICAL PEARL Knowledge of human behavior in general and the group process in particular is essential to effective group leadership.**

Summary and Key Points

- A group has been defined as a collection of individuals whose association is founded on shared commonalities of interest, values, norms, or purpose.
- Eight group functions have been identified: socialization, support, task completion, camaraderie, informational, normative, empowerment, and governance.
- The three major types of group are task groups, teaching groups, and supportive/therapeutic groups.
- The function of task groups is to solve problems, make decisions, and achieve a specific outcome.
- In teaching groups, knowledge and information are conveyed to a number of individuals.
- The function of supportive/therapeutic groups is to educate people to deal effectively with emotional stress in their lives.

- In self-help groups, members share the same type of problem and help each other to prevent decompensation related to that problem.
- Therapeutic groups differ from group therapy in that the focus is not on psychotherapy but rather on interaction and relationships among group members with regard to a selected issue. Group therapy is more focused on specific models of psychotherapy, and the leaders generally have advanced degrees in psychology, social work, nursing, or medicine. Placement of the seating and size of the group can influence group interaction.
- Groups can be open (when members leave and others join at any time while the group is active) or closed (when groups have a predetermined, fixed time frame and all members join at the same time and leave when the group disbands).
- Yalom and Leszcz (2005) describe the following therapeutic factors that individuals derive from participation in therapeutic groups: instillation of hope, universality, imparting of information, altruism, corrective recapitulation of the primary family group, development of socializing techniques, imitative behavior, interpersonal learning, group cohesiveness, catharsis, and existential factors.
- Groups progress through three phases: the initial (orientation) phase, the working phase, and the termination phase.
- Group leadership styles include autocratic, democratic, and laissez-faire.
- Members play various roles within groups. These roles are categorized as task, maintenance, and personal roles.
- Psychodrama is a specialized type of group therapy that uses a dramatic approach in which clients become "actors" in life-situation scenarios.
- The psychodrama setting provides the client with a safer and less-threatening atmosphere than the real situation in which to express and work through unresolved conflicts.
- Nurses lead various types of therapeutic groups in the psychiatric setting. Knowledge of human behavior in general and the group process in particular is essential to effective group leadership.
- Specialized training, in addition to a master's degree, is required for nurses to serve as group psychotherapists or psychodramatists.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions:

1. Nicole is the nurse leader of a childbirth preparation group. Each week she shows films and sets out reading materials. She expects the participants to utilize their time on a topic of their choice or practice skills they have observed on the films. Two couples have dropped out of the group, stating, "This is a big waste of time." Which type of group and style of leadership is described in this situation?
   a. Task group, democratic leadership
   b. Teaching group, laissez-faire leadership
   c. Self-help group, democratic leadership
   d. Supportive-therapeutic group, autocratic leadership

2. Aisha is a psychiatric nurse who has been selected to lead a group for women who desire to lose weight. The criterion for membership is that they must be at least 20 pounds overweight. All have tried to lose weight on their own many times in the past without success. At their first meeting, Aisha provides suggestions as the members determine what their goals will be and how they plan to go about achieving those goals. They decided how often they wanted to meet and what they planned to do at each meeting. Which type of group and style of leadership is described in this situation?
   a. Task group, autocratic leadership
   b. Teaching group, democratic leadership
   c. Self-help group, laissez-faire leadership
   d. Supportive-therapeutic group, democratic leadership

3. Erik is a staff nurse on a surgical unit. He has been selected as leader of a newly established group of staff nurses organized to determine ways to decrease the number of medication errors occurring on the unit. Erik has definite ideas about how to bring this about. He has also applied for the position of Head Nurse on the unit and believes that if he is successful in leading the group toward achievement of its goals, he can also facilitate his chances for promotion. At each meeting, he addresses the group in an effort to convince the members to adopt his ideas. Which type of group and style of leadership is described in this situation?
   a. Task group, autocratic leadership
   b. Teaching group, autocratic leadership
   c. Self-help group, democratic leadership
   d. Supportive-therapeutic group, laissez-faire leadership

4. The nurse leader is explaining about group "therapeutic factors" to members of the group. She tells the group that group situations are beneficial because members can see that they are not alone in their experiences. Nurse Carol appropriately identifies this as evidence of which therapeutic factor?
   a. Altruism
   b. Imitative behavior
   c. Universality
   d. Imparting of information

5. Nurse Carol is the leader of a bereavement group for widows. Elena is a new member who listens to the group and learns that Jane has been a widow for 5 years now. Jane has adjusted well and Elena thinks maybe she can too. Nurse Carol appropriately identifies this as evidence of which therapeutic factor?
   a. Universality
   b. Imitative behavior
   c. Installation of hope
   d. Imparting of information

Review Questions—cont'd
Self-Examination/Learning Exercise

6. Paul is a member of an anger management group. He knew that people did not want to be his friend because of his violent temper. In the group, he has learned to control his temper and form satisfactory interpersonal relationships with others. This is an example of which therapeutic factor?
   a. Catharsis
   b. Altruism
   c. Imparting of information
   d. Development of socializing techniques

7. Benjamin is a member of an Alcoholics Anonymous group. He learned about the effects of alcohol on the body when a nurse from the chemical dependency unit spoke to the group. This is an example of which therapeutic factor?
   a. Catharsis
   b. Altruism
   c. Imparting of information
   d. Universality

8. Sandra is the nurse leader of a supportive-therapeutic group for individuals with anxiety disorders. In this group, Helen talks incessantly. When someone else tries to make a comment, she refuses to allow him or her to speak. What type of member role is Helen assuming in this group?
   a. Aggressor
   b. Monopolizer
   c. Blocker
   d. Seducer

9. Sandra is the nurse leader of a supportive-therapeutic group for individuals with anxiety disorders. On the first day the group meets, Valerie speaks first and begins by sharing the intimate details of her incestuous relationship with her father. What type of member role is Valerie assuming in this group?
   a. Aggressor
   b. Monopolizer
   c. Blocker
   d. Seducer

10. Sandra is the nurse leader of a supportive-therapeutic group for individuals with anxiety disorders. Violet, who is beautiful but lacks self-confidence, states to the group, "Maybe if I became a blond my boyfriend would love me more." Larry responds, "Listen, dummy, you need more than blond hair to keep the guy around. A bit more in the brains department would help!" What type of member role is Larry assuming in this group?
   a. Aggressor
   b. Monopolizer
   c. Blocker
   d. Seducer

11. A nurse on the psychiatric unit is asked to lead a psychoeducational group on self-esteem for the in-patients on the unit. It is an open group, and the nurse is aware that the attendees are multicultural. Which of the following evidence-based skills are important for the nurse to possess to effectively lead this group? (Select all that apply.)
   a. Awareness that contact alone with people of different cultures will improve their intercultural communication
   b. Skills of emotional intelligence
   c. Training in culturally specific language interpretation and communication styles
   d. Recognition that people from cultures that do not value self-esteem will need to be prohibited from attending the group
   e. An attitude of willingness to identify and correct intercultural misunderstandings when they occur

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Atieno-Okech, J.E., Pimpleton, A.M., Vannatta, R., & Champe, J. (2015). Intercultural communication: An application to group work. *Journal for Specialists in Group Work, 40*(3), 268-293. doi.org/10.1080/01933922.2015.1056568

DESCRIPTION OF THE STUDY: Interdisciplinary literature on intercultural communication was reviewed to serve as a source of evidence-based strategies for improving intercultural communication. The authors note that as the diversity of the U.S. population continues to grow, counseling and therapy groups will grow in diversity and demand attention to intercultural communication in order to remain an effective tool for support, psychoeducation, and therapy.

RESULTS OF THE STUDY: The literature supports that discrepancies in communication style, differing cultural values, and ethnocentrism have been identified as major intercultural barriers in communication. "Languaculture," a concept developed by Agar (1994), refers to culturally specific ways of interpreting language and is identified as an important knowledge base for group leaders. The case study presented by the authors describes a white female group leader who was using the communication technique of reflection with an African American male who perceived this reflection of his feelings as a taunt rather than as helpful. Attempting to "curiously and respectfully" seek understanding when these miscommunications occur is identified as a group leader's responsibility.

Other studies found that contact alone did not translate into improved communication and relationships in an intercultural group. The biggest deterrents were apathy, ethnocentrism, and inexperience. The group leader therefore must be aware of and attend to cues that may indicate a breakdown in communication between members before conflict or outright hostility arises. Studies showed that emotional intelligence is associated with the ability to read verbal and nonverbal cues, so this is an important skill for group leaders.

IMPLICATIONS FOR NURSING PRACTICE: Nurses will likely be engaged in intercultural groups among peers in the workplace as well as when leading therapeutic patient groups. The following skills are identified as important to evidence-based practice when leading groups:

1. Awareness of one's own cultural values and biases to evaluate and counter ethnocentrism as a barrier to communication
2. Training in culturally specific ways of interpreting language and communication
3. Emotional intelligence skills to recognize when communication breakdowns are surfacing
4. An attitude of wanting to understand and correct intercultural miscommunication when it occurs

marital skew
paradoxical intervention
pseudohostility
pseudomutuality

reframing
scapegoating
subsystems
triangles

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define the term *family*.
2. Identify stages of family development.
3. Describe major variations to the American middle-class family life cycle.
4. Discuss characteristics of adaptive family functioning.
5. Describe behaviors that interfere with adaptive family functioning.
6. Discuss the essential components of family systems, structural, and strategic therapies.
7. Construct a family genogram.
8. Apply the steps of the nursing process in therapeutic intervention with families.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Describe the concept of reframing.
2. Describe the process of triangulation in a dysfunctional family pattern.
3. How are genograms helpful in family therapy?
4. What behaviors are indicative of a positive family climate?

What is a family? Wright and Leahey (2013) propose the following definition: a family is who they say they are. Many family structures exist within society today, such as the biological family of procreation, the nuclear family that incorporates one or more members of the extended family (family of origin), the sole-parent family, the stepfamily, the communal family, and the same-sex couple or family. Labeling individuals as "families" based on their group composition may not be the best characterization, however. Instead, family consideration may be more appropriately determined on the basis of attributes of affection, strong emotional ties, a sense of belonging, and durability of membership (Wright & Leahey, 2013).

Many nurses have interactions with family members on a daily basis. A client's illness or hospitalization affects all members of the family, and nurses must understand how to work with the family as a unit, knowing that family members can have a profound effect on the client's healing process.

Nurse generalists should be familiar with the tasks associated with adaptive family functioning. With this knowledge, they are able to assess family interaction and recognize problems when they arise. They can provide support to families with ill members and make referrals to other professionals when assistance is required to restore adaptive functioning.

Nurse specialists usually possess an advanced degree in nursing. Some nurse specialists have education or experience that qualifies them to perform family therapy. Family therapy is an approach that incorporates theories and models designed to explore family dynamics, dysfunctional patterns, and methods for adaptive change within the context of the family. This chapter explores the stages of family development and compares the "typical" family within various subcultures. Characteristics of adaptive family functioning and behaviors that interfere with this adaptation are discussed. Theoretical components of selected therapeutic approaches are described. Instructions for construction of a family genogram are included. Nursing process provides the framework for nursing intervention with families.

CORE CONCEPT

Family

Two or more individuals who depend on one another for emotional, physical, and economical support. The members of the family are self-defined (Kaakinen & Hanson, 2015, p. 5).

Stages of Family Development

McGoldrick, Garcia-Preto, and Carter (2015) discuss stages and developmental tasks that describe the traditional family life cycle and acknowledge that this is only one of many trajectories for family development in today's society. It is clear that accomplishment of these tasks would vary among diverse cultural groups and among the various forms of family structure previously described. These stages, however, provide a valuable framework from which the nurse may study families, emphasizing expansion (the addition of members), contraction (the loss of members), and realignment of relationships as members experience developmental changes. These stages of family development are described in the following paragraphs and summarized in Table 11–1.

TABLE 11–1 **Stages of the Traditional Family Life Cycle**		
FAMILY LIFE-CYCLE STAGES	**EMOTIONAL PROCESS OF TRANSITION: KEY PRINCIPLES**	**CHANGES REQUIRED IN FAMILY STATUS TO PROCEED DEVELOPMENTALLY**
The single young adult	Accepting separation from parents and emotional and financial responsibility for self	■ Differentiation of self in relation to family of origin ■ Development of intimate peer relationships ■ Establishment of self in respect to work and financial independence ■ Establishment of self in community and larger society
The family joined through marriage/union	Commitment to new system	■ Formation of partner systems ■ Realignment of relationships with extended family, friends, and larger community and social system to include new partners
The family with young children	Accepting new members into the system	■ Adjustment of couple system to make space for children ■ Collaboration in child rearing, financial and housekeeping tasks ■ Realignment of relationships with extended family to include parenting and grandparenting roles ■ Realignment of relationships with community and larger social system to include new family structure and relationships

TABLE 11–1	**Stages of the Traditional Family Life Cycle—cont'd**	
FAMILY LIFE-CYCLE STAGES	EMOTIONAL PROCESS OF TRANSITION: KEY PRINCIPLES	CHANGES REQUIRED IN FAMILY STATUS TO PROCEED DEVELOPMENTALLY
The family with adolescents	Increasing flexibility of family boundaries to permit children's independence and grandparents' frailties	■ Shifting of parent-child relationships to permit adolescents to move in and out of system ■ Refocus on midlife couple and career issues ■ Beginning shift toward caring for older generation ■ Realignment with community and larger social system to include shifting family of emerging adolescent and parents in new formation patterns of relating
The family launching children and moving on in midlife	Accepting a multitude of exits from and entries into the family system	■ Renegotiation of couple system as a dyad ■ Development of adult-to-adult relationships between parents and grown children ■ Realignment of relationships to include in-laws and grandchildren ■ Realignment of relationships with community and larger social system to include new structure and constellation of family relationships ■ Exploration of new interests/career given the freedom from child-care responsibilities ■ Dealing with care needs, disabilities and death of parents (grandparents)
The family in later life (late middle age to end of life)	■ Accepting the shifting of generational roles ■ Accepting the realities of limitations and death	■ Maintaining own and/or couple functioning and interests in face of physiological decline; exploration of new familial and social role options ■ Supporting more central role of middle generations ■ Realignment of the system in relation to community and larger social system to acknowledge changed pattern of family relationships of this stage ■ Making room in the system for the wisdom and experience of the elders; supporting the older generation without overfunctioning for them ■ Dealing with loss of spouse, siblings, and other peers and preparation for own death; life review and integration ■ Managing reversed roles in caretaking between middle and older generations

(2015). *The expanding family life cycle: Individual, family, and social perspectives* (5th ed., pp.1-19). Boston: Allyn & Bacon. Reprinted by permission.

The Single Young Adult

This model begins with the launching of the young adult from the family of origin. This is a difficult stage because young adults must decide what social standards from the family of origin will be preserved and what standards they will eventually incorporate into a new family. Tasks of this stage include forming an identity separate from the parents, establishing intimate peer relationships, and advancing toward financial independence. Problems can arise when either the young adults or the parents encounter difficulty

terminating the interdependent relationship that has existed in the family of origin.

The Family Joined Through Marriage/Union

Uniting as a couple is a difficult transition that must include the integration of contrasting issues that each partner brings to the relationship and issues they may have redefined for themselves as a couple. In addition, the new couple must renegotiate relationships with parents, siblings, and other relatives in view of

the new partnership. Tasks of this stage include establishing a new identity as a couple, realigning relationships with members of extended family, and making decisions about having children. Problems can arise if either partner remains too enmeshed with their family of origin or when the couple chooses to cut themselves off completely from extended family.

The Family With Young Children

Adjustments in relationships must occur with the arrival of children. The entire family system is affected, and role realignments are necessary for both new parents and new grandparents. Tasks of this stage include making adjustments within the marital system to meet the responsibilities associated with parenthood while maintaining the integrity of the couple relationship, sharing equally in the tasks of child rearing, and integrating the roles of extended family members into the newly expanded family organization. Problems can arise when parents lack knowledge about normal childhood development and adequate patience to allow children to express themselves through behavior.

The Family With Adolescents

This stage of family development is characterized by a great deal of turmoil and transition. Parents are approaching a midlife stage, and adolescents are undergoing biological, emotional, and sociocultural changes that place demands on each individual and on the family unit. Grandparents, too, may require assistance with the tasks of later life. These developments can create a "sandwich" effect for the parents, who must deal with issues confronting three generations. Tasks of this stage include redefining the level of dependence so that adolescents are provided with greater autonomy while parents remain responsive to the teenager's dependency needs. Midlife issues related to marriage, career, and aging parents must also be resolved during this period. Problems can arise when parents are unable to relinquish control and allow the adolescent greater autonomy and freedom to make independent decisions or when parents are unable to agree and support each other in this effort.

The Family With Children Leaving Home

A great deal of realignment of family roles occurs during this stage, characterized by the intermittent exiting and entering of various family members. Children leave home for further education and careers; marriages occur, and new spouses, in-laws, and children enter the system; and new grandparent roles are established. Adult-to-adult relationships among grown children and their parents are renegotiated. Tasks associated with this stage include reestablishing the bond of the dyadic marital relationship; realigning relationships to include grown children, in-laws, and new grandchildren; and accepting the additional caretaking responsibilities and eventual death of elderly parents. Problems can arise when feelings of loss and depression become overwhelming in response to the departure of children from the home, when parents are unable to accept their children as adults or cope with the disability or death of their own parents, and when the marital bond has deteriorated.

The Family in Later Life (Late Middle Age to End of Life)

This stage can begin with retirement and last until the death of both spouses (Wright & Leahey, 2013). However, many older people who have the opportunity to do so are choosing to retire early, while large numbers of those over age 65 are remaining in the workforce and delaying retirement. Thus, the beginning of this stage varies widely. Most adults in their later years are still a prominent part of the family system, and many are able to offer support to their grown children in the middle generation. Tasks traditionally associated with this stage include exploring new social roles related to retirement and possible change in socioeconomic status; accepting some decline in physiological functioning; dealing with the deaths of spouse, siblings, and friends; and confronting and preparing for one's own death. A growing trend is an increasing number of older adults living with and in many cases assuming primary responsibility for their grandchildren. Currently, 10 percent of all children under the age of 18 in the United States are living with a grandparent (U.S. Census Bureau, 2015). When older adults have failed to fulfill the tasks associated with earlier levels of development and are dissatisfied with the way their lives have gone, they may be unable to find happiness in retirement or emotional satisfaction with children and grandchildren and have difficulty accepting the deaths of loved ones or preparing for their own impending deaths.

Major Variations

Divorce

McGoldrick, Garcia-Preto, and Carter (2015) also discuss stages and tasks of families experiencing divorce and remarriage. Data on marriage, divorce, and remarriage in the United States show that about half of first marriages end in divorce (Centers for Disease Control [CDC], 2015). Whether related to single, never married, or divorced parents, the number of children who live with one parent has tripled since 1960 from 9 percent to 27 percent (U.S. Census Bureau, 2015). Stages in the family life cycle of divorce include

deciding to divorce, planning the breakup of the system, separation, and divorce. Tasks include accepting one's own part in the failure of the marriage, working cooperatively on problems related to finances and child custody and visitation, realigning relationships with extended family, and mourning the loss of the marriage relationship and the intact family.

After the divorce, the custodial parent must adjust to functioning as the single leader of an ongoing family while working to rebuild a new social network. The noncustodial parent must find ways to continue to be an effective parent in a different kind of parenting role.

Remarriage

Approximately 75 percent of people who divorce eventually remarry (Stepfamily Foundation, 2016). Currently, less than half (46%) of children are living in a family with two parents in their first marriage (Pew Research Center, 2015). The challenges that face the joining of two established families are immense, and statistics reveal that the rate of divorce for remarried couples is even higher than the divorce rate following first marriages (Cory, 2013). Stages in the remarried family life cycle include entering the new relationship, planning the new marriage and family, and remarriage and reestablishment of family. Tasks include making a firm commitment to confronting the complexities of combining two families, maintaining open communication, facing fears, realigning relationships with extended family to include new spouse and children, and encouraging healthy relationships with biological (noncustodial) parents and grandparents.

Problems can arise when there is a blurring of boundaries between the custodial and noncustodial families. Children may contemplate issues such as

■ Who is the boss now?
■ Who is most important, the child or the new spouse?
■ Mom loves her new husband more than she loves me.
■ Dad lets me do more than my new stepdad does.
■ I don't have to mind him; he's not my real dad.

Confusion and distress for both the children and the parents can be minimized with the establishment of clear boundaries and open communication.

Cultural Variations

It is difficult to generalize about variations in family life-cycle development according to culture. Most families have become acculturated to the U.S. society and conform to the life-cycle stages previously described. However, cultural diversity does exist, and nurses must be aware of possible differences in family expectations related to sociocultural beliefs. The following are possible variations to consider.

Marriage

A number of U.S. subcultures maintain traditional values in terms of marriage. These views, along with the influence of Roman Catholicism, exert important influences on attitudes toward marriage in many Italian American and Latino American families. Although the tradition of arranged marriages is disappearing in Asian American families, there is still frequently a strong influence by the family on mate selection in this culture. In most of these subcultures, the father is considered the authority figure and head of the household, and the mother assumes the role of homemaker and caretaker. Family loyalty is intense, and a breach of this loyalty brings considerable shame to the family.

Jewish families have traditionally valued marriage and have prohibited marriage to non-Jews, but that cultural value has shifted in recent years. Valley (2005) makes the following statement about Jewish families:

> The Jewish family today encompasses a wide variety of textures and forms. Decades of high intermarriage have diversified the customs and complexions of the family. High divorce rates, meanwhile, have altered the very definition of what is "normal." Whereas single-parent households were once a rare exception, they now account for an increasing proportion of American Jewish families. Some in the community have interpreted the changing family in strident and judgmental terms: it is a sign of rampant assimilation, loss of tradition, or moral permissiveness. But such scolding does nothing to respond to the new realities and to the changing needs of Jews today. (p. 2)

Children

In traditional Latino American and Italian American cultures, children are central to the family system. Many of these individuals have strong ties to Roman Catholicism, which historically has promoted marital relations for procreation only and encouraged families to have large numbers of children. Regarding birth control, the Catechism of the Catholic Church pronounces as immoral any means that interferes with or hinders procreation (U.S. Catholic Church, 2016).

In the traditional Jewish community, having children is seen as a scriptural and social obligation. "You shall be fruitful and multiply" is a commandment of the Torah.

In some traditional Asian American cultures, sons are more highly valued than daughters (Earp, 2017; Chang, 2017). Younger siblings are expected to follow the guidance of the oldest son throughout their lives, and when the father dies, the oldest son takes over the leadership of the family.

In all of these cultures, children are expected to be respectful of their parents and not bring shame to the family. Especially in the Asian culture, children

learn a sense of obligation to their parents for bringing them into this world and caring for them when they were helpless. This is viewed as a debt that can never be truly repaid, and no matter what the parents may do, the child is still obligated to give respect and obedience.

Extended Family

The concept of extended family varies among societies (Purnell, 2013). The extended family is extremely important in the Western European, Latino, and Asian cultures, playing a central role in all aspects of life, including decision-making.

In some U.S. subcultures, such as Asian, Latino, Italian, and Iranian, it is not uncommon to find several generations living together. Older family members are valued for their experience and wisdom. Because extended families often share living quarters or at least live nearby, tasks of child rearing may be shared by several generations.

Divorce

In the Jewish community, divorce is often seen as a violation of family togetherness. Some Jewish parents take their child's divorce personally, with a response that reflects, "How could you possibly do this to me?"

Because Roman Catholicism has traditionally opposed divorce, those cultures that are largely Catholic have followed this dictate. Historically, a low divorce rate has existed among Italian Americans, Irish Americans, and Latino Americans. The number of divorces among these subcultures is on the rise, however, particularly in successive generations that have become acculturated into a society where divorce is more acceptable.

Family Functioning

Boyer and Jeffrey (1994) describe six elements on which families are assessed to be either functional or dysfunctional. Each can be viewed on a continuum, although families rarely fall at extreme ends of the continuum. Rather, they tend to be dynamic and fluctuate from one point to another within the different areas. These six elements of assessment are described below and summarized in Table 11–2.

Communication

Functional communication patterns are those in which verbal and nonverbal messages are clear, direct, and congruent between sender and intended receiver. Family members are encouraged to express honest feelings and opinions, and all members participate in decisions that affect the family system. Each member is an active listener to the other members of the family.

Behaviors that interfere with functional communication include the following:

Making Assumptions

With this behavior, one assumes that others will know what is meant by an action or an expression (or sometimes even what one is thinking); or, conversely, assumes to know what another member is thinking or feeling without checking to make certain.

> **EXAMPLE**
>
> A mother says to her teenaged daughter, "You should have known that I expected you to clean up the kitchen while I was gone!"

Belittling Feelings

This behavior involves ignoring or minimizing another's feelings when they are expressed. Belittling a

TABLE 11–2 **Family Functioning: Elements of Assessment**		
ELEMENTS OF ASSESSMENT	**CONTINUUM**	
	FUNCTIONAL	**DYSFUNCTIONAL**
Communication	Clear, direct, open, honest, with congruence between verbal and nonverbal	Indirect, vague, controlled, with many double-bind messages
Self-concept reinforcement	Supportive, loving, praising, approving, with behaviors that instill confidence	Unsupportive, blaming, put-downs, refusing to allow self-responsibility
Family members' expectations	Flexible, realistic, individualized	Judgmental, rigid, controlling, ignoring individuality
Handling differences	Tolerant, dynamic, negotiating	Attacking, avoiding, surrendering
Family interactional patterns	Workable, constructive, flexible, promoting the needs of all members	Contradictory, rigid, self-defeating, destructive
Family climate	Trusting, growth-promoting, caring, general feeling of well-being	Distrusting, emotionally painful, with absence of hope for improvement

SOURCE: Adapted from Boyer, P.A., & Jeffrey, R.J. (1994). *A guide for the family therapist.* Northvale, NJ: Jason Aronson.

person's feelings encourages the individual to withhold honest feelings to avoid being hurt by the negative response.

EXAMPLE

When the young woman confides to her mother that she is angry because the grandfather has touched her breast, the mother responds, "Oh, don't be angry. He doesn't mean anything by that."

Failing to Listen

With this behavior, one does not hear what the other individual is saying. Failing to listen can mean not hearing the words by "tuning out" the message, or it can be "selective" listening, in which a person hears only a selective part of the message or interprets it in a selective manner.

EXAMPLE

The father explains to Johnny, "If the contract comes through and I get this new job, we'll have a little extra money and we will consider sending you to State U." Johnny relays the message to his friend, "Dad says I can go to State U!"

Communicating Indirectly

Indirect communication usually means that an individual does not or cannot present a message to a receiver directly, so he or she seeks to communicate through a third person.

EXAMPLE

A father does not want his teenage daughter to see a certain boyfriend but wants to avoid the angry response he expects from his daughter if he tells her so. He expresses his feelings to his wife, hoping she will share them with their daughter.

Presenting Double-Bind Messages

Double-bind communication conveys a "damned if I do and damned if I don't" message. A family member may respond to a direct request by another family member, only to be rebuked when the request is fulfilled. This concept appears again in the section on the strategic model of family therapy later in this chapter.

EXAMPLE

The father tells his son he is spending too much time playing football, and as a result, his grades are falling. The son is expected to bring his grades up over the next 9 weeks or his car will be taken away. When the son tells the father he has quit the football team so he can study more, Dad responds angrily, "I won't allow any son of mine to be a quitter!"

Self-Concept Reinforcement

Functional families strive to reinforce and strengthen each member's self-concept, with the positive result that family members feel loved and valued. Boyer and Jeffrey (1994) stated:

> The manner in which children see and value themselves is influenced most significantly by the messages they receive concerning their value to other members of the family. Messages that convey praise, approval, appreciation, trust, and confidence in decisions and that allow family members to pursue individual needs and ultimately to become independent are the foundation blocks of a child's feelings of self-worth. Adults also need and depend heavily on this kind of reinforcement for their own emotional well-being. (p. 27)

Behaviors that interfere with self-concept reinforcement include the following:

Expressing Denigrating Remarks

These remarks are commonly called "put-downs." Individuals receive messages that they are worthless or unloved.

EXAMPLE

A child spills a glass of milk at the table. The mother responds, "You are hopeless! How could anybody be so clumsy?!"

Withholding Supportive Messages

Some family members find it very difficult to provide others with reinforcing and supportive messages. This difficulty may occur because they themselves have not been the recipients of reinforcement from significant others and have not learned how to provide support to others.

EXAMPLE

A 10-year-old boy playing Little League baseball retrieves the ball and throws it to second base for an out. After the game he says to his Dad, "Did you see my play on second base?" Dad responds, "Yes, I did, son, but if you had been paying better attention, you could have caught the ball for a direct and immediate out."

Taking Over

Taking over occurs when one family member fails to permit another member to develop a sense of responsibility and self-worth. Instead, the person who takes over does things for the individual and thereby prevents him or her from managing the situation independently.

EXAMPLE

Twelve-year-old Eric has a job delivering the evening paper, which he usually begins right after school. Today he must serve a 1-hour detention after school for being late to class yesterday. He tells his Mom, "Tommy said he would throw my papers for me today if I help him wash his Dad's car on Saturday." Mom responds, "Never mind. Tell Tommy to forget it. I'll take care of your paper route today."

Family Members' Expectations

All individuals have some expectations about the outcomes of the life situations they experience. These expectations are related to and significantly influenced by earlier life experiences. In functional families, expectations are realistic, thereby avoiding setting up members for failure. In functional families, expectations are also flexible. Life situations are full of extraneous and unexpected interferences. Flexibility allows for changes and interruptions to occur without creating conflict. Finally, in functional families, expectations are individualized. Each family member is different, with different strengths and limitations. The outcome of a life situation for one family member may not be realistic for another. Each member must be valued independently, and comparison among members must be avoided.

Behaviors that interfere with adaptive functioning in terms of member expectations include the following:

Ignoring Individuality

When family members are expected to perform or behave in ways that undermine their individuality or do not suit their current life situation, their individuality is being ignored. This sometimes happens when parents expect their children to fulfill the hopes and dreams the parents have failed to achieve, yet the children have their own, different hopes and dreams.

EXAMPLE

Bob, an only child, leaves for college next year. Bob's father, Robert, inherited a hardware store that was founded by Bob's great-grandfather and has been in the family for three generations. Robert expects Bob to major in business, work in the store after college, and take over the business when Robert retires. Bob, however, has a talent for writing, wants to major in communication, and wants to work in television news when he graduates. Robert sees this plan as a betrayal of the family.

Demanding Proof of Love

Boyer and Jeffrey (1994) state:

> Family members place expectations on others' behavior that are used as standards by which the expecting member determines how much the other members care for him or her. The message attached to these expectations is: "If you will not be as I wish you to be, you don't love me." (p. 32)

EXAMPLE

"If you don't take over the hardware store, you don't love me" is the message that Bob receives from his father in the previous example.

Handling Differences

It is difficult to conceive of two or more individuals living together who agree on everything all of the time. Serious problems in a family's functioning appear when differences become equated with disapproval or when disagreement is perceived as offensive. Members of a functional family understand that it is acceptable to disagree and deal with differences in an open, nonattacking manner. Members are willing to hear the other person's position, respect the other person's right to hold an opposing position, and work to modify the expectations on both sides of the issue in order to negotiate a workable solution.

Behaviors that interfere with successful family negotiations include the following:

Attacking

Personal attacks can occur when a difference of opinion deteriorates. One person may blame the other with insulting remarks, reminders of past transgressions may occur, and the situation intensifies with destructive expressions of anger and hurt.

EXAMPLE

When Nadya's husband, Denis, buys an expensive set of golf clubs, Nadya responds, "How could you do such a thing? You know we can't afford those! No wonder we don't have a nice house like all our friends. You spend all our money before we can save for a down payment. You're so selfish! We'll never have anything nice, and it's all your fault!"

Avoiding

With this tactic, differences are never acknowledged openly. The individual who disagrees avoids discussing it for fear that the other person will withdraw love or approval or become angry in response to the disagreement. Avoidance also occurs when an individual fears loss of control of his or her temper if the disagreement is brought out into the open.

EXAMPLE

Vicki and Clint have been married 6 months. This is Vicki's second marriage, and she has a 4-year-old son from her first marriage, Derek, who lives with her and Clint. Both Vicki and Clint work, and Derek goes to day care. Since the marriage 6 months ago, Derek cries every night continuously unless Vicki spends all her time with him, which she does in order to keep him quiet. Clint resents this but says nothing for fear he will come across as interfering; however, he has started going back to work in his office in the evenings to avoid the family situation.

Surrendering

The person who surrenders in the face of disagreement does so at the expense of denying his or her own needs or rights. The individual avoids expressing a difference of opinion for fear of angering another person or of losing approval and support.

EXAMPLE

Elaine is the only child of wealthy parents. She attends an exclusive private college in a small New England town, where

she met Andrew, the son of a farming couple from the area. Andrew attended the local community college for 2 years but chose to work on his parents' farm rather than continue college. Elaine and Andrew love each other and want to be married, but Elaine's parents say they will disown her if she marries Andrew, who they believe is below her social status. Elaine breaks off her relationship with Andrew rather than challenge her parents' wishes.

Family Interactional Patterns

Interactional patterns have to do with the ways in which families "behave." All families develop recurring, predictable patterns of interaction over time. These are often thought of as family rules. The mentality conveys, "This is the way we have always done it," and provides a sense of security and stability for family members that comes from predictability. These interactions may have to do with communication, self-concept reinforcement, expressing expectations, and handling differences (all of the behaviors that were discussed previously), but because they are repetitive and recur over time, they become the rules that govern patterns of interaction among family members.

Family rules are functional when they are workable, constructive, and promote the needs of all family members. They are dysfunctional when they become contradictory, self-defeating, and destructive. Family therapists often find that individuals are unaware that dysfunctional family rules exist and may vehemently deny their existence even when confronted with a specific behavioral interaction. The development of dysfunctional interactional patterns occurs through a habituation process and out of fear of change or reprisal or through a lack of knowledge as to how a given situation might be handled differently. Many are derived from the parents' own childhood experiences.

Patterns of interaction that interfere with adaptive family functioning include the following:

Patterns That Cause Emotional Discomfort

Interactions can promote hurt and anger in family members. This is particularly true of emotions that individuals feel uncomfortable expressing or are not permitted (according to family rules) to express openly. These interactional patterns include behaviors such as never apologizing or never admitting that one has made a mistake, forbidding flexibility in life situations ("You must do it my way, or you will not do it at all"), making statements that devalue the worth of others, or withholding statements that promote increased self-worth.

EXAMPLE

Priscilla and Bill had been discussing buying a new car but could not agree on the make or model to buy. One day, Bill appeared at Priscilla's office over the lunch hour and said, "Come outside and see our new car." In front of the building, Bill had parked a brand new sports car that he explained he had purchased with their combined savings. Priscilla was furious but kept quiet and proceeded to finish her workday. At home she expressed her anger to Bill for making the purchase without consulting her. Bill refused to apologize or admit to making a mistake. They both remained cool and hardly spoke to each other for weeks.

Patterns That Perpetuate or Intensify Problems

When problems go unresolved over a long period of time, it sometimes appears to be easier just to ignore them. If problems of the same nature occur, the tendency to ignore them then becomes the safe and predictable pattern of interaction for dealing with this type of situation. This may occur until the problem intensifies to a point when it can no longer be ignored.

EXAMPLE

Dan works hard in the automobile factory and demands peace and quiet from his family when he comes home from work. His children have learned over the years not to share their problems with him because they fear his explosive temper. Their mother attempts to handle unpleasant situations alone as best she can. When son Ron was expelled from school for being caught smoking pot for the third time, Dan yelled, "Why wasn't I told about this before?"

Patterns That Are in Conflict With Each Other

Some family rules may appear to be functional—very workable and constructive—on the surface, but in practice they may serve to destroy healthy interactional patterns. Boyer and Jeffrey (1994) describe the following scenario as an example.

EXAMPLE

Dad insists that all members of the family eat dinner together every evening. No one may leave the table until everyone is finished because dinnertime is one of the few times left when the family can be together. Yet Dad frequently uses the time to reprimand Bobby about his poor grades in math, to scold Ann for her sloppy room, or to make not-so-subtle gibes at Mom for "spending all day on the telephone and never getting anything accomplished."

Family Climate

The atmosphere or climate of a family is composed of a blend of the feelings and experiences that result from family members' verbal and nonverbal sharing and interacting. A positive family climate is founded on trust and reflected in open communication, joyfulness and laughter, expressions of caring and mutual respect, the valuing of each individual as unique, and a general feeling of security and well-being. In a dysfunctional family, the climate is evidenced by tension, frustration, guilt, anger and resentment, depression, and despair.

CORE CONCEPT

Family Therapy

A type of therapeutic modality in which the focus of treatment is on the family as a unit. It represents a form of intervention in which members of a family are assisted to identify and change problematic, maladaptive, self-defeating, repetitive relationship patterns (Goldenberg, Goldenberg, & Pelavin, 2013).

Key:

A = Father subsystem	CD = Sibling subsystem
B = Mother subsystem	AD = Parent-child subsystem
C = Child subsystem	BC = Parent-child subsystem
D = Child subsystem	AC = Parent-child subsystem
AB = Marital subsystem	BD = Parent-child subsystem

FIGURE 11–1 A hierarchy of systems.

Therapeutic Modalities With Families

While family therapy is reserved for the advanced practice psychiatric nurse, the theoretical foundations for family therapy are useful to the generalist nurse for understanding and assessing family dynamics and making appropriate referrals when family dysfunction is identified.

The Family as a System

General systems theory is a way of organizing thought according to the holistic perspective. A system is considered greater than the sum of its parts. A system is considered dynamic and ever changing. A change in one part of the system causes a change in the other parts of the system and in the system as a whole. When studying families, it is helpful to conceptualize a hierarchy of systems.

The family can be viewed as a system composed of various **subsystems,** such as the marital subsystem, parent-child subsystems, and sibling subsystems. Each of these subsystems is further divided into subsystems of individuals. The family system is also a subsystem of a larger suprasystem, such as the neighborhood or community. A schematic of a hierarchy of systems is presented in Figure 11–1.

Major Concepts

Bowen (1978) did a great deal of work with families using a systems approach. Bowen's theoretical approach to family therapy is composed of eight major concepts: (1) differentiation of self, (2) triangles, (3) nuclear family emotional process, (4) family projection process, (5) multigenerational transmission process, (6) sibling position, (7) emotional cutoff, and (8) societal emotional process.

Differentiation of Self

Differentiation of self is the ability to define oneself as a separate being. The Bowen theory suggests that "a person with a well-differentiated self recognizes his [or her] realistic dependence on others, but can stay calm and clear headed enough in the face of conflict, criticism, and rejection to distinguish thinking rooted in a careful assessment of the facts from thinking clouded by emotionality" (Bowen Center, 2016a).

The degree of differentiation of self can be viewed on a continuum from high levels, in which an individual manifests a clearly defined sense of self, to low or undifferentiated levels, in which emotional fusion exists and the individual is unable to function separately from a relationship system. Healthy families encourage differentiation, and the process of separation from the family ego mass is most pronounced during the ages of 2 to 5 and again between the ages of 13 and 15. Families that do not understand the child's need to be different during these times may perceive the child's behavior as objectionable.

Bowen (1971) used the term *stuck-togetherness* to describe the family with the fused ego mass. When family fusion occurs, none of the members has a true sense of self as an independent individual. Boundaries between members are blurred, and the family becomes enmeshed without individual distinguishing characteristics. In this situation, family members can neither gain true intimacy nor separate and become individuals.

Triangles

The concept of **triangles** refers to a three-person emotional configuration that is considered a significant element in evaluating the communication, behavior, and relationships within the family system. Bowen (1978) offers the following description of triangles:

> The basic building block of any emotional system is the triangle. When emotional tension in a two-person system exceeds a certain level, it triangles in a third person, permitting the tension to shift about within the triangle. Any two in the original triangle can add

a new triangle. An emotional system is composed of a series of interlocking triangles. (p. 306)

Triangles are dysfunctional in that they offer relief from anxiety through diversion rather than through resolution of the issue. To diffuse stress and conflict in a two-person relationship, one or both individuals may draw a third person into the mix either for sympathy or to deflect from the issues that are creating the stress between them (Nichols & Davis, 2017). When the dynamics within a triangle stabilize, a fourth person may be brought in to form additional triangles in an effort to reduce tension. This triangulation can continue almost indefinitely as extended family and people outside the family, including the family therapist, may become entangled in the process. The therapist working with families must strive to remain "de-triangled" from this emotional system.

Nuclear Family Emotional Process

The nuclear family emotional process describes the patterns of emotional functioning in a single generation. The nuclear family begins with a relationship between two people who form a couple. The most open relationship usually occurs during courtship, when most individuals choose partners with similar levels of differentiation. The lower the level of differentiation, the greater the possibility of problems in the future. A degree of fusion occurs with permanent commitment. This fusion results in anxiety and must be dealt with by each partner in an effort to maintain a healthy degree of differentiation.

Family Projection Process

Spouses who are unable to work through the undifferentiation or fusion that occurs with permanent commitment may project the resulting anxiety onto the children when they become parents. This occurrence is manifested as a father-mother-child triangle. These triangles are common and exist in various gradations of intensity in most families with children.

The child who becomes the target of the projection may be selected for various reasons:

■ A particular child reminds one of the parents of an unresolved childhood issue.
■ The child is of a particular gender or position in the family.
■ The child is born with special needs.
■ The parent has a negative attitude about the pregnancy.

This behavior is called **scapegoating.** It is harmful to both the child's emotional stability and his or her ability to function outside the family. A child who is scapegoated may become identified as "the problem child" and is vulnerable to accepting this label as his or her identity. The potential outcomes are risk for poor self-esteem, difficulty developing healthy relationships, and other emotional problems.

Multigenerational Transmission Process

Bowen (1978) described the multigenerational transmission process as the manner in which interactional patterns are transferred from one generation to another. Attitudes, values, beliefs, behaviors, and patterns of interaction are passed along from parents to children over many lifetimes, so that it becomes possible to show in a family assessment that a certain behavior has existed within a family through multiple generations.

Genograms A convenient way to plot a multigenerational assessment is with the use of **genograms.** Genograms offer the convenience of a great deal of information in a small amount of space. They can also be used as teaching tools with the family itself. An overall picture of the life of the family over several generations can be conveyed, including roles that various family members play as well as emotional distance between specific individuals. Areas for change can be easily identified. A sample genogram is presented in Figure 11–2.

Sibling Position

This view suggests that birth order in a family influences the development of predictable personality characteristics. For example, firstborn children are thought to be perfectionistic, reliable, and conscientious; middle children are described as independent, loyal, and intolerant of conflict; and youngest children tend to be charming, precocious, and gregarious (Leman, 2009). Bowen used this thesis to help determine levels of differentiation within a family and the possible direction of the family projection process. For example, if an oldest child exhibits characteristics more representative of a youngest child, there is evidence that this child may be the product of triangulation. Sibling position profiles are also used when studying multigenerational transmission processes and verifiable data are missing for certain family members.

Is there evidence to support profiled sibling personality traits based on birth order? The answer is complex. Hartshorne (2010) states that the majority of the 65,000 research studies on this topic are flawed and the remainder show no significant effect. Eckstein and Kaufman's work (2012) suggests that perceptions about roles and personality characteristics may be influenced by parents' expectations and stereotypes about birth-order related roles. Family size has been identified as a variable that matters; in two studies that were controlled for family size, Kristensen and Bjerkedal (2007) found a small but significant difference in IQ based on
FIGURE 11–2 Sample genogram.

birth order, and Hartshorne, Salem-Hartshorne, and Hartshorne (2009) found that birth order influenced how individuals choose their friends and their spouses. When assessing a family to identify dysfunctions based on profiling sibling position, the nurse needs to consider many variables to make the best clinical judgment.

Emotional Cutoff

Emotional cutoff describes differentiation of self from the perception of the child. All individuals have some degree of unresolved emotional attachment to their parents, and the lower the level of differentiation, the greater the degree of unresolved emotional attachment.

Emotional cutoff has very little to do with how far away one lives from the family of origin. Individuals who live great distances from their parents can still be undifferentiated, whereas some individuals are emotionally cut off from their parents who live in the same town or even the same neighborhood.

Bowen (1976) suggests that emotional cutoff is the result of dysfunction within the family of origin in which fusion has occurred and that emotional cutoff promotes the same type of dysfunction in the new nuclear family. He contends that maintaining some emotional contact with the family of origin promotes healthy differentiation.

Societal Emotional Process

The Bowen theory views society as an emotional system. The concept of societal emotional process compares society's response to stress to the same type of response seen in individuals and families in response to emotional crisis: stress creates uncomfortable levels of anxiety that lead to hasty solutions, which add to the problems, and the cycle continues. This concept of Bowen's theory is explained as follows (Bowen Center, 2016b):

Human societies undergo periods of regression and progression in their history. The current regression seems related to factors such as the population explosion, a sense of diminishing frontiers, and the depletion of natural resources. The "symptoms" of societal regression include a growth of crime and violence, an increasing divorce rate, a more litigious attitude, a greater polarization between racial groups, less principled decision-making by leaders, the drug abuse epidemic, an increase in bankruptcy, and a focus on rights over responsibilities.

Goals and Techniques of Therapy

The goal of Bowen's systems approach to family therapy is to increase the level of differentiation of self while remaining in touch with the family system. The premise is that intense emotional problems within the nuclear family can be resolved only by resolving undifferentiated relationships with the family of origin. Emphasis is given to the understanding of past relationships.

The therapeutic role is that of "coach" or supervisor, and emotional involvement with the family is minimized. Therapist techniques include the following:

1. Defining and clarifying the relationship between the family members
2. Helping family members develop one-to-one relationships with each other and minimizing triangles within the system
3. Teaching family members about the functioning of emotional systems
4. Promoting differentiation by encouraging members to speak as individuals rather than as a family unit

The Structural Model

Structural family therapy is associated with a model developed by Minuchin (1974). In this model, the family is viewed as a social system within which the individual lives and to which the individual must adapt. The individual both contributes and responds to stresses within the family.

Major Concepts

Systems

The structural model views the family as a system. The structure of the **family system** is founded on a set of invisible principles that influence the interaction among family members. These principles concern how, when, and with whom to relate, and are established over time and through repeated transactions until they become rules that govern the conduct of various family members (Goldenberg, Stanton, & Goldenberg, 2016).

Transactional Patterns

Transactional patterns are the rules established over time that organize the ways in which family members relate to one another. A hierarchy of authority is one example of a transactional pattern. Usually, parents have a higher level of authority in a family than the children, so parental behavior reflects this role. A balance of authority may exist between husband and wife, or one may reflect a higher level than the other. These patterns of behavioral expectations differ from family to family and may trace their origin over generations of family negotiations.

Subsystems

Minuchin (1974) describes subsystems as smaller elements that make up the larger family system. Subsystems can be individuals or can consist of two or more persons united by gender, relationship, generation, interest, or purpose. A family member may belong to several subsystems at the same time, in which he or she may experience different levels of power and require different types of skills. For example, a young man has a different level of power and a different set of expectations in his father-son subsystem than in a subsystem with his younger brother.

Boundaries

Boundaries define the level of participation and interaction among subsystems. Boundaries are appropriate when they permit appropriate contact with others while preventing excessive interference. Clearly defined boundaries promote adaptive functioning. Maladaptive functioning can occur when boundaries are *rigid* or *diffuse.*

A rigid boundary is characterized by decreased communication and lack of support and responsiveness. Rigid boundaries prevent a subsystem (family member or subgroup) from achieving appropriate closeness or interaction with others in the system. Rigid boundaries promote **disengagement,** or extreme separateness, among family members.

A diffuse boundary is characterized by dependency and overinvolvement. Diffuse boundaries interfere with adaptive functioning because of the overinvestment, overinvolvement, and lack of differentiation between certain subsystems. Diffuse boundaries promote **enmeshment,** or exaggerated connectedness, among family members.

EXAMPLE

Sally and Jim have been married for 12 years, during which time they have tried without success to have children. Six months ago they were thrilled to have the opportunity to adopt a 5-year-old girl, Annie. Since both Sally and Jim have full-time teaching jobs, Annie stays with her maternal grandmother, Krista, during the day after she gets home from half-day kindergarten.

At first, Annie was a polite and obedient child. However, in the last few months, she has become insolent and oppositional and has temper tantrums when she cannot have her way. Sally and Krista agree that Annie should have whatever she desires and should not be punished for her behavior. Jim believes that discipline is necessary, but Sally and Krista refuse to enforce any guidelines he tries to establish. Annie is aware of this discordance and manipulates it to her full advantage.

In this situation, diffuse boundaries exist among the Sally-Krista-Annie subsystems. They have become enmeshed. They have also established a rigid boundary against Jim, disengaging him from the system.

Goal and Techniques of Therapy

The goal of structural family therapy is to facilitate change in the **family structure.** Family structure is changed with modification of the family principles, or transactional patterns, that are contributing to dysfunction within the family. The family is viewed as the unit of therapy, and all members are counseled together. Little, if any, time is spent exploring past experiences. The focus of structural therapy is on the present. Therapist techniques include the following:

■ **Joining the family:** The therapist must become a part of the family if restructuring is to occur. The therapist joins the family but maintains a leadership position. He or she may at different times join various subsystems within the family but ultimately includes the entire family system as the target of intervention.

■ **Evaluating the family structure:** Even though a family may come for therapy because of the behavior of one family member (the identified patient), the family as a unit is considered problematic. The family structure is evaluated by assessing transactional patterns, system flexibility and potential for change, boundaries, family developmental stage, and role of the identified patient within the system.

■ **Restructuring the family:** An alliance or contract for therapy is established with the family. By becoming an actual part of the family, the therapist is able to manipulate the system and facilitate the circumstances and experiences that can lead to structural change.

The Strategic Model

The strategic model of family therapy uses the interactional or communications approach. Communication theory is viewed as the foundation for this model. Communication is the actual transmission of information among individuals. All behavior sends a message, so all behavior in the presence of two or more individuals is communication. In this model, families considered to be functional are open systems where clear and precise messages, congruent with the situation, are sent and received. Healthy communication patterns promote nurturance and individual self-worth. Dysfunctional families are viewed as partially closed systems in which communication is vague and messages are often inconsistent and incongruent with the situation. Destructive patterns of communication tend to inhibit healthful nurturing and decrease individual feelings of self-worth.

Major Concepts

Double-Bind Communication

Double-bind communication occurs when a statement is made and succeeded by a contradictory statement. It also occurs when a statement is made accompanied by nonverbal expression that is inconsistent with the verbal communication. These incompatible communications can interfere with ego development in an individual and promote mistrust of all communications. Double-bind communication often results in a "damned if I do and damned if I don't" situation.

EXAMPLE

A mother freely gives and receives hugs and kisses from her 6-year-old son some of the time, while at other times she pushes him away saying, "Big boys don't act like that." The little boy receives a conflicting message and is presented with an impossible dilemma: "To please my mother I must not show her that I love her, but if I do not show her that I love her, I'm afraid I will lose her."

Pseudomutuality and Pseudohostility

A healthy, functioning individual is able to relate to other people while still maintaining a sense of separate identity. In a dysfunctional family, patterns of interaction may be reflected in the remoteness or closeness of relationships. These relationships may reflect erratic interaction (i.e., sometimes remote and sometimes close) or inappropriate interaction (i.e., excessive closeness or remoteness).

Pseudomutuality and pseudohostility are seen as collective defenses against the reality of the underlying meaning of the relationships in a dysfunctional family system. **Pseudomutuality** is characterized by a facade of mutual regard. Emotional investment is directed at maintaining outward representation of reciprocal fulfillment rather than in the relationship itself. The style of relating is fixed and rigid and allows family members to deny underlying fears of separation and hostility.

EXAMPLE

Janet, age 16, is the only child of State Senator J. and his wife. Janet was recently involved in a joyriding experience with a group of teenagers her parents call "the wrong crowd." In family therapy, Mrs. J. says, "We have always been a close family. I can't imagine why she is doing these things." Senator J. states, "I don't know another colleague who has a family that is as close as mine." Janet responds, "Yes, we are close. I just don't see my parents very much. Dad has been in politics since I was a baby, and Mom is always with him. I wish I could spend more time with them. But we are a close family."

Pseudohostility is also a fixed and rigid style of relating, but the facade being maintained is that of a state of chronic conflict and alienation among family members. This relationship pattern allows family members to deny underlying fears of tenderness and intimacy.

Jack, 14, and his sister Jill, 15, will have nothing to do with each other. When they are together, they can agree on nothing, and the barrage of put-downs is constant. This behavior reflects pseudohostility used by individuals who are afraid to reveal feelings of intimacy.

Schism and Skew

Lidz and associates (1957) observed two patterns within families that relate to a dysfunctional marital dyad. A **marital schism** is defined as "a state of severe chronic disequilibrium and discord, with recurrent threats of separation." Each partner undermines the other, mutual trust is absent, and a competition exists for closeness with the children. Often a partner establishes an alliance with his or her parent against the spouse. Children lack appropriate role models. **Marital skew** describes a relationship in which there is lack of equal partnership. One partner dominates the relationship and the other partner. The marriage remains intact as long as the passive partner allows the domination to continue. Children also lack role models when a marital skew exists.

Goal and Techniques of Therapy

The goal of strategic family therapy is to create change in destructive behavior and communication patterns among family members. The identified family *problem* is the unit of therapy, and all family members need not be counseled together. In fact, strategic therapists may prefer to see subgroups or individuals separately in an effort to achieve problem resolution. Therapy is oriented in the present, and the therapist assumes full responsibility for devising an effective strategy for family change. Therapeutic techniques include the following:

■ **Paradoxical intervention:** A paradox can be called a contradiction in therapy, or "prescribing the symptom." With **paradoxical intervention,** the therapist requests that the family continue to engage in the behavior that they are trying to change. Alternatively, specific directions may be given for continuing the defeating behavior. For example, a couple that regularly engages in insulting shouting matches is instructed to have one of these encounters on Tuesdays and Thursdays from 8:30 to 9 p.m. Boyer and Jeffrey (1994) explained this technique in the following manner:

> A family using its maladaptive behavior to control or punish other people loses control of the situation when it finds itself continuing the behavior under a therapist's direction and being praised for following instructions. If the family disobeys the therapist's instruction, the price it pays is sacrificing the old behavior pattern and experiencing more satisfying ways of interacting with one another. A family that maintains

it has no control over its behavior, or whose members contend that others must change before they can themselves suddenly finds itself unable to defend such statements. (p. 125)

■ **Reframing:** Goldenberg and associates (2016) describe **reframing** as "relabeling problematic behavior by viewing it in a new, more positive light that emphasizes its good intention." Therefore, with reframing, the *behavior* may not actually change, but the *consequences* of the behavior may change because of a change in the meaning attached to the behavior. This technique is sometimes referred to as *positive reframing*.

Tom has a construction job and makes a comfortable living for his wife, Sue, and their two children. Tom and Sue have been arguing a lot and came to the therapist for counseling. Sue says Tom frequently drinks too much and is often late getting home from work. Tom counters, "I never used to drink on my way home from work, but Sue started complaining to me the minute I walked in the door about being so dirty and about tracking dirt and mud on 'her nice, clean floors.' It was the last straw when she made me undress before I came in the house and leave my dirty clothes and shoes in the garage. I thought a man's home was his castle. Well, I sure don't feel like a king. I need a few stiff drinks to face her nagging!"

The therapist used reframing to attempt change by helping Sue to view the situation in a more positive light. He suggested to Sue that she try to change her thinking by focusing on how much her husband must love her and her children to work as hard as he does. He asked her to focus on the dirty clothes and shoes as symbols of his love for them and to respond to his "dirty" arrivals home with greater affection. This positive reframing set the tone for healing and for increased intimacy within the marital relationship.

The Evolution of Family Therapy

Bowen's family theory and the structural and strategic models are sometimes referred to as basic models of family therapy.

While some family therapists adhere to a specific theoretical framework, Nichols (2017) suggested that contemporary family therapists "borrow from each other's arsenal of techniques." The basic models described here have provided a foundation for the progression and growth of the discipline of family therapy. Examples of newer models include the following:

■ **Narrative therapy:** Narrative therapy is an approach to treatment that emphasizes the role of the stories people construct about their experience (Nichols, 2016).

■ **Feminist family therapy:** This form of family therapy employs a collaborative, egalitarian, nonsexist

intervention, applicable to both men and women, addressing family gender roles, patriarchal attitudes, and social and economic inequalities in male-female relationships (Goldenberg et al., 2016).

■ **Social constructionist therapy:** Social constructionist therapy shifts attention away from an inspection of the origin or the exact nature of a family's presenting problems to an examination of the stories (interpretations, explanations, theories about relationships) family members have told themselves that account for how they have lived their lives. Social constructionist therapists are particularly interested in expanding clients' rigid and inflexible views of the world (Goldenberg et al., 2016).

■ **Psychoeducational family therapy:** This type of family therapy emphasizes educating family members to help them understand and cope with a seriously disturbed family member While family therapists may use a psychoeducational approach in treatment, psychiatric-mental health registered nurses also use psychotherapeutic education strategies with individual clients and with families (American Nurses' Association, American Psychiatric Nurses Association, & International Society of Psychiatric-Mental Health Nurses, 2014). When provided with supportive education about mental illness and management strategies, families can have an important impact on patient recovery. In one recent 14-year follow-up study (Ran et al., 2015), researchers found that in families where psychoeducational family interventions were used for patients with schizophrenia, patient adherence to treatment and social functioning maintained enduring improvement over the course of the study.

The goal of family therapy, in general, is to promote change and improve adaptive functioning within the context of the family. Since nurses interact with families in most health-care settings, understanding these frameworks for assessing and intervening with families is an important aspect of every nurse's knowledge base.

The Nursing Process—A Case Study

Assessment

Wright and Leahey (2013) have developed the Calgary Family Assessment Model (CFAM), a multidimensional model originally adapted from a framework developed by Tomm and Sanders (1983). The CFAM consists of three major categories: structural, developmental, and functional. Wright and Leahey (2013) state:

> Each category contains several subcategories. It is important for each nurse to decide which subcategories are relevant and appropriate to explore and assess with each family at each point in time—that is, not all subcategories need to be assessed at a first meeting with a family, and some subcategories need never be assessed. If the nurse uses too many subcategories, he or she may become overwhelmed by all the data. If the nurse and the family discuss too few subcategories, each may have a distorted view of the family's strengths or problems and the family situation. (pp. 51–52)

A diagram of the CFAM is presented in Figure 11–3. The three major categories are listed, along with the subcategories for assessment under each. This diagram is used to assess the Marino family, a case study presented in Box 11–1.

Structural Assessment

A graphic representation of the Marino family structure is presented in the genogram in Figure 11–4.

Internal Structure

The Marino family consists of a husband, wife, and their biological son and daughter who live together in the same home. They conform to the traditional gender roles. John is the eldest child from a rather large family, and Nancy has no siblings. In this family, their son, Peter, is the firstborn, and his sister, Anna, is 2 years younger. Neither spousal, sibling, nor spousal-sibling subsystems appear to be close in this family, and some are clearly conflictual. Problematic subsystems include John-Nancy, John-Nancy-children, and Nancy-Ethel. The subsystem boundaries are quite rigid, and the family members appear to be emotionally disengaged from one another.

External Structure

This family has ties to extended family, although the availability of support is questionable. Nancy's parents offered little emotional support to her as a developing child. They never approved of her marriage to John and still remain distant and cold. John's family consists of a father, mother, two brothers, and two sisters. They are warm and supportive most of the time, but cultural influences interfere with their understanding of this current situation. At this time, the Marino family is probably receiving the most support from health-care professionals who have intervened during Anna's hospitalization.

Context

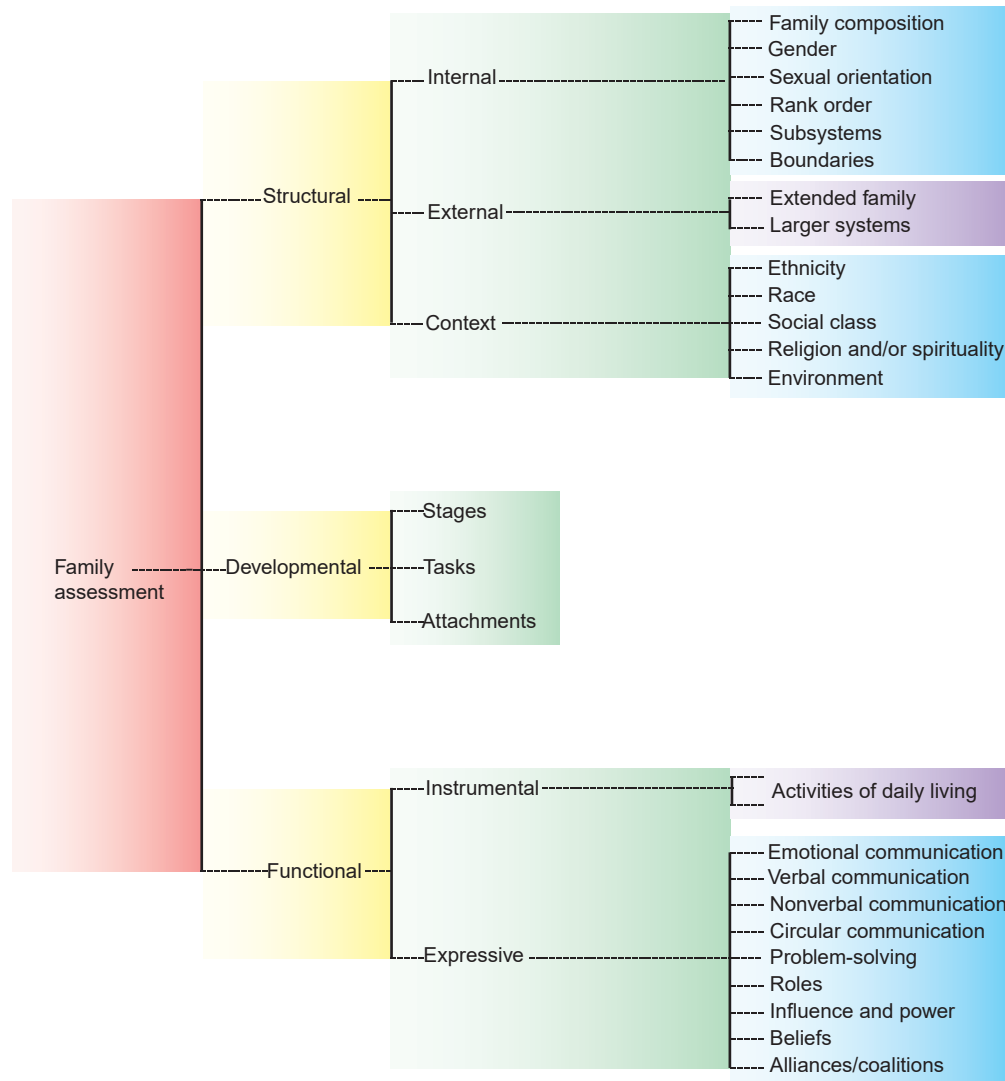
John is a second-generation Italian American. His family of origin is large, warm, and supportive. However, John's parents believe that family problems should be dealt with in the family, and they disapprove of bringing "strangers" in to hear what they consider to be private information. They believe that Anna's physical condition should be stabilized, and then she should be discharged to deal with family problems at home.


FIGURE 11–3 Branching diagram of the Calgary Family Assessment Model (CFAM). (From Wright, L. M., & Leahey, M. [2013]. *Nurses and families: A guide to family assessment and intervention* [6th ed.]. Philadelphia: F.A. Davis Company, with permission.)

BOX 11–1 The Marino Family—A Case Study

John and Nancy Marino have been married for 19 years. They have a 17-year-old son, Peter, and a 15-year-old daughter, Anna. Anna was recently hospitalized for taking an overdose of fluoxetine, her mother's prescription antidepressant. The family is attending family therapy sessions while Anna is in the hospital. Anna states, "I just couldn't take the fighting anymore! Our house is an awful place to be. Everyone hates each other, and everyone is unhappy. Dad drinks too much, and Mom is always sick! Peter stays away as much as he can and I don't blame him. I would too if I had someplace to stay. I just thought I'd be better off dead."

John Marino, age 44, is the oldest of five children. His father, Paulo, age 66, is a first-generation Italian American whose parents emigrated from Italy in the early 1900s. Paulo retired last year after 32 years as a cutter in a meatpacking plant.

His wife, Carla, age 64, has never worked outside the home. John and his siblings all worked at minimum-wage jobs during high school, and John and his two brothers worked their way through college. His two sisters married young, and both are housewives and mothers. John was able to go to law school with the help of loans, grants, and scholarships. He has held several positions since graduation and is currently employed as a corporate attorney for a large aircraft company.

Nancy, age 43, is the only child of Sam and Ethel Jones. Sam, age 67, inherited a great deal of money from his family who had been in the shipping business. He is currently the chief executive officer of this business. Ethel, also 67, was an aspiring concert pianist when she met Sam. She chose to give up her career for marriage and family, although Nancy believes her mother always resented doing so. Nancy was

Continued

BOX 11–1 The Marino Family—A Case Study—cont'd

reared in an affluent lifestyle. She attended private boarding schools as she was growing up and chose an exclusive college in the East to pursue her interest in art. She studied in Paris during her junior year. Nancy states that she was never emotionally close to her parents. They traveled a great deal, and she spent much of her time under the supervision of a nanny.

Nancy's parents were opposed to her marrying John. They perceived John's family to be below their social status. Nancy, on the other hand, loved John's family. She felt them to be very warm and loving, so unlike what she was used to in her own family. Her family is Protestant and also disapproved of her marrying in the Roman Catholic Church.

FAMILY DYNAMICS

As their marriage progressed, Nancy's health became very fragile. She had continued her artistic pursuits but seemed to achieve little satisfaction from it. She tried to keep in touch with her parents but often felt spurned by them. They traveled a great deal and often did not even inform her of their whereabouts. They were not present at the birth of her children. She experiences many aches and pains and spends many days in bed. She sees several physicians, who have prescribed various pain medications, antianxiety agents, and antidepressants but can find nothing organically wrong. Five years ago, she learned that John had been having an affair with his secretary. He promised to break it off and fired the secretary, but Nancy has had difficulty trusting him since that

time. She brings up his infidelity whenever they have an argument, which is increasingly often lately. When he is home, John drinks, usually until he falls asleep. Peter frequently comes home smelling of alcohol and a number of times has been clearly intoxicated.

When Nancy called her parents to tell them that Anna was in the hospital, Ethel replied, "I'm sorry to hear that, dear. We certainly never had any of those kinds of problems on our side of the family. But I'm sure everything will be okay now that you are getting help. Please give our love to your family. Your father and I are leaving for Europe on Saturday and will be gone for 6 weeks."

Although more supportive, John's parents view this situation as somewhat shameful for the family. John's dad responded, "We had hard times when you were growing up, but never like this. We always took care of our own problems. We never had to tell a bunch of strangers about them. It's not right to air your dirty laundry in public. Bring Anna home. Give her your love and she will be okay."

In therapy, Nancy blames John's drinking and his admitted affair for all their problems. John states that he drinks because it is the only way he can tolerate his wife's complaining about his behavior and her many illnesses. Peter is very quiet most of the time but says he will be glad when he graduates in 4 months and can leave "this looney bunch of people." Anna cries as she listens to her family in therapy and says, "Nothing's ever going to change."

John and Nancy were reared in different social classes. In John's family, money was not available to seek out professional help for every problem that arose. Italian cultural beliefs promote the provision of help within the nuclear and extended family network. If outside counseling is sought, it is often with the family priest. John and Nancy did not seek this type of counseling because they no longer attend church regularly.

In Nancy's family, money was available to obtain the very best professional help at the first sign of trouble. However, Nancy's parents refused to acknowledge, both then and now, that any difficulty ever existed in their family situation.

The Marino family lives comfortably on John's salary as a corporate attorney. They have health insurance and access to any referrals that are deemed necessary. They are well educated but have been attempting to deny the dysfunctional dynamics that exist in their family.

Developmental Assessment

The Marino family falls within the "family with adolescents" stage of McGoldrick and associates' (2015) family life cycle. In this stage, parents are expected to respond to adolescents' requests for increasing independence while being available to continue to fulfill

dependency needs. They may also be required to provide additional support to aging grandparents. This is a time when parents may also begin to reexamine their own marital and career issues.

The Marino family is not fulfilling the dependency needs of its adolescents; in fact, they may be establishing premature independence. The parents are absorbed in their own personal problems to the exclusion of their children. Peter responds to this neglect by staying away as much as possible, drinking with his friends, and planning to leave home at the first opportunity. Anna's attempted suicide is a cry for help. She has needs that are unfulfilled by her parents, and this crisis situation may be required for them to recognize that a problem exists. This may be the time when they begin to reexamine their unresolved marital issues. Extended family are still self-supporting and do not require assistance from John and Nancy at this time.

Functional Assessment

Instrumental Functioning

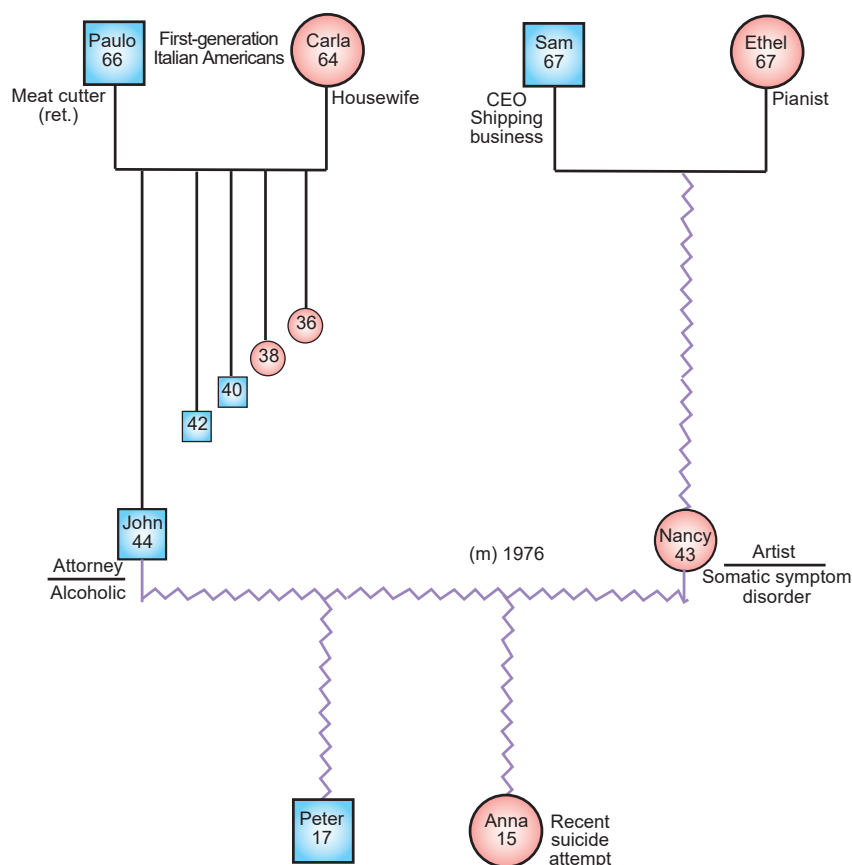
This family has managed to adjust to the maladaptive functioning in an effort to meet physical activities of daily living. They subsist on fast food, or sometimes


FIGURE 11–4 Genogram of the Marino family

Nancy or Anna will prepare a meal. Seldom do they sit down at table to eat together. Nancy must take pain medication or sedatives to sleep. John usually drinks himself to sleep. Anna and Peter take care of their own needs independently. Often they do not even see their parents in the evenings. Each manages to do fairly well in school. Peter says, "I don't intend to ruin my chances of getting out of this hell hole as soon as I can!"

Expressive Functioning

John and Nancy Marino argue a great deal about many topics. This family seldom shows affection to one another. Nancy and Anna express sadness with tears, whereas John and Peter have a tendency to withdraw or turn to alcohol when experiencing unhappiness. Nancy somaticizes her internal pain, and numbs this pain with medication. Anna internalized her emotional pain until it became unbearable. A notable lack of constructive communication is evident.

This family is unable to solve its problems effectively. In fact, it is unlikely that it has even identified its problems, which undoubtedly have been in existence for a long while. These problems have only recently been revealed in light of Anna's suicide attempt.

Diagnosis

The following nursing diagnoses were identified for the Marino family:

■ **Interrupted family processes** related to unsuccessful achievement of family developmental tasks and dysfunctional coping strategies evidenced by inability of family members to relate to each other in an adaptive manner; adolescents' unmet dependency needs; inability of family members to express a wide range of feelings and to send and receive clear messages.

■ **Disabled family coping** related to highly ambivalent family relationships and lack of support evidenced by inability to problem-solve; each member copes in response to dysfunctional family processes with destructive behavior (John drinks, Nancy somaticizes, Peter drinks and withdraws, and Anna attempts suicide).

Outcome Identification

The following criteria were identified as measurement of outcomes in counseling of the Marino family:

■ Family members will demonstrate effective communication patterns.
■ Family members will express feelings openly and honestly.

■ Family members will establish more adaptive coping strategies.

■ Family members will be able to identify destructive patterns of functioning and problem-solve them effectively.

■ Boundaries between spousal subsystems and spousal-children subsystems will become more clearly defined.

■ Family members will establish stronger bonds with extended family.

Planning and Implementation

The Marino family will undoubtedly require many months of outpatient therapy. It is even likely that each member will need individual psychotherapy in addition to the family therapy. Once Anna has been stabilized physiologically and is discharged from the hospital, family and individual therapy will begin.

Several strategies for family therapy have been discussed in this chapter. As mentioned previously, family therapy has a strong theoretical framework and is performed by individuals with specialized education in family theory and process. Some advanced practice nurses possess the credentials required to perform family therapy. It is important, however, for all nurses to have some knowledge about working with families, to be able to assess family interaction, and to recognize when problems exist.

Some interventions with the Marino family might include the following:

1. Create a therapeutic environment that fosters trust in which the family members can feel safe and comfortable. The nurse can promote this type of environment by being empathetic, listening actively (see Chapter 8, Therapeutic Communication), accepting feelings and attitudes, and being nonjudgmental.

2. Promote effective communication by
   a. Seeking clarification when vague and generalized statements are made (e.g., Anna states, "I just want my family to be like my friends' families." The nurse asks, "Anna, would you please explain to the group exactly what you mean by that?").
   b. Setting clear limits (e.g., "Peter, it is okay to state when you are angry about something that has been said. It is not okay to throw the chair against the wall").
   c. Being consistent and fair (e.g., "I encourage each of you to contribute to the group process and to respect one another's opportunity to contribute equally").
   d. Addressing each individual clearly and directly and encouraging family members to do the same (e.g., "Nancy, I think it would be more appropriate if you directed that statement to John instead of to me").

3. Identify patterns of interaction that interfere with successful problem resolution. For example, John asks Nancy many "Why?" questions that keep her on the defensive. He criticizes her for "always being sick." Nancy responds by frequently reminding John of his infidelity. Peter and Anna interrupt each other and their parents when the level of conflict reaches a certain point. Provide examples of more appropriate ways to communicate that can improve interpersonal relations and lead to more effective patterns of interaction.

4. Help the Marino family identify problems that may necessitate change. Encourage each member to discuss a family process that he or she would like to change. As a group, promote discussion of what must take place for change to occur and allow each member to explore whether he or she could realistically cooperate with the necessary requirements for change.

5. As the problem-solving process progresses, encourage all family members to express honest feelings. Address each one directly: "John (Nancy, Peter, Anna), how do you feel about what the others are suggesting?" Ensure that all participants understand that each member may express honest feelings (e.g., anger, sadness, fear, anxiety, guilt, disgust, helplessness) without criticism, judgment, or fear of personal reprisal.

6. Avoid becoming triangled in the family emotional system. Remain neutral and objective. Do not take sides in family disagreements; instead, provide alternative explanations and suggestions (e.g., "Perhaps we can look at that situation in a different light . . .").

7. Reframe vague problem descriptions into ones for which resolution is more realistic. For example, rather than defining the problem as "We don't love each other anymore," the problem could be defined as "We do not spend time together in family activities anymore." This definition evolves from the family members' description of what they mean by the more general problem description.

8. Discuss present coping strategies. Encourage each family member to describe how he or she copes with stress and with the adversity within the family. Explore each member's possible contribution to the family's problems. Encourage family members to discuss possible solutions among themselves.

9. Identify community resources that may assist individual family members and provide support for establishing more adaptive coping mechanisms. For example, Alcoholics Anonymous for John, Al-Anon for Nancy, and Alateen for Peter and Anna. Other groups that may be of assistance to this family include Emotions Anonymous, Parents

Support Group, Families Helping Families, Marriage Enrichment, Parents of Teenagers, and We Saved Our Marriage (WESOM). Local self-help networks often provide a directory of resources within specific communities.

10. Discuss with the family the possible need for psychotherapy for individual members. Provide names of therapists who would perform assessments to determine individual needs. Encourage follow-through with appointments.

11. Assist family members in planning leisure time activities together. This could include time to play together, exercise together, or engage in a shared project.

Evaluation

Evaluation is the final step in the nursing process. In this step, progress toward attainment of outcomes is measured.

1. Do family members demonstrate effective patterns of communication?
2. Can family members express feelings openly and honestly without fear of reprisal?
3. Can family members accept their own personal contributions to the family's problems?
4. Can individual members identify maladaptive coping methods and express a desire to improve?
5. Do family members work together to solve problems?
6. Can family members identify resources in the community from which they can seek assistance and support?
7. Do family members express a desire to form stronger bonds with the extended family?
8. Are family members willing to seek individual psychotherapy?
9. Are family members pursuing shared activities?

Summary and Key Points

- Nurses must have sufficient knowledge of family functioning to assess family interaction and recognize when problems exist.
- McGoldrick and associates (2015) identify the following stages that describe the family life cycle:
  - The single young adult
  - The family joined through marriage/union
  - The family with young children
  - The family with adolescents
  - The family launching children and moving on in midlife
  - The family in later life (late middle age to end of life)
- Tasks of families experiencing divorce and remarriage, and those that vary according to cultural norms, are also important to understand as the demographics of family life continue to change in society.
- Families are assessed as functional or dysfunctional on the basis of the following six elements: communication, self-concept reinforcement, family members' expectations, handling differences, family interactional patterns, and family climate.
- Bowen viewed the family as a system that was composed of various subsystems. His theoretical approach to family therapy includes eight major concepts: differentiation of self, triangles, nuclear family emotional process, family projection process, multigenerational transmission process, sibling position, emotional cutoff, and societal emotional process.
- In the structural model of family therapy, the family is viewed as a social system within which the individual lives and to which the individual must adapt.
- In the strategic model of family therapy, communication is viewed as the foundation of functioning. Functional families are open systems where clear and precise messages are sent and received. Dysfunctional families are viewed as partially closed systems in which communication is vague, and messages are often inconsistent and incongruent with the situation.
- Many family therapists today follow an eclectic approach and incorporate concepts from several models into their practices.
- The nursing process is used as a framework for assessing, diagnosing, planning, implementing, and evaluating care to families who require assistance to maintain or regain adaptive functioning.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. The nurse-therapist is counseling the Smith family: Mr. and Mrs. Smith, 10-year-old Rob, and 8-year-old Lisa. When Mr. and Mrs. Smith start to argue, Rob hits Lisa and Lisa starts to cry. The Smiths then turn their attention to comforting Lisa and scolding Rob, complaining that he is "out of control and we don't know what to do about his behavior." These dynamics are an example of which of the following?
   a. Double-bind messages
   b. Triangulation
   c. Pseudohostility
   d. Multigenerational transmission

2. Using Bowen's systems approach with a family in therapy, the therapist would:
   a. Try to change family principles that may be promoting dysfunctional behavior patterns.
   b. Strive to create change in destructive behavior through improvement in communication and inter-action patterns.
   c. Encourage increase in the differentiation of individual family members.
   d. Promote change in dysfunctional behavior by encouraging the formation of more diffuse boundaries between family members.

3. Using the structural approach with a family in therapy, the therapist would:
   a. Try to change family principles that may be promoting dysfunctional behavior patterns.
   b. Strive to create change in destructive behavior through improvement in communications and interaction patterns.
   c. Encourage increase in the differentiation of individual family members.
   d. Promote change in dysfunctional behavior by encouraging the formation of more diffuse boundaries between family members.

4. Using the strategic approach with a family in therapy, the therapist would:
   a. Try to change family principles that may be promoting dysfunctional behavior patterns.
   b. Strive to create change in destructive behavior through improvement in communication and inter-action patterns.
   c. Encourage increase in the differentiation of individual family members.
   d. Promote change in dysfunctional behavior by encouraging the formation of more diffuse boundaries between family members.

5. Emma, a nurse in a family medicine outpatient clinic, conducts initial interviews when new families are referred. She has just finished interviewing a mother who has come to the clinic with her three children, ages 5, 7, and 11. The mother says to the oldest child, "You have been such a help to me, playing with your brothers while I talk to the nurse." In assessing family interaction, the nurse recognizes this statement as a direct indicator of which of the following?
   a. Family climate
   b. Family members' expectations
   c. Handling differences
   d. Self-concept reinforcement

6. The intermittent exiting and entering of various family members and reestablishing of the bond of the dyadic marital relationship are characteristics associated with which stage of family development?
   a. The newly married couple
   b. The family with adolescents
   c. The family launching grown children
   d. The family in later life

Review Questions—cont'd
Self-Examination/Learning Exercise

7. The nurse psychotherapist is working with the Juarez family in the outpatient mental health clinic. The husband says, "We can't agree on anything! And it seems like every time we disagree on something, it ends up in a screaming match." Which of the following prescriptions by the nurse represents a paradoxical intervention for the Jones family?
   a. Mr. and Mrs. Juarez must not have a disagreement for one full day.
   b. Mr. and Mrs. Juarez will yell at each other on Tuesdays and Thursdays from 8 p.m. until 8:10 p.m.
   c. Mr. and Mrs. Juarez must refrain from yelling at each other until the next counseling session.
   d. Mr. and Mrs. Juarez must not discuss serious issues until they can do so without yelling at each other.

8. Mr. and Mrs. Jones have been married for 21 years. Mr. Jones is the family breadwinner, and Mrs. Jones has never worked outside the home. Mr. Jones has always made all the decisions for the family, and Mrs. Jones has always been compliant. According to the strategic model of family therapy, this is an example of which of the following?
   a. Marital schism
   b. Pseudomutuality
   c. Marital skew
   d. Pseudohostility

9. Jack and Ann have come to the clinic for family therapy. They have been married for 18 years. Jack had an affair with his secretary 5 years ago. He fired the secretary and assures Ann and the nurse that he has been faithful ever since. Jack tells the nurse, "We have never been able to get along with each other. We can't talk about anything—all we do is shout at each other. And every time she gets angry with me, she brings up my infidelity. I can't even imagine how many times each of us has threatened divorce over the years. Our kids don't have any idea what it is like to have parents who get along with each other. I've really had enough!" The nurse would most likely document which of the following in her assessment of this couple?
   a. Marital skew
   b. Pseudohostility
   c. Double-bind communication
   d. Marital schism

10. Mr. and Mrs. Smith and their three children (ages 5, 8, and 10) are in therapy with the nurse psychotherapist. Mrs. Smith tells the nurse that their marriage has been "falling apart" since the birth of their youngest child, Tom. She explains that they "did not want a third child, and I became pregnant even after my husband had undergone a vasectomy. We were very angry, the pregnancy was a problematic one, and the child has been difficult since birth. We had problems before he was born, but since Tom was born, things have gone from bad to worse. No one can control him, and he is wrecking our family!" The nurse assesses that which of the following may be occurring in this family?
   a. Scapegoating
   b. Triangling
   c. Disengagement
   d. Enmeshment

Milieu Therapy—The Therapeutic Community

CORE CONCEPTS
Milieu Therapy

KEY TERMS

milieu   therapeutic community

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *milieu therapy.*
2. Explain the goal of therapeutic community/milieu therapy.
3. Identify seven basic assumptions of a therapeutic community.
4. Discuss conditions that characterize a therapeutic community.
5. Identify the various therapies that may be included in the program of the therapeutic community and the health-care workers that make up the interdisciplinary treatment team.
6. Describe the role of the nurse on the interdisciplinary treatment team.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. How are unit rules established in a therapeutic community setting?
2. Which member of the interdisciplinary treatment team has a focus on rehabilitation and vocational training?
3. How are client responsibilities assigned in the therapeutic community setting?
4. Which member of the interdisciplinary treatment team serves as leader?

Standard 5F of the *Psychiatric-Mental Health Nursing: Scope and Standards of Practice* (American Nurses Association [ANA], American Psychiatric Nurses Association, & International Society of Psychiatric Nurses, 2014) states, "The psychiatric-mental health nurse provides, structures, and maintains a safe, therapeutic, and recovery-oriented environment in collaboration with healthcare consumers, families, and other healthcare clinicians" (p. 60).

This chapter defines and explains the goal of milieu therapy. The conditions necessary for a therapeutic environment are discussed, and the roles of

223

the various health-care workers within the interdisciplinary team are delineated. An interpretation of the nurse's role in milieu therapy is included.

Milieu, Defined

The word **milieu,** French for "middle," is translated in English as "surroundings, or environment." In psychiatry, therapy involving the milieu, or environment, may be called milieu therapy, **therapeutic community,** or the therapeutic environment. The goal of milieu therapy is to manipulate the environment so that all aspects of the client's hospital experience are considered therapeutic. Within this therapeutic community setting, the client is expected to learn adaptive coping, interaction, and relationship skills that can be adapted to other aspects of his or her life.

CORE CONCEPT

Milieu Therapy

A scientific structuring of the environment in order to effect behavioral changes and improve the psychological health and functioning of the individual (Skinner, 1979).

Current Status of the Therapeutic Community

Milieu therapy came into its own from the 1960s through early 1980s. During this period, psychiatric inpatient treatment provided sufficient time to implement programs of therapy that were aimed at social rehabilitation. Lengths of stay averaged from 28 to 30 days for acute care hospitalizations and several months or years for long-term hospitalizations. Nursing's focus of establishing interpersonal relationships with clients fit well within this concept of therapy. Patients were encouraged to be active participants in their therapy, and individual autonomy was emphasized.

The current focus of inpatient psychiatric care has changed. Acute care hospitalization lengths of stay now average 2 to 3 days. Hall (1995) stated:

> Care in inpatient psychiatric facilities can now be characterized as short and biologically based. By the time patients have stabilized enough to benefit from the socialization that would take place in a milieu as treatment program, they [often] have been discharged. (p. 51)

Although strategies for milieu therapy are still used, they have been modified to conform to the short-term approach to care or to outpatient treatment programs. Some programs (e.g., those for children and adolescents, clients with substance addictions, and geriatric clients) have successfully adapted the concepts of milieu treatment to their specialty needs (Bowler, 1991; DeSocio, Bowllan, & Staschak, 1997; Jani & Fishman, 2004; Menninger Clinic, 2012; Whall, 1991).

Echternacht (2001) suggested that more emphasis should be placed on unstructured components of milieu therapy. She described these components as a multitude of complex interactions between clients, staff, and visitors that occur around the clock. Echternacht called these interactions "fluid group work." They involve spontaneous opportunities within the milieu environment for the psychiatric nurse to provide "on-the-spot therapeutic interventions designed to enhance socialization competency and interpersonal relationship awareness. Emphasis is on social skills and activities in the context of interpersonal interactions" (p. 40). With fluid group work, the nurse applies psychotherapeutic knowledge and skills to brief clinical encounters that occur spontaneously in the therapeutic milieu setting. Echternacht believes that by using these techniques, nurses can "reclaim their milieu therapy functions in the midst of a changing health care environment" (p. 40).

Many of the original concepts of milieu therapy are presented in this chapter. It is important to remember that modifications to these concepts are applied for practice in a variety of settings.

Basic Assumptions

Skinner (1979) outlined seven basic assumptions on which a therapeutic community is based:

1. **The health in each individual is to be realized and encouraged to grow.** All individuals are considered to have strengths as well as limitations. These healthy aspects of the individual are identified and serve as a foundation for personality growth and the ability to function adaptively and productively in all aspects of life.
2. **Every interaction is an opportunity for therapeutic intervention.** Within this structured setting, it is virtually impossible to avoid interpersonal interaction. The ideal situation exists for clients to improve communication and relationship development skills. Learning occurs from immediate feedback of personal perceptions.
3. **The client owns his or her own environment.** Clients should have the opportunity to make decisions and solve problems related to the environment (milieu) of the unit. In this way, personal needs for autonomy as well as needs that pertain to the group as a whole are fulfilled.

4. **Each client owns his or her own behavior.** Each individual within the therapeutic community is expected to take responsibility for his or her own actions.

5. **Peer pressure is a useful and powerful tool.** Behavioral group norms are established through peer pressure. Feedback is direct and frequent so that behaving in a manner acceptable to the other members of the community becomes essential.

6. **Inappropriate behaviors are dealt with as they occur.** Individuals examine the significance of their behavior, look at how it affects other people, and discuss more appropriate ways of behaving in certain situations.

7. **Restrictions and punishment are to be avoided.** Destructive behaviors can usually be controlled with group discussion. However, if an individual requires external controls, temporary isolation is preferred over lengthy restriction or other harsh consequences.

Conditions That Promote a Therapeutic Community

In a therapeutic community setting, the setting is the foundation, and everything that happens to the client or within the client's environment is considered part of the treatment program. Community factors—such as social interactions, the physical structure of the treatment setting, and schedule of activities—may generate negative responses from some clients. These stressful experiences are used as examples to help the client learn how to manage stress more adaptively in real-life situations.

Under what conditions, then, is a hospital environment considered therapeutic? A number of classic criteria have been identified, some of which today are relevant only to long-term hospital treatment programs in which client stays are at least a month:

1. **Basic physiological needs are fulfilled.** As Maslow (1968) suggested, individuals do not move to higher levels of functioning until the basic biological needs for food, water, air, sleep, exercise, elimination, shelter, and sexual expression have been met. These needs, of course, are relevant in hospital stays of any length. As mentioned previously, stabilization of biological and safety needs has become a primary goal of short-term, acute care psychiatric hospitalizations.

2. **The physical facilities are conducive to achievement of the goals of therapy.** Space is provided so that each client has sufficient privacy, as well as physical space for therapeutic interaction with others. Furnishings are arranged to present a homelike atmosphere—usually in spaces that accommodate communal living, dining, and activity areas—for facilitation of interpersonal interaction and communication. Physical space considerations are relevant in the therapeutic milieu of any psychiatric treatment setting because the promotion of therapeutic interaction is at the core of this type of therapy.

3. **A democratic form of self-government exists.** In the classic therapeutic community, clients participate in the decision-making and problem-solving that affect the management of the treatment setting. This is accomplished through regular community meetings. These meetings are attended by staff and clients, and all individuals have equal input into the discussions. At these meetings, the norms rule, and behavioral limits of the treatment setting are identified and discussed. This reinforces the democratic posture of the treatment setting, because these are expectations that affect all clients equally. An example might be the rule that no client may enter a room occupied by a client of the opposite gender. Reasons for expectations and consequences of violating the rules may also be discussed.

Other issues that may be discussed at the community meetings include those with which certain clients have disagreements. A democratic decision is then made by the entire group. For example, several clients in an inpatient unit may disagree with the hours designated for watching television on a weekend night. They may elect to bring up this issue at a community meeting and suggest an extension in television-viewing time. After discussion by the group, a vote will be taken, and clients and staff agree to abide by the expressed preference of the majority. Some therapeutic communities in long-term settings elect officers (usually a president and a secretary) who serve for a specified time period. The president calls the meeting to order, conducts the business of discussing old and new issues, and asks for volunteers (or makes appointments, alternately, so that all clients have a turn) to accomplish the daily tasks associated with community living, such as cleaning the tables after each meal and watering plants in the treatment facility. New assignments are made at each meeting.

The secretary reads the minutes of the previous meeting and takes minutes of the current meeting. Minutes are important in the event that clients have a disagreement about issues that were discussed at previous meetings. Minutes provide written evidence of decisions made by the group. In treatment settings where clients have short attention spans or disorganized thinking, meetings are brief. Business is generally limited to introductions

and expectations of the here and now. Discussions also may include comments about a recent occurrence in the group or an issue a member is bothered by or has questions about. These meetings are usually facilitated by staff, although all clients have equal input into the discussions.

All clients are expected to attend the meetings. Exceptions are made when aspects of an individual's therapy interfere or take precedence. An explanation is made to clients present so that false perceptions of danger are not generated by another person's absence. All staff members are expected to attend the meetings unless client care precludes their attendance. Today, a formally structured self-government is feasible only in long-term hospital treatment programs. However, encouraging clients to engage in discussion and problem-solving with staff and other clients is relevant to the therapeutic milieu in any hospital treatment program.

4. **Responsibilities are assigned according to client capabilities.** Increasing self-esteem is an ultimate goal of the therapeutic community. Therefore, a client should not be set up for failure by being assigned a responsibility beyond his or her level of ability. By assigning responsibilities that promote achievement, self-esteem is enhanced. Consideration must also be given to times during which the client will show some regression in the treatment regimen. Adjustments in assignments should be made in a way that preserves self-esteem and provides for progression to greater degrees of responsibility as the client returns to previous level of functioning.

5. **A structured program of social and work-related activities is scheduled as part of the treatment program.** Each client's therapeutic program consists of group activities in which interpersonal interaction and communication with other individuals are emphasized. Time is also devoted to personal problems. Various group activities may be selected for clients with specific needs (e.g., an exercise group for a person who expresses anger inappropriately, an assertiveness group for a person who is passive-aggressive, or a stress-management group for a person who is anxious). A structured schedule of activities is the major focus of a therapeutic community. Through these activities, change in the client's personality and behavior can be achieved. New coping strategies are learned and social skills are developed. In the group situation, the client is able to practice what he or she has learned to prepare for transition to the general community.

6. **Community and family are included in the program of therapy in an effort to facilitate discharge from treatment.** An attempt is made to include family members and the community in the treatment program with respect to the client's rights and preferences for confidentiality. It is important to retain as many links as possible to the client's life outside of therapy. Family members are invited to participate in specific therapy groups and, in some instances, to share meals with the client in the communal dining room. Connection with community life may be maintained through client group activities, such as shopping, picnicking, attending movies, bowling, and visiting the zoo. Inpatient clients may be awarded passes to visit family and may participate in work-related activities, the length of time being determined by the activity and the client's condition. These connections with family and community facilitate the discharge process and may help to prevent the client from becoming too dependent on therapy.

The Program of Therapeutic Community

Care for clients in the therapeutic community is coordinated by an interdisciplinary treatment (IDT) team. An initial assessment is made by the admitting psychiatrist, nurse, or other designated admitting agent who, in collaboration with the client, establishes priorities for care. The IDT team then develops a comprehensive treatment plan and goals of therapy and assigns intervention responsibilities. (See Box 12–1 for a QSEN Teaching Strategy on Teamwork and Collaboration within the Interdisciplinary Treatment Team.) All members sign the treatment plan and meet regularly to update the plan as needed. Depending on the size of the treatment facility and scope of the therapy program, members representing a variety of disciplines may participate in the promotion of a therapeutic community. For example, an IDT team may include a psychiatrist, clinical psychologist, psychiatric clinical nurse specialist, psychiatric nurse, mental health technician, psychiatric social worker, occupational therapist, recreational therapist, art therapist, music therapist, psychodramatist, dietitian, and chaplain.

The client, whenever possible, should be at the center of this team process and an active participant in decisions about the treatment plan. The essence of patient-centered care emphasizes client involvement and decision-making authority unless the client's cognitive processes and decision-making are so impaired by illness that they are harmful to self or others. Table 12–1 provides an explanation of responsibilities and educational preparation required for professional members of the IDT team.

BOX 12–1 QSEN TEACHING STRATEGY

Assignment: Interviewing Members of the Interdisciplinary Team
The Process of Teamwork and Collaboration

Competency Domain: Teamwork and Collaboration, Safety

Learning Objectives: Student will:
• Explain the process for collaboration between nursing and other members of the interdisciplinary team.
• Identify different team members' responsibilities with regard to key safety issues such as suicide prevention, reporting to outside individuals/agencies regarding suspicions of abuse and duty to warn, and managing safety within the therapeutic milieu.
• Evaluate the contributions of each discipline within the interdisciplinary team to elements of milieu therapy.

Strategy Overview:
This assignment is meant to familiarize the student with the roles and responsibilities of various members of the interdisciplinary team and to evaluate the processes that promote teamwork and collaboration within milieu therapy. Students may be assigned to specific activities in preparation for a clinical conference discussion or asked to complete a reflective writing assignment on the function of the interdisciplinary treatment team in the provision of milieu therapy.
1. Attend an interdisciplinary treatment team meeting to evaluate individual disciplines' contributions and describe the process of collaboration.
2. Interview one or more members of the interdisciplinary team to identify their perceptions of how the process of collaboration works between their discipline and nursing. Sample questions might include the following:
   In what ways does your discipline collaborate with nursing?
   How effective is collaboration between disciplines within the IDT?
   What barriers exist to effective collaboration between disciplines?
   What is your disciplines role in
      Suicide prevention within the milieu?
      Reporting to outside individuals or agencies?
      Managing safety within the milieu?
3. Attend structured group activities to evaluate the contributions of various team members in promoting the therapeutic milieu.

TABLE 12–1 The Interdisciplinary Treatment Team in Psychiatry

TEAM MEMBER	RESPONSIBILITIES	CREDENTIALS
Psychiatrist	Serves as the leader of the team. Responsible for diagnosis and treatment of mental disorders. Performs psychotherapy; prescribes medication and other somatic therapies.	Medical degree with residency in psychiatry and license to practice medicine.
Clinical psychologist	Conducts individual, group, and family therapy. Administers, interprets, and evaluates psychological tests that assist in the diagnostic process.	Doctorate in clinical psychology with 2- to 3-year internship supervised by a licensed clinical psychologist. State license is required to practice
Psychiatric clinical nurse specialist	Conducts individual, group, and family therapy. Presents educational programs for nursing staff. Provides consultation services to nurses who require assistance in the planning and implementation of care for individual clients.	Registered nurse with minimum of a master's degree in psychiatric nursing. Some institutions require certification by national credentialing association.
Psychiatric nurse	Provides ongoing mental and physical assessment of client condition. Manages the therapeutic milieu on a 24-hour basis. Administers medications. Assists clients with all therapeutic activities as required. Focus is on one-to-one relationship development.	Registered nurse with hospital diploma, associate degree, or baccalaureate degree. Some psychiatric nurses have national certification.

Continued

TABLE 12–1 The Interdisciplinary Treatment Team in Psychiatry—cont'd		
TEAM MEMBER	**RESPONSIBILITIES**	**CREDENTIALS**
Mental health technician (also called psychiatric aide or assistant or psychiatric technician)	Functions under the supervision of the psychiatric nurse. Provides assistance to clients in the fulfillment of their activities of daily living. Assists activity therapists as required in conducting their groups. May also participate in one-to-one relationship development.	Varies by state. Requirements include high school education, with additional vocational education or on-the-job training. Some hospitals hire individuals with baccalaureate degree in psychology in this capacity. Some states require a licensure examination to practice.
Psychiatric social worker	Conducts individual, group, and family therapy. Is concerned with client's social needs, such as placement, financial support, and community requirements. Conducts in-depth psychosocial history on which the needs assessment is based. Works with client and family to ensure that requirements for discharge are fulfilled and needs can be met by appropriate community resources.	Minimum of a master's degree in social work. Some states require additional supervision and subsequent licensure by examination.
Occupational therapist	Works with clients to help develop (or redevelop) independence in performance of activities of daily living. Focus is on rehabilitation and vocational training in which clients learn to be productive, thereby enhancing self-esteem. Creative activities and therapeutic relationship skills are used.	Baccalaureate or master's degree in occupational therapy.
Recreational therapist	Uses recreational activities to promote clients to redirect their thinking or to rechannel destructive energy in an appropriate manner. Clients learn skills (e.g., bowling, volleyball, exercises, jogging) that can be used during leisure time and during times of stress following discharge from treatment. Some programs include activities such as picnics, swimming, and even group attendance at the state fair when it is in session.	Baccalaureate or master's degree in recreational therapy.
Music therapist	Encourages clients in self-expression through music. Clients listen to music, play instruments, sing, dance, and compose songs that help them get in touch with feelings and emotions that they may not be able to experience in any other way.	Graduate degree with specialty in music therapy.
Art therapist	Uses the client's creative abilities to encourage expression of emotions and feelings through artwork. Helps clients to analyze their own work in an effort to recognize and resolve underlying conflict.	Graduate degree with specialty in art therapy.
Psychodramatist	Directs clients in the creation of a "drama" that portrays real-life situations. Individuals select problems they wish to enact, and other clients play the roles of significant others in the situations. Some clients are able to "act out" problems that they are unable to work through in a more traditional manner. All members benefit through intensive discussion that follows.	Graduate degree in psychology, social work, nursing, or medicine with additional training in group therapy and specialty preparation to become a psychodramatist.
Dietitian	Plans nutritious meals for all clients. Consults with clients with specific eating disorders, such as anorexia nervosa, bulimia nervosa, obesity, and pica.	Baccalaureate or master's degree with specialty in dietetics.

TABLE 12–1	The Interdisciplinary Treatment Team in Psychiatry—cont'd	
TEAM MEMBER	**RESPONSIBILITIES**	**CREDENTIALS**
Chaplain	Assesses, identifies, and attends to the spiritual needs of clients and their family members. Provides spiritual support and comfort as requested by client or family. May provide counseling if educational background includes this type of preparation.	College degree with advanced education in theology, seminary, or rabbinical studies.

The Role of the Nurse in Milieu Therapy

One of the first nursing interventions in establishing a foundation for trust and maintaining a therapeutic milieu is orienting the new client to the environment, to his or her rights and responsibilities within the unit milieu, to the structured activities designed for personal growth, and to any limits or restrictions necessary to maintain safety. Availability to provide support and validation to clients throughout their treatment is also an essential nursing competency in milieu therapy (ANA et al., 2014), and this, too, is rooted in a trusting relationship. Active listening and inquiring about the client's expectations for treatment are key communication skills in providing support and validation and in establishing a foundation for patient-centered care.

Milieu therapy can take place in a variety of inpatient and outpatient settings. In the hospital, nurses are generally the only members of the IDT team who spend time with the clients on a 24-hour basis, and they assume responsibility for management of the therapeutic milieu. In all settings, the nursing process is used for the delivery of nursing care. In the management of the therapeutic milieu, the same model (ongoing assessment, diagnosis, outcome identification, planning, implementation, and evaluation) is necessary for effective treatment. Nurses are involved in all day-to-day activities that pertain to client care, and their suggestions and options are given serious consideration in care planning for individual clients. Information from the initial nursing assessment is used to create the IDT plan. Nurses have input into therapy goals and participate in the regular updates and modification of treatment plans.

In some treatment facilities, a separate nursing care plan is required in addition to the IDT plan. In this case, the nursing care plan must reflect diagnoses specific to nursing and include problems and interventions from the IDT plan that have been assigned to the nurse. Attention must be given to assure that the nursing care plan effectively collaborates with the IDT plan so that care is coordinated and consistent among team members.

In the therapeutic milieu, nurses are responsible for ensuring that clients' physiological needs are met. Clients must be encouraged to perform as independently as possible in fulfilling activities of daily living. However, the nurse must make ongoing assessments and provide assistance for those who require it. Assessing physical status is an important nursing responsibility that must not be overlooked in a psychiatric setting that emphasizes holistic care.

Reality orientation for clients who have disorganized thinking or who are disoriented or confused is important in the therapeutic milieu. Clocks with large hands and numbers, calendars that give the day and date in large print, and orientation boards that discuss daily activities and news happenings can help keep clients oriented to reality. Nurses should ensure that clients have written schedules of assigned activities and that they arrive at those activities on schedule. Some clients may require an identification sign on their door to remind them which room is theirs. On short-term units, nurses who are dealing with psychotic clients usually rely on a basic activity or topic that helps keep people oriented: for example, showing pictures of the hospital where they are housed, introducing people who were admitted during the night, and providing name badges with their first names.

Nurses are responsible for the management of medication administration on inpatient psychiatric units. In some treatment programs, clients are expected to accept the responsibility and request their medication at the appropriate time. Although ultimate responsibility lies with the nurse, he or she must encourage clients to be self-reliant. Nurses must work with the clients to determine methods that result in achievement and provide positive feedback for successes.

A major focus of nursing in the therapeutic milieu is the one-to-one relationship that grows out of developing trust between client and nurse. Many clients with psychiatric disorders have never achieved the ability to trust. If this can be accomplished in a relationship with the nurse, the trust may be generalized

to other relationships in the client's life. Within an atmosphere of trust, the client is encouraged to express feelings and emotions and discuss unresolved issues that are creating problems in his or her life.

In acute care hospitalizations, the ability to establish trust quickly and to assess and collaborate with the client about their post-discharge needs has become an essential role for nurses, since many aspects of the recovery treatment plan will occur in treatment settings other than inpatient hospitalization. Do not underestimate the importance of these short-term relationships. Clients in outpatient treatment often identify that something a nurse said or something they learned within the hospital milieu planted the seeds for their ongoing recovery plan.

> **CLINICAL PEARL** 💬
>
> **Developing trust means keeping promises that have been made. It means total acceptance of the individual as a person, separate from behavior that is unacceptable. It means responding to the client with concrete behaviors that are understandable to him or her (e.g., "If you are frightened, I will stay with you"; "If you are cold, I will bring you a blanket"; "If you are thirsty, I will bring you a drink of water").**

The nurse is responsible for setting limits on unacceptable behavior in the therapeutic milieu. This requires stating to the client in understandable terminology what behaviors are not acceptable and what the consequences will be if the limits are violated. These limits must be established, written, and carried out by all staff. Consistency in enforcing the consequences of violating the established limits is essential for learning is to be reinforced.

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. Nurses must be able to assess learning readiness in individual clients. Do they want to learn? What is their level of anxiety? What is their level of ability to understand the information being presented? Topics for client education in psychiatry include information about medical diagnoses, side effects of medications, the importance of continuing to take medications, and stress management, among others. Some topics must be individualized for specific clients, whereas others may be taught in group situations. Table 12–2 outlines various topics of nursing concern for client education in psychiatry. (Sample teaching guides are online.)

Echternacht (2001) stated:

Milieu therapy interventions are recognized as one of the basic-level functions of psychiatric-mental health nurses as addressed [in the *Psychiatric-Mental Health Nursing: Scope and Standards of Practice*, (ANA, 2014)]. Milieu therapy has been described as an

TABLE 12–2	The Therapeutic Milieu—Topics for Client Education

1. Ways to increase self-esteem
2. Ways to deal with anger appropriately
3. Stress-management techniques
4. How to recognize signs of increasing anxiety and intervene to stop progression
5. Normal stages of grieving and behaviors associated with each stage
6. Assertiveness techniques
7. Relaxation techniques
   a. Progressive relaxation
   b. Tense and relax
   c. Deep breathing
   d. Autogenics
8. Medications (specify)
   a. Reason for taking
   b. Harmless side effects
   c. Side effects to report to physician
   d. Importance of taking regularly
   e. Importance of not stopping abruptly
9. Effects of (substance) on the body
   a. Alcohol
   b. Other depressants
   c. Stimulants
   d. Hallucinogens

excellent framework for operationalizing [Hildegard] Peplau's interpretation and extension of Harry Stack Sullivan's Interpersonal Theory for use in nursing practice. (p. 39). . . .

Now is the time to rekindle interest in the therapeutic milieu concept and to reclaim nursing's traditional milieu intervention functions. Nurses need to identify the number of registered nurses necessary to carry out structured and unstructured milieu functions consistent with their Standards of Practice. (p. 43)

Summary and Key Points

■ In psychiatry, milieu therapy (or a therapeutic community) constitutes a manipulation of the environment in an effort to create behavioral changes and to improve the psychological health and functioning of the individual.

- The goal of therapeutic community is for the client to learn adaptive coping, interaction, and relationship skills that can be generalized to other aspects of his or her life.
- The community environment itself serves as the primary tool of therapy.
- According to Skinner (1979), a therapeutic community is based on seven basic assumptions:
  - The health in each individual is to be realized and encouraged to grow.
  - Every interaction is an opportunity for therapeutic intervention.
  - The client owns his or her own environment.
  - Each client owns his or her behavior.
  - Peer pressure is a useful and a powerful tool.
  - Inappropriate behaviors are dealt with as they occur.
  - Restrictions and punishment are to be avoided.
- Because the goals of milieu therapy relate to helping the client learn to generalize that which is learned to other aspects of his or her life, the conditions that promote a therapeutic community in the psychiatric setting are similar to the types of conditions that exist in real-life situations.
- Conditions that promote a therapeutic community include the following:
  - The fulfillment of basic physiological needs
  - Physical facilities that are conducive to achievement of the goals of therapy
  - The existence of a democratic form of self-government
  - The assignment of responsibilities according to client capabilities
  - A structured program of social and work-related activities
  - The inclusion of community and family in the program of therapy in an effort to facilitate discharge from treatment
- The program of therapy on the milieu unit is conducted by the IDT team.
- The team centers on the patient and includes some or all of the following disciplines (and potentially others): psychiatrist, clinical psychologist, psychiatric clinical nurse specialist, psychiatric nurse, mental health technician, psychiatric social worker, occupational therapist, recreational therapist, art therapist, music therapist, psychodramatist, dietitian, and chaplain.
- Nurses play a crucial role in the management of a therapeutic milieu. They are involved in the assessment, diagnosis, outcome identification, planning, implementation, and evaluation of all treatment programs.
- Nurses have significant input into the IDT plans, which are developed for all clients. They are responsible for ensuring that clients' basic needs are fulfilled; assessing physical and psychosocial status; administering medication; helping the client develop trusting relationships; setting limits on unacceptable behaviors; educating clients; and ultimately, helping clients, within the limits of their capability, to become productive members of society.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Which of the following are basic assumptions of milieu therapy? (Select all that apply.)
   a. The client owns his or her own environment.
   b. Each client owns his or her behavior.
   c. Peer pressure is a useful and powerful tool.
   d. Inappropriate behaviors are punished immediately.

2. John tells the nurse, "I think lights out at 10 o'clock on a weekend is stupid. We should be able to watch TV until midnight!" Which of the following is the most appropriate response from the nurse on the milieu unit?
   a. "John, you were told the rules when you were admitted."
   b. "You may bring it up before the others at the community meeting, John."
   c. "Some people want to go to bed early, John."
   d. "You are not the only person on this unit, John. You must think of others besides yourself."

Review Questions—cont'd
Self-Examination/Learning Exercise

3. In prioritizing care within the therapeutic environment, which of the following nursing interventions would receive the highest priority?
a. Ensuring that the physical facilities are conducive to achievement of the goals of therapy
b. Scheduling a community meeting for 8:30 each morning
c. Attending to the nutritional and comfort needs of all clients
d. Establishing contacts with community resources

4. In the community meeting, which of the following actions is most important for reinforcing the democratic posture of the therapy setting?
a. Allowing each person a specific and equal amount of time to talk
b. Reviewing group rules and behavioral limits that apply to all clients
c. Reading the minutes from yesterday's meeting
d. Waiting until all clients are present before initiating the meeting

5. One of the goals of therapeutic community is for clients to become more independent and accept self-responsibility. Which of the following approaches by staff best encourages fulfillment of this goal?
a. Including client input and decisions into the treatment plan
b. Insisting that each client take a turn as "president" of the community meeting
c. Making decisions for the client regarding plans for treatment
d. Requiring that the client be bathed, dressed, and attend breakfast on time each morning

6. Client teaching is an important nursing function in milieu therapy. Which of the following statements by the client indicates the need for knowledge and a readiness to learn?
a. "Get away from me with that medicine! I'm not sick!"
b. "I don't need psychiatric treatment. It's my migraine headaches that I need help with."
c. "I've taken Valium every day of my life for the last 20 years. I'll stop when I'm good and ready!"
d. "The doctor says I have bipolar disorder. What does that really mean?"

7. Which of the following activities would be a responsibility of the clinical psychologist member of the IDT?
a. Locates halfway house and arranges living conditions for client being discharged from the hospital
b. Manages the therapeutic milieu on a 24-hour basis
c. Administers and evaluates psychological tests that assist in diagnosis
d. Conducts psychotherapy and administers electroconvulsive therapy treatments

8. Which of the following activities would be a responsibility of the psychiatric clinical nurse specialist on the IDT team?
a. Manages the therapeutic milieu on a 24-hour basis
b. Conducts group therapies and provides consultation and education to staff nurses
c. Directs a group of clients in acting out a situation that is otherwise too painful for a client to discuss openly
d. Locates halfway house and arranges living conditions for client being discharged from the hospital

9. On the milieu unit, duties of the staff psychiatric nurse include which of the following? (Select all that apply.)
a. Medication administration
b. Client teaching
c. Medical diagnosis
d. Reality orientation
e. Relationship development
f. Group therapy

Review Questions—cont'd
Self-Examination/Learning Exercise

10. Lashona was sexually abused as a child. She is a client on the milieu unit with a diagnosis of Borderline Personality Disorder. She has refused to talk to anyone. Which of the following therapies might the IDT team choose for Lashona? (Select all that apply.)
   a. Music therapy
   b. Art therapy
   c. Psychodrama
   d. Electroconvulsive therapy

Crisis Intervention

KEY TERMS

crisis intervention   disaster

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *crisis.*
2. Describe four phases in the development of a crisis.
3. Identify types of crises that occur in people's lives.
4. Discuss the goal of crisis intervention.
5. Describe the steps in crisis intervention.
6. Identify the role of the nurse in crisis intervention.
7. Apply the nursing process to care of victims of disasters.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Name the three factors that determine whether or not a person experiences a crisis in response to a stressful situation.
2. What is the goal of crisis intervention?
3. Individuals in crisis need to develop more adaptive coping strategies. How does the nurse provide assistance with this process?
4. Describe behaviors common to preschool children following a traumatic event.

Stressful situations are a part of everyday life. Any stressful situation can precipitate a crisis. Crises result in a disequilibrium from which many individuals require assistance to recover. **Crisis intervention** and resolution require problem-solving skills that are often diminished by the level of anxiety accompanying disequilibrium. Assistance with problem-solving during the crisis period preserves self-esteem and promotes growth with resolution.

In recent years, individuals in the United States have been faced with a number of catastrophic events, including natural disasters such as tornados, earthquakes, hurricanes, and floods. Man-made disasters, such as the Oklahoma City and Boston Marathon

234

bombings and the attacks on the World Trade Center and the Pentagon, have created psychological stress of astronomical proportions in populations around the world.

This chapter examines the phases in the development of a crisis and the types of crises that occur in people's lives. The methodology of crisis intervention, including the role of the nurse, is explored. A discussion of disaster nursing is also presented.

CORE CONCEPTS

Crisis

A sudden event in one's life that disturbs homeostasis, during which usual coping mechanisms cannot resolve the problem (Lagerquist, 2012, p. 795).

Characteristics of a Crisis

A number of characteristics have been identified that can be viewed as assumptions upon which the concept of crisis is based (Aguilera, 1998; Caplan, 1964):

1. Crisis occurs in all individuals at one time or another and is not necessarily equated with psychopathology.
2. Crises are precipitated by specific identifiable events.
3. Crises are personal by nature. What may be considered a crisis situation by one individual may not be so for another.
4. Crises are acute, not chronic, and will be resolved in one way or another within a brief period.
5. A crisis situation contains the potential for psychological growth or deterioration.

Individuals who are in crisis feel helpless to change. They do not believe they have the resources to deal with the precipitating stressor. Levels of anxiety rise to the point that the individual becomes nonfunctional, thoughts become obsessional, and all behavior is aimed at relief of the anxiety being experienced. The feeling is overwhelming and may affect the individual physically as well as psychologically.

Bateman and Peternelj-Taylor (1998) have stated:

Outside Western culture, a crisis is often viewed as a time for movement and growth. The Chinese symbol for crisis consists of the characters for *danger* and *opportunity* [Fig. 13–1]. When a crisis is viewed as an opportunity for growth, those involved are much more capable of resolving related issues and more able to move toward positive changes. When the crisis experience is overwhelming because of its scope and nature or when there has not been adequate preparation for the necessary changes, the dangers seem paramount and overshadow any potential

FIGURE 13–1   Chinese symbol for crisis.

growth. The results are maladaptive coping and dysfunctional behavior. (pp. 144–145)

Phases in the Development of a Crisis

The development of a crisis situation follows a relatively predictable course. Caplan (1964) outlined four phases through which individuals progress in response to a precipitating stressor and that culminate in the state of acute crisis.

Phase 1: *The individual is exposed to a precipitating stressor.* Anxiety increases; previous problem-solving techniques are employed.

Phase 2: *When previous problem-solving techniques do not relieve the stressor, anxiety increases further.* The individual begins to feel a great deal of discomfort at this point. Coping techniques that have worked in the past are attempted, only to create feelings of helplessness when they are not successful. Feelings of confusion and disorganization prevail.

Phase 3: *All possible resources, both internal and external, are called on to resolve the problem and relieve the discomfort.* The individual may try to view the problem from a different perspective or even to overlook certain aspects of it. New problem-solving techniques may be used, and, if effectual, resolution may occur at this phase, with the individual returning to a higher, a lower, or the previous level of precrisis functioning.

Phase 4: *If resolution does not occur in previous phases, Caplan states that "the tension mounts beyond a further threshold or its burden increases over time to a breaking point. Major disorganization of the individual with drastic results often occurs"* (p. 41). Anxiety may reach panic levels. Cognitive functions are disordered, emotions are labile, and behavior may reflect the presence of psychotic thinking.

These phases are congruent with the transactional model of stress adaptation outlined in Chapter 1, The Concept of Stress Adaptation. The relationship between the two perspectives is presented in Figure 13–2. When an individual perceives a stressor as a threat to
FIGURE 13–2 Relationship between transactional model of stress/adaptation and Caplan's phases in the development of a crisis.

his or her well-being and lacks adaptive coping strategies or employs maladaptive strategies, crisis ensues. Similarly, Aguilera (1998) spoke of "balancing factors" that affect the way in which an individual perceives and responds to a precipitating stressor. A schematic of these balancing factors is illustrated in Figure 13–3.

The paradigm set forth by Aguilera suggests that whether or not an individual experiences a crisis in response to a stressful situation depends on the following three factors:

1. **The individual's perception of the event:** If the event is perceived realistically, the individual is more likely to draw upon adequate resources to restore equilibrium. If the perception of the event is distorted, attempts at problem-solving are likely to be ineffective, and equilibrium is not restored.
2. **The availability of situational supports:** Aguilera stated, "Situational supports are those persons who are available in the environment and who can be depended on to help solve the problem" (p. 37).

Without adequate situational supports during a stressful situation, an individual is most likely to feel overwhelmed and alone.
3. **The availability of adequate coping mechanisms:** When a stressful situation occurs, individuals draw upon behavioral strategies that have been successful for them in the past. If these coping strategies work, a crisis may be diverted. If not, disequilibrium may continue and tension and anxiety increase.

Crises are acute, time-limited situations that will be resolved in one way or another within 1 to 3 months. Crises can become growth opportunities when individuals learn new methods of coping that can be preserved and used when similar stressors recur. However, when new coping mechanisms or balancing factors are not identified and incorporated, the crisis situation can evolve into longer-term problems and sometimes symptoms of emotional or mental illness, including depression, anxiety, and trauma/stressor-related disorders.
Stressful event is balanced by realistic perceptions, adequate support, effective coping mechanisms ➡ Equilibrium ➡ **No crisis**

Problem unresolved ➡ Disequilibrium ➡ **Crisis**

FIGURE 13–3   The effect of balancing factors in a stressful event.

Types of Crises

Baldwin (1978) identified six classes of emotional crises, which progress by degree of severity. As the measure of psychopathology increases, the source of the stressor changes from external to internal. The type of crisis determines the method of intervention selected.

Class 1: Dispositional Crises

Definition An acute response to an external situational stressor.

EXAMPLE

Brittany and Ethan have been married for 3 years and have a 1-year-old daughter. Ethan has been having difficulty with his boss at work. Twice during the past 6 months, he has exploded in anger at home and become abusive with Brittany. Last night he became angry that dinner was not ready when he expected. He grabbed the baby from Brittany and tossed her, screaming, into her crib. He hit and punched Brittany until she feared for her life. This morning when he left for work, she took the baby and went to the emergency department of the city hospital, not knowing what else to do.

Intervention Physical care of wounds and screening for domestic violence issues should be conducted in the emergency department. The mental health counselor can provide support and guidance in terms of presenting alternatives for managing the health and safety of herself and her child. The emergency department nurse should encourage and empower Brittany to clarify her needs and issues so referrals for agency assistance can be made.

Class 2: Crises of Anticipated Life Transitions

Definition Normal life-cycle transitions that are anticipated but over which the individual may feel a lack of control.

EXAMPLE

College student J.T. is placed on probationary status because of low grades this semester. His wife had a baby and had to quit her job. He increased his working hours from part time to full time to compensate and therefore had little time for studies. He presents himself to the student-health nurse practitioner complaining of numerous vague physical complaints.

Intervention Physical examination should be performed (physical symptoms could be caused by depression) and ventilation of feelings encouraged. Reassurance and support should be provided as needed. J.T. should be referred to services that can provide financial and other types of needed assistance. Problematic areas should be identified and approaches to change discussed.

Class 3: Crises Resulting From Traumatic Stress

Definition Crisis precipitated by an unexpected external stressor over which the individual has little or no control and as a result of which he or she feels emotionally overwhelmed and defeated.

EXAMPLE

Ava is a waitperson whose shift ended at midnight. Two weeks ago, while walking to her car in the deserted parking lot, she was abducted by two men with guns, taken to an abandoned building, and raped and beaten. Since that time, her physical wounds have nearly healed. However,

Ava cannot be alone, is constantly fearful, relives the experience in flashbacks and dreams, and is unable to eat, sleep, or work at her job in the restaurant. Her friend offers to accompany her to the mental health clinic.

Intervention The nurse should offer Ava the opportunity to talk about the experience and express her feelings about the trauma when she demonstrates readiness. The nurse should offer reassurance and support; discuss stages of grief and how rape may precipitate feelings of loss, including loss of control, loss of power, and loss of a sense of self-worth, triggering the grief response; identify support systems that can help Ava to resume her normal activities; and explore new methods of coping with emotions arising from a situation with which she has had no previous experience. These interventions should be conducted in an environment that is sensitive to the impact of trauma on a person's sense of self, and all interventions should convey dignity, respect, and hopefulness and promote the client's empowerment to make choices in her or his care (SAMHSA, 2014). See Chapter 28, Trauma- and Stressor-Related Disorders, for more information on trauma-informed care.

Class 4: Maturational/Developmental Crises

Definition Crises that occur in response to failed attempts to master developmental tasks associated with transitions in the life cycle.

EXAMPLE

Jada and Caleb have been married for 2 years, and their firstborn child is 4 months old. Jada's mother was recently diagnosed with cancer, and the prognosis is unclear. Over the past 3 weeks, Jada has become increasingly anxious and disorganized, calling the nurse practitioner 10 to 15 times each day with new fears that she is not addressing her child's health needs. Jada has been screaming at Caleb that he is never there when she needs help with the baby and states she is thinking of dropping their child off at the Children's Service Agency because she believes they are both unable to be effective parents. She agrees to see a counselor at Caleb's insistence.

Intervention The primary intervention is to help Jada with anxiety reduction. When individuals have intense anxiety, their ability to gain insight about contributing factors and explore options for behavior change is impaired. The safety of their child should also be carefully assessed. Referrals and guidance in parenting skills may lessen the anxiety associated with this new developmental phase. Anxiety and grief related to Jada's mother's illness could also be explored as a possible factor contributing to the current crisis.

Class 5: Crises Reflecting Psychopathology

Definition A crisis that is influenced or triggered by preexisting psychopathology. Examples of psychopathology that may precipitate crises include personality disorders, anxiety disorders, bipolar disorder, and schizophrenia.

EXAMPLE

Sonja, age 29, was diagnosed with borderline personality disorder at age 18. This disorder is believed to be rooted in deep fear of abandonment. She has been in weekly therapy for 10 years, with several hospitalizations for suicide attempts during that time. She has had the same therapist for the past 6 years. This therapist told Sonja today that she is to be married in 1 month and will be moving across the country with her new husband. Sonja is distraught, stating that no one cares about her and that she would be better off dead. She is found wandering in and out of traffic on a busy expressway, oblivious to her surroundings. Police bring her to the emergency department of the hospital.

Intervention The initial intervention is aimed at helping Sonja to reduce her anxiety. She requires that someone stay with her and reassure her of her safety and security. After the feelings of panic and anxiety have subsided, she should be encouraged to verbalize her feelings of abandonment. Regressive behaviors should be discouraged. Positive reinforcement should be given for independent activities and accomplishments. The primary therapist will need to pursue this issue of termination with Sonja and facilitate transfer of services to another therapist or treatment program. Hospitalization may be necessary to maintain patient safety.

Class 6: Psychiatric Emergencies

Definition Crisis situations in which general functioning has been severely impaired and the individual rendered incompetent or unable to assume personal responsibility for his or her behavior. Examples include acute suicide risk, drug overdose, reactions to hallucinogenic drugs, acute psychoses, uncontrollable anger, and alcohol intoxication.

EXAMPLE

Jennifer, age 16, had been dating Joe, the star high school football player, for 6 months. After the game on Friday night, Jennifer and Joe went to Jackie's house, where a number of high school students had gathered for an after-game party. No adults were present. About midnight, Joe told Jennifer that he did not want to date her anymore. Jennifer became hysterical, and Jackie was frightened by her behavior. She took Jennifer to her parent's bedroom and gave her a Valium from a bottle in her mother's medicine cabinet. She left Jennifer lying on her parent's bed and returned to the party downstairs. About an hour later, she returned to her parent's

bedroom and found that Jennifer had removed the bottle of Valium from the cabinet and swallowed all of the tablets. Jennifer was unconscious and Jackie could not awaken her. An ambulance was called and Jennifer was transported to the local hospital.

Intervention Emergency medical care, including monitoring vital signs, ensuring maintenance of adequate airway, and initiating gastric lavage and/or activated charcoal, is the priority in this case. Jennifer is a minor, so notifying the parents is essential as well. Inpatient hospitalization is justifiable to assure patient safety. Discussing feelings about self-esteem, rejection, and loss will help Jennifer explore more adaptive methods of dealing with stressful situations.

Crisis Intervention

Individuals experiencing crises have an urgent need for assistance. In **crisis intervention,** the therapist or other intervener becomes part of the individual's life situation. Because of the individual's emotional state, he or she is unable to problem-solve and consequently requires guidance and support from another to help mobilize the resources needed to resolve the crisis.

Lengthy psychological interpretations are not appropriate for crisis intervention. It is a time for doing what is needed to help the individual get relief and for calling into action all the people and resources required to do so. Aguilera (1998) has stated:

> The goal of crisis intervention is the resolution of an immediate crisis. Its focus is on the supportive, with the restoration of the individual to his precrisis level of functioning or possibly to a higher level of functioning. The therapist's role is direct, supportive, and that of an active participant. (p. 24)

Crisis intervention takes place in inpatient settings, outpatient settings, and the community. In the past few decades, people with mental illness have been increasingly involved with criminal justice personnel as first responders to manage mental health crisis situations. In 1988, the fatal shooting by police officers of a man with mental illness prompted the development of the *crisis intervention team (CIT) model* to assure that select police officers are trained to identify mental illness and substance abuse, use de-escalation techniques, and divert individuals from criminal justice systems to mental health professionals (Watson & Fulambarker, 2012). Not all states have developed CIT training programs, but several studies have demonstrated improved safety outcomes for patients with mental illness where CIT-trained officers are available. Other resources that may be available for patients with mental illness who are experiencing an

acute crisis include 24-hour crisis phone lines, walk-in crisis centers, mobile crisis teams, respite and residential services, and hospital services, including 23-hour observation beds (National Alliance on Mental Illness [NAMI], 2015). Nurses have a responsibility to know what resources exist in their community of practice. They can then become an important advocate for crisis intervention training in communities and can also be a support to families by encouraging them to ask for CIT-trained officers (where available) when faced with a family member's psychiatric crisis.

A more recent trend in some states, counties, and mental health facilities is to utilize *peer support specialists*. These individuals have personal experience with mental illness and are trained and/or credentialed to help clients navigate everyday challenges of living with a mental illness. Evidence has demonstrated their effectiveness in diffusing psychiatric crises (NAMI, 2014).

The basic methodology for crisis intervention work by health-care professionals relies heavily on orderly problem-solving techniques and structured activities focused on change. Through adaptive change, crises are resolved and growth occurs. Because of the time limitation of crisis intervention, the individual must experience some degree of relief almost from the first interaction. Crisis intervention, then, is not aimed at major personality change or reconstruction (as may be the case in long-term psychotherapy), but rather at using a given crisis situation at the very least to restore functioning and at most to enhance personal growth.

Phases of Crisis Intervention: The Role of the Nurse

Nurses respond to crisis situations on a daily basis. Crises can occur on every unit in the general hospital, in the home setting, in the community health-care setting, in schools and offices, and in private practice. Nurses may be called on to function as crisis helpers in virtually any setting committed to the practice of nursing.

Roberts and Ottens (2005) describe the clinical application of Robert's seven-stage model of crisis intervention. This model is summarized in Table 13–1. Aguilera (1998) described four phases in the technique of crisis intervention that are clearly comparable to the steps of the nursing process. These phases are discussed in the following paragraphs.

Phase 1. Assessment

In this phase, the nurse gathers information regarding the precipitating stressor and the resulting crisis

TABLE 13–1 **Roberts' Seven-Stage Crisis Intervention Model**	
STAGE	**INTERVENTIONS**
Stage I. Psychosocial and Lethality Assessment	■ Conduct a rapid but thorough biopsychosocial assessment.
Stage II. Rapidly Establish Rapport	■ The counselor uses genuineness, respect, and unconditional acceptance to establish rapport with the client. ■ Skills such as good eye contact, a nonjudgmental attitude, flexibility, and maintaining a positive mental attitude are important.
Stage III. Identify the Major Problems or Crisis Precipitants	■ Identify the precipitating event that has led the client to seek help at the present time. ■ Identify other situations that led up to the precipitating event. ■ Prioritize major problems with which the client needs help. ■ Discuss client's current style of coping, and offer assistance in areas where modification would be helpful in resolving the present crisis and preventing future crises.
Stage IV. Deal With Feelings and Emotions	■ Encourage the client to vent feelings. Provide validation. ■ Use therapeutic communication techniques to help the client explain his or her story about the current crisis situation. ■ Eventually, and cautiously, begin to challenge maladaptive beliefs and behaviors, and help the client adopt more rational and adaptive options.
Stage V. Generate and Explore Alternatives	■ Collaboratively explore options with the client. ■ Identify coping strategies that have been successful for the client in the past. ■ Help the client problem-solve strategies for confronting current crisis adaptively.
Stage VI. Implement an Action Plan	■ There is a shift at this stage from crisis to resolution. ■ Develop a concrete plan of action to deal directly with the current crisis. ■ Having a concrete plan restores the client's equilibrium and psychological balance. ■ Work through the meaning of the event that precipitated the crisis. How could it have been prevented? What responses may have aggravated the situation?
Stage VII. Follow-Up	■ Plan a follow-up visit with the client to evaluate the postcrisis status of the client. ■ Beneficial scheduling of follow-up visits include 1-month and 1-year anniversaries of the crisis event.

Adapted from Roberts, A.R., & Ottens, A.J. (2005). The seven-stage crisis intervention model: A road map to goal attainment, problem solving, and crisis resolution. *Brief Treatment and Crisis Intervention, 5*(4), 329-339.

that prompted the individual to seek professional help. A nurse in crisis intervention might perform some of the following assessments:

■ Ask the individual to describe the event that precipitated this crisis.
■ Determine when it occurred.
■ Assess the individual's mental *and* physical status.
■ Determine if the individual has experienced this stressor before. If so, what method of coping was used? Have these methods been tried this time?
■ If previous coping methods were tried, what was the result?

■ If new coping methods were tried, what was the result?
■ Assess suicide or homicide potential, plan, and means.
■ Assess the adequacy of support systems.
■ Determine level of precrisis functioning. Assess the usual coping methods, available support systems, and ability to problem-solve.
■ Assess the individual's perception of personal strengths and limitations.
■ Assess the individual's use of substances.

Information from the comprehensive assessment is then analyzed, and appropriate nursing diagnoses

reflecting the immediacy of the crisis situation are identified. Some nursing diagnoses that may be relevant include the following:

■ Ineffective coping
■ Anxiety (severe to panic)
■ Disturbed thought processes (resigned from the NANDA-I list of approved diagnoses but used for purposes of this textbook)
■ Risk for self- or other-directed violence
■ Rape-trauma syndrome
■ Posttrauma syndrome
■ Fear

Phase 2. Planning of Therapeutic Intervention

In the planning phase of crisis intervention, the nurse selects the appropriate nursing actions for the identified nursing diagnoses. In planning the interventions, the type of crisis, as well as the individual's strengths, desired choices, and available resources for support, are taken into consideration. Goals are established for crisis resolution and a return to or increase in the precrisis level of functioning.

Phase 3. Intervention

During phase 3, the actions identified in phase 2 are implemented. The following interventions are the focus of nursing in crisis intervention:

■ Use a reality-oriented approach. The focus of the problem is on the here and now.
■ Remain with the individual experiencing panic anxiety.
■ Establish a rapid working relationship by showing unconditional acceptance, by active listening, and by attending to immediate needs.
■ Discourage lengthy explanations or rationalizations of the situation; promote an atmosphere for verbalization of true feelings.
■ Set firm limits on aggressive, destructive behaviors. At high levels of anxiety, behavior is likely to be impulsive and regressive. Establish at the outset what is acceptable and what is not, and maintain consistency.
■ Clarify the problem the individual is facing. The nurse does this by describing his or her perception of the problem and comparing it with the individual's perception of the problem.
■ Help the individual determine what he or she believes precipitated the crisis.
■ Acknowledge feelings of anger, guilt, helplessness, and powerlessness without judgment.
■ Guide the individual through a problem-solving process by which he or she may move in the direction of positive life change.

■ Help the individual confront the factors that are contributing to the experience of crisis.
■ Encourage the individual to discuss changes he or she would like to make. Jointly determine whether or not desired changes are realistic.
■ Encourage exploration of feelings about aspects of the situation that cannot be changed, and explore alternative ways of coping more adaptively in these situations.
■ Discuss alternative strategies for creating changes that are realistically possible.
■ Weigh benefits and consequences of each alternative.
■ Assist the individual to select alternative coping strategies that will help alleviate future crisis situations.
■ Identify external support systems and new social networks from which the individual may seek assistance in times of stress.

> **CLINICAL PEARL** Coping mechanisms are highly individual, and the choice ultimately must be made by the client. The nurse may offer suggestions and provide guidance to help the client identify realistic coping mechanisms that can promote positive outcomes in a crisis situation.

Phase 4. Evaluation of Crisis Resolution and Anticipatory Planning

To evaluate the outcome of crisis intervention, a reassessment is made to determine if the stated objective was achieved:

■ Have positive behavioral changes occurred?
■ Has the individual developed more adaptive coping strategies? Have they been effective?
■ Has the individual grown from the experience by gaining insight into his or her responses to crisis situations?
■ Does the individual believe that he or she could respond with healthy adaptation in future stressful situations to prevent crisis development?
■ Can the individual describe a plan of action for dealing with stressors similar to the one that precipitated this crisis?

During the evaluation period, the nurse and client summarize what has occurred during the intervention. They review what the individual has learned and anticipate how he or she will respond in the future. A determination is made regarding follow-up therapy; if needed, the nurse provides referral information.

Disaster Nursing

Although there are many definitions of **disaster,** a common feature is that the event overwhelms local

resources and threatens the function and safety of the community (Norwood, Ursano, & Fullerton, 2000). A violent disaster, whether natural or man-made, may cause devastation to property or life. Such tragedies leave victims with a damaged sense of safety and well-being and varying degrees of emotional trauma. Spiritual distress often occurs as victims question, "How could this have happened?" and "What is most important in life?" A care plan for responding to spiritual distress is included in Table 13–2. Children, who lack life experiences and coping skills, are particularly vulnerable. Their sense of order and security has been seriously disrupted, and they are unable to understand that the disruption is time-limited and that their world will eventually return to normal.

Application of the Nursing Process to Disaster Nursing

Background Assessment Data

Individuals respond to traumatic events in many ways. Grieving is a natural response following any loss, and it may be more extreme if the disaster is directly experienced or witnessed. The emotional effects of loss and disruption may show up immediately or appear weeks or months later.

Psychological and behavioral responses common in adults following trauma and disaster include anger; disbelief; sadness; anxiety; fear; irritability; arousal; numbing; sleep disturbance; and increases in alcohol, caffeine, and tobacco use (Norwood et al., 2000). Preschool children commonly experience separation anxiety, regressive behaviors, nightmares, and hyperactive or withdrawn behaviors. Older children may have difficulty concentrating, somatic complaints, sleep disturbances, and concerns about safety. Adolescents' responses are often similar to those of adults.

Norwood and associates (2000) stated:

> Traumatic bereavement is recognized as posing special challenges to survivors. While the death of loved ones is always painful, an unexpected and violent death can be more difficult to assimilate. Family members may develop intrusive images of the death based on information gleaned from authorities or the media. Witnessing or learning of violence to a loved one also increases vulnerability to psychiatric disorders. The knowledge that one has been exposed to toxins is a potent traumatic stressor . . . and the focus of much concern in the medical community preparing for responses to terrorist attacks using biological, chemical, or nuclear agents. (p. 214)

Nursing Diagnoses and Outcome Identification

Information from the assessment is analyzed, and appropriate nursing diagnoses reflecting the immediacy of the situation are identified. Some nursing diagnoses that may be relevant include the following:

■ Risk for injury (trauma, suffocation, poisoning)
■ Risk for infection
■ Anxiety (panic)
■ Fear
■ Spiritual distress
■ Risk for post-trauma syndrome
■ Ineffective community coping

The following criteria may be used for measurement of outcomes in the care of the client having experienced a traumatic event. Time lines are individually determined.

The client:

■ Demonstrates behaviors necessary to protect self from further injury
■ Identifies interventions to prevent/reduce risk of infection
■ Is free of infection and/or physical injury
■ Maintains anxiety at manageable level
■ Expresses beliefs and values about spiritual issues
■ Demonstrates ability to deal with emotional reactions in an individually appropriate manner
■ Demonstrates an increase in activities to improve community functioning

Planning and Implementation

Table 13–2 provides a plan of care for the client who has experienced a traumatic event. Selected nursing diagnoses are presented, along with outcome criteria, appropriate nursing interventions, and rationales for each.

Evaluation

In the final step of the nursing process, a reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client who has experienced a traumatic event may be facilitated by gathering information utilizing the following types of questions:

■ Has the client escaped serious injury, or have injuries been resolved?
■ Have infections been prevented or resolved?
■ Is the client able to maintain anxiety at manageable level?
■ Does he or she demonstrate appropriate problem-solving skills?

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT

NURSING DIAGNOSIS: ANXIETY (PANIC)/FEAR

RELATED TO: Real or perceived threat to physical well-being; threat of death; situational crisis; exposure to toxins; unmet needs

EVIDENCED BY: Persistent feelings of apprehension and uneasiness; sense of impending doom; impaired functioning; verbal expressions of having no control or influence over situation, outcome, or self-care; sympathetic stimulation; extraneous physical movements

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client demonstrates that anxiety is at a manageable level. Client demonstrates use of positive coping mechanisms to manage anxiety.	1. Determine degree of anxiety/fear present, associated behaviors (e.g., laughter, crying, calm or agitation, excited or hysterical behavior, expressions of disbelief and/or self-blame), and reality of perceived threat.	1. Clearly understanding client's perception is pivotal to providing appropriate assistance in overcoming the fear. Individual may be agitated or totally overwhelmed. Panic state increases risk for client's own safety and the safety of others in the environment.
	2. Note degree of disorganization.	2. Client may be unable to handle activities of daily living or work requirements and need more intensive intervention.
	3. Create as quiet an area as possible. Maintain a calm confident manner. Speak in even tone using short, simple sentences.	3. Decreases sense of confusion or overstimulation; enhances sense of safety. Helps client focus on what is said and reduces transmission of anxiety.
	4. Develop trusting relationship with client.	4. Trust is the basis of a therapeutic nurse-client relationship and enables them to work effectively together.
	5. Identify whether incident has reactivated preexisting or coexisting situations (physical or psychological).	5. Concerns and psychological issues may be recycled every time trauma is reexperienced and affect how client views the current situation.
	6. Determine presence of physical symptoms (e.g., numbness, headache, tightness in chest, nausea, and pounding heart).	6. Physical problems need to be differentiated from anxiety symptoms so appropriate treatment can be given.
	7. Identify psychological responses (e.g., anger, shock, acute anxiety, panic, confusion, denial). Record emotional changes.	7. Although these are normal responses at the time of the trauma, they will recycle repeatedly until they are dealt with adequately.
	8. Discuss with client the perception of what is causing the anxiety.	8. Increases the ability to connect symptoms to subjective feeling of anxiety, providing opportunity to gain insight/control and make desired changes.
	9. Assist client to correct any distortions being experienced. Share perceptions with client.	9. Perceptions based on reality will help to decrease fearfulness. How the nurse views the situation may help client to see it differently.

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	10. Explore with client or significant other the manner in which client has previously coped with anxiety-producing events.	10. May help client regain sense of control and recognize significance of trauma.
	11. Engage client in learning new coping behaviors (e.g., progressive muscle relaxation, thought-stopping).	11. Replacing maladaptive behaviors can enhance ability to manage and deal with stress. Interrupting obsessive thinking allows client to use energy to address underlying anxiety, whereas continued rumination about the incident can retard recovery.
	12. Encourage use of techniques to manage stress and vent emotions such as anger and hostility.	12. Reduces the likelihood of eruptions that can result in abusive behavior.
	13. Give positive feedback when client demonstrates better ways to manage anxiety and is able to calmly and realistically appraise the situation.	13. Provides acknowledgment and reinforcement, encouraging use of new coping strategies. Enhances ability to deal with fearful feelings and gain control over situation, promoting future successes.
	14. Administer medications as indicated: antianxiety: diazepam, alprazolam, oxazepam; or antidepressants: fluoxetine, paroxetine, bupropion.	14. Antianxiety medication provides temporary relief of anxiety symptoms, enhancing ability to cope with situation. Antidepressants lift mood and help suppress intrusive thoughts and explosive anger.

NURSING DIAGNOSIS: SPIRITUAL DISTRESS

RELATED TO: Physical or psychological stress; energy-consuming anxiety; loss(es), intense suffering; separation from religious or cultural ties; challenged belief and value system

EVIDENCED BY: Expressions of concern about disaster and the meaning of life and death or belief systems; inner conflict about current loss of normality and effects of the disaster; anger directed at deity; engaging in self-blame; seeking spiritual assistance

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client expresses beliefs and values about spiritual issues.	1. Determine client's religious/ spiritual orientation, current involvement, and presence of conflicts.	1. Provides baseline for planning care and accessing appropriate resources.
	2. Establish environment that promotes free expression of feelings and concerns. Provide calm, peaceful setting when possible.	2. Promotes awareness and identification of feelings so they can be dealt with.

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	3. Listen to client's and significant others' expressions of anger, concern, alienation from God, belief that situation is a punishment for wrongdoing, and so on.	3. It is helpful to understand client's and significant others' points of view and how they are questioning their faith in the face of tragedy.
	4. Note sense of futility, feelings of hopelessness and helplessness, lack of motivation to help self.	4. These thoughts and feelings can result in client feeling paralyzed and unable to move forward to resolve the situation.
	5. Listen to expressions of inability to find meaning in life and reason for living. Evaluate for suicidal ideation.	5. May indicate need for further intervention to prevent suicide attempt.
	6. Determine support systems available to client.	6. Presence or lack of support systems can affect client's recovery.
	7. Ask how you can be most helpful. Convey acceptance of client's spiritual beliefs and concerns.	7. Promotes trust and comfort, encouraging client to be open about sensitive matters.
	8. Make time for nonjudgmental discussion of philosophic issues and questions about spiritual impact of current situation.	8. Helps client to begin to look at basis for spiritual confusion. *Note:* There is a potential for care provider's belief system to interfere with client finding own way. Therefore, it is most beneficial to remain neutral and not espouse own beliefs.
	9. Discuss difference between grief and guilt and help client to identify and deal with each, assuming responsibility for own actions, expressing awareness of the consequences of acting out of false guilt.	9. Blaming self for what has happened impedes dealing with the grief process and needs to be discussed and dealt with.
	10. Use therapeutic communication skills of reflection and active-listening.	10. Helps client find own solutions to concerns.
	11. Encourage client to experience meditation, prayer, and forgiveness. Provide information that anger with God is a normal part of the grieving process.	11. This can help to heal past and present pain.
	12. Assist client to develop goals for dealing with life situation.	12. Enhances commitment to goal, optimizing outcomes and promoting sense of hope.

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	13. Identify and refer to resources that can be helpful (e.g., pastoral/parish nurse or religious counselor, crisis counselor, psychotherapy, Alcoholics/ Narcotics Anonymous).	13. Specific assistance may be helpful to recovery (e.g., relationship problems, substance abuse, suicidal ideation).
	14. Encourage participation in support groups.	14. Discussing concerns and questions with others can help client resolve feelings.

NURSING DIAGNOSIS: RISK FOR POST-TRAUMA SYNDROME

RELATED TO: Events outside the range of usual human experience; serious threat or injury to self or loved ones; witnessing violent or tragic events; exaggerated sense of responsibility; survivor's guilt or role in the event; inadequate social support

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client demonstrates ability to deal with emotional reactions in an individually appropriate manner.	1. Determine involvement in event (e.g., survivor, significant other, rescue/aid worker, health-care provider, family member).	1. All those concerned with a traumatic event are at risk for emotional trauma and have needs related to their involvement in the event. *Note:* Close involvement with victims affects individual responses and may prolong emotional suffering.
	2. Evaluate current factors associated with the event, such as displacement from home due to illness or injury, natural disaster, or terrorist attack. Identify how client's past experiences may affect current situation.	2. Affects client's reaction to current event and is basis for planning care and identifying appropriate support systems and resources.
	3. Listen for comments of taking on responsibility (e.g., "I should have been more careful or gone back to get her").	3. Statements such as these are indicators of "survivor's guilt" and blaming self for actions.
	4. Identify client's current coping mechanisms.	4. Noting positive or negative coping skills provides direction for care.
	5. Determine availability and usefulness of client's support systems, family, social contacts, and community resources.	5. Family and others close to client may also be at risk and require assistance to cope with the trauma.
	6. Provide information about signs and symptoms of posttrauma response, especially if individual is involved in a high-risk occupation.	6. Awareness of these factors helps individual identify need for assistance when signs and symptoms occur.

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	7. Identify and discuss client's strengths as well as vulnerabilities.	7. Provides information to build on for coping with traumatic experience.
	8. Evaluate individual's perceptions of events and personal significance (e.g., rescue worker trained to provide lifesaving assistance but recovering only dead bodies).	8. Events that trigger feelings of despair and hopelessness may be more difficult to deal with, and require long-term interventions.
	9. Provide emotional and physical presence by sitting with client/ significant other and offering solace.	9. Strengthens coping abilities.
	10. Encourage expression of feelings. Note whether feelings expressed appear congruent with events experienced.	10. It is important to talk about the incident repeatedly. Incongruencies may indicate deeper conflict and can impede resolution.
	11. Note presence of nightmares, reliving the incident, loss of appetite, irritability, numbness and crying, and family or relationship disruption.	11. These responses are normal in the early postincident time frame. If prolonged and persistent, they may indicate need for more intensive therapy.
	12. Provide a calm, safe environment.	12. Helps client deal with the disruption in his or her life.
	13. Encourage and assist client in learning stress-management techniques.	13. Promotes relaxation and helps individual exercise control over self and what has happened.
	14. Recommend participation in debriefing sessions that may be provided following major disaster events.	14. Dealing with the stresses promptly may facilitate recovery from the event or prevent exacerbation.
	15. Identify employment, community resource groups.	15. Provides opportunity for ongoing support to deal with recurrent feelings related to the trauma.
	16. Administer medications as indicated, such as antipsychotics (e.g., chlorpromazine, haloperidol, olanzapine, or quetiapine) or carbamazepine (Tegretol).	16. Low doses of antipsychotics may be used for reduction of psychotic symptoms when loss of contact with reality occurs, usually for clients with especially disturbing flashbacks. Carbamazepine may be used to alleviate intrusive recollections or flashbacks, impulsivity, and violent behavior.

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT–cont'd

NURSING DIAGNOSIS: INEFFECTIVE COMMUNITY COPING

RELATED TO: History of exposure to disasters (earthquakes, tornados, floods, reemerging infectious agents, terrorist activity); ineffective or nonexistent community resources (e.g., lack of or inadequate emergency medical system, transportation system, or disaster planning systems), inadequate resources for problem-solving

EVIDENCED BY: Deficits of community participation; community does not meet expectations of its members; expressed perception of vulnerability and powerlessness; stressors perceived as excessive; excessive community conflicts or problems (vandalism, robbery, unemployment, homicides, terrorism, poverty); high illness rates

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client demonstrates an increase in activities to improve community functioning.	1. Evaluate community activities that are related to meeting collective needs within the community and between the community and the larger society. Note immediate needs, such as health care, food, shelter, funds.	1. Provides a baseline to determine community needs in relation to current concerns or threats.
	2. Note community reports of functioning, including areas of weakness or conflict.	2. Provides a view of how the community sees these areas.
	3. Identify effects of related factors on community activities.	3. In the face of a current threat, local or national, community resources need to be evaluated, updated, and given priority to meet the identified need.
	4. Determine availability and use of resources. Identify unmet demands or needs of the community.	4. Information necessary to identify what else is needed to meet the current situation.
	5. Determine community strengths.	5. Promotes understanding of the ways in which the community is already meeting the identified needs.
	6. Encourage community members/groups to engage in problem-solving activities.	6. Promotes a sense of working together to meet the needs.
	7. Develop a plan jointly with the members of the community to address immediate needs.	7. Deals with deficits in support of identified goals.
	8. Create plans managing interactions within the community and between the community and the larger society.	8. Meets collective needs when the concerns/threats are shared beyond a local community.
	9. Make information accessible to the public. Provide channels for dissemination of information to the community as a whole (e.g., print media, radio/television reports and community bulletin boards; Internet sites; speaker's bureau; reports to committees, councils, advisory boards).	9. Readily available accurate information can help citizens deal with the situation.

Table 13–2 | CARE PLAN FOR THE CLIENT WHO HAS EXPERIENCED A TRAUMATIC EVENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	10. Make information available in different modalities and geared to differing educational levels and cultures of the community.	10. Using languages other than English and making written materials accessible to all members of the community promotes understanding.
	11. Seek out and evaluate needs of underserved populations.	11. Homeless and those residing in lower income areas may have special requirements that need to be addressed with additional resources.

SOURCE: Doenges, M.E., Moorhouse, M.F., & Murr, A.C. (2016). *Nurse's pocket guide: Diagnoses, prioritized interventions, and rationales* (14th ed.). Philadelphia: F.A. Davis. With permission.

■ Is the client able to discuss his or her beliefs about spiritual issues?

■ Does the client demonstrate the ability to deal with emotional reactions in an individually appropriate manner?

■ Does he or she verbalize a subsiding of the physical manifestations (e.g., pain, nightmares, flashbacks, fatigue) associated with the traumatic event?

■ Has there been recognition of factors affecting the community's ability to meet its own demands or needs?

■ Has there been a demonstration of increased activities to improve community functioning?

■ Has a plan been established and put in place to deal with future contingencies?

When acute crises are not resolved, an individual may be vulnerable to acute stress disorders and trauma-related disorders. See Chapter 28 for more information on these topics.

Summary and Key Points

■ A *crisis* is defined as "a sudden event in one's life that disturbs homeostasis, during which usual coping mechanisms cannot resolve the problem" (Lagerquist, 2012, p. 795).

■ All individuals experience crises at one time or another. This does not necessarily indicate psychopathology. However, individuals with psychopathology are also vulnerable to crisis and may experience an exacerbation of psychiatric symptoms when in crisis.

■ Crises are precipitated by specific identifiable events and are determined by an individual's personal perception of the situation.

■ Crises are acute rather than chronic and generally last no more than a few weeks to a few months.

■ Crises occur when an individual is exposed to a stressor and previous problem-solving techniques are ineffective. This causes the level of anxiety to rise. Panic may ensue when new techniques are tried and resolution fails to occur.

■ Six types of crises have been identified: dispositional crises, crises of anticipated life transitions, crises resulting from traumatic stress, maturation/developmental crises, crises reflecting psychopathology, and psychiatric emergencies. The type of crisis determines the method of intervention selected.

■ Crisis intervention is designed to provide rapid assistance for individuals who have an urgent need.

■ The minimum therapeutic goal of crisis intervention is psychological resolution of the individual's immediate crisis and restoration to at least the level of functioning that existed before the crisis period. A maximum goal is improvement in functioning above the precrisis level.

■ Nurses regularly respond to individuals in crisis in all types of settings. Nursing process is the vehicle by which nurses assist individuals in crisis with a short-term problem-solving approach to change.

■ A four-phase technique of crisis intervention includes assessment/analysis, planning of therapeutic intervention, intervention, and evaluation of crisis resolution and anticipatory planning.

■ Through this structured method of assistance, nurses help individuals in crisis to develop more adaptive coping strategies for dealing with stressful situations in the future.

■ Nurses have many important skills that can assist individuals and communities in the wake of traumatic events. Nursing interventions presented in this chapter were developed for the nursing diagnoses of panic anxiety/fear, spiritual distress, risk for posttrauma syndrome, and ineffective community coping.

Review Questions
Self-Examination/Learning Exercise

Select the best response to each of the following questions.

1. Which of the following is a correct assumption regarding the concept of crisis?
    a. Crises occur only in individuals with psychopathology.
    b. The stressful event that precipitates crisis is seldom identifiable.
    c. A crisis situation contains the potential for psychological growth or deterioration.
    d. Crises are chronic situations that recur many times during an individual's life.

2. Crises occur when an individual:
    a. Is exposed to a precipitating stressor.
    b. Perceives a stressor to be threatening.
    c. Has no support systems.
    d. Experiences a stressor and perceives coping strategies to be ineffective.

3. Amanda's mobile home was destroyed by a tornado. Amanda received only minor injuries but is experiencing disabling anxiety in the aftermath of the event. What is this type of crisis called?
    a. Crisis resulting from traumatic stress
    b. Maturational/developmental crisis
    c. Dispositional crisis
    d. Crisis of anticipated life transitions

4. The most appropriate crisis intervention with Amanda (from question 3) would be to:
    a. Encourage her to recognize how lucky she is to be alive.
    b. Discuss stages of grief and feelings associated with each.
    c. Identify community resources that can help Amanda.
    d. Suggest that she find a place to live that provides a storm shelter.

5. Jenny reported to the high school nurse that her mother drinks too much. She is drunk every afternoon when Jenny gets home from school. Jenny is afraid to invite friends over because of her mother's behavior. What is this type of crisis called?
    a. Crisis resulting from traumatic stress
    b. Maturational/developmental crisis
    c. Dispositional crisis
    d. Crisis reflecting psychopathology

6. The most appropriate nursing intervention with Jenny (from question 5) would be to:
    a. Facilitate arrangements for her to start attending Alateen meetings.
    b. Help her identify the positive things in her life and recognize that her situation could be a lot worse than it is.
    c. Teach her about the effects of alcohol on the body and that it can be hereditary.
    d. Refer her to a psychiatrist for private therapy to learn to deal with her home situation.

7. Ginger, age 19 and an only child, left 3 months ago to attend a college of her choice 500 miles away from her parents. It is Ginger's first time away from home. She has difficulty making decisions and will not undertake anything new without first consulting her mother. They talk on the phone almost every day. Ginger has recently started having anxiety attacks. She consults the nurse practitioner in the student health center. What is this type of crisis called?
    a. Crisis resulting from traumatic stress
    b. Dispositional crisis
    c. Psychiatric emergency
    d. Maturational/developmental crisis

Review Questions—cont'd
Self-Examination/Learning Exercise

8. The most appropriate nursing intervention with Ginger (from question 7) would be to:
   a. Suggest she move to a college closer to home.
   b. Work with Ginger on unresolved dependency issues.
   c. Help her find someone in the college town from whom she could seek assistance rather than calling her mother regularly.
   d. Recommend that the college physician prescribe an antianxiety medication for Ginger.

9. Marie, age 56, is the mother of five children. Her youngest child, who had been living at home and attending the local college, recently graduated and accepted a job in another state. Marie has never worked outside the home and has devoted her life to satisfying the needs of her husband and children. Since the departure of her last child from home, Marie has become increasingly despondent. Her husband has become very concerned and takes her to the local mental health center. What is this type of crisis called?
   a. Dispositional crisis
   b. Crisis of anticipated life transitions
   c. Psychiatric emergency
   d. Crisis resulting from traumatic stress

10. The most appropriate nursing intervention with Marie (from question 9) would be to:
    a. Refer her to her family physician for a complete physical examination.
    b. Suggest she seek outside employment now that her children have left home.
    c. Identify convenient support systems for times when she is feeling particularly despondent.
    d. Begin grief work and assist her to recognize areas of self-worth separate and apart from her children.

11. Which of the following is a desired outcome of working with an individual who has witnessed a traumatic event and is now experiencing panic anxiety?
    a. The individual will experience no anxiety.
    b. The individual will demonstrate hope for the future.
    c. The individual will identify that anxiety is at a manageable level.
    d. The individual will verbalize acceptance of self as worthy.

12. Andrew, a New York City firefighter, and his entire unit responded to the terrorist attacks at the World Trade Center. Working as a team, he and his best friend, Carlo, entered the area together. Carlo was killed when the building collapsed. Andrew was injured but survived. Since that time, Andrew has had frequent nightmares and anxiety attacks. He says to the mental health worker, "I don't know why Carlo had to die and I didn't!" This statement by Andrew suggests that he is experiencing:
    a. Spiritual distress.
    b. Night terrors.
    c. Survivor's guilt.
    d. Suicidal ideation.

13. Intervention with Andrew (from question 15) would include:
    a. Encouraging expression of feelings.
    b. Antianxiety medications.
    c. Participation in a support group.
    d. a and c.
    e. All of the above.

Communication Exercises

1. A client you have been working with for several days approaches you with apparent signs of agitation and yells in a loud voice, "I want out of this hospital right now! You don't listen to a thing I say, and my doctor just wants my money." How will you respond?

2. Shelley enters the emergency room accompanied by a friend who reports that Shelley was raped after leaving a college campus party the night before. Shelley is staring off into space, exhibits a closed posture, and is mumbling inaudibly. How will you introduce yourself and begin to intervene in this crisis situation?

3. Thomas was secluded and restrained after punching another patient on the inpatient psychiatric unit. The next day he asks you what happened last night, stating he does not remember, and says he wants to know why he was arrested and tied up like an animal. What will you communicate to Thomas about the prior events and the crisis intervention process?

OBJECTIVES

After reading this chapter, the student will be able to:

1. Define *assertive behavior.*
2. Discuss basic human rights.
3. Differentiate among nonassertive, assertive, aggressive, and passive-aggressive behaviors.
4. Describe techniques that promote assertive behavior.
5. Demonstrate thought-stopping techniques.
6. Discuss the role of the nurse in assertiveness training.

HOMEWORK ASSIGNMENT

Please read the chapter and answer the following quetions

1. What is the goal of assertive behavior?
2. Assertive individuals accept negative aspects about themselves and admit when they have made a mistake. What is this technique called?
3. What technique may be used to rid the mind of negative thoughts with which an individual may be obsessed? Give an example.
4. Why are "I" statements an effective communication technique?

Alberti and Emmons (2008) have proposed the following questions:

Are you able to express warm, positive feelings to another person? Are you comfortable starting a conversation with strangers at a party? Do you sometimes feel ineffective in making your desires clear to others? Do you have difficulty saying no to persuasive people?

Are you often at the bottom of the "pecking order," pushed around by others? Or maybe you're the one who pushes others around to get your way? (p. 5)

Assertive behavior promotes a feeling of personal power and self-confidence. These two components are commonly lacking in clients with emotional disorders. Becoming more assertive empowers individuals

by promoting self-esteem without diminishing the esteem of others.

This chapter describes a number of rights that are considered basic to human beings. Various kinds of behaviors are explored, including assertive, non-assertive, aggressive, and passive-aggressive. Techniques that promote assertive behavior and the nurse's role in assertiveness training are presented.

CORE CONCEPT

Assertive Behavior

Assertive behavior promotes equality in human relation-ships, enabling us to act in our own best interests, to stand up for ourselves without undue anxiety, to express honest feelings comfortably, to exercise personal rights without denying the rights of others (Alberti & Emmons, 2008, p. 8).

Assertive Communication

Assertive behavior helps us feel good about ourselves and increases our self-esteem. It helps us feel good about other people and increases our ability to develop satisfying relationships. Assertive communication is characterized by honesty, directness, appropriateness, and respect for one's own basic rights as well as the rights of others.

Honesty is basic to assertive behavior. Assertive honesty is not an outspoken declaration of everything that is on one's mind. It is instead an accurate representation of feelings, opinions, or preferences expressed in a manner that promotes self-respect and respect for others.

Direct communication is stating what one wants to convey with clarity and candor. Hinting and "beating around the bush" are indirect forms of communication.

Communication must occur in an appropriate context to be considered assertive. The location and timing, as well as the manner (tone of voice, nonverbal gestures) in which the communication is presented, must be correct for the situation.

Basic Human Rights

A number of authors have identified "assertive rights" (Bishop, 2013; Davis, Eshelman, & McKay, 2008; Lloyd, 2002; Schuster, 2000; Sobel & Ornstein, 1996). Following is a composite of 10 basic assertive human rights adapted from an aggregation of sources:

1. The right to be treated with respect
2. The right to express feelings, opinions, and beliefs
3. The right to say "no" without feeling guilty
4. The right to make and accept responsibility for mistakes
5. The right to be listened to and taken seriously
6. The right to change your mind
7. The right to ask for what you want
8. The right to put yourself first, sometimes
9. The right to set your own priorities
10. The right to refuse justification for your feelings or behavior

In accepting these rights, an individual also accepts the responsibilities that accompany them. Rights and responsibilities are reciprocal entities. To experience one without the other is inherently destructive to an individual. Some responsibilities associated with basic assertive human rights are presented in Table 14–1.

Response Patterns

Individuals develop patterns of responding to others. Some of these patterns have developed through

- Watching other people (role modeling).
- Being positively reinforced or punished for a certain response.
- Inventing an individual response style.
- Not being able to think of different or better ways to respond.
- Not developing the proper skills for a better response.
- Consciously and intentionally choosing a response style.

The nurse should be able to recognize his or her own pattern of responding as well as that of others. Four common response patterns are discussed here: nonassertive, assertive, aggressive, and passive-aggressive.

Nonassertive Behavior

Individuals who behave in a **nonassertive** (sometimes called *passive*) manner seek to please others at the expense of their own basic human rights. They seldom let their true feelings show and often feel hurt and anxious because they allow others to choose for them. They seldom achieve their own desired goals. They come across as very apologetic and tend to be self-deprecating. They use actions instead of words and hope someone will "guess" what they want. Their voices are hesitant, weak, and expressed in a monotone. Their eyes are usually downcast. They feel uncomfortable in interpersonal interactions. All they want is to please and to be liked by others. Their behavior helps them avoid unpleasant situations and confrontations with others; however, they often harbor anger and resentment.

TABLE 14–1 **Assertive Rights and Responsibilities**

RIGHTS	RESPONSIBILITIES
1. To be treated with respect	To treat others in a way that recognizes their human dignity
2. To express feelings, opinions, and beliefs	To accept ownership of our feelings and show respect for those that differ from our own
3. To say "no"	To analyze each situation individually, recognizing all human rights as equal (others have the right to say "no," too)
4. To make mistakes	To accept responsibility for own mistakes and try to correct them
5. To be listened to	To listen to others
6. To change your mind	To accept the possible consequences that the change may incur; to accept the same flexibility in others
7. To ask for what you want	To accept others' right to refuse your request
8. To put yourself first, sometimes	To put others first, sometimes
9. To set your own priorities	To consider one's limitations as well as strengths in directing independent activities, to be a dependable person
10. To refuse to justify feelings or behavior	To accept ownership of own feelings and behavior, to accept others without requiring justification for their feelings and behavior

Assertive Behavior

Individuals who demonstrate **assertive** behavior stand up for their own rights while protecting the rights of others. Feelings are expressed openly and honestly. They assume responsibility for their own choices and allow others to choose for themselves. They maintain self-respect and respect for others by treating everyone equally and with human dignity. They communicate tactfully, using lots of "I" statements. Their voices are warm and expressive, and eye contact is intermittent but direct. These individuals desire to communicate effectively with and be respected by others. They are self-confident and experience satisfactory and pleasurable relationships with others.

Aggressive Behavior

Individuals who use **aggressive** response patterns defend their own basic rights by violating the basic rights of others. Feelings are often expressed dishonestly and inappropriately. They say what is on their mind, often at the expense of others. Aggressive behavior commonly results in *put-downs,* leaving the receiver feeling hurt, defensive, and humiliated. Individuals responding aggressively devalue the self-worth of those on whom they impose their choices. They typically express an air of superiority, and their voices are often loud, demanding, angry, or cold and emotionless. Eye contact may be an attempt to intimidate others by "staring them down." They want to increase their feelings of power by dominating or humiliating others. Aggressive behavior hinders interpersonal relationships.

Passive-Aggressive Behavior

Individuals using **passive-aggressive** behavior *respond* to others by appearing passive and accepting of other's demands while *behaving* in ways that suggest anger and resentment are their true feelings. This kind of behavior is sometimes referred to as *indirect,* or *covert, aggression* and takes the form of passive, nonconfrontational action. This pattern of communication is dishonest, manipulative, and sly, and it undermines others with behavior that expresses the opposite of what they are feeling. It is critical and sometimes sarcastic. Individuals employing passive-aggressive behavior allow others to make choices for them, then resist by using passive behaviors such as procrastination, dawdling, stubbornness, and "forgetfulness." They use actions instead of words to convey their messages, and the actions express covert aggression. They become sulky, irritable, or argumentative when asked to do something they do not want to do. They may protest to others about the demand but will not confront the person who has made the demand. The goal is domination through retaliation. This behavior offers a feeling of control and power, although the individual actually feels resentment. This style of communication is associated with extremely low self-confidence.

A comparison of these four behavior patterns is presented in Table 14–2.

TABLE 14–2 **Comparison of Behavioral Response Patterns**			
	NONASSERTIVE	ASSERTIVE	AGGRESSIVE	PASSIVE-AGGRESSIVE
BEHAVIORAL CHARACTERISTICS	Passive, does not express true feelings, self-deprecating, denies own rights	Stands up for own rights, protects rights of others, honest, direct, appropriate	Violates rights of others, expresses feelings dishonestly and inappropriately	Defends own rights with passive resistance, is critical and sarcastic; often expresses opposite of true feelings
EXAMPLES	"Uh, well, uh, sure, I'll be glad to stay and work an extra shift."	"I don't want to stay and work an extra shift today. I stayed over yesterday. It's someone else's turn today."	"You've got to be kidding!"	"Okay, I'll stay and work an extra shift." (Then to peer: "How dare she ask me to work over again! Well, we'll just see how much work she gets out of me!")
GOALS	To please others; to be liked by others	To communicate effectively; to be respected by others	To dominate or humiliate others	To dominate through retaliation
FEELINGS	Anxious, hurt, disappointed with self, angry, resentful	Confident, successful, proud, self-respecting	Self-righteous, controlling, superior	Anger, resentment, manipulated, controlled
COMPENSATION	Is able to avoid unpleasant situations and confrontations with others	Increased self-confidence, self-respect, respect for others, satisfying interpersonal relationships	Anger is released, increasing feeling of power and superiority	Feels self-righteous and in control
OUTCOMES	Goals not met; others meet *their* goals at nonassertive person's expense; anger and resentment grow; feels violated and manipulated	Goals met; desires most often fulfilled while defending own rights as well as rights of others	Goals may be met but at the expense of others; they feel hurt and vengeful	Goals not met, nor are the goals of others met due to retaliatory nature of the interaction

(2002). *Developing positive assertiveness* (3rd ed.). Menlo Park, CA: Crisp Publications; and Powell, T.J., & Enright, S.J. (1990). *Anxiety and stress management.* London: Routledge.

Behavioral Components of Assertive Behavior

Alberti and Emmons (2008) have identified several defining characteristics of assertive behavior:

■ **Eye contact:** Eye contact is considered appropriate when intermittent (i.e., looking directly at the person to whom one is speaking but looking away now and then). Individuals feel uncomfortable when someone stares at them continuously and intently. Intermittent eye contact conveys the message that one is interested in what is being said.

■ **Body posture:** Sitting and leaning slightly toward the other person in a conversation suggests an active interest in what is being said. Emphasis on an assertive stance can be achieved by standing with an erect posture squarely facing the other person. A slumped posture conveys passivity or nonassertiveness.

■ **Distance/physical contact:** The distance between two individuals in an interaction or the physical contact between them has a strong cultural influence. For example, mainstream culture of the United States considers intimate distance as approximately 18 inches from the body. Invasion of this space may be interpreted by some individuals as very aggressive.

■ **Gestures:** Nonverbal gestures also are variable among different cultures. In assertive communication,

gestures add emphasis, warmth, depth, or power to the spoken word with awareness of and sensitivity to the impact on the receiver .

■ **Facial expression:** Various facial expressions convey different messages (e.g., surprise, anger, fear). It is difficult to "fake" these messages. In assertive communication, the facial expression is congruent with the verbal message.

■ **Voice:** The voice conveys a message by its loudness, softness, degree and placement of emphasis, and evidence of emotional tone. In assertive communication, the voice conveys an acceptable volume to communicate confidence without being too loud or forceful.

■ **Fluency:** The ability to discuss a subject with ease and obvious knowledge conveys assertiveness and self-confidence. This message is impeded by numerous pauses or filler words such as "and, uh . . ." or "you know. . . ."

■ **Timing:** Assertive responses are most effective when they are spontaneous and immediate. However, most people have experienced times when it was inappropriate to respond (e.g., in front of a group of people) or times when an appropriate response is generated only after the fact ("If only I had said . . ."). Alberti and Emmons (2008, p. 77) stated that "it is never too late to be assertive!" It is correct and worthwhile to seek out the individual at a later time and express the assertive response.

■ **Listening:** Assertive listening means giving the other individual full attention by making eye contact, nodding to indicate acceptance of what is said, and taking time to understand the message before responding.

■ **Thoughts:** Cognitive processes affect one's assertive behavior. Two such processes are an individual's attitudes about the appropriateness of assertive behavior in general and the appropriateness of assertive behavior for oneself specifically. Assertive communication is supported by a belief that being assertive is a reasonable, appropriate, and healthy way to communicate.

■ **Content:** The content of assertive communication includes "I" statements to describe one's feelings and needs. "You" statements, such as "You never listen to me" or "You don't respect my parenting decisions," tend to put others on the defensive. Instead, "I" statements such as "I'm upset because I don't feel like you're hearing me" or "I need you to respect my decision on this parenting issue," tend to lessen defensiveness and increase the likelihood that the message will be received and heard.

■ **Persistence:** This element of assertive behavior involves maintaining confidence in and commitment to one's needs and feelings even when someone is pressuring the individual to cave in to demands. It often means repeating a stated feeling or need in an effort to be heard and respected. Persistence, as with other aspects of assertive behavior, employs "I" communication statements. For example, when someone is trying to pressure another person to drink alcohol, a persistent response might be "As I already told you, I am not interested in drinking alcohol, and I need for you to stop pressuring me."

Techniques That Promote Assertive Behavior

The following techniques have been shown to be effective in responding to criticism and avoiding manipulation by others:

1. **Standing up for one's basic human rights**

EXAMPLE

"I have the right to express my opinion."

2. **Assuming responsibility for one's own statements**

EXAMPLE

"I *don't want* to go out with you tonight," instead of "I *can't* go out with you tonight." The latter implies a lack of power or ability.

3. **Responding as a broken record;** that is, persistently repeating in a calm voice what is wanted

EXAMPLE

Telephone salesperson: I want to help you save money by changing long-distance services.

Assertive response: I don't want to change my long-distance service.

Telephone salesperson: I can't believe you don't want to save money!

Assertive response: I don't want to change my long-distance service.

4. **Agreeing assertively;** that is, assertively accepting negative aspects about oneself and admitting when an error has been made

EXAMPLE

Ms. Jones: You sure let that meeting get out of hand. What a waste of time.

Ms. Smith: Yes, I didn't do a very good job of conducting the meeting today.

5. **Inquiring assertively;** that is, seeking additional information about critical statements

EXAMPLE

Male board member: You made a real fool of yourself at the board meeting last night.

Female board member: Oh, really? Just what about my behavior offended you?

Male board member: You were so damned pushy!

Female board member: Were you offended that I spoke up for my beliefs, or was it because my beliefs are in direct opposition to yours?

6. **Shifting from content to process;** that is, changing the focus of the communication from discussing the topic at hand to analyzing what is actually going on in the interaction

EXAMPLE

Wife: Would you please call me if you will be late for dinner?

Husband: Why don't you just get off my back! I always have to account for every minute of my time with you!

Wife: Sounds to me like we need to discuss some other things here. What are you *really* angry about?

7. **Clouding or fogging;** that is, concurring with the critic's argument without becoming defensive and without agreeing to change

EXAMPLE

Nurse 1: You never come to the Nurses Association meetings. I don't know why you even belong!

Nurse 2: You're right. I haven't attended very many of the meetings.

8. **Defusing;** that is, putting off further discussion with an angry individual until he or she is calmer

EXAMPLE

"You are very angry right now. I don't want to discuss this matter with you while you are so upset. I will discuss it with you in my office at 3 o'clock this afternoon."

9. **Delaying assertively;** that is, putting off further discussion with another individual until one is calmer

EXAMPLE

"That's a very challenging position you have taken, Mr. Brown. I'll need time to give it some thought. I'll call you later this afternoon."

10. **Responding assertively with irony**

EXAMPLE

Man: I bet you're one of them so-called women's libbers, aren't you?

Woman: Why, yes. Thank you for noticing.

11. **Using "I" statements,** which allow an individual to take ownership for his or her feelings rather than saying they are caused by another person

"I" statements are sometimes called "feeling" statements. They express directly what an individual is feeling. "You" statements are accusatory and put the receiver on the defensive. "I" statements have four parts:

1. How I feel: *These are my feelings and I accept ownership of them.*
2. When: *Describe in a neutral manner the behavior that is the problem.*
3. Why: *Describe what it is about the behavior that is objectionable.*
4. What I need (suggesting change): *Offer a preferred alternative to the behavior using "I" statements.*

EXAMPLE

John has just returned from a hunting trip and walked into the living room in his muddy boots, leaving a trail of mud on the carpet. His wife, Mary, may respond as follows:

With a "you" statement: "You are such a jerk! Can't you see the trail of mud you are leaving on the carpet? I just cleaned this carpet. You make me so angry!"

With an "I" statement: "I feel so angry when you walk on the carpet in your muddy boots. I just cleaned it, and now I will have to clean it again. I would appreciate it if you would remove your boots on the porch before you come in the house."

"You" statements are negative and focus on what the person has done wrong. They do not explain what is being requested of the person. "I" statements are more positive. They explain *how* one is feeling, *why* he or she is feeling that way, and *what* the individual wants instead. Hopkins (2013) stated the following about the importance of "I" statements:

> Part of being assertive involves the ability to appropriately express your needs and feelings. You can accomplish this by using "I" statements. These [statements] indicate ownership, do not attribute blame, focus on behavior, identify the effect of the behavior, are direct and honest, and contribute to the growth of your relationship with each other. (p. 2)

Thought-Stopping Techniques

Assertive thinking is sometimes inhibited by repetitive, negative thoughts of which the mind refuses to let go. Individuals with low self-worth may be obsessed with thoughts such as, "I know he'd never want to go out with me. I'm too ugly (or plain, or fat, or dumb)" or "I just know I'll never be able to do this job well" or "I just can't seem to do anything right." This type of thinking fosters the belief that one's individual rights do not deserve the same consideration as those of others and reflects nonassertive communication and behavioral response patterns.

Thought-stopping techniques, as described here, were developed by psychiatrist Joseph Wolpe (1990) and are intended to eliminate intrusive, unwanted thoughts.

Method

In a practice setting, with eyes closed, the individual concentrates on an unwanted recurring thought. Once the thought is clearly established in the mind, he or she shouts aloud: "STOP!" This action interrupts the thought, and it is actually removed from one's awareness. The individual then immediately shifts his or her thoughts to one that is considered pleasant and desirable.

It is possible that the unwanted thought may soon recur, but with practice, the length of time between recurrences will increase until the unwanted thought is no longer intrusive.

Obviously, one cannot go about his or her daily life shouting, "STOP!" in public places. After a number of practice sessions, the technique is equally effective if "stop!" is used silently in the mind.

Role of the Nurse in Assertiveness Training

It is important for nurses to become aware of and recognize their own behavioral responses. Common questions used to assess and develop self-awareness include: Are my behaviors mostly nonassertive? Assertive? Aggressive? Passive-aggressive? Do I consider my behavioral responses effective? Do I wish to change? Remember, all individuals have the right to choose whether or not they want to be assertive. A self-assessment of assertiveness is found in Box 14–1.

Assertive communication is part of a larger set of competencies referred to as **emotional intelligence (EI).** This concept, first developed by Salovey and Mayer (1990) and elaborated by Goleman (2006), includes four sets of competencies: self-awareness (of emotions and behavior), social awareness (awareness of other's feelings, or empathy), self-management (which includes self-control), and relationship management (which includes skills in teamwork and collaboration). Each of these competencies is relevant to developing skill in assertive communication. To communicate assertively, individuals must be aware of their own feelings and the feelings of others; they must be aware of and develop skill in their ability to control their emotions and behavior; and they must respond in ways

---

BOX 14–1 An Assertiveness Quiz

Assign a number to each item using the following scale: 1 = Never; 3 = Sometimes; 5 = Always

_____ 1. I ask others to do things without feeling guilty or anxious.
_____ 2. When someone asks me to do something I don't want to do, I say no without feeling guilty or anxious.
_____ 3. I am comfortable when speaking to a large group of people.
_____ 4. I confidently express my honest opinions to authority figures (such as my boss).
_____ 5. When I experience powerful feelings (anger, frustration, disappointment, and so on), I verbalize them easily.
_____ 6. When I express anger, I do so without blaming others for "making me mad."
_____ 7. I am comfortable speaking up in a group situation.
_____ 8. If I disagree with the majority opinion in a meeting, I can "stick to my guns" without feeling uncomfortable or being abrasive.
_____ 9. When I make a mistake, I acknowledge it.
_____ 10. I tell others when their behavior creates a problem for me.
_____ 11. Meeting new people in social situations is something I do with ease and comfort.
_____ 12. When discussing my beliefs, I do so without labeling the opinions of others as "crazy," "stupid," "ridiculous," or "irrational."
_____ 13. I assume that most people are competent and trustworthy, and I do not have difficulty delegating tasks to others.
_____ 14. When considering doing something I have never done, I feel confident I can learn to do it.
_____ 15. I believe that my needs are as important as those of others, and I am entitled to have my needs satisfied.
_____ TOTAL SCORE

SCORING:

1. If your total score is 60 or higher, you have a consistently assertive philosophy and probably handle most situations well.
2. If your total score is 45 to 59, you have a fairly assertive outlook but may benefit from some assertiveness training.
3. If your total score is 30 to 44, you may be assertive in some situations, but your natural response is either nonassertive or aggressive. Assertiveness training is suggested.
4. If your total score is 15 to 29, you have considerable difficulty being assertive. Assertiveness training is recommended.

SOURCE: Lloyd, S.R. (2002). Developing positive assertiveness (3rd ed.). Menlo Park, CA: Crisp Publications. With permission.

that effectively manage relationships, including skills that resolve conflicts rather than escalate them.

> In professional roles, assertive communication and EI are important competencies for effective teamwork and collaboration.

The ability to respond assertively is especially important to nurses who are committed to further development of the profession. Assertiveness skills facilitate the implementation of change—change that is required if the image of nursing is to be upheld to the level of professionalism that most nurses desire. Assertive communication is useful in the political arena for nurses who choose to become involved at state and national levels in striving to influence legislation and ultimately improve our country's system of health-care provision.

Nurses who understand and use assertiveness skills themselves can in turn assist clients who wish to effect behavioral change in an effort to increase self-esteem and improve interpersonal relationships. When using assertive communication and teaching clients about assertiveness, it is important to be clear that assertive communication does not necessarily assure a particular response. For example, a spouse may assertively communicate that she or he feels overwhelmed and needs more help with the housework, but the other spouse still has control over whether or not to respect those wishes. Instead, assertive communication is a way to communicate one's feelings and needs in a manner that is less likely to generate defensiveness from the receiver and more likely to allow the message to be heard. Evidence supports that assertiveness skills training is beneficial in reducing symptoms of depression and interpersonal difficulties and for improving one's self-esteem, even among individuals with severe mental illness such as schizophrenia (Maaly, Merfat, & Faten, 2016; Shean, 2013; Tavakoli et al., 2014).

The nursing process is a useful tool for nurses who are involved in helping clients increase their assertiveness.

Assessment

Nurses can help clients become more aware of their behavioral responses. Many tools exist for assessing the level of assertiveness, but it is difficult to *generalize* when attempting to measure assertive behaviors. Box 14–2 and Figure 14–1 represent examples of assertiveness inventories that could be personalized to explore life situations of individual clients more specifically. Obviously, the everyday situations that require assertiveness are not the same for all individuals.

Diagnosis

Possible nursing diagnoses for individuals needing assistance with assertiveness include the following:

- Coping, defensive
- Coping, ineffective
- Decisional conflict
- Denial
- Personal identity, disturbed
- Powerlessness
- Rape-trauma syndrome
- Self-esteem, low
- Social interaction, impaired
- Social isolation

BOX 14–2 Everyday Situations That May Require Assertiveness

AT WORK
How do you respond when:

1. You receive a compliment on your appearance or someone praises your work?
2. You are criticized unfairly?
3. You are criticized legitimately by a superior?
4. You have to confront a subordinate for continual lateness or sloppy work?
5. Your boss makes a sexual innuendo or makes a pass at you?

IN PUBLIC
How do you respond when:

1. In a restaurant, the food you ordered arrives cold or overcooked?
2. A fellow passenger in a no-smoking compartment lights a cigarette?
3. You are faced with an unhelpful shop assistant?
4. Somebody barges in front of you in a waiting line?
5. You take an inferior article back to a shop?

AMONG FRIENDS
How do you respond when:

1. You feel angry with the way a friend has treated you?
2. A friend makes what you consider to be an unreasonable request?
3. You want to ask a friend for a favor?
4. You ask a friend for repayment of a loan of money?
5. You have to negotiate with a friend on which film to see or where to meet?

AT HOME
How do you respond when:

1. One of your parents criticizes you?
2. You are irritated by a persistent habit in someone you love?
3. Everybody leaves the cleaning-up chores to you?
4. You want to say "no" to a proposed visit to a relative?
5. Your partner feels amorous but you are not in the mood?

SOURCE: From Powell, T.J., & Enright, S.J. (1990). Anxiety and stress management. *London: Routledge. With permission.*

DIRECTIONS: Fill in each block with a rating of your assertiveness on a 5-point scale. A rating of 0 means you have no difficulty asserting yourself. A rating of 5 means that you are completely unable to assert yourself. Evaluation can be made by analyzing the scores:

1. Totally by activity, including all of the different people categories
2. Totally by people, including all of the different activity categories
3. On an individual basis, considering specific people and specific activities

PEOPLE / ACTIVITY	Friends of the same sex	Friends of the opposite sex	Intimate relations or spouse	Authority figures	Relatives/ family members	Colleagues and sub-ordinates	Strangers	Service workers: waiters, shop assistants, etc.
Giving and receiving compliments								
Asking for favors/help								
Initiating and maintaining conversation								
Refusing requests								
Expressing personal opinions								
Expressing anger/dis-pleasure								
Expressing liking, love, affection								
Stating your rights and needs								

FIGURE 14–1 Rating your assertiveness. (From Powell, T.J., & Enright, S.J. [1990]. *Anxiety and stress management*. London: Routledge, with permission.)

Outcome Identification and Implementation

The goal for nurses working with individuals needing assistance with assertiveness is to help them develop more satisfying interpersonal relationships. Individuals who do not feel good about themselves either allow others to violate their rights or cover up their low self-esteem by being overtly or covertly aggressive. Individuals should be given information regarding their individual human rights. They must know these rights before they can assert them.

Outcome criteria are derived from specific nursing diagnoses. Time lines are individually determined. Examples include the following:

- The client verbalizes and accepts responsibility for his or her own behavior.
- The client is able to express opinions and disagree with the opinions of others in a socially acceptable manner without feeling guilty.
- The client is able to verbalize positive aspects about self.
- The client verbalizes choices made in a plan to maintain control over his or her life situation.
- The client approaches others in an appropriate manner for one-to-one interaction.

In a clinical setting, nurses can teach clients techniques to increase their assertive responses. This can be done on a one-to-one basis or in group situations. Once these techniques have been discussed, nurses can assist clients to practice them through role-playing. Each client should compose a list of specific personal examples of situations that create difficulties for him or her. These situations will then be simulated in the therapy setting so that the client may practice assertive responses in a nonthreatening environment. In a group situation, feedback from peers can provide valuable insight about the effectiveness of the response.

CLINICAL PEARL An important part of this type of intervention is to ensure that clients are aware of the differences among assertive, nonassertive, aggressive, and passive-aggressive

behaviors in the same situation. When discussion is held about what the best (assertive) response would be, it is also important to discuss the other types of responses as well so that clients can begin to recognize their pattern of response and make changes accordingly.

CLINICAL EXAMPLE

Linda comes to day hospital once a week to attend group therapy and assertiveness training. She has had problems with depression and low self-esteem and is married to a man who is verbally abusive. He is highly critical, is seldom satisfied with anything Linda does, and blames her for negative consequences that occur in their lives whether or not she is involved.

Since the beginning of the assertiveness training group, the nurse who leads the group has taught the participants about basic human rights and the various types of response patterns. When the nurse asks for client situations to be presented in group, Linda volunteers to discuss an incident that occurred in her home this week. She related that she had just put some chicken on the stove to cook for supper when her 7-year-old son came running in the house yelling that he had been hurt. Linda went to him and observed that he had blood dripping down the side of his head from his forehead. He said he and some friends had been playing on the jungle gym in the schoolyard down the street and he had fallen and hit his head. Linda went with him to the bathroom to clean the wound and apply some medication. Her husband, Joe, was reading the newspaper in the living room. By the time she got back to the chicken on the stove, it was burned and inedible. Her husband shouted, "You stupid woman! You can't do anything right!" Linda did not respond but burst into tears.

The nurse asked the other members in the group to present some ideas about how Linda could have responded to Joe's criticism. After some discussion, they agreed that Linda might have stated, "I made a mistake. I am not stupid and I do lots of things right." They also discussed other types of responses and why they were less acceptable. They recognized that Linda's lack of verbal response and bursting into tears was a nonassertive response. They also agreed on other examples, such as the following:

1. An aggressive response might be, "Cook your own supper!" and toss the skillet out the back door.
2. A passive-aggressive response might be to fix sandwiches for supper and not speak to Joe for 3 days.

Practice on the assertive response began, with the nurse and various members of the group playing the role of Joe so that Linda could practice until she felt comfortable with the response. She participated in the group for 6 months, regularly submitting situations with which she needed help. She also learned from the situations presented by other members of the group. These weekly sessions gave Linda the self-confidence that she needed to stand up to Joe's criticism. She became aware of her basic human rights and, with practice, was able to protect her rights by communicating them assertively. She was happy to report to the group after a few months that Joe seemed to be less critical and that their relationship was improving.

Evaluation

Evaluation requires that the nurse and client assess whether or not these techniques are achieving the desired outcomes. Reassessment might include the following questions:

■ Is the client able to accept criticism without becoming defensive?
■ Can the client express true feelings to (spouse, friend, boss, and others) when his or her basic human rights are violated?
■ Is the client able to decline a request without feeling guilty?
■ Can the client verbalize positive qualities about himself or herself?
■ Does the client verbalize improvement in interpersonal relationships?

Assertiveness training serves to extend and create more flexibility in an individual's communication style so that he or she has a greater choice of responses in various situations. Although change does not come easily, assertiveness training can be an effective way of changing behavior. Nurses can assist individuals to become more assertive, thereby encouraging them to become what they want to be, promoting an improvement in self-esteem, and fostering a respect for their own rights and the rights of others.

Summary and Key Points

■ Assertive behavior helps individuals feel better about themselves by encouraging them to stand up for their own basic human rights.
■ Basic human rights have equal representation for all individuals.
■ Along with rights comes an equal number of responsibilities. Part of being assertive includes living up to these responsibilities.
■ Assertive behavior increases self-esteem and the ability to develop satisfying interpersonal relationships. This is accomplished through honesty, directness, appropriateness, and respecting one's own rights and the rights of others.
■ Individuals develop patterns of responding in various ways, such as role modeling, by receiving positive or negative reinforcement, or by conscious choice.
■ Patterns of responding can take the form of nonassertiveness, assertiveness, aggressiveness, or passive-aggressiveness.

- Individuals who communicate in a *nonassertive* manner seek to please others at the expense of denying their own basic human rights.
- Individuals who communicate in an *assertive* manner stand up for their own rights while protecting the rights of others.
- Those who respond *aggressively* defend their own rights by violating the basic rights of others.
- Individuals who respond in a *passive-aggressive* manner defend their own rights by expressing resistance to social and occupational demands.
- Some important behavioral considerations of assertive behavior include eye contact, body posture, distance/physical contact, gestures, facial expression, voice, fluency, timing, listening, thoughts, content, and persistence.
- Using "I" statements is an important technique of assertive communication.

- Competency in the skills of emotional intelligence is foundational to effective assertive communication and behavior.
- Negative thinking can sometimes interfere with one's ability to respond assertively. Thought-stopping techniques help individuals remove negative, unwanted thoughts from awareness and promote the development of a more assertive attitude.
- Nurses can assist individuals to learn and practice assertiveness techniques.
- The nursing process is an effective vehicle for providing the information and support to clients as they strive to create positive change in their lives.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Your husband says, "You're crazy to think about going to college! You're not smart enough to handle the studies and the housework, too." Which of the following is an example of a nonassertive response?
   a. "I will do what I can and the best that I can."
   b. (Thinking to yourself): "We'll see how *he* likes cooking dinner for a change."
   c. "You're probably right. Maybe I should reconsider."
   d. "I'm going to do what I want to do, when I want to do it, and you can't stop me!"

2. You are having company for dinner, and they are due to arrive in 20 minutes. You are about to finish cooking and still have to shower and dress. The doorbell rings and it is a man selling a new product for cleaning windows. Which of the following is an example of an aggressive response?
   a. "I don't do windows!" and slam the door in his face.
   b. "I'll take a case," and write him a check.
   c. "Sure, I'll take three bottles." Then to yourself you think: "I'm calling this company tomorrow and complaining to the manager about their salespeople coming around at dinnertime!"
   d. "I'm very busy at the moment. I don't wish to purchase any of your product. Thank you."

3. You are in a movie theater that prohibits smoking. The person in the seat next to you just lit a cigarette and the smoke is very irritating. Which of the following is an example of an assertive response?
   a. You say nothing.
   b. "Please put your cigarette out. Smoking is prohibited."
   c. You say nothing but begin to frantically fan the air in front of you and cough loudly and convulsively.
   d. "Put your cigarette out, you slob! Can't you read the 'no smoking' sign?"

Review Questions—cont'd
Self-Examination/Learning Exercise

4. You have been studying for a nursing exam all afternoon and lost track of time. Your husband expects dinner on the table when he gets home from work. You have not started cooking yet when he walks in the door and shouts, "Why the heck isn't dinner ready?" Which of the following is an example of a passive-aggressive response?
   a. "I'm sorry. I'll have it done in no time, honey." But then you move very slowly and take a long time to cook the meal.
   b. "I'm tired from studying all afternoon. Make your own dinner, you bum! I'm tired of being your slave!"
   c. "I haven't started dinner yet. I'd like some help from you."
   d. "I'm so sorry. I know you're tired and hungry. It's all my fault. I'm such a terrible wife!"

5. You and your best friend, Jill, have had plans for 6 months to go on vacation together to Hawaii. You have saved your money and have plane tickets to leave in 3 weeks. She has just called you and reported that she is not going. She has a new boyfriend, they are moving in together, and she does not want to leave him. You are very angry with Jill for changing your plans. Which of the following is an example of an assertive response?
   a. "I'm very disappointed and very angry. I'd like to talk to you about this later. I'll call you."
   b. "I'm very happy for you, Jill. I think it's wonderful that you and Jack are moving in together."
   c. You tell Jill that you are very happy for her, but then say to another friend, "Well, that's the end of my friendship with Jill!"
   d. "What? You can't do that to me! We've had plans! You're acting like a real slut!"

6. A typewritten report for your psychiatric nursing class is due tomorrow at 8 a.m. The assignment was made 4 weeks ago, and yours is ready to turn in. Your roommate says, "I finally finished writing my report, but now I have to go to work, and I don't have time to type it. Please be a dear and type it for me. Otherwise, I'll fail!" You have a date with your boyfriend. Which of the following is an example of an aggressive response?
   a. "Okay, I'll call Ken and cancel our date."
   b. "I don't want to stay here and type your report. I'm going out with Ken."
   c. "You've got to be kidding! What kind of a fool do you take me for, anyway?"
   d. "Okay, I'll do it." However, when your roommate returns from work at midnight, you are asleep and the report has not been typed.

7. You are asked to serve on a committee on which you do not wish to serve. Which of the following is an example of a nonassertive response?
   a. "Thank you, but I don't wish to be a member of that committee."
   b. "I'll be happy to serve." But then you don't show up for any of the meetings.
   c. "I'd rather have my teeth pulled!"
   d. "Okay, if I'm really needed, I'll serve."

8. You're on your way to the laundry room when you encounter a fellow dorm tenant who often asks you to "throw a few of my things in with yours." You view this as an imposition. He asks you where you're going. Which of the following is an example of a passive-aggressive response?
   a. "I'm on my way to the Celtics game. Where do you think I'm going?"
   b. "I'm on my way to do some laundry. Do you have anything you want me to wash with mine?"
   c. "It's none of your damn business!"
   d. "I'm going to the laundry room. Please don't ask me to do some of yours. I resent being taken advantage of in that way."

Review Questions—cont'd
Self-Examination/Learning Exercise

9. At a hospital committee meeting, a fellow nurse who is the chairperson has interrupted you each time you have tried to make a statement. The next time it happens, you intend to respond assertively. Which of the following is an example of an assertive response?
   a. "You make a lousy leader! You won't even let me finish what I'm trying to say!"
   b. You say nothing.
   c. "Excuse me. I would like to finish my statement."
   d. You say nothing, but you fail to complete your assignment and do not show up for the next meeting.

10. A fellow worker often borrows small amounts of money from you with the promise that she will pay you back "tomorrow." She currently owes you $15 and has not yet paid back any that she has borrowed. She asks if she can borrow a couple of dollars for lunch. Which of the following is an example of a nonassertive response?
    a. "I've decided not to loan you any more money until you pay me back what you already borrowed."
    b. "I'm so sorry. I only have enough to pay for my own lunch today."
    c. "Get a life, will you? I'm tired of you sponging off me all the time!"
    d. "Sure, here's two dollars." Then to the other workers in the office: "Be sure you never lend Cindy any money. She never pays her debts. I'd be sure never to go to lunch with her if I were you!"

Promoting Self-Esteem

CHAPTER OUTLINE

KEY TERMS

body image

boundaries

contextual stimuli

enmeshed boundaries

flexible boundaries

focal stimuli

moral-ethical self

residual stimuli

rigid boundaries

self-consistency

self-ideal

OBJECTIVES

After reading this chapter, the student will be able to:

1. Identify and define components of the self-concept.
2. Discuss influencing factors in the development of self-esteem and its progression through the life span.
3. Describe the verbal and nonverbal manifestations of low self-esteem.
4. Discuss the concept of boundaries and its relationship to self-esteem.
5. Apply the nursing process with clients who are experiencing disturbances in self-esteem.

HOMEWORK ASSIGNMENT

Please read the chapter and answer the following questions:

1. Children need unconditional love to promote positive self-esteem. How do parents demonstrate unconditional love?
2. Since her parents' divorce, 10-year-old Juliet and her mother have become inseparable. They spend all their spare time together, and Juliet has become her mother's confidant. This is an example of what type of boundary?
3. How does fulfillment of the developmental tasks described by Erikson promote a healthy self-esteem?
4. Name the three components of self-concept and the meaning that individuals attach to each.

Whereas self-concept describes individuals' *thoughts and beliefs* about themselves, self-esteem describes how individuals *feel* about themselves. Hosogi and associates (2012) describe self-esteem as a feeling of self-appreciation that is indispensable for adaptation in society. The awareness of self (i.e., the ability to form an identity and then attach a value to it) is an important differentiating factor between humans and other animals. This capacity for judgment becomes a contributing factor in disturbances of self-esteem.

The promotion of self-esteem is about stopping irrational self-judgments. It is about helping individuals change how they perceive and feel about themselves. A healthy self-esteem means having a balanced, accurate view of oneself which includes being able to recognize one's flaws while maintaining a good opinion of one's abilities (Mayo Clinic, 2014). This chapter describes the developmental progression and the verbal and behavioral manifestations of self-esteem. The concept of **boundaries** and its relationship to self-esteem is explored. Nursing care of clients with disturbances in self-esteem is described in the context of the nursing process.

CORE CONCEPT
Self-Concept
Self-concept is the cognitive or thinking component of the self that evolves through dynamic interaction in the environment and personal reflection to develop a set of beliefs about oneself (Huitt, 2011).

Components of Self-Concept

Body Image
An individual's **body image** is a subjective perception of one's physical appearance based on self-evaluation and on reactions and feedback from others. Gorman and Sultan (2008) state:

> Body image is the mental picture a person has of his or her own body. It significantly influences the way a person thinks and feels about his or her body as a whole, about its functions, and about the internal and external sensations associated with it. It also includes perceptions of the way others see the person's body and is central to self-concept and self-esteem. (p. 9)

An individual's body image may not necessarily coincide with his or her actual appearance. For example, individuals who have been overweight for many years and then lose weight often have difficulty perceiving of themselves as thin. They may even continue to choose clothing in the size they were before they lost weight.

A disturbance in one's body image may occur with changes in structure or function. Examples of changes in bodily structure include amputations, mastectomy, and facial disfigurements. Functional alterations are conditions such as colostomy, paralysis, and impotence. Alterations in body image are often experienced as losses.

Personal Identity
This component of self-concept is composed of the moral-ethical self, self-consistency, and self-ideal.

The **moral-ethical self** is that aspect of the personal identity that evaluates who the individual says he or she is. This component of the personal self observes, compares, sets standards, and makes judgments that influence an individual's self-evaluation.

Self-consistency is the component of the personal identity that strives to maintain a stable self-image. Even if the self-image is negative, because of this need for stability and self-consistency, the individual resists letting go of the image from which he or she has achieved a measure of constancy.

Self-ideal relates to an individual's perception of what he or she wants to be, to do, or to become. The concept of the ideal self arises out of the perception one has of the expectations of others. Disturbances in self-concept can occur when individuals are unable to achieve their ideals and self-expectations.

CORE CONCEPT
Self-Esteem
Self-esteem is the degree of regard or respect that individuals have for themselves and is a measure of worth that they place on their abilities and judgments.

Self-Esteem
Warren (1991) stated:

> Self-esteem breaks down into two components: (1) the ability to say that "I am important," "I matter," and (2) the ability to say "I am competent," "I have something to offer to others and the world. (p. 1)

Maslow (1970) postulated that individuals must achieve positive self-esteem before they can achieve self-actualization (see Chapter 2, Mental Health and Mental Illness: Historical and Theoretical Concepts). On a day-to-day basis, one's self-value is challenged by changes within the environment. With a positive self-worth, individuals are able to adapt successfully to the demands associated with situational and maturational

stressors that occur. The ability to adapt to these environmental changes is impaired when individuals hold themselves in low esteem.

Self-esteem is very closely related to the other components of the self-concept. Just as with body image and personal identity, the development of self-esteem is largely influenced by perceptions about how one is viewed by significant others. It begins in early childhood and vacillates throughout the life span.

Development of Self-Esteem

How self-esteem is established has been the topic of investigation for a number of theorists and clinicians. In a longitudinal study of self-esteem development (Erol & Orth, 2011), several factors were consistently correlated with higher self-esteem:

- **Emotional stability:** At each age, individuals who had emotional stability had higher self-esteem than those who had unstable emotions.
- **Extraversion:** The personality trait of extroversion, which includes a social, outgoing personality, was consistently associated with higher self-esteem than was the trait of introversion.
- **Conscientiousness:** At each age, the personality trait of conscientiousness, which includes a desire to be thoughtful, careful, and to do the right thing, was associated with higher self-esteem.
- **A high sense of mastery:** The sense that one has control over the forces affecting one's life or that one is able to be effective was consistently associated with higher self-esteem. Part of developing a sense of mastery involves clear differentiation of those things over which a person has control and those things that are beyond a person's ability to control. For example, individuals can choose how they communicate with another person, but they do not have control over how the other person responds. Clarity about these differences supports a person's sense of mastery. In contrast, becoming overly concerned with what someone else's responses and opinions (something one has no control over) say about their worth may contribute to a person devaluing himself or herself, which is the foundation for low self-esteem.
- **Low risk taking:** At any age, proneness to engage in risky behavior was associated with lower self-esteem, and low risk taking was correlated with higher self-esteem.
- **Being healthy:** At any age, the perception of being healthy was associated with higher self-esteem.

Warren (1991) outlined the following focus areas to be emphasized by parents and others who work with children when encouraging the growth and development of positive self-esteem:

- **A sense of competence:** Everyone needs to feel skilled at something. Warren (1991) stated, "Children do not necessarily need to be THE best at a skill in order to have positive self-esteem; what they need to feel is that they have accomplished their PERSONAL best effort" (p. 1).
- **Unconditional love:** Children need to know that they are loved and accepted by family and friends regardless of success or failure. Unconditional love is demonstrated by expressive touch, realistic praise, and separation of criticism of the person from criticism of the behavior.
- **A sense of survival:** Everyone fails at something from time to time. Self-esteem is enhanced when individuals learn from failure and grow in the knowledge that they are stronger for having experienced it.
- **Realistic goals:** Low self-esteem can be the result of not being able to achieve established goals. Individuals may set themselves up for failure by setting goals that are unattainable. Goals can be unrealistic when they are beyond a child's capability to achieve, require an inordinate amount of effort to accomplish, and are based on exaggerated fantasy.
- **A sense of responsibility:** Children gain positive self-worth when they are assigned areas of responsibility or are expected to complete tasks that they perceive are valued by others.
- **Reality orientation:** Personal limitations abound within our world, and it is important for children to recognize and achieve a healthy balance between what they can possess and achieve and what is beyond their capability or control.

Other factors have been found to be influential in the development of self-esteem:

- **The responses of others:** The development of self-esteem can be positively or negatively influenced by the responses of others, particularly significant others, and by how individuals perceive those responses. Role modeling and teaching children strategies for evaluating and keeping in perspective the responses of others contributes to their ability to develop self-esteem.
- **Hereditary factors:** Factors that are genetically determined, such as physical appearance, size, or inherited infirmity, can affect the development of self-esteem. Reinforcing a child's strengths and helping the child to differentiate factors over which her or she has control or the ability to change contributes to a sense of mastery and self-esteem.
- **Environmental conditions:** The development of self-esteem can be influenced by demands from the environment. For example, intellectual prowess

may be incorporated into the self-worth of an individual who is reared in an academic environment.

Developmental Progression of Self-Esteem Through the Life Span

The development of self-esteem progresses throughout the life span. Erikson's (1963) theory of personality development provides a useful framework for illustration. Erikson describes eight transitional or maturational crises, the resolution of which can have a profound influence on self-esteem. If a crisis is successfully resolved at one stage, the individual develops healthy coping strategies that he or she can draw on to help fulfill tasks of subsequent stages. When an individual fails to achieve the tasks associated with a developmental stage, emotional growth is inhibited, and he or she is less able to cope with subsequent maturational or situational crises.

Trust versus Mistrust (Birth to 18 Months)

The development of trust results in a feeling of confidence in the predictability of the environment. Achievement of trust results in positive self-esteem through the instillation of self-confidence, optimism, and faith in the gratification of needs.

Unsuccessful resolution results in the individual experiencing emotional dissatisfaction with the self and suspiciousness of others, thereby promoting negative self-esteem.

Autonomy versus Shame and Doubt (18 Months to 3 Years)

With motor and mental development come greater movement and independence within the environment. The child begins active exploration and experimentation. Achievement of the task results in a sense of self-control and the ability to delay gratification, as well as a feeling of self-confidence in one's ability to perform.

This task remains unresolved when the child's independent behaviors are restricted or when the child fails because of unrealistic expectations. Negative self-esteem is promoted by a lack of self-confidence, a lack of pride in the ability to perform, and a sense of being controlled by others.

Initiative versus Guilt (3 to 6 Years)

Positive self-esteem is gained through initiative when creativity is encouraged and performance is recognized and positively reinforced. In this stage, children strive to develop a sense of purpose and the ability to initiate and direct their own activities.

This is the stage during which the child begins to develop a conscience. He or she becomes vulnerable to the labeling of behaviors as "good" or "bad." Guidance and discipline that rely heavily on shaming the child creates guilt and results in a decrease in self-esteem.

Industry versus Inferiority (6 to 12 Years)

Self-confidence is gained at this stage through learning, competing, performing successfully, and receiving recognition from significant others, peers, and acquaintances.

Negative self-esteem is the result of nonachievement, unrealistic expectations, or when accomplishments are consistently met with negative feedback. The child develops a sense of personal inadequacy.

Identity versus Role Confusion (12 to 20 Years)

During adolescence, the individual is striving to redefine the sense of self. Positive self-esteem occurs when individuals are allowed to experience independence by making decisions that influence their lives.

Failure to develop a new self-definition results in a sense of self-consciousness, doubt, and confusion about one's role in life. This can occur when adolescents are encouraged to remain in the dependent position; when discipline in the home has been overly harsh, inconsistent, or absent; and when parental support has been lacking. These conditions are influential in the development of low self-esteem.

Intimacy versus Isolation (20 to 30 Years)

Intimacy is achieved when one is able to form a lasting relationship or a commitment to another person, a cause, an institution, or a creative effort (Murray, Zentner, & Yakimo, 2009). Positive self-esteem is promoted through this capacity for giving of oneself to another.

Failure to achieve intimacy results in behaviors such as withdrawal, social isolation, aloneness, and the inability to form lasting intimate relationships. Isolation occurs when love in the home has been deprived or distorted through the younger years, causing a severe impairment in self-esteem.

Generativity versus Stagnation (30 to 65 Years)

Generativity promotes positive self-esteem through gratification from personal and professional achievements and from meaningful contributions to others.

Failure to achieve generativity occurs when earlier developmental tasks are not fulfilled and the individual does not achieve the degree of maturity required to derive gratification out of a personal concern for the welfare of others. He or she lacks self-worth and becomes withdrawn and isolated.

Ego Integrity versus Despair (65 Years and older)

Ego integrity results in a sense of self-worth and self-acceptance as one reviews life goals, accepting that some were achieved and some were not. The individual has little desire to make major changes in how his or her life has progressed. Positive self-esteem is evident.

Individuals in despair possess a sense of self-contempt and disgust with how life has progressed. They feel worthless and helpless and would like to have a second chance at life. Earlier developmental tasks of self-confidence, self-identity, and concern for others remain unfulfilled. Negative self-esteem prevails.

In the late 1990s, Erikson advanced the concept of transcendence as an additional stage that occurs after the stage of integrity versus despair (Erikson & Erikson, 1997). This stage incorporates the tasks of broadening personal boundaries and developing an increased sense of meaning in life. Accomplishment of these tasks in the life span of 80 years and beyond contributes to one's sense of self-worth and satisfaction with life.

Manifestations of Low Self-Esteem

Individuals with low self-esteem perceive themselves to be incompetent, unlovable, insecure, and unworthy and manifest behaviors that demonstrate their feelings about themselves. The number of manifestations exhibited is influenced by the degree to which an individual experiences low self-esteem. Nursing theorist Roy (1976, 2009) categorized these behaviors according to the type of stimuli that give rise to manifestations of low self-esteem and affirmed the importance of collecting this type of information in the nursing assessment. Stimulus categories are identified as *focal, contextual,* and *residual.* A summary of these types of influencing factors is presented in Table 15–1.

Focal Stimuli

A **focal stimulus** is the *immediate* concern that is causing the threat to self-esteem and the stimulus that is engendering the current behavior. Examples of focal stimuli include termination of a significant relationship or loss of employment.

Contextual Stimuli

Contextual stimuli are all of the other stimuli present in the person's environment that *contribute* to the behavior being caused by the focal stimulus. Examples

TABLE 15–1 Factors That Influence Manifestations of Low Self-Esteem		
FOCAL	**CONTEXTUAL**	**RESIDUAL**
Any experience or situation causing the individual to question or decrease his or her value of self; experiences of loss are particularly significant.	1. Body changes experienced because of growth or illness 2. Maturational crises associated with developmental stages 3. Situational crises and the individual's ability to cope 4. The individual's perceptions of feedback from significant others 5. Ability to meet expectations of self and others 6. The feeling of control one has over life situation 7. One's self-definition and the use of it to measure self-worth 8. How one copes with feelings of guilt, shame, and powerlessness 9. How one copes with the required changes in self-perception 10. Awareness of what affects self-concept and the manner with which these stimuli are dealt 11. The number of failures experienced before judging self as worthless 12. The degree of self-esteem one possesses 13. How one copes with limits within the environment 14. The type of support from significant others and how one responds to it 15. One's awareness of and ability to express feelings 16. One's current feeling of hope and comfort with the self	1. Age and coping mechanisms one has developed 2. Stressful situations previously experienced and how well one coped with them 3. Previous feedback from significant others that contributed to self-worth 4. Coping strategies developed through experiences with previous developmental crises 5. Previous experiences with powerlessness and hopelessness and how one coped with them 6. Coping with previous losses 7. Coping with previous failures 8. Previous experiences meeting expectations of self and others 9. Previous experiences with control of self and the environment and quality of coping response 10. Previous experience with decision-making and subsequent consequences 11. Previous experience with childhood limits and whether those limits were clear, defined, and enforced

SOURCE: From Driever, M.J. (1976). Problem of low self-esteem. In C. Roy (Ed.), *Introduction to nursing: An adaptation model* (pp. 232-242). Englewood Cliffs, NJ: Prentice-Hall, with permission.

of contextual stimuli (related to the previously mentioned focal stimuli) might be preoccupation with guilt about the effects a divorce may have on one's children or the perception that advanced age will interfere with obtaining employment.

Residual Stimuli

Residual stimuli are previous experiences that influence one's maladaptive behavior in response to focal and contextual stimuli. For example, being reared in an atmosphere of ridicule and deprecation may affect current adaptation to divorce. Previous experiences with multiple job losses may affect one's current perceptions about self-efficacy in acquiring a new job.

Symptoms of Low Self-Esteem

Driever (1976) identified a number of behaviors manifested by the individual with low self-esteem. It is clear that low self-esteem and depression share many of the same symptoms. Indeed, low self-esteem is an underlying feature in many types of depressive disorders. These behaviors are presented in Box 15–1.

Boundaries

The word *boundary* is used to denote the personal space, both physical and psychological, that individuals identify as their own. Boundaries are sometimes referred to as *limits:* the limit or degree to which individuals feel comfortable in a relationship. Boundaries define and differentiate an individual's physical and psychological space from the physical and psychological space of others.

Boundaries help individuals define the self and are part of the individuation process. More important, boundaries are a measure of self-esteem; healthy boundaries communicate self-respect and an expectation to be treated well in interpersonal relationships (Collingwood, 2016). Types of physical boundaries include physical closeness, touching, sexual behavior, eye contact, privacy (e.g., mail, diary, doors, nudity, bathroom, telephone), and pollution (e.g., noise and smoke), among others. Examples of invasions of physical boundaries are reading someone else's diary, smoking in a nonsmoking public area, and touching someone who does not wish to be touched.

Types of psychological boundaries include beliefs, feelings, choices, needs, time alone, interests, confidences, individual differences, and spirituality, among others. Examples of invasions of psychological boundaries are being criticized for doing something differently than others; having personal information shared in confidence told to others; and being told one "should" believe, feel, decide, choose, or think in a certain way.

BOX 15–1 Manifestations of Low Self-Esteem

1. Loss of appetite/weight loss
2. Overeating
3. Constipation or diarrhea
4. Sleep disturbances (insomnia or difficulty falling or staying asleep)
5. Hypersomnia
6. Complaints of fatigue
7. Poor posture
8. Withdrawal from activities
9. Difficulty initiating new activities
10. Decreased libido
11. Decrease in spontaneous behavior
12. Expression of sadness, anxiety, or discouragement
13. Expression of feeling of isolation, being unlovable, unable to express or defend oneself, and too weak to confront or overcome difficulties
14. Fearful of angering others
15. Avoidance of situations of self-disclosure or public exposure
16. Tendency to stay in background, be a listener rather than a participant
17. Sensitivity to criticism; self-conscious
18. Expression of feelings of helplessness
19. Various complaints of aches and pains
20. Expression of being unable to do anything "good" or productive; expression of feelings of worthlessness and inadequacy
21. Expressions of self-deprecation, self-dislike, and unhappiness with self
22. Denial of past successes and accomplishments and of possibility for success with current activities
23. Feeling that anything one does will fail or be meaningless
24. Ruminating about problems
25. Seeking reinforcement from others; making efforts to gain favors but failing to reciprocate such behavior
26. Seeing self as a burden to others
27. Alienation from others by clinging and self-preoccupation
28. Self-accusatory
29. Demanding reassurance but not accepting it
30. Hostile behavior
31. Angry at self and others but unable to express these feelings directly
32. Decreased ability to meet responsibilities
33. Decreased interest, motivation, concentration
34. Decrease in self-care, hygiene

Adapted from Lloyd, S. R. (2002). Developing positive assertiveness *(3rd ed.). Menlo Park, CA: Crisp Learning.*

Boundary Pliancy

Boundaries can be rigid, flexible, or enmeshed. The behavior of dogs and cats can be a good illustration of **rigid boundaries** and **flexible boundaries.** Most dogs want to be as close to people as possible. When "their people" walk into the room, the dog is likely to be all over them. They want to be where their people are and do what they are doing. Dogs have very flexible boundaries.

Cats, on the other hand, have very distinct boundaries. They do what they want, when they want. They decide how close they will be to their people, and when. Cats take notice when their people enter a room but may not even acknowledge their presence (until the cat decides the time is right). Their boundaries are less flexible than those of dogs.

Rigid Boundaries

Individuals who have rigid boundaries often have a hard time trusting others. They keep others at a distance and are difficult to communicate with. They reject new ideas or experiences and often withdraw, both emotionally and physically.

EXAMPLE

Brent and Meghan were seeing a marriage counselor because they were unable to agree on many aspects of raising their children, and it was beginning to interfere with their relationship. Meghan runs a day-care service out of their home, and Brent is an accountant. Meghan states, "He never once changed a diaper or got up at night with a child. Now that they are older, he refuses to discipline them in any way." Brent responds, "In my family, my Mom took care of the house and kids and my Dad kept us clothed and fed. That's the way it should be. It's Meghan's job to raise the kids. It's my job to make the money." Brent's boundaries are considered rigid because he refuses to consider the ideas of others or to experience alternative ways of doing things.

Flexible Boundaries

Healthy boundaries are flexible. That is, individuals must be able to let go of their boundaries and limits *when appropriate*. In order to have flexible boundaries, individuals must be aware of who is considered safe and when it is safe to let others invade their personal space.

EXAMPLE

Kristen always takes the hour from 4 to 5 p.m. for her own. She takes no phone calls and tells the children that she is not to be disturbed during that hour. She reads or takes a long leisurely bath and relaxes before it is time to start dinner. Today her private time was interrupted when her 15-year-old daughter came home from school crying because she had not made the cheerleading squad. Kristen used her private time to comfort her daughter who was experiencing a traumatic response to the failure.

Sometimes boundaries can be too flexible. Individuals with boundaries that are too loose are like chameleons. They take their "colors" from whomever they happen to be with at the time. That is, they allow others to make their choices and direct their behavior.

EXAMPLE

At a cocktail party, Diane agreed with one person that the winter had been so unbearable she had hardly been out of the house. Later, at the same party, she agreed with another person that the winter had seemed milder than usual.

Enmeshed Boundaries

Enmeshed boundaries occur when two people's boundaries are so blended together that neither can be sure where one stops and the other begins, or one individual's boundaries may be blurred with another's. The individual with enmeshed boundaries may be unable to differentiate his or her feelings, wants, and needs from the other person's.

EXAMPLES

1. Fran's parents are in town for a visit. They say to Fran, "Dear, we want to take you and Dave out to dinner tonight. What is your favorite restaurant?" Fran automatically responds, "Villa Roma," knowing that the Italian restaurant is Dave's favorite.
2. If a mother has difficulty allowing her daughter to individuate, the mother may perceive the daughter's experiences as happening to her. For example, Aileen got her hair cut without her mother's knowledge. It was styled with spikes across the top of her head. When her mother saw it, she said, "How dare you go around looking like that! What will people think of me?"

Establishing Boundaries

Boundaries are established in childhood. Unhealthy boundaries are the products of unhealthy, troubled, or dysfunctional families. The boundaries enclose painful feelings that have their origin in the dysfunctional family and that have not been dealt with. McKay and Fanning (2000) explain the correlation between unhealthy boundaries and self-esteem disturbances and how they can arise out of negative role models:

> Modeling self-esteem means valuing oneself enough to take care of one's own basic needs. When parents put themselves last or chronically sacrifice for their kids, they teach them that a person is only worthy insofar as he or she is of service to others. When parents set consistent, supportive limits and protect themselves from overbearing demands, they send a message to their children that both are important and both have legitimate needs. (p. 312)

In addition to the lack of positive role models, unhealthy boundaries may also be the result of abuse

or neglect. These circumstances can cause a delay in psychosocial development. Individuals must then resume the grief process as an adult in order to continue the developmental progression. They learn to recognize feelings, work through core issues, and tolerate emotional pain as their own. They complete the individuation process, go on to develop healthy boundaries, and learn to appreciate their self-worth.

The Nursing Process

Assessment

Clients with self-esteem problems may manifest any of the symptoms presented in Box 15–1. Some clients with disturbances in self-esteem make direct statements that reflect guilt, shame, or negative self-appraisal, but often it is necessary for the nurse to ask specific questions to obtain this type of information. In particular, clients who have experienced abuse or other severe trauma often have kept feelings and fears buried for years, and behavioral manifestations of low self-esteem may not be readily evident.

Various tools for measuring self-esteem exist. One is presented in Box 15–2. This particular tool can be used as a self-inventory by the client, or it can be adapted and used by the nurse to format questions for assessing level of self-esteem in the client.

Diagnosis and Outcome Identification

NANDA International has accepted, for use and testing, four nursing diagnoses that relate to self-esteem. These diagnoses are chronic low self-esteem, situational low self-esteem, risk for chronic low self-esteem, and risk for situational low self-esteem (Herdman & Kamitsuru, 2014). Each is described here with its definitions and defining characteristics.

BOX 15–2 Self-Esteem Inventory

Place a check mark in the column that most closely describes your answer to each statement. Each check is worth the number of points listed above each column.

	3 Often or a Great Deal	2 Sometimes	1 Seldom or Occasionally	0 Never or Not at All
1. I become angry or hurt when criticized.				
2. I am afraid to try new things.				
3. I feel stupid when I make a mistake.				
4. I have difficulty looking people in the eye.				
5. I have difficulty making small talk.				
6. I feel uncomfortable in the presence of strangers.				
7. I am embarrassed when people compliment me.				
8. I am dissatisfied with the way I look.				
9. I am afraid to express my opinions in a group.				
10. I prefer staying home alone to participating in group social situations.				
11. I have trouble accepting teasing.				
12. I feel guilty when I say "no" to people.				
13. I am afraid to make a commitment to a relationship for fear of rejection.				
14. I believe that most people are more competent than I.				
15. I feel resentment toward people who are attractive and successful.				
16. I have trouble thinking of any positive aspects about my life.				
17. I feel inadequate in the presence of authority figures.				
18. I have trouble making decisions.				
19. I fear the disapproval of others.				
20. I feel tense, stressed out, or uptight.				

Problems with low self-esteem are indicated by items scored with a 3 or by a total score higher than 46.

Chronic Low Self-Esteem

Definition Long-standing negative self-evaluating and/or negative feelings about self or self-capabilities.

Defining characteristics

- Dependent on others' opinions
- Hesitant to try new situations
- Underestimates ability to deal with situations
- Hesitant to try new things
- Indecisive behavior
- Exaggerates negative feedback about self
- Guilt
- Nonassertive behavior
- Excessively seeks reassurance
- Overly conforming
- Shame
- Passive
- Frequent lack of success in life events
- Rejection of positive feedback

Situational Low Self-Esteem

Definition Development of a negative perception of self-worth in response to a current situation.

Defining characteristics

- Helplessness
- Indecisive behavior
- Nonassertive behavior
- Purposelessness
- Self-negating verbalizations
- Situational challenges to self-worth
- Underestimates ability to deal with the situation

Risk for Chronic Low Self-Esteem

Definition Vulnerable to long-standing negative self-evaluating and/or negative feelings about self or self-capabilities, which may compromise health.

Risk factors

- Cultural incongruence
- Exposure to traumatic situation
- Inadequate affection received
- Inadequate group membership
- Inadequate respect from others
- Ineffective coping with loss
- Insufficient feeling of belonging
- Psychiatric disorder
- Spiritual incongruence
- Repeated failures
- Repeated negative reinforcement

Risk for Situational Low Self-Esteem

Definition Vulnerable to developing negative perception of self-worth in response to a current situation, which may compromise health.

Risk factors

- Alterations in body image
- Alteration in social role
- Behavior inconsistent with values
- Decrease in control over environment
- Developmental transition
- Functional impairment
- History of abandonment
- History of abuse
- History of loss
- History of neglect
- History of rejection
- Inadequate recognition
- Pattern of failure
- Pattern of helplessness
- Physical illness
- Unrealistic self-expectations

Outcome Criteria

Outcome criteria include short- and long-term goals. Time lines for achievement are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with disturbances of self-esteem.

The client:

- Is able to express positive aspects about self and life situation
- Is able to accept positive feedback from others
- Is able to attempt new experiences
- Is able to accept personal responsibility for own problems
- Is able to accept constructive criticism without becoming defensive
- Is able to make independent decisions about life situation
- Uses intermittent, appropriate eye contact
- Is able to develop positive interpersonal relationships
- Is able to communicate needs and wants to others assertively

Planning and Implementation

In Table 15–2, a plan of care using selected self-esteem diagnoses accepted by NANDA International is presented. Outcome criteria, appropriate nursing interventions, and rationales are included for each diagnosis.

> **CLINICAL PEARL** Ensure that client goals are realistic. Unrealistic goals set up the client for failure. Provide encouragement and positive reinforcement for attempts at change. Give recognition of accomplishments, however small.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives

Table 15–2 | CARE PLAN FOR THE CLIENT WITH PROBLEMS RELATED TO SELF-ESTEEM

NURSING DIAGNOSIS: CHRONIC LOW SELF-ESTEEM

RELATED TO: Lack of affection/approval; repeated failures; repeated negative reinforcement

EVIDENCED BY: Exaggerates negative feedback about self and expressions of shame and guilt

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client verbalizes positive aspects of self and abandons irrational, negative self-judgments.	1. Be supportive, accepting, and respectful without invading client's personal space.	1. Individuals who have had long-standing feelings of low self-worth may be uncomfortable with personal attentiveness.
	2. Explore inaccuracies in self-perception with client.	2. Client may not see positive aspects of self that others see, and bringing it to awareness may help change perception.
	3. Have client list successes and strengths. Provide positive feedback.	3. Helps client to develop internal self-worth and new coping behaviors.
	4. Assess content of negative self-talk and educate client about the impact of cognitive distortions (irrational thinking) on self-esteem.	4. Self-blame, shame, and guilt promote feelings of low self-worth. Depending on chronicity and severity of the problem, this is likely to be the focus of long-term psychotherapy with client. Assisting client to recognize the impact of negative cognition on self-esteem lays the foundation for referral to longer-term treatment such as cognitive therapies (see Chapter 19, Cognitive Therapy).

NURSING DIAGNOSIS: SITUATIONAL LOW SELF-ESTEEM

RELATED TO: Failure (either real or perceived) in a situation of importance to the individual or loss (either real or perceived) of a concept of value to the individual

EVIDENCED BY: Indecisive behavior and expressions of helplessness and uselessness

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client identifies source of threat to self-esteem and works through the stages of the grief process to resolve the loss or failure.	1. Convey an accepting attitude; encourage client to express self openly.	1. An accepting attitude enhances trust and communicates to client that the nurse believes he or she is a worthwhile person, regardless of what is expressed.
	2. Encourage client to express anger. Do not become defensive if initial expression of anger is displaced on nurse/therapist. Assist client to explore angry feelings and direct them toward the intended object/person or other loss.	2. Verbalization of feelings in a nonthreatening environment may help client come to terms with unresolved issues related to the loss.

Continued

Table 15–2 | CARE PLAN FOR THE CLIENT WITH PROBLEMS RELATED TO SELF-ESTEEM–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	3. Assist client to avoid ruminating about past failures. Withdraw attention if client persists.	3. Lack of attention to these undesirable behaviors may discourage their repetition.
	4. Educate client about the importance of focusing on positive attributes if self-esteem is to be enhanced. Encourage discussion of past accomplishments and offer support in undertaking new tasks. Offer recognition of successful endeavors and positive reinforcement of attempts made.	4. Recognition and positive reinforcement enhance self-esteem and encourage repetition of desirable behaviors.

NURSING DIAGNOSIS: RISK FOR SITUATIONAL LOW SELF-ESTEEM

RISK FACTORS: Developmental changes; functional impairment; disturbed body image; loss; history of abuse or neglect; unrealistic self-expectations; physical illness; failures/rejections

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client's self-esteem is preserved.	1. Provide an open environment and trusting relationship.	1. Facilitates client's ability to deal with current situation.
	2. Determine client's perception of the loss/failure and the meaning of it to him or her.	2. Assessment of the cause or contributing factor is necessary to provide assistance to client.
	3. Identify response of family or significant others to client's current situation.	3. Provides additional background assessment data with which to plan client's care.
	4. Permit appropriate expressions of anger.	4. Anger is a stage in the normal grieving process and must be dealt with for progression to occur.
	5. Provide information about normalcy of individual grief reaction.	5. Individuals who are unaware of normal feelings associated with grief may feel guilty and try to deny certain feelings.
	6. Discuss and assist with planning for the future. Communicate hope, but avoid giving false reassurance.	6. In a state of anxiety and grief, individuals need assistance with decision-making and problem-solving. They may find it difficult or impossible to envision any hope for the future.

of care. Evaluation of the nursing actions for the client with self-esteem disturbances may be facilitated by gathering information using the following types of questions:

■ Is the client able to discuss past accomplishments and other positive aspects about his or her life?
■ Does the client accept praise and recognition from others in a gracious manner?

■ Is the client able to try new experiences without extreme fear of failure?
■ Can he or she accept constructive criticism now without becoming overly defensive and shifting the blame to others?
■ Does the client accept personal responsibility for problems rather than attributing feelings and behaviors to others?

- Does the client participate in decisions that affect his or her life?
- Can the client make rational decisions independently?
- Has he or she become more assertive in interpersonal relations?
- Is improvement observed in the physical presentation of self-esteem, such as eye contact, posture, changes in eating and sleeping, fatigue, libido, elimination patterns, self-care, and complaints of aches and pains?

Summary and Key Points

- Emotional wellness requires that an individual have some degree of self-worth—a perception that he or she possesses a measure of value to self and others.
- Self-concept is a cognitive component of the self that includes a set of beliefs about oneself.
- Body image encompasses one's appraisal of physical attributes, functioning, sexuality, wellness-illness state, and appearance.
- The personal identity component of self-concept is composed of the moral-ethical self, the self-consistency, and the self-ideal.
- Self-consistency is the component of the personal identity that strives to maintain a stable self-image.
- Self-ideal relates to an individual's perception of what he or she wants to be, do, or become.
- Self-esteem refers to the degree of regard or respect that individuals have for themselves and is a measure of worth that they place on their abilities and judgments. It is largely influenced by the perceptions of how one is viewed by significant others.

- High self-esteem is associated with emotional stability, extroversion, conscientiousness, a sense of mastery, low risk taking, and better health. Genetics and environmental conditions may also be influencing factors.
- The development of self-esteem progresses throughout the life span. Erikson's theory of personality development elaborates on the importance of accomplishing developmental tasks in self-esteem. The behaviors associated with low self-esteem are numerous and correlated with signs and symptoms of depression.
- Stimuli that trigger behaviors associated with low self-esteem may include focal, contextual, and/or residual stimuli.
- Boundaries, or personal limits, help individuals define the self and are part of the individuation process.
- Boundaries are a measure of self-esteem.
- Boundaries are physical and psychological and may be rigid, flexible, or enmeshed.
- Unhealthy boundaries are often the result of dysfunctional family systems.
- The nursing process is the vehicle for delivery of care to clients needing assistance with self-esteem disturbances.
- The four nursing diagnoses relating to self-esteem that have been accepted by NANDA International include chronic low self-esteem, situational low self-esteem, risk for chronic low self-esteem, and risk for situational low self-esteem.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Kaylee, age 26, graduated from law school with a 3.2/4.0 grade point average. She recently took the bar exam and did not pass. Because of this, she had to give up her job at a law firm. She became very depressed and sought counseling at the mental health clinic. During the intake assessment, Kaylee says to the psychiatric nurse, "I am a complete failure. I'm so dumb, I can't do anything right." What is the most appropriate nursing diagnosis for Kaylee?
   a. Chronic low self-esteem
   b. Situational low self-esteem
   c. Defensive coping
   d. Risk for situational low self-esteem

Continued

Review Questions—cont'd
Self-Examination/Learning Exercise

2. Which of the following outcome criteria would be most appropriate for the client described in question 1?
   a. Kaylee is able to express positive aspects about herself and her life situation.
   b. Kaylee is able to accept constructive criticism without becoming defensive.
   c. Kaylee is able to develop positive interpersonal relationships.
   d. Kaylee is able to accept positive feedback from others.

3. Amanda tried out for the cheerleading squad in junior high but was rejected. At age 15, she had looked forward to trying out for the cheerleading squad in high school. She took cheerleading classes and practiced for many hours every day. However, when tryouts were held, she was not selected. She has become despondent, and her mother takes her to the mental health clinic for counseling. Amanda tells the nurse, "What's the use of trying? I'm not good at anything!" Which of the following nursing interventions is best for Amanda's specific problem?
   a. Encourage Amanda to talk about her feeling of shame over the second failure.
   b. Assist Amanda to problem-solve her reasons for not making the team.
   c. Help Amanda understand the importance of good self-care and personal hygiene in the maintenance of self-esteem.
   d. Explore with Amanda her past successes and accomplishments.

4. The psychiatric nurse encourages Amanda (the client in question 3) to express her anger. Why is this an appropriate nursing intervention?
   a. Anger is the basis for self-esteem problems.
   b. The nurse suspects that Amanda was abused as a child.
   c. The nurse is attempting to guide Amanda through the grief process.
   d. The nurse recognizes that Amanda has long-standing repressed anger.

5. A law school graduate failing the bar exam and a 15-year-old high school girl not being selected for the cheerleading squad are examples of which of the following?
   a. Focal stimuli
   b. Contextual stimuli
   c. Residual stimuli
   d. Spatial stimuli

6. The husband says to his wife, "What do you want to do tonight?" and his wife responds, "Whatever you want to do." This is an example of which of the following?
   a. Extremely rigid boundaries
   b. A boundary violation
   c. Extremely flexible boundaries
   d. Showing respect for the boundary of another

7. Twins Jan and Jean still dress alike even though they are grown and married. This is an example of which of the following?
   a. Rigid boundary
   b. Enmeshed boundary
   c. A boundary violation
   d. Boundary pliancy

8. Karen's counselor asked her if she would like a hug. This is an example of which of the following?
   a. Rigid boundary
   b. A boundary violation
   c. Enmeshed boundary
   d. Showing respect for the boundary of another

Review Questions—cont'd
Self-Examination/Learning Exercise

9. Jessica told Andrea a secret that Eva had told her. This is an example of which of the following?
   a. Too flexible a boundary
   b. A boundary violation
   c. Too rigid a boundary
   d. An enmeshed boundary

10. Tommy says to his friend, "I can't ever talk to my Daddy until after he has read his newspaper." This is an example of which of the following?
    a. A rigid boundary
    b. A boundary violation
    c. An enmeshed boundary
    d. A flexible boundary

11. A nurse is engaging in psychoeducation about improving self-esteem with Shelley, who has depression and low self-esteem. Which of the following are important for the nurse to assess? (Select all that apply.)
    a. Shelley's focal, contextual, and residual stimuli
    b. Shelley's abilities with regard to establishment of boundaries
    c. Shelley's age and whether or not she is married
    d. The nurse's awareness of his or her own ability to establish appropriate boundaries
    e. Shelley's predominant communication style and her understanding of assertiveness

16 Anger and Aggression Management

CHAPTER OUTLINE

KEY TERMS

modeling   operant conditioning   prodromal syndrome

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define and differentiate between *anger* and *aggression*.
2. Identify when the expression of anger becomes a problem.
3. Discuss predisposing factors to the maladaptive expression of anger.
4. Apply the nursing process to clients expressing anger or aggression.
   a. **Assessment:** Describe physical and psychological responses to anger.

b. **Diagnosis/Outcome Identification:** Formulate nursing diagnoses and outcome criteria for clients expressing anger and aggression.
c. **Planning/Intervention:** Describe nursing interventions for clients demonstrating maladaptive expressions of anger.
d. **Evaluation:** Evaluate achievement of the projected outcomes in the intervention with clients demonstrating maladaptive expression of anger.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What symptoms often precede violent behavior?
2. What is the goal of anger management?
3. What psychiatric diagnoses are correlated with increased risk of violence?

4. Under what conditions might a nurse determine that a client should be placed in restraints?

Anger need not be a negative expression. It is a normal human emotion that, when handled appropriately and expressed assertively, can provide an individual with a positive force to solve problems and make decisions concerning life situations. Anger becomes a problem when it is not expressed or when it is expressed aggressively. Violence occurs when individuals lose control of their anger. Violent acts are becoming commonplace in the United States. In 2015, according to Bureau of Justice statistics, 2.7 million people experienced at least one violent victimization (Truman & Morgan, 2016). Violent crimes are reported daily by the news media, and health-care workers see the results each day in the emergency departments of general hospitals.

This chapter addresses the concepts of anger and aggression. Predisposing factors to the maladaptive expression of anger are discussed, and the nursing process as a vehicle for delivery of care to assist

clients in the management of anger and aggression is described.

Anger and Aggression, Defined

> ### CORE CONCEPTS
> **Anger**
> Anger is "an emotional state that varies in intensity from mild irritation to intense fury and rage," according to Charles Spielberger, a clinical psychologist best known for developing the State/Trait Anxiety Inventory. Anger is accompanied by physiological and biological changes, such as increases in heart rate, blood pressure, and levels of the energy hormones adrenaline and noradrenaline (American Psychological Association [APA], 2017).

Anger is a normal, healthy emotion that serves as a warning signal and alerts us to potential threat or trauma. It triggers energy that sets us up for a good fight or quick flight and can range from mild irritation to rage. Warren (1993) outlines some fundamental points about anger:

■ Anger is not a primary emotion, but it is typically experienced as an almost automatic inner response to hurt, frustration, or fear.

■ Anger is physiological arousal. It instills feelings of power and generates preparedness.

■ Anger and aggression are significantly different.

■ The expression of anger is learned.

■ The expression of anger can come under personal control.

Anger is a very powerful emotion. When it is denied or buried, it can precipitate a number of physical problems such as migraine headaches, ulcers, colitis, and even coronary heart disease. When turned inward on oneself, anger can result in depression and low self-esteem. When it is expressed inappropriately, it commonly interferes with relationships. When suppressed, anger may turn into resentment, which often manifests in negative, passive-aggressive behavior.

Anger creates a state of preparedness by arousing the sympathetic nervous system. The activation of this system results in increased heart rate and blood pressure, increased secretion of epinephrine (resulting in additional physiological arousal), and increased levels of serum glucose, among others. Anger prepares the body, physiologically, to fight. When anger goes unresolved, this physiological arousal can be the predisposing factor to a number of health problems. Even if the situation that created the anger is removed by miles or years, it can be replayed through the memory, reactivating the sympathetic arousal when this occurs.

Table 16–1 lists positive and negative functions of anger.

> ### CORE CONCEPT
> **Aggression**
> *Aggression* has many different definitions depending on the context in which it is described. When describing aggression as a behavioral response to anger, aggression has been defined as a behavior intended to threaten or injure the victim's security or self-esteem. It means "to go against," "to assault," or "to attack." It is a response that aims at inflicting pain or injury on objects or persons (Warren, 1993, pp. 119–120). Aggression may include verbal and physical attacks that intend harm to another and often reflect a desire for dominance and control (Kassinove, 2016). Aggression, in general, may range from a self-protective response to a destructive, violent act (Perry, 2016).

The term *anger* often takes on a negative connotation because of its link with aggression. Aggression is one way individuals express anger. It is sometimes used to try to force someone into compliance with the aggressor's wishes, but at other times, the only objective seems to be the infliction of punishment and pain. In virtually all instances, aggression is a negative function or destructive use of anger.

Predisposing Factors to Anger and Aggression

A number of factors have been implicated in the way an individual expresses anger. Some theorists view aggression as purely biological, and some suggest that it results from individuals' interactions with their environments. It is likely a combination of both.

Modeling

Role **modeling** is one of the strongest forms of learning. Children model their behavior at a very early age after their primary caregivers, usually parents. How parents or significant others express anger becomes the child's method of anger expression.

Whether role modeling is positive or negative depends on the behavior of the models. Much has been written about the abused child becoming physically abusive as an adult, which may be connected to a learned response.

Role models are not always in the home, however. Evidence supports the role of television and video violence as a predisposing factor to later aggressive behavior (American Psychological Association, 2013). Whether modeling occurs in the home, the community,

TABLE 16–1 **The Functions of Anger**	
POSITIVE FUNCTIONS OR CONSTRUCTIVE USES	NEGATIVE FUNCTIONS OR DESTRUCTIVE USES
Anger energizes and mobilizes the body for self-defense.	Without cognitive input, anger may result in impulsive behavior, disregarding possible negative consequences.
Communicated assertively, anger can promote conflict resolution.	Communicated passive-aggressively or aggressively, conflict escalates, and the problem that created the conflict goes unresolved.
Anger arousal is a personal signal of threat or injustice against the self. The signal elicits coping responses to deal with the distress.	Anger can lead to aggression when the coping response is displacement. Anger can be destructive if it is discharged against an object or person unrelated to the true target of the anger.
Anger is constructive when it provides a feeling of control over a situation and the individual is able to assertively take charge of a situation.	Anger can be destructive when the feeling of control is exaggerated and the individual uses the power to intimidate others.
Anger is constructive when it is expressed assertively, serves to increase self-esteem, and leads to mutual understanding and forgiveness.	Anger can be destructive when it masks honest feelings, weakens self-esteem, and leads to hostility and rage.

SOURCES: Adapted from Gorman, L.M., & Sultan, D.F. (2008). *Psychosocial nursing for general patient care* (3rd ed.). Philadelphia: F.A. Davis; Waughfield, C.G. (2002). *Mental health concepts* (5th ed.). Albany, NY: Delmar.

or popular media, its role in the development of aggression has been well supported.

Operant Conditioning

Operant conditioning occurs when a specific behavior is reinforced. A positive reinforcement is a response to specific behavior that is pleasurable or offers a reward. A negative reinforcement is a response to specific behavior that prevents an undesirable result from occurring.

Anger responses can be learned through operant conditioning. For example, when a child wants something and has been told no by a parent, he or she might have a temper tantrum. If the parent then gives the child an ice cream cone, the anger displayed during the temper tantrum has been positively reinforced (or rewarded).

An example of learning by negative reinforcement follows: A mother asks the child to pick up her toys, and the child becomes angry and has a temper tantrum. If, when the temper tantrum begins, the mother thinks, "Oh, it's not worth all this!" and picks up the toys herself, the anger has been negatively reinforced (the child was rewarded by not having to pick up her toys).

Neurophysiological Factors

The neurophysiology of aggression is extremely complex and only partially understood despite years of research. Perry (2016) describes the findings as such: "Any factors which increase the activity or reactivity of the brainstem (e.g., chronic traumatic stress, testosterone, dysregulated serotonin or norepinephrine systems) or decrease the moderating capacity of the limbic or cortical areas (e.g., neglect) will increase an individual's aggressivity, impulsivity, and capacity to display violence." Loss of function in the cortex (and subsequently decreased moderating capacity) can also occur as a result of many pathological processes, including stroke, dementia, alcohol intoxication, and traumatic brain injuries. Tumors in the brain, particularly in the areas of the limbic system and the temporal lobes; trauma to the brain resulting in cerebral changes; and diseases such as encephalitis (or medications that may effect this syndrome), have all been implicated in the predisposition to aggression and violent behavior.

Individuals may be genetically predisposed to aggression attributable to the effects of genetic variants of the serotoninergic systems that control levels of serotonin in the central and peripheral nervous systems, its biological effects, its rate of production, and synaptic release (Pavlov, Chistiakov, & Chekhonin, 2012).

Biochemical Factors

The impact of hormones, particularly testosterone, in aggression has been the focus of animal research, and although it has been associated with increased aggression in animals and in correlation studies in humans, the effects of testosterone administration have yielded mixed results (Sadock, Sadock, & Ruiz, 2015). For example, in one controlled study where anabolic-androgenic steroids were given to normal subjects, the participants reported both positive and negative mood symptoms; the latter included anger, hostility, and violent feelings (Sadock et al., 2015). Although aggression is modulated by several hormonal systems,

testosterone is identified as playing a key role, while deficits in serotonin have been associated with an increase in impulsivity (Vetulani, 2013).

Socioeconomic Factors

High rates of violence exist within the subculture of poverty in the United States. Exposure to violence has been identified as having an impact on future tendencies toward aggression. An ongoing controversy exists as to whether economic inequality or absolute poverty is most responsible for aggressive and violent behavior within this subculture. That is, does violence occur because individuals perceive themselves as disadvantaged relative to other persons, or does violence occur because of the deprivation itself? These concepts are not easily understood and are still under investigation.

Environmental Factors

Three environmental factors that have been shown to increase risks for aggression are crowding, temperature, and noise (Archer, 2012). All three of these environmental factors increase stress, which has a multitude of effects on mood and behavior. Current behavior and past experiences are also environmental factors that influence aggressive expression. The three best predictors of violent behavior in this context are alcohol intake, a history of childhood abuse, and a history of violent acts with criminal activity or arrests (Sadock et al., 2015). Numerous other substances of abuse have been associated with aggression, including cocaine, methamphetamines and amphetamines, bath salts, anabolic steroids, synthetic marijuana, PCP, and alpha PVP (also known as *flakka*).

The Nursing Process

CORE CONCEPT

Anger Management
The use of various techniques and strategies to control responses to anger-provoking situations. The goal of anger management is to reduce both the emotional feelings and the physiological arousal that anger engenders.

Assessment

Nurses must be aware of the risk factors and symptoms associated with anger and aggression in order to make an accurate assessment. In a meta-analysis of prevalence and risk factors for violence by psychiatric acute inpatients (Iozzino et al., 2015), the researchers found that close to 1 in 5 patients may commit an act of violence. The highest risk factors were male gender, a diagnosis of schizophrenia, substance use, and a history of violence. The best intervention is prevention, so risk factors for assessing violence potential are also presented.

Anger

Anger is often manifested in the following ways:

- Frowning facial expression
- Clenched fists
- Low-pitched verbalizations forced through clenched teeth
- Yelling and shouting
- Intense eye contact or avoidance of eye contact
- Hypersensitivity, easily offended
- Defensive response to criticism
- Passive-aggressive behaviors
- Lack of control or overcontrolled emotions
- Intense discomfort; continuous state of tension
- Flushed face
- Anxious, tense, angry facial expression (affect)

Anger is often described as a secondary emotion. For example, it may be a response to unresolved grief, depression, fear, anxiety, or unresolved posttraumatic stress. Anger is also one of the stages of the normal grief process and thus is an expected emotion. Because of the negative connotation of the word *anger,* some clients will not acknowledge that they are feeling angry. These individuals need assistance to recognize their true feelings and understand that anger is a perfectly acceptable emotion; it is one's *behavior* in response to anger that may be unacceptable, such as when it results in aggression.

Aggression

Aggression can arise from a number of feeling states, including anger, anxiety, guilt, frustration, or suspiciousness. Aggressive behaviors can be classified as mild (e.g., sarcasm), moderate (e.g., slamming doors), severe (e.g., threats of physical violence against others), or extreme (e.g., physical acts of violence against others). Aggression may be associated with (but not limited to) the following defining characteristics:

- Pacing, restlessness
- Threatening body language
- Verbal or physical threats
- Loud voice, shouting, use of obscenities, argumentative
- Threats of homicide or suicide
- Increase in agitation, with overreaction to environmental stimuli
- Panic anxiety, leading to misinterpretation of the environment
- Suspiciousness and defensive posturing
- Angry mood, often disproportionate to the situation
- Destruction of property
- Acts of physical harm toward another person

Aggression is often differentiated as reactive versus proactive. Reactive aggression is defined as fear based and impulsive; proactive aggression is described as predatory and calculated. In both cases, there is intent to harm another, but the motives differ. *Intent* is a requisite in the definition of aggression. It refers to behavior that is *intended* to inflict harm or destruction. Accidents that lead to *unintentional* harm or destruction are not considered aggression.

Assessing Risk Factors

Prevention is the key issue in managing aggressive or violent behavior. The individual who becomes violent usually feels an underlying helplessness. The following three factors have been identified as important considerations in assessing for potential violence:

1. Past history of violence
2. Client diagnosis
3. Current behavior

Past history of violence is widely recognized as a major risk factor for violence in a treatment setting. Also highly correlated with assaultive behavior is diagnosis. Diagnoses such as schizophrenia, major depression, bipolar disorder, and substance use disorders have a strong correlation with violent behavior (Friedman, 2006). Substance abuse, in addition to mental illness, compounds the increased risk of violence. Neurocognitive disorders and antisocial, borderline, and intermittent explosive personality disorders have also been associated with a risk for violent behavior.

Novitsky, Julius, and Dubin (2009) state:

> The successful management of violence is predicated on an understanding of the dynamics of violence. A patient's threatening behavior is commonly an overreaction to feelings of impotence, helplessness, and perceived or actual humiliation. Aggression rarely occurs suddenly and unexpectedly. (p. 50)

Novitsky and associates describe a **prodromal syndrome** characterized by anxiety and tension, verbal abuse and profanity, and increasing hyperactivity. These escalating behaviors usually do not occur in stages but most often overlap and sometimes occur simultaneously. Behaviors associated with this prodromal stage include rigid posture; clenched fists and jaws; grim, defiant affect; talking in a rapid, raised voice; arguing and demanding; using profanity and threatening verbalizations; agitation and pacing; and pounding and slamming.

Most assaultive behavior is preceded by a period of increasing hyperactivity. Behaviors associated with the prodromal syndrome should be considered emergent and demand immediate attention. Keen observation skills and background knowledge for accurate assessment are critical factors in predicting potential for violent behavior. The Brøset Violence Checklist is presented in Box 16–1. It is a quick, simple, and reliable checklist that can be used as a risk assessment for potential violence. Testing has shown a 63 percent accuracy for prediction of violence at a score of 2 and above (Almvik, Woods, & Rasmussen, 2000). De-escalation techniques are also included.

Diagnosis and Outcome Identification

NANDA International does not include a separate nursing diagnosis for anger. The nursing diagnosis of complicated grieving may be used when anger is expressed inappropriately and the etiology is related to a loss.

The following nursing diagnoses may be considered for clients demonstrating inappropriate expression of anger or aggression:

■ Ineffective coping related to negative role modeling and dysfunctional family system, evidenced by

---

BOX 16–1 The Brøset Violence Checklist

Score 1 point for each behavior observed. At a score of ≥ 2, begin de-escalation techniques.

Behaviors	Score
Confusion	
Irritability	
Boisterousness	
Physical threats	
Verbal threats	
Attacks on objects	
TOTAL SCORE	

DE-ESCALATION TECHNIQUES

Calm voice	Helpful attitude
Walk outdoors or fresh air	Reduction in demands
Identify consequences	Decrease waiting times and request refusals
Group participation	
Open hands and nonthreatening posture	Verbal redirection and limit setting
Relaxation techniques	Distract with a more positive activity (e.g., soft music or a quiet room)
Allow phone call	
Express concern	
Offer food or drink	Time-out/quiet time/open seclusion
Reduce stimulation and loud noise	Offer prn medication

If de-escalation techniques fail:

1. Suggest prn medications
2. Time-out or unlocked seclusion, which can progress to locked seclusion

SOURCE: From Almvik, R., Woods, P., & Rasmussen, K. (2000). The Brøset violence checklist: Sensitivity, specificity, and interrater reliability. Journal of Interpersonal Violence, 15(12), 1284-1296, with permission. De-escalation techniques reprinted with permission from Barbara Barnes, Milwaukee County Behavioral Health Division.

yelling, name calling, hitting others, and temper tantrums as expressions of anger
■ Risk for self-directed or other-directed violence related to having been nurtured in an atmosphere of violence; history of violence

Outcome Criteria

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client needing assistance with management of anger and aggression.

The client:

■ Is able to recognize when he or she is angry and seeks out staff/support person to talk about his or her feelings
■ Is able to take responsibility for own feelings of anger
■ Demonstrates the ability to exert internal control over feelings of anger
■ Is able to diffuse anger before losing control

■ Uses the tension generated by the anger in a constructive manner
■ Does not cause harm to self or others
■ Is able to use steps of the problem-solving process rather than becoming violent as a means of seeking solutions

Planning and Implementation

In Table 16–2, a plan of care is presented for the client who expresses anger inappropriately. Outcome criteria, appropriate nursing interventions, and rationales are included for each diagnosis. Cognitive-behavioral therapy (CBT) as a strategy for anger management and aggression reduction is an evidence-based treatment that, especially when incorporated in treatment for children and adolescents, has demonstrated effectiveness in reducing maladaptive aggression (Smeets et al., 2015). While CBT is typically conducted by advanced practice nurses and other trained specialists, the generalist psychiatric nurse can incorporate principles of this modality in psychoeducation, which provides a foundation for referral to longer-term CBT.

Table 16–2 | CARE PLAN FOR THE INDIVIDUAL WHO EXPRESSES ANGER INAPPROPRIATELY

NURSING DIAGNOSIS: INEFFECTIVE COPING
RELATED TO: Negative role modeling and dysfunctional family system
EVIDENCED BY: Yelling, name calling, hitting others, and temper tantrums as expressions of anger

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client is able to recognize anger in self and take responsibility before losing control.	1. Remain calm when dealing with an angry client.	1. Anger expressed by the nurse will most likely incite increased anger in client.
	2. Set verbal limits on behavior. Clearly delineate the consequences of inappropriate expression of anger and always follow through.	2. Consistency in enforcing the consequences is essential if positive outcomes are to be achieved. Inconsistency creates confusion and encourages testing of limits.
	3. Have client keep a diary of angry thoughts and feelings, what triggered them, and how they were handled.	3. This provides a more objective measure of the problem. Introducing client to some basic principles of cognitive reflection not only encourages problem-solving in the short term but lays the groundwork for referral to longer-term CBT if this is identified as desirable.
	4. Avoid touching client when he or she becomes angry.	4. Client may view touch as threatening and could become violent.

Continued

Table 16–2 | CARE PLAN FOR THE INDIVIDUAL WHO EXPRESSES ANGER INAPPROPRIATELY–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	5. Help client determine the true source of the anger.	5. Many times, anger is being displaced onto a safer object or person. If resolution is to occur, the first step is to identify the source of the problem.
	6. Help client find alternative ways of releasing tension, such as physical outlets, and more appropriate ways of expressing anger, such as seeking out staff when feelings emerge.	6. Client will likely need assistance to problem-solve more appropriate ways of behaving.
	7. Role-model appropriate ways of expressing anger assertively, such as, "I dislike being called names. I get angry when I hear you saying those things about me."	7. Role modeling is one of the strongest methods of learning.

NURSING DIAGNOSIS: RISK FOR SELF-DIRECTED OR OTHER-DIRECTED VIOLENCE

RISK FACTORS: Having been nurtured in an atmosphere of violence; history of violence

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Client will not harm self or others. Client verbalizes anger rather than hit others.	1. Observe client for escalation of anger (called the *prodromal syndrome*): increased motor activity, pounding, slamming, tense posture, defiant affect, clenched teeth and fists, arguing, demanding, and challenging or threatening staff.	1. Violence may be prevented if risks are identified in time.
	2. When these behaviors are observed, first ensure that sufficient staff are available to help with a potentially violent situation. Attempt to defuse the anger beginning with the least restrictive means.	2. The initial consideration must be having enough help to diffuse a potentially violent situation. Client rights must be honored, while preventing harm to client and others.
	3. Techniques for dealing with aggression:	3. Aggression control techniques promote safety and reduce risk of harm to client and others:
	a. Talking down. Say, "John, you seem very angry. Let's sit down and talk about it." (Be attentive to safe physical distance from the patient and the nurse's ability to exit [i.e., ensure that client does not position self between a door and nurse].)	a. Promotes a trusting relationship and may prevent client's anxiety from escalating while attending to the safety needs of the nurse as well.
	b. Physical outlets. "such as exercise, using a punching bag, or engaging in another activity that provides an acceptable outlet for	b. Provides effective way for client to release tension associated with high levels of anger. Staying with the client offers an opportunity to

Table 16–2 | CARE PLAN FOR THE INDIVIDUAL WHO EXPRESSES ANGER INAPPROPRIATELY—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	energy. Offer to stay with the client during this activity."	provide support and to assess the client's perception of the activity's effectiveness.
	c. Medication. If agitation continues to escalate, offer client choice of taking medication voluntarily. If he or she refuses, reassess the situation to determine if harm to self or others is imminent.	c. Tranquilizing medication may calm client and prevent violence from escalating.
	d. Call for assistance. Remove self and other clients from the immediate area. Call violence code, push panic button, call for assault team, and follow other measures established by the institution. Sufficient staff to indicate a show of strength may be enough to de-escalate the situation, and client may agree to take the medication.	d. Client and staff safety are of primary concern. Many states, accrediting bodies (such as The Joint Commission), and/or facilities require that staff members working with hospitalized psychiatric patients be trained and/or certified in psychiatric emergency interventions to assure that the strategies used are in the best interest of staff and patient safety.
	e. Seclusion or restraints. If client is not calmed by talking down or by medication, use of mechanical restraints and/or seclusion may be necessary. Be sure to have sufficient staff available to assist and appropriately deal with an out-of-control client. Follow protocol for restraints/ seclusion established by the institution. Restraints should be used as a last resort, after all other interventions have been unsuccessful and client is clearly at risk of harm to self or others.	e. Clients who do not have internal control over their own behavior may require external controls, such as seclusion and/or mechanical restraints, in order to prevent harm to self or others, but since they are a more restrictive measure, they should be used only as a last resort after all other measures have been attempted and have failed.
	f. Observation and documentation. Hospital policy typically dictates the requirements for observation of client in restraints. Basic safety principles include that client in restraints should be observed throughout the period of restraint. Every 15 minutes, client should be monitored to ensure that circulation to extremities is not compromised (check temperature, color, pulses). Assist client	f. Client safety and well-being are nursing priorities.

Table 16–2	CARE PLAN FOR THE INDIVIDUAL WHO EXPRESSES ANGER INAPPROPRIATELY—cont'd		
OUTCOME CRITERIA	**NURSING INTERVENTIONS**	**RATIONALE**
	with needs related to nutrition, hydration, and elimination. Position client so that comfort is facilitated, breathing is unobstructed, and aspiration prevented. Clients should not be restrained in the prone position.	
	g. Ongoing assessment. As agitation decreases, assess client's readiness for restraint removal or reduction. With assistance from other staff members, remove one restraint at a time, while assessing client's response. This minimizes the risk of injury to client and staff.	g. Gradual removal of the restraints allows for testing of the client's self-control. Client and staff safety are of primary concern.
	h. Debriefing. It is important, when a client loses control, for staff to follow up with a discussion about the situation. This discussion should occur among staff and with client (when client has regained control). The staff should discuss factors that necessitated the crisis intervention, factors that contributed to the failure of less restrictive interventions, and staff's thoughts about the safety and effectiveness of the intervention. When client has regained control, a debriefing should occur in which client is encouraged to discuss thoughts about what contributed to the crisis situation and about staff interventions and to explore strategies to avert a crisis situation in the future. It is also important to discuss the situation with other clients who witnessed the episode so they understand and process what happened. Some clients may fear that they could be at risk for experiencing a crisis or that they might be in danger when someone else's behavior becomes aggressive.	h. Debriefing helps to diminish the emotional impact of the intervention. Mutual feedback is shared, and staff has an opportunity to process and learn from the event.

Evaluation

Evaluation consists of reassessment to determine if the nursing interventions have been successful in achieving the objectives of care. The following type of information may be gathered to determine the success of working with a client exhibiting inappropriate expression of anger:

- Is the client able to recognize when he or she is angry now?
- Can the client take responsibility for these feelings and keep them in check without losing control?
- Does the client seek out staff/support person to talk about feelings of anger when they occur?
- Is the client able to transfer tension generated by the anger into constructive activities?
- Has harm to client and others been avoided?
- Is the client able to solve problems adaptively without undue frustration and without becoming violent?

Summary and Key Points

- Anger, a normal human emotion, is not necessarily a negative response.
- When used appropriately, anger can provide positive assistance with problem-solving and decision-making in everyday life situations.
- Violence occurs when individuals lose control of their anger.
- Anger is viewed as the emotional response to one's perception of a situation.
- When denied or buried, anger can precipitate a number of psychophysiological disorders.
- When anger is turned inward on the self, it can result in depression.
- When expressed inappropriately, anger commonly interferes with interpersonal relationships.
- When anger is suppressed, it often turns to resentment.
- Anger generates a physiological arousal comparable to the stress response discussed in Chapter 1, The Concept of Stress Adaptation.

- Aggression is one way in which individuals express anger.
- Aggression is behavior intended to threaten or injure the victim's security or self-esteem.
- Aggression can be physical or verbal, but it is virtually always designed to punish.
- Aggression is a negative function or destructive use of anger.
- Various predisposing factors to the way individuals express anger have been implicated. Some theorists suggest that the etiology is purely biological, whereas others believe it depends on psychological and environmental factors.
- Some possible predisposing factors include role modeling, operant conditioning, neurophysiological disorders (e.g., brain tumors, trauma, or diseases), biochemical factors (e.g., increased levels of androgens or other alterations in hormone levels and neurotransmitter involvement), socioeconomic factors (e.g., living in poverty), and environmental factors (e.g., physical crowding, uncomfortable temperature, use of alcohol or drugs).
- Nurses must be aware of the symptoms associated with anger and aggression in order to make an accurate assessment.
- Prevention is the key issue in the management of aggressive or violent behavior.
- Elements identified as key risk factors in the potential for violence among acute psychiatric inpatients include (1) male gender, (2) substance use, (3) past history of violence, and (4) a diagnosis of schizophrenia.
- CBT is an evidence-based treatment strategy for reducing maladaptive aggression, especially in the treatment of aggression in children and adolescents.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. John, age 27, was brought to the emergency department by two police officers. He smelled strongly of alcohol and was combative. His blood alcohol level was measured at 293 mg/dL. His girlfriend reports that he drinks excessively every day and is verbally and physically abusive. The nurses give John the nursing diagnosis of Risk for other-directed violence. What would be appropriate outcome objectives for this diagnosis? (Select all that apply.)
   a. The client will not verbalize anger or hit anyone.
   b. The client will verbalize anger rather than hit others.
   c. The client will not harm self or others.
   d. The client will be restrained if he becomes verbally or physically abusive.

2. John, who was hospitalized with alcohol intoxication and violent behavior, is sitting in the dayroom watching TV with the other clients when the nurse approaches with his 5 p.m. dose of haloperidol. John says, "I feel in control now. I don't need any drugs." The nurse's best response is based on which of the following statements?
   a. John must have the medication, or he will become violent.
   b. John knows that if he will not take the medication orally, he will be restrained and given an intramuscular injection.
   c. John has the right to refuse the medication provided there is no immediate danger to self or others.
   d. John must take the medication at this time in order to maintain adequate blood levels.

3. The nurse hears John, a client with a history of violence, yelling in the dayroom. The nurse observes his increased agitation, clenched fists, and loud, demanding voice. He is challenging and threatening staff and the other clients. The nurse's *priority* intervention would be to:
   a. Call for assistance.
   b. Draw up a syringe of prn haloperidol.
   c. Ask John if he would like to talk about his anger.
   d. Tell John if he does not calm down he will have to be restrained.

4. John, a client with a history of violence, has been hospitalized on the psychiatric unit. He becomes agitated and begins to threaten the staff and other clients. When all other interventions fail, John is placed in restraints in the seclusion room for his and others' protection. Which of the following are interventions for the client in restraints? (Select all that apply.)
   a. Check temperature and pulse of extremities.
   b. Document all observations.
   c. Explain to the client that restraint is his punishment for violent behavior.
   d. Provide ongoing assessment and observation.
   e. Withhold food and fluid until client is calm and can be released from restraints.

5. When it has been assessed that a client is in control and no longer requires restraining, how does the nurse proceed?
   a. The nurse removes the restraints.
   b. The nurse calls for assistance to remove the restraints.
   c. With assistance, the nurse removes one restraint.
   d. The nurse tells the client he will have to wait until the doctor comes in.

6. Which of these procedures is important immediately following an episode of violence on the unit? (Select all that apply.)
   a. Document all observations and occurrences.
   b. Conduct a debriefing with staff.
   c. Discuss what occurred with other clients who witnessed the incident.
   d. Warn the client that it could happen again if he becomes violent.

Review Questions—cont'd
Self-Examination/Learning Exercise

7. A client who has been in restraints is now calm. He apologizes to the nurse and says, "I hope I didn't hurt anyone." The nurse's best response is:
   a. "This is our job. We know how to handle violent clients."
   b. "We understand you were out of control and didn't really mean to hurt anyone."
   c. "It is fortunate that no one was hurt. You will not be placed in restraints as long as you can control your behavior."
   d. "It is an unpleasant situation to have to restrain someone, but we have to think of the other clients. We can't have you causing injury to others. I just hope it won't happen again."

8. John and his girlfriend had an argument during her visit. Which behavior by John would indicate he is learning to adaptively problem-solve his frustrations?
   a. John says to the nurse, "Give me some of that medication before I end up in restraints!"
   b. When his girlfriend leaves, John goes to the exercise room and punches on the punching bag.
   c. John says to the nurse, "I guess I'm going to have to dump that broad!"
   d. John says to his girlfriend, "You'd better leave before I do something I'm sorry for."

9. Which of the following assessment data would the nurse consider as risk factors for possible violence in a client? (Select all that apply.)
   a. A diagnosis of somatization disorder
   b. A diagnosis of schizophrenia or bipolar disorder
   c. Substance intoxication
   d. Argumentative and demanding behavior
   e. Past history of violence

10. Which of the following is true about *aggression*? (Select all that apply.)
   a. It is goal directed.
   b. Its aim is to do harm to a person or object.
   c. It has a requisite of *intent*.
   d. It energizes and mobilizes the body for self-defense.

Suicide Prevention

CORE CONCEPTS
Suicide
Suicide Risk Assessment
Suicide Prevention

KEY TERMS

altruistic suicide
anomic suicide
collaborative safety plan

egoistic suicide
suicide risk factors
suicide warning signs

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss epidemiological statistics and risk factors related to suicide.
2. Describe predisposing factors implicated in the etiology of suicide.
3. Differentiate between facts and myths regarding suicide.
4. Apply the nursing process to individuals exhibiting suicidal behavior.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. How are age, race, and gender associated with suicide risk?
2. Your neighbor tells you he is going to visit his sister-in-law in the hospital. The sister-in-law has been hospitalized after attempting suicide. Your neighbor asks, "What should I say when I go to visit Jane?" What suggestions might you give him?
3. John's father died by suicide when John was a teenager. John's wife, Mary, tells the mental health nurse that she is afraid John "inherited" that predisposition from his father. How should the nurse respond to Mary?
4. The nurse notes that the mood of a client being treated for depression and suicidal ideation suddenly brightens, and the client states, "I feel fine now. I don't feel depressed anymore." Why would this statement alert the nurse of a potential problem?
5. Write a one- to two-page journal reflecting on your previous experiences with suicide, examining your thoughts and feelings and their potential impact on your nursing practice. (Note: Self-awareness on the issue of suicide is identified as an essential competency for psychiatric nurses [American Psychiatric Nurses Association (APNA), 2015] and is relevant to all nurses in developing skills necessary for this aspect of nursing assessment and intervention).

Suicide is not a diagnosis or a disorder; it is a behavior. Specifically, it is the act of taking one's own life, and it derives from the Latin words for "one's own killing." Many religions hold that suicide is a sin that is strictly forbidden. Canetto (American Psychiatric Association, 2010) states, "Everywhere, suicidal behavior is culturally scripted. Women and men adopt the self-destructive behaviors that are expected of them within their cultures." A recent, more secular view has influenced how some individuals view suicide in our society. Growing support for an individual's right to choose death over pain has been evidenced by an increasing number of states that are considering or have adopted physician-assisted suicide laws. Some individuals are striving to advance the cause of physician-assisted suicides for the terminally ill. In 2008, Oregon was the only state in which physician-assisted suicide was legal. Since then, Montana, Vermont, Washington, and most recently, California, adopted similar laws. New Mexico did so as well, but it was overturned on appeal in August 2015. Can suicide be a rational act? Most people in our society do not yet believe that it can.

In the field of psychiatry, suicide is considered an irrational act associated with mental illness and most commonly, but not exclusively, with depression. More than 90 percent of all persons who attempt or die by suicide have a diagnosed mental disorder (National Institute of Mental Health [NIMH], 2015). However, since this phenomenon does not capture all of those who take their own lives, we must not ignore individuals in the community and in nonpsychiatric health-care settings who may be at risk. This chapter explores suicide from an epidemiological and etiological perspective. Care of the suicidal client is presented in the context of the nursing process.

Historical Perspectives

In ancient Greece, individuals were said to have "committed" suicide because it was an offense against the state, and individuals who committed suicide were denied burial in community sites (Minois, 2001). In the culture of the imperial Roman army, individuals sometimes resorted to suicide to escape humiliation or abuse. In the Middle Ages, suicide was viewed as a selfish or criminal act (Minois, 2001). Individuals who "committed" suicide were often denied cemetery burial, and their property was confiscated and shared by the crown and the courts (MacDonald & Murphy, 1991).

The issue of suicide changed during the Renaissance period. Although condemnation was still expected, the view became philosophical, allowing intellectuals to discuss the issue more freely. Most philosophers of the 17th and 18th centuries condemned suicide, but some writers recognized a connection between suicide and melancholy or other severe mental disturbances (Minois, 2001). Suicide was illegal in England until 1961, and only in 1993 was it decriminalized in Ireland.

Most religions consider suicide as a sin against God. Judaism, Christianity, Islam, Hinduism, and Buddhism all condemn suicide. The Catholic church today still teaches that suicide is wrong, that it is in opposition to proper love of self and love of God, and that it wrongs others through the experience of loss and grief (Byron, 2016). But as Byron (2016) points out, some of the church's condemnation may have been rooted in a "denial of the responsibility to understand the pain that produces such an act," and he stresses the importance of encouraging those who "are hurting to open up," which, it is hoped, will remove some of the taboos of discussing suicide within the church. Replacing the term *committed* suicide (which has persisted in use long since its decriminalization) may also help to reduce the stigma and taboo that has historically been associated with open conversation about suicide.

Epidemiological Factors

In 2014, the most recent year for which statistics have been recorded, 42,773 people died by suicide (American Foundation for Suicide Prevention [AFSP], 2016). This is the highest rate of suicide in more than 15 years. These statistics have established suicide as the second-leading cause of death (behind unintentional injuries) among young Americans aged 10 to 34 years, the fourth-leading cause of death for individuals aged 35 to 54, the eighth-leading cause of death for individuals aged 55 to 64, and the tenth-leading cause of death overall (Centers for Disease Control and Prevention [CDC], 2016). Many more people attempt suicide than die by suicide (about 12:1), and countless others seriously contemplate the act without carrying it out. Since statistics about numbers of suicide attempts reflect only those who have entered a treatment setting, the numbers could be much higher. With a steady incline in suicide rates from 2000 to 2014, suicide has become a major health-care problem in the United States. Not only are the number of suicides on the incline, but the demographics have changed. Historically, the highest rates of suicide were among the elderly, but currently the highest rate of suicide occurs among middle-aged individuals and those ages 85 and older. Historically, the suicide rate has been lower among military personnel than among the general population. However, in some time periods since the Iraq War began—including in 2010 and 2011—more

soldiers died by suicide than died in combat (Nock et al., 2013). See Chapter 38, Military Families, for further discussion.

A wealth of research is being conducted to better understand the best strategies for prevention, the best methods for assessment of suicide risk, what differentiates those with suicidal ideation from those who attempt, and what kind of treatments and interventions are supported by evidence. The federal government, through the Substance Abuse and Mental Health Services Administration, has endorsed the Zero Suicide movement (National Action Alliance for Suicide Prevention, 2015), an effort to identify evidence-based strategies for suicide prevention, so there is a great deal of national attention to this issue. Within the next several years, our understanding of and approaches to treatment may dramatically change. We are certainly beginning to recognize that, with suicide rates on the rise, our conventional interventions have not adequately addressed the complex needs of this population.

Confusion exists over the reality of various notions regarding suicide. Some currently accepted facts and myths relating to suicide are presented in Table 17–1.

TABLE 17–1 Facts and Myths About Suicide

MYTHS	FACTS
People who talk about suicide do not act on their ideas. Suicide happens without warning.	Eight out of 10 people who kill themselves have given definite clues and warnings about their suicidal intentions. Very subtle clues may be ignored or disregarded by others.
You cannot stop a suicidal person. He or she is fully intent on dying.	Most suicidal people are very ambivalent about their feelings regarding living or dying. Most are "gambling with death" and see it as a cry for someone to save them.
Once a person is suicidal, he or she is suicidal forever.	Suicidal ideation and risk fluctuate over time and may be time-limited. If provided adequate support and resources, a suicidal person can go on to lead a normal life. However, multiple suicide attempts may reflect greater chronicity of suicidal ideation. Reassessment over time is important to identify current risks.
Improvement after severe depression means that the suicidal risk is over.	Most suicides occur within about 3 months after the beginning of "improvement," when the individual has the energy to carry out suicidal intentions.
Suicide is inherited, or "runs in families."	Suicide is not inherited. It is an individual matter and can be prevented. However, suicide by a close family member increases an individual's risk factor for suicide.
All suicidal individuals are mentally ill, and suicide is the act of a psychotic person.	Although a majority of people who attempt suicide are extremely unhappy or clinically depressed, they are not necessarily psychotic. They are merely unable at that point in time to see an alternative solution to what they consider an unbearable problem.
Suicidal thoughts and attempts should be considered manipulative or attention-seeking behavior and should not be taken seriously.	All suicidal behavior must be approached with the gravity of the potential act in mind. Attention should be given to the possibility that the individual is issuing a cry for help.
People usually take their own lives by overdosing on drugs.	Gunshot wounds are the leading cause of death among suicide victims.
If an individual has attempted suicide, he or she will not do it again.	Between 50% and 80% of all people who ultimately kill themselves have at least one previous attempt.
Suicide always happens in an impulsive moment.	People often contemplate, imagine, plan strategies, write notes, post things on the Web. The importance of in-depth exploration and assessment cannot be overstated.
Young children (aged 5–12) can't be suicidal.	Annually, 30 to 35 children under the age of 12 take their own lives and not all are clinically depressed.

Risk Factors

Suicide risk factors are identified as factors that have statistically been correlated with a higher incidence of suicide. They should be differentiated from **suicide warning signs** which are identified as factors suggesting a more immediate concern. Both are included as part of a comprehensive assessment of overall risk for suicide.

Marital Status

Some evidence has suggested that the suicide rate for single, never-married persons is twice that for married persons and that divorce increases risk for suicide particularly among men, who are three times more likely than divorced women to take their own lives (Sadock, Sadock, & Ruiz, 2015). Widows and widowers have also been identified at higher risk, but a longitudinal study (Kposowa, 2000) found being single or widowed had no effect on suicide rates. However, their evidence supported that divorced men are twice as likely as married men to die by suicide. Among women, the study showed no significant difference in risk of suicide by marital categories. The authors highlight that the evidence is difficult to sort out and can be misleading if data is not stratified over several variables, including age, socioeconomic status, and other factors.

For those who are divorced and widowed, the stresses associated with major life changes and loss are influential. Evidence has demonstrated that *change* in marital status increases risk for suicidal behavior, particularly in the first year after the change and particularly among older people (Roškar et al., 2011; Yamauchi et al., 2013). Again, it should be noted that demographics such as marital status, age, and gender may inform about populations that are statistically at higher risk, but none of these factors are predictive of immediate risk. A thorough assessment of variables, including risk factors, warning signs, and a host of other data, are essential to identifying individuals at acute risk for attempting suicide.

Gender

More women than men attempt suicide, but men succeed more often. Successful suicides number about 70 percent for men and 30 percent for women. This success rate has to do with the lethality of the means. Women tend to overdose; men use more lethal means, such as firearms. These differences between men and women may also reflect differing societal expectations; women are more likely than men to seek and accept help from friends or professionals.

Age

Suicide risk and age are, in general, positively correlated, particularly with men. Although rates among women remain fairly constant throughout life, rates among men increase with age. The most recent statistics, according to the American Foundation for Suicide Prevention, revealed that in 2013, the highest rate of suicide occurred in the 45- to 64-year-old age group and among those 85 or older (AFSP, 2016). A consistent high rate of suicide in both age groups was shown for the period 2000 to 2014, but the 45 to 64 age group showed a steady incline in suicide rates over the same period.

Although adolescents may statistically have a lower rate of suicide than some other age groups, it is still important to note that suicide has been the third-leading cause of death in this population over several years, and in 2013 jumped to the second-leading cause of death where it remained in 2014 (CDC, 2016). Several factors put adolescents at risk for suicide, including impulsive and high-risk behaviors, untreated mood disorders (e.g., major depression and bipolar disorder), access to lethal means (e.g., firearms), and substance abuse. One recent study (Reyes et al., 2015) found a link between some modes of anger expression in adolescents and suicide risk; in particular, hopelessness and hostility modes of anger expression were associated with an increase in suicidal tendency. The latest statistics from the Centers for Disease Control and Prevention (CDC) indicate that the most common method of completed suicide for adolescent males is firearms; for adolescent females, it is suffocation (CDC, 2015a).

Among children younger than age 10, the statistics demonstrate a low number of suicides, and some have argued that younger children do not have the capacity to intentionally consider and follow through with a suicide attempt. Anecdotal evidence has shown this is not always the case, with some therapists identifying 5- to 9-year-old children actively talking about suicide (Jobes, 2015). Research is beginning to emerge that supports real risk in young children (Duran & McGuinness, 2016). Bridge and associates (2015) studied a large sample of children aged 5 to 11 and found that an average of 33 children per year die by suicide within this age group in the United States, predominately from suffocation and hanging. These researchers also noted that suicide was never coded as a cause of death for children under 5 years of age. But when Whalen and associates (2015) studied children in the 3 to 7 age group, they found about 11 percent with suicidal ideation. This risk was correlated with male gender, psychiatric illness in their mothers, and psychiatric illness in the child. Duran and McGuinness (2016) stress that the implications for nursing are clear; direct inquiry about suicide ideas is a "necessary component in healthcare encounters with children," including those in primary care, emergency departments, and with the school nurse.

Although the elderly comprise just over 13 percent of the population, they account for almost 15 percent of all suicides. In general, 70 percent of all suicides are among white males, but white males over the age of 80 are at the greatest risk of all age, gender, and race groups. Almost 84 percent of elderly suicides are male, which is about five times greater than for females, and firearms are the most common means of taking one's own life (American Association of Suicidology, 2015). The overall rate of suicide for females declines after age 65.

Religion

Historically, suicide rates among Protestants and Jews have been higher than among Roman Catholic or Muslim populations, but the degree of orthodoxy and affiliation with one's religion may be an important variable (Sadock et al., 2015). One study revealed that men and women who consider themselves affiliated with a religion are less likely than their nonreligious counterparts to attempt suicide (Rasic et al., 2009). The authors found that religious affiliation is associated with decreased suicide attempts in both the general population and in those with a mental illness, independent of the availability of social support systems.

Socioeconomic Status

Individuals in the very highest and lowest social classes have higher suicide rates than those in the middle classes (Sadock et al., 2015). With regard to occupation, suicide rates are higher among physicians, artists, dentists, law enforcement officers, lawyers, and insurance agents. There are more suicides among the unemployed than among the employed, and suicide rates increase during economic recessions and depressions.

Ethnicity

With regard to ethnicity, statistics show that whites are at highest risk for suicide (14.7%), followed by American Indian and Alaska Natives (10.9%), Hispanic Americans (6.3%), Asian Americans (5.9%), and African Americans (5.5%) (CDC, 2016). Recent research has highlighted two trends that illuminate issues of concern within specific groups. First, although suicide rates among whites are higher in adults and the elderly, within the American Indian community, young adults have a higher risk for suicide than in any other ethnic group, and the rate is higher than that of the general population (Almendrala, 2015). Almendrala relays the story of a psychiatrist called to a reservation where there had been 17 suicides in the previous 8 months, and the community members described themselves as "grieved out." The second trend of concern, as Almendrala reports, is that the rates of suicide may be underestimated in this population because death certificates do not always report accurately regarding ethnicity.

Another recent study examined suicide trends among school-aged children younger than 12 (Bridge et al., 2015). A significant finding was that suicide rates for black children 5 to 11 years of age nearly doubled over the period from 1993 to 2012, while the overall suicide rate in this age group remained relatively stable during the same time period. The use of hanging and/or suffocation as a means of taking one's own life also significantly increased in this population. It is hard to imagine what causes children so young to take their own lives. The contributing factors to these recent trends are not well understood and will require further research, including a review of the impact of healthcare disparities for select communities and populations.

Other Risk Factors

As previously stated, more than 90 percent of people who kill themselves have a diagnosable mental disorder, most commonly a mood disorder or a substance abuse disorder (NIMH, 2015). Individuals who have been hospitalized for a psychiatric illness have a 5 to 10 times greater suicide risk than those with psychiatric illness in the general population (Sadock et al., 2015). This higher risk may be a reflection of the severity of their mental illness. Other recent research supports an increased risk of suicide in the period following discharge from psychiatric hospitalization, especially for those not connected to a system of care (Olfson et al., 2016). Suicide risk may increase early in treatment with antidepressants. One possible reason is that as an individual's energy returns, he or she may have an increased ability to act out self-destructive wishes. Although suicide is often thought of as strictly related to depression, there is also a recognized risk of suicide among people with schizophrenia, bipolar disorders, personality disorders, eating disorders, anxiety disorders, and substance use disorders. The importance of thorough suicide risk assessment for anyone seeking mental health services cannot be overstated.

Severe insomnia is associated with increased suicide risk even in the absence of depression. Use of alcohol, and particularly a combination of alcohol and barbiturates, increases the risk of suicide. Withdrawal from stimulants increases suicide risk as the person begins to "crash." Psychosis, especially with command hallucinations (hearing voices telling one to harm or kill oneself), increases risk, as does affliction with a chronic, painful, and/or disabling illness.

Several studies have indicated a higher risk factor for suicide among gay men, lesbians, and transgender (LGBT) individuals (Cassels, 2011; Cochran & Mays, 2000; Eisenberg & Resnick, 2006; King et al., 2008; Plöderl, 2013). This increased risk may be a function of the social stigma and discrimination associated with being part of a marginalized group. Additional personal stressors, including isolation,

victimization, and stressful interpersonal relationships with family, peers, and community, are not uncommon. A report from the CDC (2015b) identified that in a study of youth in grades 7 to 12, lesbian, gay, and bisexual youth were twice as likely as their heterosexual peers to attempt suicide (this study did not address the risk for transgender individuals). Another study, however, found that transgender individuals are also a high-risk population for suicide, with an alarming 41 percent lifetime prevalence (Stroumsa, 2014). See Chapter 30, Issues Related to Human Sexuality and Gender Dysphoria, for further discussion on this topic.

Higher risk is also associated with a family history of suicide, especially in a same-gender parent, and with individuals who have made previous suicide attempts. About half of individuals who kill themselves have previously attempted suicide. Loss of a loved one through death or separation and lack of employment or increased financial burden also increase risk.

In recent years, a number of suicides have been reported in the media among young people who are the victims of bullying. Zweig and Dank (2013) reported that 41 percent of youth are victims of physical bullying (most often boys), 17 percent are victims of cyberbullying, and girls are more likely to be victims of psychological bullying. Clearly, bullying is a prevalent concern among youth. Klomek, Sourander, and Gould (2011) report:

> Studies among middle school and high school students show an increased risk of suicidal behavior among bullies and victims. Both perpetrators and victims are at the highest risk for suicidal ideation.

Being bullied via the Internet or e-mail (called *cyberbullying*) has also been associated with increased risk of depression and suicidal behavior among young people. Researchers found that both perpetrators and victims of cyberbullying had more suicidal ideation and were more likely to attempt suicide than those who had not experienced such forms of peer aggression (Bauman, Toomey, & Walker, 2013; Hinduja & Patchin, 2010). Edgerton and Limber (2013), in a research brief on suicide and bullying, caution that although research does show that those who are bullied have high levels of suicidal thoughts and attempts, there is not enough research to identify a cause-and-effect relationship. Other risk factors such as mental health problems appear to play a larger role.

Predisposing Factors: Theories of Suicide

Psychological Theories

Anger Turned Inward

Freud (1957) believed that suicide was a response to intense self-hatred. The anger originated toward a love object but was ultimately turned inward against the self. In other words, Freud thought that suicide occurred as a result of an earlier repressed desire to kill someone else.

Hopelessness and Other Symptoms of Depression

Hopelessness has long been identified as a symptom of depression and an underlying factor in the predisposition to suicide. Although the many symptoms identified in suicide assessment tools attempt to assess for seriousness of suicide ideation, current research is attempting to glean which symptoms might be more predictive of the move from ideation to attempts. In addition to hopelessness, the strength of the person's intention to die has also been identified as significant (Jobes, 2015).

History of Aggression and Violence

A history of violent behavior or impulsive acts has been associated with increased risk for suicide (Sadock et al., 2015), although recent evidence suggests that impulsive traits are higher in individuals with suicide ideation but not necessarily associated with more attempts (Klonsky & May, 2015b).

Shame and Humiliation

Some individuals have viewed suicide as a "face-saving" mechanism—a way to prevent public humiliation following a social defeat such as a sudden loss of status or income. Often, these individuals are too embarrassed to seek treatment or other support systems.

Sociological Theories

Durkheim's Theory

Durkheim's classic work (1951) studied the individual's interaction with the society in which he or she lived. He believed that the more cohesive the society and the more that the individual felt an integrated part of society, the less likely he or she was to carry out suicide. Durkheim described three social categories of suicide:

1. **Egoistic suicide** is the response of the individual who feels separate from the mainstream of society. Integration is lacking, and the individual does not feel a part of any cohesive group (such as a family or a church).
2. **Altruistic suicide** is the opposite of egoistic suicide. The individual who is prone to altruistic suicide is excessively integrated into the group. The group is often governed by cultural, religious, or political ties, and allegiance is so strong that the individual will sacrifice his or her life for the group.
3. **Anomic suicide** occurs in response to changes in an individual's life (e.g., divorce, loss of job) that

disrupt feelings of relatedness to the group. An interruption in the customary norms of behavior instills feelings of separateness and fears of being without support from the formerly cohesive group.

Interpersonal Theory of Suicide

Thomas Joiner's (2005) interpersonal theory of suicide supports some of the same principles advanced by Durkheim associating lack of a feeling of belonging with suicide risk. But Joiner's theory introduces the concept that suicide ideation and suicide attempts need to be understood as distinct processes. He proposed that low connectedness and a high sense of burden interact with each other to increase suicide thoughts and desires, but those features in the presence of high capability for suicide are strongly associated with the move from ideation to lethal attempts.

The Three-Step Theory

Klonsky and May (2015a), inspired by Joiner's theory and based on their research finding that impulsivity is elevated in people who have made suicide attempts and those who have thoughts and have never made an attempt, sought to identify the factors that elevate suicide ideation to an active risk for attempts. Their research supported the following three-step trajectory:

1. Pain (usually psychological pain) when combined with hopelessness significantly increases suicide ideation (for both men and women and across age groups).
2. Connectedness prevents suicide ideation from escalating in those at risk, but when pain and hopelessness exceed one's sense of connectedness to others, suicide ideation becomes active.
3. When strong, active suicide ideation is present, it leads to an attempt only if one has the capacity to make an attempt.

Biological Theories
Genetics

Twin studies have shown a much higher concordance rate for monozygotic twins than for dizygotic twins. Some studies with people who have attempted suicide have focused on the genotypic variations in the gene for tryptophan hydroxylase, with results indicating significant association to suicidality (Sadock et al., 2015). Tryptophan hydroxylase is an enzyme associated with the synthesis of serotonin, and diminished serotonin has implications for both depression and suicidal behavior. These findings suggest the potential for genetic predisposition toward suicidal behavior.

Neurochemical Factors

A number of studies have revealed a deficiency of serotonin (measured as a decrease in the levels of 5-hydroxyindole acetic acid [5-HIAA] in the cerebrospinal fluid) in depressed clients who attempted suicide (Sadock et al., 2015). These studies, as well as postmortem studies, have supported the hypothesis that deficiencies in central nervous system serotonin are associated with suicide.

However, a recent meta-analysis examining biological factors found that they are, in general, weak predictors of a future suicide attempt or death by suicide (Chang et al., 2016). The only two biological factors that had statistical significance in this analysis were cytokines (anti-inflammatory response chemicals) and low levels of fish oil nutrients (including omega-3).

Application of the Nursing Process With the Suicidal Client

A multitude of research studies are being published that explore suicide from many different vantage points to identify demographics, risk factors, predictors of risk for suicide attempts, and strategies for prevention. Many of these studies are helping nurses become more aware of the phenomenon of suicide and understand the limitations of research in making a clinical judgment about a patient's actual risks versus statistical risks.

Influential organizations across the nation are advancing the importance of improving the quality of care, documentation, and reporting of details around sentinel events related to acts of or deaths by suicide. In addition to government-initiated national strategies for suicide prevention, The Joint Commission (2016) has advanced standards that include requiring hospitals to conduct risk assessments "identifying specific patient characteristics and environmental features that may increase or decrease the risk of suicide." The American Psychiatric Nurses Association (APNA, 2015; Puntil et al., 2013) has taken a leadership role in identifying psychiatric-mental health nurse essential competencies for assessment and management of individuals at risk for suicide. The CDC (2011) has advanced strategies for uniform definition and reporting about acts of self-directed violence to improve data collection and ultimately improve our understanding and prevention of suicide.

At the heart of this wealth of information is the necessity for accurate, comprehensive assessment that includes collaboration with the patient and other clinicians and is rooted in strategies to form a therapeutic relationship of trust and open communication.

Assessment

When nurses assess a client's suicide ideation, it is important to identify and distinguish ideas (thoughts), plans (intentions), and attempts (behavior). Each of

these assessment factors can provide information about level of risk. When the client has attempted self-injury, it is important to distinguish between *suicidal self-injury* and *nonsuicidal self-injury*. The latter injury is often used as a method to release emotions, but it may also be a way of communicating the severity of distress that the client is experiencing (Nock et al., 2013).

The following basic items should be considered when conducting a suicidal assessment: demographics; presenting symptoms and medical-psychiatric diagnoses; suicidal ideas or acts; interpersonal support system; analysis of the suicidal crisis; psychiatric, medical, and family history; and coping strategies. Dr. David Satcher, as Surgeon General of the United States, spoke of risk factors and protective factors in his "Call to Action to Prevent Suicide" (U.S. Public Health Service, 1999). This report initiated a national movement toward research designed to better understand predictors of suicide risk and develop more effective evidence-based interventions. Current models have clarified risk factors as different from warning signs that are associated with a greater potential for suicide and suicidal behavior. Protective factors have been identified that are associated with reduced potential for suicide. Examples of protective factors are outlined in Box 17–1. Figure 17–1 presents a model for differentiating low, high, and imminent

suicide risk. The goal of such models is not to predict a suicide attempt but to identify the level of intervention needed to prevent an attempt.

Demographics

The following demographics are identified when evaluating a client for suicide risk. Although demographics alone do not directly translate into an individual's risk, they provide information as part of a comprehensive assessment of proximal or potentiating risk factors.

- **Age:** Adolescents and the elderly have been generally identified as high-risk groups, but recent statistics demonstrating the highest incidence in the 45- to 64-years age group suggests that nurses should pay close attention to assessing for suicide risk in all age groups.
- **Gender:** Males are at higher risk for suicide than females, but females attempt suicide more frequently.
- **Ethnicity/race:** The CDC reports highest rates of suicide among Caucasians followed by American Indians (CDC, 2015a).
- **Marital status:** Single, divorced, and widowed individuals are at higher risk for suicide than are married people particularly during periods of change in status.
- **Socioeconomic status:** Individuals in the highest and lowest socioeconomic classes are at higher risk than those in the middle classes.
- **Occupation:** Health-care professionals (especially physicians), law enforcement officers, dentists, artists, mechanics, lawyers, and insurance agents have all been identified as occupational groups incurring greater risks for suicide (Sadock et al., 2015).
- **Religion:** People with close religious affiliations may be at lower risk for attempting suicide if they believe, for example, that suicide is an unforgivable sin that is strictly forbidden within the religion. Conversely, people without close affiliations that impose restrictions about suicide may be at greater risk.
- **Family history:** A family history of suicide increases an individual's risk for suicide.
- **Military history:** Suicide rates among military personnel now exceed those of the general population (Nock et al., 2013).

BOX 17–1 Examples of Protective Factors

Resilient temperament

Social competency

Skills in problem-solving, coping, and conflict resolution

Perception of social support from adults and peers

Positive expectations, optimism for the future; identification of future goals

Connectedness to family, school, community

Presence and involvement of caring adults (for adolescents)

Integration in social networks

Cultural and religious beliefs that discourage suicide and encourage preservation of life

Access to quality social services and clinical health care for mental, physical, and substance use disorders

Support through ongoing medical and mental health-care relationships

Restricted access to highly lethal means of suicide

SOURCE: Crosby, A.E., Ortega, L., & Melanson, C. (2011). Self-directed Violence Surveillance: Uniform definitions and recommended data elements, Version 1.0. Atlanta (GA): Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Retrieved from www.cdc.gov/violenceprevention/pdf/Self-Directed-Violence-a.pdf

Presenting Symptoms and Medical-Psychiatric Diagnosis

Assessment data must be gathered regarding any psychiatric or physical condition for which a client is being treated. Mood disorders (major depression and bipolar disorders) are the disorders most commonly

WARNING SIGNS:

- Threatening to harm or end one's life
- Seeking or access to means: seeking pills, weapons, or other means
- Evidence or expression of a suicide plan
- Expressing (writing or talking) ideation about suicide, wish to die or death
- Hopelessness
- Rage, anger, seeking revenge
- Acting recklessly, engaging impulsively in risky behavior
- Expressing feelings of being trapped with no way out
- Increasing or excessive substance use
- Withdrawing from family, friends, society
- Anxiety, agitation, abnormal sleep (too much or too little)
- Dramatic changes in mood
- Expresses no reason for living, no sense of purpose in life

Very High Risk: seek immediate help from emergency or mental health professional.

Number of Warning Signs

High Risk: seek help from mental health professional

POTENTIATING RISK FACTORS:

- Unemployed or recent financial difficulties
- Divorced, separated, widowed
- Social isolation
- Prior traumatic life events or abuse
- Previous suicide behavior
- Chronic mental illness
- Chronic, debilitating physical illness

Low Risk: recommend counseling and monitor for development of warning signs.

FIGURE 17–1 Risk factors and warning signs for suicide. Reprinted with permission from the Ontario Hospital Association.

associated with suicide. Substance use disorders are also associated with risk for suicide attempts. Other psychiatric disorders in which suicide risks have been identified include anxiety disorders, schizophrenia, anorexia nervosa, and borderline and antisocial personality disorders. Chronic and terminal physical illnesses have also been identified as potentiating risk factors.

Suicidal Ideas or Acts

How serious is the client's intent to die by suicide? Does the person have a plan? If so, does he or she have the means? How lethal are the means? Does he or she intend to carry out this plan? Has the individual ever attempted suicide before? These questions must be asked by the person conducting the assessment of the client who is suicidal.

Individuals may provide both behavioral and verbal clues as to the intent of their act. Examples of behavioral clues that may indicate a decision to carry out

suicidal intent include giving away prized possessions, getting financial affairs in order, writing suicide notes, and sudden lift in mood.

Verbal clues may be both direct and indirect. Examples of direct statements include "I want to die" or "I'm going to kill myself." Examples of indirect statements include "This is the last time you'll see me," "I won't be around much longer for the doctor to worry about," or "I don't have anything worth living for anymore."

Other assessments include determining whether the individual has a plan, and if so, whether he or she has the means to carry out that plan. If the person states the suicide will be carried out with a gun, does he or she have access to a gun? Bullets? If pills are planned, what kind of pills? Are they accessible? The lethality of the method identified by an individual with suicide ideation or by one who has already made an attempt provides meaningful information about the client's intent to die. Use of firearms, for

example, is considered a highly lethal method. Asking the client, "How likely are you to carry out this plan?" may provide verbal confirmation of their level of intent.

Interpersonal Support System

Does the individual have support persons on whom he or she can rely during a crisis situation? Lack of a meaningful network of satisfactory relationships may implicate an individual as a high risk for suicide during an emotional crisis.

Analysis of the Suicidal Crisis

Three aspects of assessment that enhance understanding of the client's current suicidal crisis are evaluation of the client's precipitating stressors, relevant history, and life stage issues.

- **The precipitating stressor:** Adverse life events in combination with other risk factors, such as depression, may lead to suicide. Life stresses accompanied by an increase in emotional disturbance include the loss of a loved one either by death or by divorce, problems in major relationships, changes in social or occupational roles, or serious physical illness.
- **Relevant history:** Has the individual experienced numerous failures or rejections that would increase his or her vulnerability for a dysfunctional response to the current situation?
- **Life stage issues:** The ability to tolerate loss and disappointment is often compromised if those losses and disappointments occur during stages of life in which the individual struggles with developmental issues (e.g., adolescence, midlife).

Psychiatric, Medical, and Family History

The individual should be assessed with regard to previous psychiatric treatment for depression, alcoholism, or previous suicide attempts. Medical history should be obtained to determine the presence of chronic, debilitating, or terminal illness. Is there a history of depressive disorder in the family, and has a close relative committed suicide in the past?

Coping Strategies

How has the individual handled previous crisis situations? How does this situation differ from previous ones?

Presenting Symptoms

Several acronyms have been developed as mnemonic devices to summarize important factors that may increase a person's risk for suicidal behavior. One of these is the acronym IS PATH WARM? (American Association of Suicidology, 2015; Juhnke, Granello,

& Lebrón-Striker, 2007). The assessment items and descriptors for each letter are as follows:

Ideation: Has suicide ideas that are current and active, especially with an identified plan

Substance abuse: Has current and/or excessive use of alcohol or other mood-altering drugs

Purposelessness: Expresses thoughts that there is no reason to continue living

Anger: Expresses uncontrolled anger or feelings of rage

Trapped: Expresses the belief that there is no way out of the current situation

Hopelessness: Expresses lack of hope and perceives little chance of positive change

Withdrawal: Expresses desire to withdraw from others or has begun withdrawing

Anxiety: Expresses anxiety, agitation, and/or changes in sleep patterns

Recklessness: Engages in reckless or risky activities with little thought of consequences

Mood: Expresses dramatic mood shifts

Mnemonic devices such as IS PATH WARM? can be helpful in remembering what types of presenting symptoms to assess for, but the overall assessment and management of suicidal behavior is far more complex and must consider available support systems, the client's willingness to accept support, and the client's ability to establish a trusting therapeutic alliance with health-care professionals intervening on his or her behalf.

The Collaborative Assessment and Management of Suicidality (CAMS) model is an evidence-based approach that focuses on the importance of patient-centered, problem-focused intervention to build an alliance with patients for collaboration in reducing risk for suicidal behavior (Jobes, 2012). This model focuses on assessment, which necessarily includes asking the patient to identify what is driving the desire to take his or her own life so that alternatives (identifying and capitalizing on motivations to live) can be explored. For all health-care professionals, this work begins with developing skill in asking basic and direct questions such as "Are you having thoughts of hurting or killing yourself?"

Beyond the basic questions of whether or not a person has suicidal ideas, a plan, and access to means, there must be recognition that patients are not always forthcoming or truthful in their answers to such questions. Several strategies for enhancing a collaborative, therapeutic relationship and communication about suicide assessment have been elaborated. Since nurses are often at the front line of this assessment in medical-surgical, emergency

department, outpatient care, schools, and other health-care settings, they must be thoughtful, comprehensive, and conscientious in this pursuit regardless of the practice setting and whether or not the patient has been identified as having mental health issues. Shea (2009) states that nurses need to assess not only what the client is directly stating about his or her suicidal intent (stated intent) but also the amount of thinking, planning, and behaviors associated with suicide ideation (reflected intent) and the suicide intent that is withheld from the nurse (withheld intent). A summary of guiding principles in suicide risk assessment are included in Table 17–2.

One model for enhancing communication in suicide assessment is the CASE (Chronological Assessment of Suicide Events) approach. It is described as a flexible guide for interviewing that includes communication techniques designed to elicit and enhance detailed, valid feedback from clients about sensitive topics such as suicide. Several examples, as elaborated by Shea (2009), follow:

■ *Normalizing* communicates that the client is not the only one who experiences suicidal ideation. Example: "Sometimes when people are in a lot of emotional pain, they have thoughts of killing themselves. Have you had any thoughts like that?"

TABLE 17–2 **Guiding Principles for Suicide Risk Assessment**	
PRINCIPLES	**EXPLANATION**
Screening for suicide risk should be conducted as an essential component of health assessment, and risk factors, warning signs, and threats should be taken seriously.	This includes identifying through detailed assessment the individual's unique situation to discern additional resources, consults, and interventions needed to ensure patient safety.
Establishment of a therapeutic relationship is foundational to effective suicide risk assessment.	This includes establishing trust through empathy and respect, which provides a safe environment for the client to tell his or her story.
Suicide risk assessment is complex and challenges the nurse to use many different communication strategies.	This includes exploring the client's thoughts, feelings, and behaviors from a variety of perspectives.
Suicide risk assessment is an ongoing process, and level of risk can increase or decrease over time.	This includes assessing over time for fluctuations in risk factors, changes in stress level, changes in intensity of ideation, changes in intention to act on suicide ideation, and changes in support systems.
Collaboration with the client and other sources of information facilitates confidence in clinical judgments.	This includes information provided by other people who are familiar with the client from home, work, or school and other clinical team members. Collaboration also implies that all those involved in the client's care are working together.
Suicide risk assessment uses direct rather than indirect language.	This includes using terminology such as "suicide" and "death" rather than "not happy with living" or other indirect statements. It also communicates to the client that these are acceptable topics to discuss.
Suicide risk assessment attempts to discern the underlying message.	This includes attempting to discern when the patient is communicating unbearable distress, feeling trapped, feeling hopeless, and/or feeling driven to avoid additional emotional or physical pain.
Suicide risk assessment considers cultural context.	This includes recognizing that anyone regardless of race, religion, or culture may be at risk for suicide. Some cultural or religious prohibitions may influence someone's willingness to openly discuss personal feelings.
Suicide risk assessment is documented in detail.	This includes risk factors, warning signs, underlying themes, level of risk, clinical judgments, and recommended interventions.

SOURCE: Adapted from Perlman, C.M., Neufeld, E., Martin, L., Goy, M., & Hirdes, J.P. (2011). Risk Assessment Inventory: A resource guide for Canadian healthcare organizations. Toronto: Ontario Hospital Association and Canadian Patient Safety Institute.

■ Asking about behavioral events rather than the client's opinions may elicit more concrete information. Example: "What did you do when you had those thoughts?" "How many pills did you take?" "What happened next?"

■ Gentle assumptions encourage further discussion by assuming there is more to tell. Example: "What other times have you attempted suicide?"

■ Denial of the specific is helpful when a client generally denies suicidal ideation. This strategy encourages more in-depth thought and response by asking questions that might trigger memories of specific events. Example: After the client denies suicidal ideation in response to a general question, the nurse asks more specifically, "Have you ever had thoughts of overdosing?" "Have you ever had thoughts about shooting yourself?"

■ Chronologically exploring the presenting suicide event, recent suicide events, past suicide events, and finally the immediate suicide events can broaden the nurse's understanding of the client's immediate suicidal intent in the context of his or her behavior over time.

Diagnosis and Outcome Identification

Nursing diagnoses for the suicidal client may include the following:

■ Risk for suicide related to feelings of hopelessness and desperation

■ Hopelessness related to absence of support systems and perception of worthlessness

Outcome Criteria

Outcome criteria include short- and long-term goals. Time lines are individually determined. The criteria that follow may be used for measurement of outcomes in the care of the suicidal client.

The client:

1. Has experienced no physical harm to self
2. Develops a safety plan and sets realistic goals for self
3. Expresses some optimism and hope for the future

Planning and Implementation

Table 17–3 provides a plan of care for the hospitalized client who is suicidal. Nursing diagnoses are presented, along with outcome criteria, appropriate nursing interventions, and rationales for each.

Intervention With the Client Who Is Suicidal Following Discharge or in an Outpatient Setting

In some instances, it may be determined that suicidal intent is low and that hospitalization is not required. Instead, the client with suicidal ideation may be treated in an outpatient setting. Guidelines for treatment of such clients on an outpatient basis include the following:

■ The person should have immediate access to support systems and be tied in to a system of care, as the term following hospital discharge is a high-risk period. Arrangements must be made for the client to stay with family or friends.

Table 17–3 | CARE PLAN FOR THE SUICIDAL CLIENT

NURSING DIAGNOSIS: RISK FOR SUICIDE
RELATED TO: Feelings of hopelessness and desperation

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALES
Client will not harm self.	1. Ask client directly: "Have you thought about harming yourself in any way? If so, what do you plan to do? Do you have the means to carry out this plan? How strong are your intentions to die?"	1. The risk of suicide is greatly increased if client has developed a plan with lethal means and particularly if means are accessible for client to execute the plan.
	2. Create a safe environment for client. Remove all potentially harmful objects from client's access (sharp objects, straps, belts, ties, glass items, alcohol). Supervise closely during meals and medication administration. Perform room searches as deemed necessary.	2. Client safety is a nursing priority.

Table 17–3 | CARE PLAN FOR THE SUICIDAL CLIENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALES
	3. Maintain close observation of client. Depending on level of suicide precaution, provide one-to-one contact, constant visual observation, or every-15-minute checks. Place in room close to nurse's station; do not assign to private room. Accompany to off-unit activities if attendance is indicated. May need to accompany to bathroom.	3. Close observation is necessary to ensure that client does not harm self in any way. Being alert for suicidal and escape attempts facilitates prevention or interruption of harmful behavior.
	4. Maintain special care in administration of medications.	4. Prevents saving up to overdose or discarding and not taking.
	5. Make rounds at frequent, *irregular* intervals (especially at night, toward early morning, at change of shift, or other predictably busy times for staff).	5. Prevents staff surveillance from becoming predictable. To be aware of client's location is important, especially when staff is busy and least available and observable.
	6. Encourage client to express honest feelings, including anger. Provide hostility release if needed.	6. Depression and suicidal behaviors may be viewed as anger turned inward on the self. If this anger can be verbalized in a nonthreatening environment, client may be able to eventually resolve these feelings.
Client develops a safety plan for management of suicidal thoughts and urges.	1. Establish a trusting, therapeutic relationship to encourage open discussion of suicide.	1. Establishing trust and open communications encourages client to share thoughts and feelings.
	2. Collaborate with client to develop a safety plan that includes recognition of warning signs, coping strategies, supportive people and places, resources and contact information for crisis management, and plans to restrict access to lethal means.	2. Development of a comprehensive **collaborative safety plan** concretizes resources and management strategies. Actively engaging the client in collaboration on the development of a safety plan promotes client ownership and investment in the process.
	3. Assess verbal and nonverbal clues to identify the likelihood that client intends to follow through with the established safety plan and evaluate client's follow-through with safety plan measures while still hospitalized.	3. Assessment of client safety includes analyzing congruence of verbal communication, nonverbal communication, and behavior.

Continued

Table 17–3 | CARE PLAN FOR THE SUICIDAL CLIENT–cont'd

NURSING DIAGNOSIS: HOPELESSNESS
RELATED TO: Absence of support systems and perception of worthlessness
EVIDENCED BY: Verbal cues (despondent content, "I can't"); decreased affect; lack of initiative; suicidal ideas or attempts

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALES
Client verbalizes a measure of hope and acceptance of life and situations over which he or she has no control.	1. Identify stressors in client's life that precipitated current crisis. Include assessing degree of emotional pain and hopelessness in relationship to feelings of connectedness or lack of connectedness with others.	1. It is important to identify causative or contributing factors in order to plan appropriate assistance.
	2. Determine coping behaviors previously used and client's perception of effectiveness then and now.	2. It is important to identify client's strengths and encourage their use in current crisis situation.
	3. Encourage client to explore and verbalize feelings and perceptions related to reasons for wanting to die as well as reasons for wanting to live.	3. Identification of feelings underlying behaviors helps client to begin process of taking control of own life and enables the nurse to help client focus on maximizing his or her reasons for wanting to live.
	4. Provide expressions of hope to client in positive, low-key manner (e.g., "I know you feel you cannot go on, but I believe that things can get better for you. What you are feeling is temporary. It is okay if you don't see it just now.").	4. Even though client feels hopeless, it is helpful to hear positive expressions from others. Client's current state of mind may prevent him or her from identifying anything positive in life. It is important to accept client's feelings nonjudgmentally and to affirm his or her personal worth and value.
	5. Help client identify areas of life situation that are under his or her own control.	5. Client's emotional condition may interfere with ability to problem solve. Assistance may be required to perceive benefits and consequences of available alternatives accurately.
	6. Identify sources that client may use after discharge when crises occur or feelings of hopelessness and possible suicidal ideation prevail.	6. Client should be informed of local suicide hotlines or other local support services from which he or she may seek assistance following discharge from hospital. A concrete plan provides hope in the face of a crisis situation.

If this is not possible, hospitalization should be reconsidered.

■ A detailed safety plan should be developed that is an outgrowth of a comprehensive risk assessment and a collaborative, problem-solving discussion with the client. This intervention explores with the client what he or she will do to stay safe if there is a repeat or increase in suicidal thoughts or urges.

See Box 17–2 for more on the essential components of a safety plan.

■ A safety plan should not be confused with a no-suicide contract. See Box 17–3 to learn about issues associated with this type of document.

■ Enlist the help of family or friends to ensure that the home environment is safe from dangerous items, such as firearms or stockpiled drugs. Give

---

BOX 17–2 Essential Components of a Safety Plan

According to Stanley and Brown (2008, pp. 3–4), the essential components of a safety plan include nursing support and assistance for the following:

1. Recognizing warning signs that precede suicide crises
2. Identifying and employing internal coping strategies that the client can implement without needing to contact additional support people
3. Identifying supportive family members and friends with whom he or she can discuss suicide and who may help resolve a potential crisis
4. Identifying people and healthy social settings that he or she can use for general support and distraction from suicidal thoughts and urges
5. Identifying resources and contact information for mental health professionals and agencies when needed in an escalating crisis situation
6. Problem-solving with the client ways to reduce the potential for access to and use of lethal means

Once the safety plan is elaborated with the client, an evaluation of the appropriateness of the plan and a collaborative assessment of the likelihood that the client will implement this plan should be conducted.

Assessment for suicidal risk and responsive intervention must be ongoing, as suicidal ideas and intent may change over hours, days, or longer time periods. The need for revision of the safety plan may become evident. Critical times for reassessment of risk and reevaluation of the safety plan (Hoffman, 2013) include the following:

1. When there is a change in the client's clinical presentation or worsening of symptoms
2. When medications or treatments are changed
3. When significant others identify an increase in concern
4. When a client stops treatment

BOX 17–3 The Issue of No-Suicide Contracts

A critical issue that needs to be understood is that of no-suicide contracts, sometimes called *safety contracts,* a strategy used by some clinicians in the context of a long-term, therapeutic relationship in which the client "promises" to contact the clinician before acting on suicidal ideation. No-suicide contracts are not the same as the development of a thorough safety plan. Contracting with a client is a controversial and often misused strategy (Hoffman, 2013; Shea, 2009). Evidence has not supported the efficacy of this method as a primary intervention (Drew, 2001; Freedenthal, 2013; Rudd, Mandrusiak, & Joiner, 2006). In fact, it may even be counterproductive in clients with borderline or passive-aggressive pathology (Shea, 2009). Such contracts should *never* be used in short-term encounters with clients, such as in emergency departments or during brief hospital stays, or with clients who are unknown, agitated, psychotic, impulsive, or under the influence of drugs and alcohol (Hoffman, 2013). They should never be used with the presumption that they will deter a client from attempting

suicide. Shea adds that if clinicians use a safety contract with the belief that it will be a deterrent to suicide, they should understand that it not only "guarantees nothing [but also] may yield a false sense of security" among clinicians (2009, p. 21). The consequential danger is that clinicians may become less watchful or feel less need to reassess the client, thus missing critical signs of increasing suicide risk. Outside of practicing therapy in an advanced practice role, nurses should avoid no-suicide contracting altogether. Even in the conduct of therapy, it should be used with great caution and for limited, specific assessment purposes.

In general, it is important to recognize that not all suicidal individuals are alike, so interventions should be multifaceted, and suicide prevention plans should be comprehensive. Many models and tools for suicide assessment have been developed. One such model, SAFE-T (**S**uicide **A**ssessment **F**ive-step **E**valuation and **T**riage), summarizes the key elements in suicide assessment (see Box 17–4).

support persons the telephone number of the counselor or an emergency contact person in the event that the counselor is not available.

■ Appointments may need to be scheduled daily or every other day at first until the immediate suicidal crisis has subsided.

■ Establish rapport and promote a trusting relationship. It is important for the suicide counselor to become a key person in the client's support system at this time.

■ Accept the client's feelings in a nonjudgmental manner.

> **CLINICAL PEARL** Be direct. Talk openly and matter-of-factly about suicide. Listen actively and encourage expression of feelings, including anger.

■ Discuss the current crisis situation in the client's life using the problem-solving approach. Offer alternatives to suicide while at the same time empathizing with the client's pain that led to viewing suicide as an option (Jobes, 2012). An example of this kind of communication might be:

"I understand how this emotional pain you've been experiencing led you to consider suicide, but I'd like to explore with you some alternative ways to decrease your pain and to identify some reasons for continuing to live."

■ Help the client identify areas of life that are within his or her control and those that cannot be controlled. Discuss feelings associated with these control issues. It is important for the client to feel some control over his or her life situation in order to perceive a measure of self-worth.

■ The physician or nurse practitioner may prescribe antidepressants for an individual who is experiencing suicidal depression. It is wise to prescribe no more than a three-day supply of the medication with no refills. The prescription can then be renewed at the client's next counseling session.

NOTE: Sadock and associates (2015) have stated:

Patients with depressive disorders are at increased risk of suicide as they begin to improve and regain the energy needed to plan and carry out a suicide (paradoxical suicide). It is usually unwise to give a depressed patient a prescription for a large number of antidepressants, especially tricyclic drugs, at the time of hospital discharge. (p. 366)

■ Psychological interventions that have demonstrated effectiveness in reducing suicidal behavior include dialectical behavior therapy, cognitive-behavioral therapy, and CAMS (Jobes, 2015).

Single interventions, including hospitalization, medication alone, and no-suicide contracts, are not supported by evidence as effective in reducing suicides (Jobes, 2015). Clients need to be actively engaged as partners in each step of the assessment and intervention process.

Information for Family and Friends of the Suicidal Client

The following suggestions are recommended for family and friends of an individual who is suicidal:

■ Take any hint of suicide seriously. Anyone expressing suicidal feelings needs immediate attention.

■ Do not keep secrets. If a suicidal person says, "Promise you won't tell anyone," do not make that promise. Suicidal individuals are ambivalent about dying, and suicidal behavior is a cry for help. It is that ambivalence that leads the person to confide to you the suicidal thoughts. Get help for the person and for yourself. 1-800-SUICIDE is a national hotline that is available 24 hours a day.

■ Be a good listener. If a person expresses suicidal thoughts or feels depressed, hopeless, or worthless, be supportive. Let the person know you are there for him or her and are willing to help the person seek professional help.

■ Many people find it awkward to put into words how another person's life is important for their own well-being, but it is important to stress that the person's life is important to you and to others. Emphasize in specific terms the ways in which the person's suicide would be devastating to you and to others.

■ Express concern for an individual who expresses thoughts about suicide. The individual may make veiled comments or comments that sound as if he or she is joking, or the person may be withdrawn and reluctant to discuss his or her thoughts and feelings. In each case, ask questions, acknowledge the person's pain and feelings of hopelessness, and encourage the individual to talk to someone else if he or she does not feel comfortable talking with you.

■ Familiarize yourself with suicide intervention resources, such as mental health centers and suicide hotlines.

■ Ensure that access to firearms or other means of self-harm is restricted.

■ Communicate caring and commitment to provide support. Fleener (2013) offers the following specific suggestions for families and friends when interacting with someone who is suicidal.
  ■ Acknowledge and accept the person's feelings, and be an active listener.
  ■ Try to give the person hope, and remind the person that what he or she is feeling is temporary.

- Stay with the person. Do not leave the person alone. Go to where he or she is, if necessary.
- Show love and encouragement. Hold the person, hug him or her, touch him or her. Allow the person to cry and express anger.
- Help the person seek professional help.
- Remove any items from the home with which the person may harm himself or herself.
- If there are children present, try to remove them from the home. Perhaps a friend or relative can assist by taking the children to their home. This type of situation can be extremely traumatic for children.
- DO NOT judge suicidal people, show anger toward them, provoke guilt in them, discount their feelings, or tell them to "snap out of it." This is a very real and serious situation to individuals experiencing suicidal ideation. They are in real pain. They feel the situation is hopeless and that there is no other way to resolve it aside from suicide.

Intervention With Families and Friends of Suicide Victims

Suicide of a family member can induce a whole gamut of feelings in the survivors. It has long been recognized that the bereavement process for families in which a member has taken his or her own life is complicated and requires an understanding by health-care providers of the unique burdens of this type of loss. Macnab (1993) identified the following symptoms that may be evident after the suicide of a loved one:

- A sense of guilt and responsibility
- Anger, resentment, and rage that can never find its "object"

BOX 17–4 SAFE-T: Suicide Assessment Five-Step Evaluation and Triage

1. Identify risk factors
   Note those that can be modified to reduce risk.
2. Identify protective factors
   Note those that can be enhanced.
3. Conduct suicide inquiry
   Evaluate suicidal thoughts, plans, behavior, and intent.
4. Determine risk level and intervention
   Choose appropriate intervention to address and reduce level of risk.
5. Document
   Record assessment of risk, rationale, intervention, and follow-up.

SOURCE: Reprinted from U.S. Department of Health and Human Services, Substance Abuse and Mental Health Services Administration, www.samhsa.gov.

- A heightened sense of emotionality, helplessness, failure, and despair
- A recurring self-searching: "If only I had done something," "If only I had not done something," "If only . . ."
- A sense of confusion and search for an explanation: "Why did this happen?" "What does it mean?" "What could have stopped it?" "What will people think?"
- A sense of inner injury; the family feels wounded and does not know how they will ever get over it and get on with life
- A severe strain placed on relationships; a sense of impatience, irritability, and anger among family members
- A heightened feeling of vulnerability to illness and disease with this added burden of emotional stress

Read "Real People, Real Stories" for a better understanding of one person's lived experience of losing a child to suicide. Strategies for assisting survivors of suicide victims include the following:

- Encourage the clients to talk about the suicide, each responding to the others' viewpoints and reconstructing of events. Share memories.
- Be aware of any blaming or scapegoating of specific family members. Discuss how each person fits into the family situation, both before and after the suicide.
- Listen to feelings of guilt and self-persecution. Gently move the individuals toward the reality of the situation.
- Encourage the family members to discuss individual relationships with the lost loved one. Focus on both positive and negative aspects of the relationships. Gradually point out the irrationality of any idealized concepts of the deceased person. The family must be able to recognize both positive and negative aspects about the person before grief can be resolved.
- No two people grieve in the same way. It may appear that some family members are overcoming the grief faster than others. All family members must be made to understand that if this occurs, it is not because those family members care less—it is just that they grieve differently. Variables that enter into this phenomenon include individual past experiences, personal relationship with the deceased person, and individual temperament and coping abilities.
- Recognize how the suicide has caused disorganization in family coping. Reassess interpersonal relationships in the context of the event. Discuss coping strategies that have been successful in times of stress in the past, and work to reestablish these strategies within the family. Identify new adaptive coping strategies that can be incorporated.

Real People, Real Stories: Surviving the Loss of a Loved One to Suicide

Losing a loved one to suicide results in a grief process often complicated by stigma, misinformation, lack of information, and sometimes a sense of alienation from others. Emmy's story describes her ongoing journey to grapple with the loss of her son to suicide.

Karyn: We've talked before, but tell me more about your journey since Paul's death.

Emmy: My son Paul died in 1986 at age 17. The thing I remember most is that no one was talking about it. There were 10 students who died in his high school. Two others were known to be suicides.

Karyn: Do you mean no one was talking about it in the school system?

Emmy: Well, the students in Paul's class took up a collection that was for Paul, but the school couldn't decide how to use it, so it just sat there for the longest time. My other son heard they were going to use the money for supplies, so I went and talked to them to make sure that didn't happen. The school eventually built a memorial garden that became dedicated to all of the students who had died.

Paul died in June, and in August, when all the other students were returning to school, I got a call from a community suicide survivors counselor who told me she was holding a high school assembly to discuss suicide. I wanted her to talk to the ninth and tenth graders, but they wouldn't permit it. I thought the younger kids needed to talk about and learn about this too—they had been my younger son's classmates, and they were affected by it as well. When the suicide counselor intervened, the teachers were told to watch Paul's friends for any evidence of "copycat" behavior, but that was all. I felt the school administration thought there was a stigma in talking about the cause of his death. I found out later that the seniors were talking about and memorializing Paul in their study halls. They were remembering him as a friend who was missed.

Karyn: How has your family coped with Paul's death?

Emmy: We didn't talk about Paul for the longest time; it was as if he didn't exist. We were very separate; we all went in our own directions. My husband started taking long bicycle trips, and he worked on a suicide hotline. I got very involved with offering a program for high school students called Listening POST (people offering students time), which allowed students to talk about anything they wanted to.

Karyn: I know you've told me that you're still close to several of Paul's peers.

Emmy: Oh yes, and their children too. But our family just became very separate. I don't even know how my other son got through his freshman year of high school. We went to a suicide survivors group as a family, and it was important to me as an outlet to talk, but we didn't talk as a family . . . and then we just stopped going, and the people who knew Paul didn't talk to us. I *so* wanted to talk to people who knew Paul.

After we stopped going to the survivors group, I started going to CoDA [Co-Dependents Anonymous] meetings, even though I don't think I'm codependent. It was more because I needed to talk . . . to understand how this happened. I felt like I wasn't there for him. . . . I was busy with my job and maybe I wasn't tuned in to his moods. I was always taught that boys don't like to talk about feelings.

Karyn: Yes, I guess I've been taught that, too.

Emmy: I just remember that night he told his dad and I that he loved us, he went to bed, and the next morning we found him. I just couldn't make sense of it. Years later, one of Paul's peers, who now has a teenage son, said he could finally tell me what he remembered. And there were signs. Apparently, he had said to some friends (while they were drinking alcohol), "Have you ever thought of killing yourself?" and they all laughed about it and nothing more was said. I also found out that he told an older peer, whom he had met at church camp, that he didn't want to live. The peer smacked him and told him if he ever had thoughts like that again that

Real People, Real Stories: Surviving the Loss of a Loved One to Suicide–cont'd

he [Paul] needed to come talk to him first. But they never told anyone else; they kept it among their peers. They thought they were all-knowing, and never told an adult. He was hysterical when he found out what happened.

On that last weekend, he had been partying with his friends . . . there was alcohol involved . . . and the friend that was with him told me that someday he would tell me what went down that day. But it's 30 years later, and I still don't know. I know he was at the party with a girl, but I've never been able to find her or talk with her. She went to a different school.

Karyn: And much of this information that you do know came 10 or more years after his death?

Emmy: Yes.

Karyn: What a long journey you've been on trying to put all the pieces together

Emmy: (tearful) That's exactly it. Trying to put the pieces together, sort it out . . . but it never gets solved. . . . It's like being in a maze and you can't get out, and I had a lot of guilt. . . . Now I recognize that he just made some tragic bad choices.

Karyn: Appreciating that we don't "get over" such tremendous loss but rather amend our lives with some different understanding of love and loss, what has been most helpful in your healing?

Emmy: Yes, I think there was a point when I realized it was okay to feel some happiness. Being with people who don't know me makes it easier. My faith and fellowship group has been an important part of healing. CoDA was helpful because we talked about how different people process things, and I could understand better how

people can get stuck. I used to say that my other son had lost his brother. I couldn't say that I had lost a son. When I had to fill out a health assessment at one point, and I had to respond to the question of how many pregnancies I'd had, that was the most difficult question . . . because I had to acknowledge . . . the reality. And I involved myself with all the boys who were on the track team with Paul and the Listening POST and just talked about everything.

Karyn: What is the most important thing that nurses need to know?

Emmy: By the time we would have had any contact with nurses, it was too late. There were no ER, medical, or mental health visits prior to that. If they were to have an impact, it would have been in prevention in the schools. For example, I didn't know at that time to ask questions like, "Are you having thoughts of hurting yourself?" and "Do you have a plan in mind?" And Paul put on a different face for me. He wasn't solitary; he had lots of friends; he was active on the track team. . . .

Karyn: I think you're not alone with not having been taught about things like suicide assessment. Because, as you've said, historically people haven't talked about it. There is an organization called Red Flags National that promotes mental health education for students, parents, and teachers as a standard part of health education in schools.

Emmy: Yes. It needs to be talked about. It's been helpful for me to talk about it even now. I've never had to try to explain the story before.

To learn more about Red Flags National, go to www.redflags.org.

■ Identify resources that provide support: religious beliefs and spiritual counselors, close friends and relatives, support groups for survivors of suicide. One online connection that puts individuals in contact with survivors' groups specific to each state is the American Foundation for Suicide Prevention at www.afsp.org. A list of resources that provide information and help for issues regarding suicide is presented in Box 17–5.

Evaluation

Evaluation of the client who is suicidal is an ongoing process accomplished through continuous reassessment and determination of goal achievement. Once

the immediate crisis has been resolved, extended psychotherapy may be indicated. The long-term goals of individual or group psychotherapy for the client would be for him or her to:

■ Develop and maintain a more positive self-concept.
■ Learn more effective ways to express feelings to others.
■ Achieve successful interpersonal relationships.
■ Feel accepted by others and achieve a sense of belonging.

A person contemplating suicide feels worthless and hopeless. These goals serve to instill a sense of self-worth while offering a measure of hope and a meaning for living.

Summary and Key Points

■ More than 90 percent of all persons who attempt or die by suicide have a diagnosed mental disorder.

■ Suicide is the second-leading cause of death among young Americans aged 15 to 34 years, the fourth-leading cause of death for those aged 35 to 44, and the fifth-leading cause of death for individuals aged 45 to 64. Based on recent statistics, the highest rates of suicide among all age groups occurred among those 45 to 64 years of age followed by those 85 years of age and older.

■ Single (never married), divorced, and widowed people may be at greater risk for suicide than married people, but evidence supports that recent change in status is a proximal risk factor

■ More women than men attempt suicide, but men succeed more often.

■ Depressed men and women who consider themselves affiliated with a religion are less likely than their nonreligious counterparts to attempt suicide.

■ Individuals in the very highest and lowest social classes have higher suicide rates than those in the middle classes.

■ Whites are at highest risk for suicide, followed by American Indians and Alaska Natives, Hispanic Americans, Asian Americans, and African Americans.

■ Psychiatric disorders that predispose individuals to suicide include mood disorders, substance use disorders, schizophrenia, anorexia nervosa, borderline and antisocial personality disorders, and anxiety disorders.

■ Predisposing factors include internalized anger, hopelessness and other symptoms of severe depression, history of aggression and violence, shame and humiliation, developmental stressors, sociological influences, genetics, and neurochemical factors.

■ Suicide risk assessment should be a patient-centered, collaborative process in the context of a therapeutic relationship and should chronologically explore presenting suicide events, recent events, past events, and immediate intentions.

■ Assessment of the level of intervention needed includes identifying the number of proximal or potentiating risks as well as the number of warning signs.

■ It is important for the nurse to determine the seriousness of the client's suicidal intentions, the existence of a plan, and the availability and lethality of the method.

■ The suicidal person should not be left alone.

■ A safety plan is developed with the client following a comprehensive suicide risk assessment and includes assisting the client to recognize warning signs, identify and employ internal coping strategies, engage family members and friends as available support persons, identify people and social settings that can be used to distract from suicidal thoughts or urges, identify resources and contact information for crisis intervention, and problem-solve ways to restrict access to lethal means.

■ Once the crisis intervention is complete, the individual may require long-term psychotherapy, during which he or she works to:
  ■ Develop and maintain a more positive self-concept.
  ■ Learn more effective ways to express feelings.
  ■ Improve interpersonal relationships.
  ■ Achieve a sense of belonging and a measure of hope for living.

■ Evidence-based psychological interventions include dialectical behavior therapy, cognitive-behavioral therapy, and the CAMS approach.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Which of the following individuals is at highest risk for a suicide attempt?
   a. John, who reports he is in deep emotional pain, feels hopeless, and says "No one is there for me."
   b. Kelly, who has been seeing a doctor for chronic, intractable pain and is taking pain medication.
   c. Jim, an American Indian who just graduated from high school with honors.
   d. Mike, a physician who reports feeling "burnt out" and is considering retirement.

2. The nurse in the emergency department encounters a patient, Niko, who is expressing suicide ideation. The nurse recognizes that which of the following considerations are important to good suicide risk assessment? (Select all that apply.)
   a. Collaborating with the patient
   b. Asking specific questions about leisure activities
   c. Establishing trust and open communication with the patient
   d. Asking the patient specific questions about the strength of his intention to die
   e. Identifying whether the patient has thought about a plan for trying to kill himself

3. Theresa, age 27, was admitted to the psychiatric unit from the medical intensive care unit where she was treated for taking a deliberate overdose of her antidepressant medication, trazodone (Desyrel). She says to the nurse, "My boyfriend broke up with me. We had been together for six years. I love him so much. I know I'll never get over him." Which is the best response by the nurse?
   a. "You'll get over him in time, Theresa."
   b. "Forget him. There are other fish in the sea."
   c. "You must be feeling very sad about your loss."
   d. "Why do you think he broke up with you, Theresa?"

4. The nurse identifies the primary nursing diagnosis for Theresa as Risk for suicide related to feelings of hopelessness from loss of relationship. Which is the outcome criterion that would be most appropriate for this diagnosis?
   a. The client has experienced no physical harm to herself.
   b. The client sets realistic goals for herself.
   c. The client expresses some optimism and hope for the future.
   d. The client has reached a stage of acceptance in the loss of the relationship with her boyfriend.

Review Questions—cont'd
Self-Examination/Learning Exercise

5. Theresa is hospitalized following a suicide attempt after breaking up with her boyfriend. Freudian psychoanalytic theory would explain Theresa's suicide attempt in which of the following ways?
   a. She feels hopeless about her future without her boyfriend.
   b. Without her boyfriend, she feels like an outsider with her peers.
   c. She is feeling intense guilt because her boyfriend broke up with her.
   d. She is angry at her boyfriend for breaking up with her and has turned the anger inward on herself.

6. Theresa is hospitalized following a suicide attempt after breaking up with her boyfriend. Theresa says to the nurse, "When I get out of here, I'm going to try this again, and next time I'll choose a no-fail method." Which is the best response by the nurse?
   a. "You are safe here. We will make sure nothing happens to you."
   b. "You're just lucky your roommate came home when she did."
   c. "What exactly do you plan to do?"
   d. "I don't understand. You have so much to live for."

7. In determining degree of suicidal risk with a client, the nurse assesses the following behavioral manifestations: severely depressed, withdrawn, statements of worthlessness, difficulty accomplishing activities of daily living, no close support systems. The nurse identifies the client's risk for suicide as which of the following?
   a. Low risk
   b. High risk
   c. Imminent risk
   d. Unable to be determined

8. Theresa, who has been hospitalized following a suicide attempt, is placed on suicide precautions on the psychiatric unit. She admits that she is still feeling suicidal. Which of the following interventions are most appropriate in this instance? (Select all that apply.)
   a. Restrict access to any item that might be harmful by placing the client in a seclusion room.
   b. Check on Theresa every 15 minutes at irregular intervals, or assign a staff person to stay with her on a one-to-one basis.
   c. Obtain an order from the physician to give Theresa a sedative to calm her and reduce suicide ideas.
   d. Do not allow Theresa to participate in any unit activities while she is on suicide precautions.
   e. Ask Theresa specific questions about her thoughts, plans, and intentions related to suicide.

9. Which of the following interventions are appropriate for a client on suicide precautions? (Select all that apply.)
   a. Remove all sharp objects, belts, and other potentially dangerous articles from the client's environment.
   b. Accompany the client to off-unit activities.
   c. Reassess intensity of suicidal thoughts and urges on a regular basis.
   d. Put all of the client's possessions in storage and explain to her that she may have them back when she is off suicide precautions.

10. Success of long-term psychotherapy with Theresa (who attempted suicide following a break-up with her boyfriend) could be measured by which of the following behaviors?
   a. Theresa has a new boyfriend.
   b. Theresa has an increased sense of self-worth.
   c. Theresa does not take antidepressants anymore.
   d. Theresa told her old boyfriend how angry she was with him for breaking up with her.

Communication Exercises

1. Mr. J. was brought to the emergency department by his brother, who is concerned about Mr. J.'s worsening depression. During the assessment, Mr. J. tells the nurse, "None of this matters. There's nothing that can make this any better." What would be an appropriate response by the nurse?

2. Mr. J. admits to the nurse that he has had suicidal ideas for the last couple of weeks. How would the nurse intervene with Mr. J. at this point?

3. Mr. J. tells the nurse that ever since his wife died 3 months ago, he does not want to go on living. What would be an example of empathic communication in response to this statement by Mr. J.?

Behavior Therapy

CHAPTER OUTLINE

KEY TERMS

aversive stimulus

classical conditioning

conditioned response

conditioned stimulus

contingency contracting

covert sensitization

discriminative stimuli

extinction

flooding

modeling

negative reinforcement

operant conditioning

overt sensitization

positive reinforcement

Premack principle

reciprocal inhibition

shaping

stimulus generalization

systematic desensitization

time-out

token economy

unconditioned response

unconditioned stimulus

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss the principles of classical and operant conditioning as foundations for behavior therapy.
2. Identify various techniques used in the modification of client behavior.
3. Implement the principles of behavior therapy using the steps of the nursing process.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. A mother is teaching her young child how to dress himself. Each time he makes an attempt, she praises him profusely, even though he has made several mistakes. She does this until he is able to dress himself appropriately. What is this technique called?
2. Flooding (implosive therapy) is used to desensitize individuals to phobic stimuli. When is this technique contraindicated?
3. A nurse is working with parents of a toddler whom they say falls to the ground, screams, and kicks his legs whenever he does not get his way. They usually just give in to his wishes to keep him from behaving this way. The nurse decides to teach the parents about the technique of extinction. What would this entail?

A behavior is considered maladaptive when it is age inappropriate, interferes with adaptive functioning, or is misunderstood by others in terms of cultural inappropriateness. In the behavioral approach to therapy, behavior and personality develop through learning processes or, more correctly, through the interaction of the environment with an individual's genetic endowment. The basic assumption of this approach is that problematic behaviors occur when there has been inadequate learning and therefore can be corrected through the provision of appropriate learning experiences. The principles of behavior therapy as we know it today are based on the early studies of **classical conditioning** by Pavlov (1927) and **operant conditioning** by Skinner (1938). Although in this text the concepts are presented separately for reasons of clarification, behavioral change procedures are often combined with cognitive procedures *(cognitive behavior therapy)* and with issues related to emotional regulation *(dialectical behavior therapy)*. Concepts of cognitive therapy are presented in Chapter 19, Cognitive Therapy.

Classical Conditioning

Classical conditioning is a process of learning introduced by the Russian physiologist Ivan Pavlov. In his experiments with dogs, during which he hoped to learn more about the digestive process, he inadvertently discovered that organisms can learn to respond in specific ways if they are conditioned to do so. Pavlov found that, as expected, the dogs salivated when they began to eat the food offered to them, a reflexive response that Pavlov called an **unconditioned response.** However, he also noticed that with time, the dogs began to salivate when the food came into their range of view, before it was even presented to them for consumption. Pavlov, concluding that this response was not reflexive but had been learned, called it a **conditioned response.** He carried the experiments even further by introducing an unrelated stimulus, one that had had no previous connection to the animal's food. He simultaneously presented the food with the sound of a bell. The animal responded with the expected reflexive salivation to the food. After a number of trials with the combined stimuli (food and bell), Pavlov found that the reflexive salivation began to occur when the dog was presented with the sound of the bell in the absence of food.

CORE CONCEPT

Stimulus

A stimulus is an environmental event that interacts with and influences an individual's behavior.

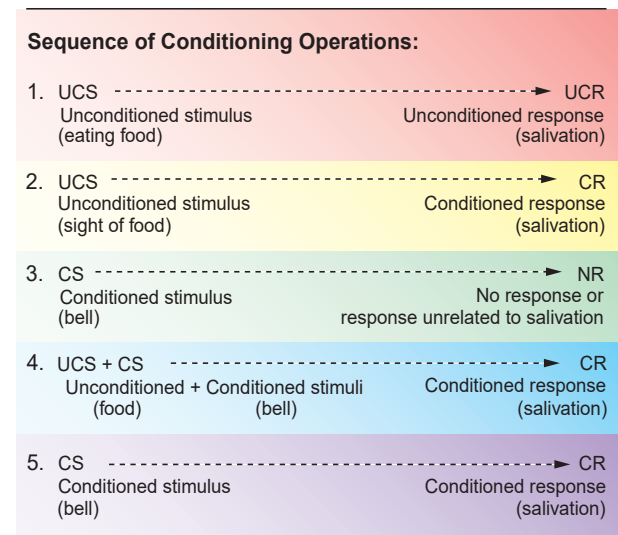
Pavlov's discovery was important in terms of how learning can occur. Pavlov found that unconditioned responses (salivation) occur in response to unconditioned stimuli (eating food). He also found that, over time, an unrelated stimulus (sound of the bell) introduced with the **unconditioned stimulus** can elicit the same response alone—that is, the conditioned response. The unrelated stimulus is called the **conditioned stimulus.** A graphic of Pavlov's classical conditioning model is presented in Figure 18–1. An example of the application of Pavlov's classical conditioning model to humans is shown in Figure 18–2. The process by which the fear response is elicited from similar stimuli (all individuals in white uniforms) is called **stimulus generalization.**


FIGURE 18–1 Pavlov's model of classic conditioning.
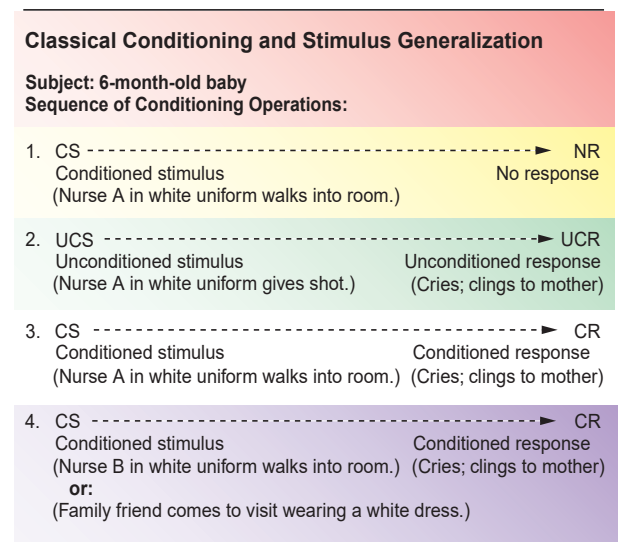

FIGURE 18–2 Example: Classical conditioning and stimulus generalization.

Operant Conditioning

The focus of operant conditioning differs from that of classical conditioning. With classical conditioning, the focus is on behavioral responses elicited by specific objects or events. With operant conditioning, additional attention is given to the consequences of the behavioral response.

Operant conditioning was introduced by B. F. Skinner (1953), an American psychologist whose work was largely influenced by Edward Thorndike's (1911) law of effect—that is, that the connection between a stimulus and a response is strengthened or weakened by the consequences of the response. A number of terms must be defined in order to understand the concept of operant conditioning.

As defined previously, stimuli are environmental events that interact with and influence an individual's behavior. Stimuli may precede or follow a behavior. A stimulus that follows a behavior (or response) is called a reinforcing stimulus, or *reinforcer*. The function is called *reinforcement*. When the reinforcing stimulus increases the probability that the behavior will recur, it is called a *positive reinforcer,* and the function is called **positive reinforcement. Negative reinforcement** increases the probability that a behavior will recur by removal of an undesirable reinforcing stimulus. A stimulus that follows a behavioral response and decreases the probability that the behavior will recur is called an **aversive stimulus,** or *punisher*. Examples of these reinforcing stimuli are presented in Table 18–1.

Stimuli that precede a behavioral response and predict that a particular reinforcement will occur are called **discriminative stimuli.** Discriminative stimuli are under an individual's control. He or she is able to *discriminate* between stimuli and *choose* according to the type of reinforcement he or she has come to associate with a specific stimulus. The following is an example of the concept of discrimination:

EXAMPLE

Mrs. M. was admitted to the hospital from a nursing home 2 weeks ago. She has no family, and no one visits her. She is very lonely. Nurse A and Nurse B have taken care of Mrs. M. on a regular basis during her hospital stay. When she is feeling particularly lonely, Mrs. M. calls Nurse A to her room, for she has learned that Nurse A will stay and talk to her for a while, but Nurse B only takes care of her physical needs and leaves. She no longer seeks out Nurse B for emotional support and comfort.

After several attempts, Mrs. M. is able to discriminate between stimuli. She can predict with assurance that calling Nurse A (and not Nurse B) will result in the reinforcement she desires.

CORE CONCEPT

Behavior Therapy
A form of psychotherapy that aims to modify maladaptive behavior patterns by reinforcing more adaptive behaviors.

Techniques for Modifying Client Behavior

Shaping

In **shaping** the behavior of another, reinforcements are given for increasingly closer approximations to the desired response. For example, in eliciting speech from an autistic child, the teacher may first reward the child for (a) watching the teacher's lips, then (b) making any sound in imitation of the teacher, then (c) forming sounds similar to the word uttered by the teacher. Shaping has been shown to be an effective way of modifying behavior for tasks that a child has not mastered on command or are not in the child's repertoire (Souders et al., 2002).

Modeling

Modeling refers to the learning of new behaviors by imitating the behavior in others. Role models are individuals who have qualities or skills that a person admires and wishes to imitate. Modeling occurs in various ways. Children imitate the behavior patterns of their parents, teachers, friends, and others. Adults and children alike model many of their behaviors after individuals observed on television and in movies. Unfortunately, modeling can result in maladaptive behaviors as well as adaptive ones.

TABLE 18–1 **Examples of Reinforcing Stimuli**			
TYPE	STIMULUS	BEHAVIORAL RESPONSE	REINFORCING STIMULUS
Positive	Messy room	Child cleans her messy room.	Child gets allowance for cleaning room.
Negative	Messy room	Child cleans her messy room.	Child does not receive scolding from the mother.
Aversive	Messy room	Child does not clean her messy room.	Child receives scolding from the mother.

In the practice setting, clients may imitate the behaviors of practitioners who are charged with their care. This can occur naturally in the therapeutic community environment. It can also occur in a therapy session in which the client watches a model demonstrate appropriate behaviors in a role-play of the client's problem. The client is then instructed to imitate the model's behaviors in a similar role-play and is positively reinforced for appropriate imitation.

Premack Principle

This technique, named for its originator, states that a frequently occurring response (R_1) can serve as a positive reinforcement for a response (R_2) that occurs less frequently (Premack, 1959). The **Premack principle** is applied by allowing R_1 to occur only after R_2 has been performed. That is, to encourage more of a particular behavior that an individual is not doing very often, a situation is created in which the person must perform that behavior *before* being permitted to do the "fun stuff" that he or she prefers to do. The person's preferred behavior becomes a reinforcement for accomplishing the desired behavior change. For example, 13-year-old Jennie has been neglecting her homework for the past few weeks. She spends a lot of time on her cell phone talking to her friends. Applying the Premack principle, being allowed to talk on the cell phone to her friends could serve as a positive reinforcement for completing her homework. A schematic of the Premack principle for this situation is presented in Figure 18–3.

Extinction

Extinction is the gradual decrease in frequency or disappearance of a response when the positive reinforcement is withheld. A classic example of this technique is its use with children who have temper tantrums. The tantrum behaviors continue as long as the parent gives attention to them but decrease and often disappear when the parent simply walks away from the child and ignores the behavior.

Contingency Contracting

In **contingency contracting,** a contract is drawn up among all parties involved. The desired behavior change and specified reinforcers for performing this behavior are stated explicitly in writing. The negative consequences, or punishers, that will be rendered for not fulfilling the terms of the contract are also delineated. The contract is specific about how reinforcers and punishment will be presented; however, flexibility is important so that renegotiations can occur if necessary.

Token Economy

Token economy is a type of contingency contracting in which the reinforcers for desired behaviors are presented in the form of *tokens*. Essential to this technique is the prior determination of items and situations of significance to the client that can be employed as reinforcements. With this therapy, tokens are awarded when desired behaviors are performed and may be exchanged for designated privileges. For example, a client may be able to "buy" a snack or cigarettes for 2 tokens, a trip to the coffee shop or library for 5 tokens, or even a trip outside the hospital (if that is a realistic possibility) for another designated number of tokens. The use of token economies was developed in the 1950s as a strategy for reinforcing desirable behaviors in long-term hospitalized patients with schizophrenia and, despite studies demonstrating their effectiveness in reinforcing adaptive behaviors, they have fallen out of favor over time (Dickerson, Tenhula, & Green-Paden, 2005). A recent review of token economy (Doll, McLaughlin, & Barretto, 2013) as a behavior modification strategy points out that most of the research predates the 1990s and that it may have meaningful current application with the advent of more research on its use in contemporary settings and therapies.

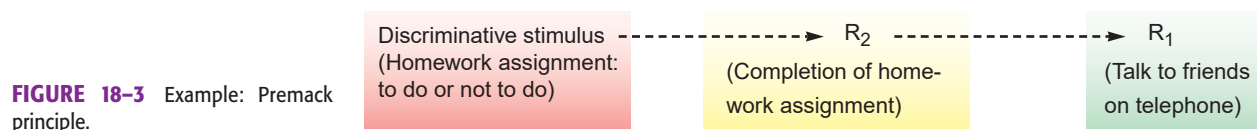
Time-Out

Time-out is an aversive stimulus or punishment during which the client is removed from the environment where the unacceptable behavior is being exhibited. The client is usually isolated so that reinforcement from the attention of others is absent.

Reciprocal Inhibition

Also called *counterconditioning,* **reciprocal inhibition** decreases or eliminates a behavior by introducing a more adaptive behavior, but one that is incompatible with the unacceptable behavior (Wolpe, 1958). An example is the introduction of relaxation exercises to an individual who is phobic. Relaxation is practiced in the presence of anxiety so that in time the individual is able to manage the anxiety in the presence of the phobic stimulus by engaging in

FIGURE 18–3 Example: Premack principle.

Discriminative stimulus (Homework assignment: to do or not to do) - - - → R_2 (Completion of homework assignment) - - - → R_1 (Talk to friends on telephone)


relaxation exercises. Relaxation and anxiety are incompatible behaviors.

Overt Sensitization

Overt sensitization is a type of aversion therapy that produces unpleasant consequences for undesirable behavior. For example, disulfiram (Antabuse) is a drug given to individuals who wish to stop drinking alcohol. If an individual consumes alcohol while on Antabuse therapy, symptoms of severe nausea and vomiting, dyspnea, palpitations, and headache will occur. Instead of the euphoric feeling normally experienced from the alcohol (the positive reinforcement for drinking), the individual receives a severe punishment that is intended to extinguish the unacceptable behavior (drinking alcohol).

Covert Sensitization

Covert sensitization relies on the individual's imagination rather than on medication to produce unpleasant symptoms. The technique is under the client's control and can be used whenever and wherever it is required. The individual learns to visualize nauseating scenes and even to induce a mild feeling of nausea through mental imagery. This mental image is visualized when the individual is about to succumb to an attractive but undesirable behavior. It is most effective when paired with relaxation exercises that are performed instead of the undesirable behavior. The primary advantage of covert sensitization is that the individual does not have to perform the undesired behaviors but simply imagine them.

Systematic Desensitization

Systematic desensitization is a technique for assisting individuals to overcome their fear of a phobic stimulus. It is "systematic" in that there is a hierarchy of anxiety-producing events through which the individual progresses during therapy. An example of a hierarchy of events associated with a fear of elevators may be as follows:

1. Discuss riding an elevator with the therapist.
2. Look at a picture of an elevator.
3. Walk into the lobby of a building and see the elevators.
4. Push the button for the elevator.
5. Walk into an elevator with a trusted person; disembark before the doors close.
6. Walk into an elevator with a trusted person. Allow doors to close, then open the doors and walk out.
7. Ride one floor with a trusted person, then walk back down the stairs.
8. Ride one floor with a trusted person and ride the elevator back down.
9. Ride the elevator alone.

As each of these steps is attempted, it is paired with relaxation exercises as an antagonistic behavior to anxiety. Generally, the desensitization procedures occur in the therapy setting, where the client is instructed to engage in relaxation exercises. When relaxation has been achieved, the client uses mental imagery to visualize the hierarchical step described by the therapist. If the client becomes anxious, the therapist suggests relaxation exercises again, and presents a scene that is lower in the hierarchy. Therapy continues until the individual is able to progress through the entire hierarchy with manageable anxiety. The effects of relaxation in the presence of imagined anxiety-producing stimuli transfer to the real situation once the client has achieved relaxation capable of suppressing or inhibiting anxiety responses (Ford-Martin, 2005). However, some clients are not successful in extinguishing phobic reactions through imagery. For these clients, *real-life desensitization* may be required. In these instances, the therapist may arrange for the client to be exposed to the hierarchy of steps in the desensitization process, but in real-life situations. Relaxation exercises may or may not be a part of real-life desensitization.

Flooding

This technique, sometimes called *implosive therapy,* is also used to desensitize individuals to phobic stimuli. It differs from systematic desensitization in that, instead of working up a hierarchy of anxiety-producing stimuli, the individual is "flooded" with a continuous presentation (through mental imagery) of the phobic stimulus until it no longer elicits anxiety. **Flooding** is believed to produce results faster than systematic desensitization; however, some therapists report more lasting behavioral changes with systematic desensitization. Some questions have also been raised about the ethics of encouraging a patient to endure prolonged fear and psychological discomfort, and clients may avoid this type of therapy for that reason. Flooding is contraindicated with clients for whom intense anxiety would be hazardous, such as individuals with heart disease or fragile psychological adaptation (Sadock, Sadock, & Ruiz, 2015).

Role of the Nurse in Behavior Therapy

The nursing process is the vehicle for delivery of nursing care with the client requiring assistance with behavior modification. The steps of the nursing process are illustrated in the following case study.

CASE STUDY

This example focuses on inpatient care, but these interventions can be modified and are applicable to various healthcare settings, including partial hospitalization, community outpatient clinic, home health, and private practice.

ASSESSMENT

Zach, age 8, has been admitted to the child psychiatric unit of a university medical center following evaluation by a child psychiatrist. His parents, Tom and Deborah, are at an impasse, and their marriage is suffering because of constant conflict over their son's behavior at home and at school. Tom complains bitterly that Deborah is overly permissive with their son. Tom reports that Zach argues and has temper tantrums and insists on continuing games, books, and TV whenever Deborah puts him to bed, so that an 8:30 p.m. bedtime regularly is delayed until 10:30 or later every night. Also, Deborah often cooks four or five different meals for her son's dinner if Zach stubbornly insists that he will not eat what has been prepared. At school, several teachers have complained that the child is stubborn and argumentative, is often disruptive in the classroom, and refuses to follow established rules.

When asked by the psychiatric nurse about other maladaptive behaviors, such as destruction of property, stealing, lying, or setting fires, the parents denied that these had been a problem. During the interview, Zach sat quietly without interrupting. He answered questions that were directed to him with brief responses and made light of the problems described by his parents and reported by his teachers. The nurse conducted an assessment to rule out history of trauma as an alternate explanation for his behavior, and there was no evidence of trauma in Zach's history.

During his first 3 days on the unit, the following assessments were made:

1. Zach loses his temper when he cannot have his way. He screams, stomps his feet, and sometimes kicks the furniture.
2. Zach refuses to follow directions given by staff. He merely responds, "No, I won't."
3. Zach likes to engage in behaviors that annoy the staff and other children: belching loudly, scraping his fingernails across the blackboard, making loud noises when the other children are trying to watch television, opening his mouth when it is full of food.
4. Zach blames others when he makes a mistake. He spilled his milk at lunchtime while racing to get to a specific seat he knew Tony wanted. He blamed the accident on Tony, saying, "He made me do it! He tripped me!"

Upon completion of the initial assessments, the psychiatrist diagnosed Zach with oppositional defiant disorder.

DIAGNOSIS/OUTCOME IDENTIFICATION

Nursing diagnoses and outcome criteria for Zach include the following:

NURSING DIAGNOSES	OUTCOME CRITERIA
Noncompliance with therapy	Zach participates in and cooperates during therapeutic activities.
Defensive coping	Zach accepts responsibility for own behaviors and interacts with others without becoming defensive.
Impaired social interaction	Zach interacts with staff and peers using age-appropriate, acceptable behaviors.

PLANNING/IMPLEMENTATION

A contract for Zach's care was drawn up by the admitting nurse and others on the treatment team. Zach's contract was based on a system of token economies. He discussed with the nurse the kinds of privileges he would like to earn:

- Having a can of pop for a snack (2 tokens)
- Getting to watch 30 minutes of TV (5 tokens)
- Getting to stay up later on Friday nights with the other clients (7 tokens)
- Getting to play the video games (3 tokens)
- Getting to walk with the nurse to the gift shop to spend some of his money (8 tokens)
- Getting to go on the outside therapeutic recreation activities such as movies, the zoo, and picnics (10 tokens)

Tokens were awarded for appropriate behaviors:

- Gets out of bed when the nurse calls him (1 token)
- Gets dressed for breakfast (1 token)
- Presents himself for *all* meals in an appropriate manner: no screaming, no belching, no opening his mouth when it is full of food, no throwing of food, staying in his chair during the meal, putting his tray away in the appropriate place when he is finished (2 tokens × 3 meals = 6 tokens)
- Completes hygiene activities (1 token)
- Accepts blame for own mistakes (1 token)
- Does not fight; uses no obscene language; does not "sass" staff (1 token)
- Remains quiet while others are watching TV (1 token)
- Participates and is not disruptive in unit meetings and group therapy sessions (2 tokens)
- Displays no temper tantrums (1 token)
- Follows unit rules (1 token)
- Goes to bed at designated hour without opposition (1 token)

Tokens are awarded at bedtime for absence of inappropriate behaviors during the day. For example, if Zach has

CASE STUDY—cont'd

no temper tantrums during the day, he is awarded 1 token. Likewise, if Zach has a temper tantrum (or exhibits other inappropriate behavior), he must pay back the token amount designated for that behavior. No other attention is given to inappropriate behaviors other than withholding and payback of tokens.

> **EXCEPTION:** If Zach is receiving reinforcement from peers for inappropriate behaviors, staff has the option of imposing time-out or isolation until the behavior is extinguished.

> The contract may be renegotiated at any time between Zach and staff. Additional privileges or responsibilities may be added as they develop and are deemed appropriate.

> All staff members are consistent with the terms of the contract and do not allow Zach to manipulate. There are no exceptions without renegotiation of the contract.

> **NOTE:** Parents meet regularly with the case manager from the treatment team. Effective parenting techniques are discussed, as are other problems identified within the marriage relationship. Parenting instruction coordinates with the pattern of behavior modification Zach is receiving on the psychiatric unit. The importance of follow-through is emphasized, along with strong encouragement that the parents maintain a united front in disciplining Zach. Oppositional behaviors are nurtured by divided management.

EVALUATION

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of Zach care. Evaluation can be facilitated by gathering information using the following questions:

- Does Zach participate in and cooperate during therapeutic activities?
- Does he follow the rules of the unit (including mealtimes, hygiene, and bedtime) without opposition?
- Does Zach accept responsibility for his own mistakes?
- Is he able to complete a task without becoming defensive?
- Does he refrain from interrupting when others are talking and from making noise in situations where quiet is in order?
- Does he refrain from attempts to manipulate the staff?
- Is he able to express anger appropriately without tantrum behaviors?
- Does he demonstrate acceptable behavior in interactions with peers?

Summary and Key Points

- The basic assumption of behavior therapy is that problematic behaviors occur when there has been inadequate learning and, therefore, can be corrected through the provision of appropriate learning experiences.
- The antecedents of today's principles of behavior therapy are largely the products of laboratory efforts by Pavlov and Skinner.
- Pavlov introduced a process that came to be known as *classical conditioning*.
- Pavlov demonstrated in his trials with laboratory animals that a neutral stimulus could acquire the ability to elicit a conditioned response through pairing with an unconditioned stimulus. He considered the conditioned response to be a new, learned response.
- Skinner, in his model of operant conditioning, gave additional attention to the consequences of the response as an approach to learning new behaviors.
- Skinner believed that the connection between a stimulus and a response is strengthened or weakened by the consequences of the response.

- Various techniques for modifying client behavior include the following:
  - Shaping: A technique in which reinforcements are given for increasingly closer approximations to the desired response
  - Modeling: The learning of new behaviors by imitating the behavior of others
  - Premack principle: The concept that a frequently occurring response can serve as a positive reinforcement for a response that occurs less frequently
  - Extinction: The gradual decrease in frequency or disappearance of a response when the positive reinforcement is withheld
  - Contingency contracting: A contract specifying a specific behavior change and the reinforcers to be given for performing the desired behaviors
  - Token economy: A type of contingency contracting in which the reinforcers for desired behaviors are presented in the form of tokens
  - Time-out: An aversive stimulus or punishment during which the client is removed from the environment where the unacceptable behavior is being exhibited
  - Reciprocal inhibition: A technique that decreases or eliminates a behavior by introducing

a more adaptive behavior that is incompatible with the unacceptable behavior

■ Overt sensitization: A type of aversion therapy that produces unpleasant consequences for undesirable behavior

■ Covert sensitization: Relies on an individual's imagination to produce unpleasant consequences for undesirable behaviors

■ Systematic desensitization: A technique for overcoming phobias in which there is a hierarchy of anxiety-producing events through which the individual progresses

■ Flooding (also called *implosion therapy*): Desensitizes individuals to phobic stimuli by "flooding" them with a continuous presentation (through mental imagery) of the phobic stimulus until it no longer elicits anxiety

■ Nurses can implement behavior therapy techniques to help clients modify maladaptive behavior patterns.

■ The nursing process is a systematic method of directing care for clients who require this type of assistance.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. A positive reinforcer:
   a. Increases the probability that a behavior will recur.
   b. Decreases the probability that a behavior will recur.
   c. Has nothing to do with modifying behavior.
   d. Always results in positive behavior.

2. A negative reinforcer:
   a. Increases the probability that a behavior will recur.
   b. Decreases the probability that a behavior will recur.
   c. Has nothing to do with modifying behavior.
   d. Always results in unacceptable behavior.

3. An aversive stimulus or punisher:
   a. Increases the probability that a behavior will recur.
   b. Decreases the probability that a behavior will recur.
   c. Has nothing to do with modifying behavior.
   d. Always results in unacceptable behavior.

Situation: B.J. has been out with his friends. He is late getting home. He knows his wife will be angry and will yell at him for being late. He stops at the florist and buys a dozen red roses for her. Questions 4, 5, and 6 are related to this situation.

4. Which of the following behaviors represents positive reinforcement on the part of the wife?
   a. She meets him at the door, accepts the roses, and says nothing further about his being late.
   b. She meets him at the door, yelling that he is late, and makes him spend the night on the couch.
   c. She meets him at the door, expresses delight with the roses, and kisses him on the cheek.
   d. She meets him at the door and says, "How could you? You know I'm allergic to roses!"

5. Which of the following behaviors represents negative reinforcement on the part of the wife?
   a. She meets him at the door, accepts the roses, and says nothing further about his being late.
   b. She meets him at the door, yelling that he is late, and makes him spend the night on the couch.
   c. She meets him at the door, expresses delight with the roses, and kisses him on the cheek.
   d. She meets him at the door and says, "How could you? You know I'm allergic to roses!"

Self-Examination/Learning Exercise

6. Which of the following behaviors represents an aversive stimulus on the part of the wife?
   a. She meets him at the door, accepts the roses, and says nothing further about his being late.
   b. She meets him at the door, yelling that he is late, and makes him spend the night on the couch.
   c. She meets him at the door, expresses delight with the roses, and kisses him on the cheek.
   d. She meets him at the door and says, "How could you? You know I'm allergic to roses!"

7. Fourteen-year-old Sally has been spending many hours after school watching TV. She has virtually stopped practicing her piano lessons. Sally's parents ask for advice about how to encourage Sally to practice more. The nurse believes the Premack principle may be helpful. Which of the following does she suggest to Sally's parents?
   a. She tells Sally's parents to reward Sally each time she practices the piano, even if it is only for 5 minutes.
   b. She tells Sally's parents to ignore this behavior and eventually she will start practicing on her own.
   c. She tells Sally's parents to draw up a contract with Sally stating what the consequences will be if she does not practice the piano.
   d. She tells Sally's parents to explain to Sally that she may watch TV only after she has practiced the piano for 1 hour.

8. Jill has a fear of dogs. In helping her overcome this fear, the therapist is using systematic desensitization. List the following steps in the order in which the therapist would proceed.
   Have Jill:
   a. Look at a real dog.
   b. Look at a stuffed toy dog.
   c. Pet a real dog.
   d. Pet the stuffed toy dog.
   e. Walk past a real dog.
   f. Look at a picture of a dog.

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss historical perspectives associated with cognitive therapy.
2. Identify various indications for cognitive therapy.
3. Describe goals, principles, and basic concepts of cognitive therapy.
4. Discuss a variety of cognitive therapy techniques.
5. Apply techniques of cognitive therapy within the context of the nursing process.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Define *automatic thoughts.*
2. Why are automatic thoughts problematic for some people?
3. What are the three major components of cognitive therapy?
4. John submits his design of a house to some prospective clients. They ask for a few changes to be made. John thinks, "I'm a terrible architect!" What automatic thought does this statement represent?

Wright, Thase, and Beck (2008) stated:

> The writing of Epictetus in the *Enchiridion, "Men are disturbed not by things, but by the views which they take of them,"* captures the essence of the perspective that our ideas or thoughts are a controlling factor in our emotional lives. (p. 1212)

This concept provides a foundation on which the cognitive model is established. In cognitive therapy, the therapist uses various methods to create change in the client's thinking and belief system in an effort to bring about lasting emotional and behavioral change (Beck, 1995). Distorted cognitions are at the

foundation of many emotional, mental, and behavioral disorders: clients with depression often seem to be consumed by negative thoughts about themselves and about how others see them, clients with anxiety disorders often have worried thoughts about past and future events, clients with personality disorders often struggle with maladaptive thoughts about their relationships with others, and so on. Could helping clients change the way they think actually improve their mood and their behavior? There is much evidence to support that it can (Brenes et al., 2015; Brent et al., 2015; Guille et al., 2015; Rohan et al., 2015; Weck & Neng, 2015).

This chapter examines the historical development of the cognitive model, defines the goals of therapy, and describes various techniques of the cognitive approach. A discussion of the role of the nurse in the implementation of cognitive behavioral techniques with clients is presented.

> **NOTE:** Although in this text the concepts are presented separately for reasons of clarification, cognitive therapy procedures are often combined with behavioral modification techniques and are referred to as *cognitive-behavioral therapy* (CBT).

CORE CONCEPT

Cognitive
Relating to the mental processes of thinking and reasoning.

Historical Background

Cognitive therapy has its roots in the early 1960s research on depression conducted by Aaron Beck (1963, 1964). Beck was trained in the Freudian psychoanalytic view of depression as "anger turned inward." In his clinical research, he began to observe a common theme of negative cognitive processing in the thoughts and dreams of his depressed clients (Beck & Weishaar, 2011).

A number of theorists have taken from and expanded upon Beck's original concept. The common theme is the rejection of the passive listening used in psychoanalysis in favor of active, direct dialogues with clients (Beck & Weishaar, 2011). The work of contemporary behavioral therapists has also influenced the evolution of cognitive therapy. Behavioral techniques such as expectancy of reinforcement and modeling are based in cognitive processes. Lazarus and Folkman (1984), whose premises about *personal appraisal* and *coping* shape the conceptual framework of this book, have also substantially contributed to the cognitive approach to therapy. The model for cognitive therapy is based on an individual's cognition, or more specifically, an individual's personal cognitive appraisal of an event and the resulting emotions or behaviors. Personality—which undoubtedly influences our cognitive appraisal of an event—is viewed as shaped by the interaction between innate predisposition and the environment (Beck, Davis, & Freeman, 2015). Whereas some types of therapy may be directed toward improvement in coping strategies or adaptiveness of behavioral response, cognitive therapy is aimed at modifying distorted cognitions about a situation. Since behavior and emotions are intimately linked to thoughts, this approach assumes that behavior and emotions will change as a result of changing one's thinking.

CORE CONCEPT

Cognitive Therapy
Cognitive therapy is a type of psychotherapy based on the concept of pathological mental processing. The focus of treatment is on the modification of distorted cognitions and maladaptive behaviors.

Indications for Cognitive Therapy

Cognitive therapy was originally developed for use with depression and is now used to treat a broad range of emotional disorders. In addition to depression, cognitive therapy may be used with the following clinical conditions: panic disorder, generalized anxiety disorder, social phobias, obsessive-compulsive disorder, posttraumatic stress disorder, eating disorders, substance abuse, personality disorders, schizophrenia, couples' problems, bipolar disorder, illness anxiety disorder, and somatic symptom disorder. The proponents of cognitive therapy suggest that the emphasis of therapy must be varied and individualized for clients according to their specific diagnosis, symptoms, and level of functioning (Beck, 1995; Sadock, Sadock, & Ruiz, 2015; Wright et al., 2008).

Goals and Principles of Cognitive Therapy

Beck and associates (1987) defined the goals of cognitive therapy as follows.

The client will:

1. Monitor his or her negative, automatic thoughts.
2. Recognize the connections between cognition, affect, and behavior.
3. Examine the evidence for and against distorted automatic thoughts.
4. Substitute more realistic interpretations for these biased cognitions.

5. Learn to identify and alter the dysfunctional beliefs that predispose him or her to distort experiences.

Cognitive therapy is highly structured and short-term, lasting from 12 to 16 weeks (Beck & Weishaar, 2011). Sadock and associates (2015) suggested that if a client does not improve within 25 weeks of therapy, a reevaluation of the diagnosis should be made. Although therapy must be tailored to the individual, the following principles underlie cognitive therapy for all clients (Beck, 1995).

Principle 1. Cognitive therapy is based on an ever-evolving formulation of the client and his or her problems in cognitive terms. The therapist identifies the event that precipitated the distorted cognition. Current thinking patterns that serve to maintain the problematic behaviors are reviewed. The therapist then hypothesizes about certain developmental events and enduring patterns of cognitive appraisal that may have predisposed the client to specific emotional and behavioral responses.

Principle 2. Cognitive therapy requires a sound therapeutic alliance. A trusting relationship between therapist and client must exist for cognitive therapy to succeed. The therapist must convey warmth, empathy, caring, and genuine positive regard. Development of a working relationship between therapist and client is an individual process, and clients with various disorders will require varying degrees of effort to achieve this therapeutic alliance.

Principle 3. Cognitive therapy emphasizes collaboration and active participation. Teamwork between therapist and client is emphasized. They decide together what to work on during each session, how often they should meet, and what homework assignments should be completed between sessions.

Principle 4. Cognitive therapy is goal oriented and problem focused. At the beginning of therapy, the client is encouraged to identify what he or she perceives to be the problem or problems. With guidance from the therapist, goals are established as outcomes of therapy. Assistance in problem-solving is provided as required as the client comes to recognize and correct distortions in thinking.

Principle 5. Cognitive therapy initially emphasizes the present. Resolution of distressing situations that are based in the present usually leads to symptom reduction. It is therefore more beneficial to begin with current problems and delay shifting attention to the past until (1) the client expresses a desire to do so, (2) the work on current problems produces little or no change, or (3) the therapist decides it is important to determine how dysfunctional ideas affecting the client's current thinking originated.

Principle 6. Cognitive therapy is educative, aims to teach the client to be his or her own therapist, and emphasizes relapse prevention. From the beginning of therapy, the client is taught about the nature and course of his or her disorder, about the cognitive model (i.e., how thoughts influence emotions and behavior), and about the process of cognitive therapy. The client is taught how to set goals, plan behavioral change, and intervene on his or her own behalf.

Principle 7. Cognitive therapy aims to be time limited. Clients often are seen weekly for a couple of months, followed by a number of biweekly sessions, then possibly a few monthly sessions. Some clients want periodic "booster" sessions every few months.

Principle 8. Cognitive therapy sessions are structured. Each session has a set structure which includes (1) reviewing the client's week, (2) collaboratively setting the agenda for this session, (3) reviewing the previous week's session, (4) reviewing the previous week's homework, (5) discussing this week's agenda items, (6) establishing homework for next week, and (7) summarizing this week's session. This format focuses attention on important items to maximize the use of therapy time.

Principle 9. Cognitive therapy teaches clients to identify, evaluate, and respond to their dysfunctional thoughts and beliefs. Through gentle questioning and review of data, the therapist helps the client identify his or her dysfunctional thinking, evaluate the validity of the thoughts, and devise a plan of action. This is done by helping the client examine evidence that supports or contradicts the accuracy of the thought rather than directly challenging or confronting the belief.

Principle 10. Cognitive therapy uses a variety of techniques to change thinking, mood, and behavior. Techniques from various therapies may be used within the cognitive framework. Emphasis in treatment is guided by the client's particular disorder and directed toward modification of the dysfunctional cognitions that contribute to the maladaptive behavior associated with his or her disorder. Examples of disorders and the dysfunctional thinking for which cognitive therapy may be of benefit are discussed later in this chapter.

Basic Concepts

Wright and associates (2008) stated, "The general thrust of cognitive therapy is that emotional responses are largely dependent upon cognitive appraisals of the significance of environmental cues" (p. 1213). Basic concepts include **automatic thoughts** and **schemas,** or core beliefs.

Automatic Thoughts

Automatic thoughts are those that occur rapidly in response to a situation and without rational analysis.

These thoughts are often negative and based on er-roneous logic. Beck and associates (1987) called these thoughts *cognitive errors*. Following are some examples of common cognitive errors:

Arbitrary Inference In a type of thinking error known as **arbitrary inference,** the individual automatically comes to a conclusion about an incident without the facts to support it or even despite contradictory evidence.

EXAMPLE

Two months ago, Mrs. B. sent a wedding gift to the daughter of an old friend. She has not yet received acknowledgment of the gift. Mrs. B. thinks, "They obviously think I have poor taste."

Overgeneralization (Absolutistic Thinking) Sweeping conclusions are **overgeneralizations** made on the basis of one incident—an "all-or-nothing" kind of thinking.

EXAMPLE

Frank submitted an article to a nursing journal, and it was re-jected. Frank thinks, "No journal will ever be interested in anything I write."

Dichotomous Thinking An individual who is using **dichotomous thinking** views situations in terms of all-or-nothing, black-or-white, or good-or-bad.

EXAMPLE

Frank submits an article to a nursing journal, and the editor returns it and asks Frank to rewrite parts of it. Frank thinks, "I'm a bad writer," instead of recognizing that revision is a common part of the publication process.

Selective Abstraction A **selective abstraction** (some-times referred to as a *mental filter*) is a conclusion that is based on only a selected portion of the evidence. The selected portion is usually the negative evidence or what the individual views as a failure, rather than any successes that have occurred.

EXAMPLE

Jackie just graduated from high school with a 3.98/4.00 grade point average. She won a scholarship to the large state university near her home. She was active in sports and ac-tivities in high school and well liked by her peers. However, she is very depressed and dwells on the fact that she did not earn a scholarship to a prestigious Ivy League college to which she had applied.

Magnification Exaggerating the negative significance of an event is known as **magnification.**

EXAMPLE

Nancy hears that her colleague at work is having a cocktail party over the weekend, and she is not invited. Nancy thinks, "She doesn't like me."

Minimization Undervaluing the positive significance of an event is called **minimization.**

EXAMPLE

Mrs. M. is feeling lonely. She telephones her granddaughter Amy, who lives in a nearby town, and invites her to visit. Amy apologizes that she must go out of town on business and would not be able to visit at that time. While Amy is out of town, she calls Mrs. M. twice, but Mrs. M. still feels unloved by her granddaughter.

Catastrophic Thinking Always thinking that the worst will occur without considering the possibility of more likely positive outcomes is considered **catastrophic thinking.**

EXAMPLE

On Janet's first day in her secretarial job, her boss asked her to write a letter to another firm and put it on his desk for his signature. She did so and left for lunch. When she returned, the letter was on her desk with a typographical error circled in red and a note from her boss to redo the letter. Janet thinks, "This is it! I will surely be fired now!"

Personalization With **personalization,** the person takes complete responsibility for situations without consid-ering that other circumstances may have contributed to the outcome.

EXAMPLE

Jack, who sells vacuum cleaners door-to-door, has just given a 2-hour demonstration to Mrs. W. At the end of the demonstration, Mrs. W tells Jack that she appreciates his demonstration, but she won't be purchasing a vacuum cleaner from him. Jack thinks, "I'm a lousy salesman" (when in fact, Mrs. W.'s husband lost his job last week, and they have no extra money to buy a new vacuum cleaner at this time).

Schemas (Core Beliefs)

Beck and Weishaar (2011) defined cognitive schemas as:

> Structures that contain the individual's fundamental beliefs and assumptions. Schemas develop early in life from personal experience and identification with significant others. These concepts are reinforced by further learning experiences and, in turn, influence the formation of beliefs, values, and attitudes. (p. 284)

These schemas, or core beliefs, may be adaptive or maladaptive. They may be general or specific, and they may be latent, becoming evident only when trig-gered by a specific stressful stimulus. Schemas differ from automatic thoughts in that they are deeper cog-nitive structures that serve to screen information from the environment. For this reason, they are often more difficult to modify than automatic thoughts.

However, the same techniques used for automatic thoughts can be used at the schema level. Schemas can be positive or negative and generally fall into two broad categories: those associated with *helplessness* and those associated with *unlovability* (Beck, 1995). Some examples of types of schemas are presented in Table 19–1.

Techniques of Cognitive Therapy

The three major components of cognitive therapy are didactic aspects, cognitive techniques, and behavioral interventions (Sadock et al., 2015).

Didactic (Educational) Aspects

A basic principle of cognitive therapy is to prepare the client to eventually become his or her own cognitive therapist. The therapist provides information to the client about what cognitive therapy is, how it works, and the structure of the cognitive process. Explanation about expectations of both client and therapist is provided. Reading assignments are given to reinforce learning. Some therapists use audiotape or videotape sessions to teach clients about cognitive therapy. A full explanation about the relationship between depression (or anxiety, or whatever maladaptive response the client is experiencing) and distorted thinking patterns is an essential part of cognitive therapy.

Cognitive Strategies

Strategies used in cognitive therapy include recognizing and modifying automatic thoughts and recognizing and modifying schemas. Several techniques of cognitive therapy have been elaborated (Freeman-Clevenger, 2014; Wright et al., 2008) and are described in the following sections.

Recognizing Automatic Thoughts and Schemas
Socratic Dialogue

In **Socratic dialogue** (also called *guided discovery*), the therapist questions the client to elaborate the "who, what, when, where, why, and how" of his or her situation The client is asked to describe feelings associated with specific scenarios. Questions are primarily restatements of the client's own words in a way that may stimulate insight into possible dysfunctional thinking and produce dissonance about the validity of the thoughts.

Guided Relaxation and Behavioral Rehearsal

Guided relaxation is aimed at reducing autonomic response to anxiety. Techniques may include deep breathing, imagery, mindfulness meditation, and other exercises. These techniques also increase awareness of conscious control over breathing, anxiety symptoms, and thoughts.

Behavioral rehearsal, often accomplished through role-play, affords the client an opportunity to practice a new way of responding to distressing situations and explore possible outcomes with the counselor before trying out the behavior in real-life situations. *Role-play* is a technique that should be used only when the relationship between client and therapist is exceptionally strong and there is little likelihood of maladaptive transference occurring. With role-play, the therapist assumes the role of an individual in a situation that produces a maladaptive response in the client. The situation is played out in an effort to elicit recognition of automatic thinking on the part of the client.

Automatic Thought Records

This technique, one of the most frequently used methods of recognizing automatic thoughts, is taught to and discussed with the client in the therapy session. Thought recording is assigned as homework for the client outside of therapy. The client is asked to keep a written record of situations that occur and the automatic thoughts elicited by the situation. This is called a *two-column thought recording*. Some therapists ask their clients to keep a three-column recording, which includes a description of the emotional response also associated with the situation, as illustrated in Table 19–2.

Modifying Automatic Thoughts and Schemas
Questioning the Evidence

With this technique, the client and therapist set forth the automatic thought as the hypothesis, and the

TABLE 19–1 **Examples of Types of Schemas**		
SCHEMA CATEGORY	MALADAPTIVE/NEGATIVE	ADAPTIVE/POSITIVE
Helplessness	No matter what I do, I will fail. I must be perfect. If I make one mistake, I will lose everything.	If I try and work very hard, I will succeed. I am not afraid of a challenge. If I make a mistake, I will try again.
Unlovability	I'm stupid. No one would love me. I'm nobody without a man.	I'm a lovable person. People respect me for myself.

TABLE 19–2 **Three-Column Thought Recording**		
SITUATION	AUTOMATIC THOUGHTS	EMOTIONAL RESPONSE
My girlfriend broke up with me.	I'm a stupid person. No one would ever want to marry me.	Sadness; depression
I was turned down for a promotion.	Stupid boss! He doesn't know how to manage people. It's not fair!	Anger

client is assisted to question the facts associated with their cognitions.

Examining Options and Alternatives

To help the client see a broader range of possibilities than originally considered, the therapist guides the client in learning how to generate alternatives.

Decatastrophizing

With the technique of **decatastrophizing,** the therapist assists the client to examine the validity of a negative automatic thought. The client is assisted to examine "what is the worst thing that could happen?" and then to develop a plan of action. Even if some validity exists, the client is encouraged to review ways to cope adaptively and move beyond the current crisis situation.

Reattribution

Through Socratic questioning and testing of automatic thoughts, this technique aims to reverse negative attribution of clients from self-blame (common in depression) or placing blame solely on others (common in

some personality disorders) to a more balanced attribution of responsibility.

Daily Record of Dysfunctional Thoughts (DRDT)

The DRDT is a tool commonly used in cognitive therapy to help clients identify and modify automatic thoughts. Two more columns are added to the three-column thought record presented earlier. Clients are then asked to rate the intensity of the thoughts and emotions on a 0 percent to 100 percent scale. The fourth column of the DRDT asks the client to describe a more rational cognition than the automatic thought identified in the second column and rate the intensity of the belief in the rational thought. In the fifth column, the client records any changes that have occurred as a result of modifying the automatic thought and the new rate of intensity associated with it. With this tool, the client is able to modify automatic thoughts by identifying them and actually formulating a more rational alternative. Table 19–3 presents an example of a DRDT as an extension to the three-column thought recording presented in Table 19–2.

TABLE 19–3 **Sample Daily Record of Dysfunctional Thoughts (DRDT)**				
SITUATION	AUTOMATIC THOUGHT	EMOTIONAL RESPONSE	RATIONAL RESPONSE	OUTCOME: EMOTIONAL RESPONSE
My girlfriend broke up with me.	I'm a stupid person. No one would ever want to marry me. (95%)	Sadness; depression (90%)	I'm not stupid. Lots of people like me. Just because one person doesn't want to date me doesn't mean that no one would want to. (75%)	Sadness; depression (50%)
I was turned down for a promotion.	Stupid boss! He doesn't know how to manage people. It's not fair! (90%)	Anger (95%)	I guess I have to admit the other guy's education and experience fit the position better than mine. The boss was being fair because he filled the position based on qualifications. I'll try for the next promotion that fits my qualifications better. (70%)	Anger (20%) Disappointment (80%) Hope (80%)

Cognitive Rehearsal

This technique uses mental imagery to uncover potential automatic thoughts in advance of their occurrence in a stressful situation. A discussion is held to identify ways to modify these dysfunctional cognitions. The client is then given "homework" assignments to try these newly learned methods in real situations.

Behavioral Interventions

It is believed that in cognitive therapy, an interactive relationship exists between cognitions and behavior; that is, that cognitions affect behavior and behavior influences cognitions. With this concept in mind, a number of interventions are structured for the client to assist him or her to identify and modify maladaptive cognitions and behaviors.

The following procedures, which are behavior oriented, are directed to help clients learn more adaptive behavioral strategies that will in turn have a positive effect on cognitions (Basco et al., 2004; Freeman-Clevenger, 2014; Sadock et al., 2015; Wright et al., 2008):

1. **Activity scheduling:** With this intervention, clients are asked to keep a daily log of their activities on an hourly basis and rate each activity, for mastery and pleasure, on a 0-to-10 scale. The schedule is then shared with the therapist and used to identify important areas needing concentration during therapy.
2. **Graded task assignments:** This intervention is used with clients who are facing a situation that they perceive as overwhelming. The task is broken down into subtasks that clients can complete one step at a time. Each subtask has a goal and a time interval attached to it. Successful completion of each subtask helps to increase self-esteem and decrease feelings of helplessness.
3. **Distraction:** When dysfunctional cognitions have been recognized, **distraction** can occur by engaging in activities that redirect the client's thinking and divert him or her from the intrusive thoughts or depressive ruminations that are contributing to the maladaptive responses.
4. **Miscellaneous techniques:** Relaxation exercises, assertiveness training, role modeling, social skills training, and contingency management contracts are all types of behavioral interventions used in cognitive therapy to help clients modify dysfunctional cognitions. Thought-stopping techniques (described in Chapter 14, Assertiveness Training) may also be used to restructure dysfunctional thinking patterns.

Role of the Nurse in Cognitive Therapy

Many of the techniques used in cognitive therapy are well within the scope of nursing practice, from generalist through specialist levels. Cognitive therapy requires an understanding of educational principles and the ability to use problem-solving skills to guide clients' thinking through a reframing process. The scope of contemporary psychiatric nursing practice is expanding, and although psychiatric nurses have been using some of these techniques in various degrees within their practices for years, it is important that knowledge and skills related to this type of therapy be promoted further. The value of cognitive therapy as a useful and cost-effective tool has been observed in a number of inpatient and community outpatient mental health settings.

The following case study presents the role of the nurse in cognitive therapy in the context of the nursing process.

CASE STUDY

ASSESSMENT

Brian is a 45-year-old white male admitted to the psychiatric unit of a general medical center by his family physician, Dr. Jones, who reported that Brian has become increasingly despondent over the last month. His wife reported that he has made statements such as, "Life is not worth living," and "I think I could just take all those pills Dr. Jones prescribed at one time; then it would all be over." He was admitted at 6:40 p.m., via wheelchair from admissions, accompanied by his wife. He reports no known allergies. Vital signs upon admission were temperature, 97.9°F; pulse, 80; respirations, 16; and blood pressure, 132/77. He is 5 feet 11 inches tall and weighs 160 pounds. He was referred to the psychiatrist on call, Dr. Smith. Orders include suicide precautions, level I; regular diet; chemistry profile and routine urinalysis in a.m.; Desyrel, 200 mg tid; Dalmane, 30 mg HS prn for sleep.

FAMILY DYNAMICS

Brian says he loves his wife and children and does not want to hurt them, but he feels they no longer need him. He states, "They would probably be better off without me." His wife appears to be very concerned about his condition, although in his despondency, he seems oblivious to her feelings. His mother lives in a neighboring state, and he sees her infrequently. He admits that he is somewhat bitter toward her for allowing him and his siblings to "suffer from the physical and emotional brutality of their father." His siblings and their families live in distant states, and he sees them rarely,

CASE STUDY—cont'd

during holiday gatherings. He feels closest to the older of the two brothers.

MEDICAL/PSYCHIATRIC HISTORY

Brian's father died 5 years ago at age 65 of a myocardial infarction. Brian and both his brothers have a history of high cholesterol and triglycerides from approximately age 30. During his regular physical examination 1 month ago, Brian's family doctor recognized symptoms of depression and prescribed fluoxetine. Brian's mother has a history of depressive episodes. She was hospitalized once about 7 years ago for depression, and she has taken various antidepressant medications over the years. Her family physician has also prescribed Valium for her on numerous occasions for her "nerves." No other family members have a history of psychiatric problems.

PAST EXPERIENCES

Brian was the first child in a family of four. He is 2 years older than his sister and 4 years older than the third child, a brother. He was 6 years old when his youngest sibling, also a boy, was born. Brian's father was a career Army man who moved his family many times during Brian's childhood years. Brian attended 15 schools from the time he entered kindergarten until he graduated from high school.

Brian reports that his father was very autocratic and had many rules that he expected his children to obey without question. Infraction resulted in harsh discipline. Because Brian was the oldest child, his father believed he should assume responsibility for the behavior of his siblings. Brian describes the severe physical punishment he received from his father when he or his siblings allegedly violated one of the rules. It was particularly intense when Brian's father had been drinking, which he did most evenings and weekends.

Brian's mother was very passive. Brian believes she was afraid of his father, particularly when he was drinking, so she quietly conformed to his lifestyle and offered no resistance, even though she did not agree with his disciplining of the children. Brian reports that he observed his father physically abusing his mother on a number of occasions, most often when he had been drinking.

Brian states that he had very few friends when he was growing up. With all the family moves, he gave up trying to make new friends because it became too painful to give them up when it was time to leave. He took a paper route when he was 13 years old and then worked in fast-food restaurants from age 15 on. He was a hard worker and never seemed to have difficulty finding work in any of the places where the family relocated. He states that he appreciated the independence and the opportunity of being away from home as much as his job would allow. "I guess I can honestly say I hated my father, and working was my way of getting away from all the stress that was going on in that house. I guess my dad hated me, too, because he never was satisfied with anything I did. I never did well enough for him in school, on the job, or even at home. When I think of my dad now, the memories I have are of being criticized and beaten with a belt."

On graduation from high school, Brian joined the Navy, where he learned a skill that he used after discharge to obtain a job in a large aircraft plant. He also attended the local university at night, where he earned his accounting degree. When he completed his degree, he was reassigned to the administration department of the aircraft company, and he has been in the same position for 12 years without a promotion.

PRECIPITATING EVENT

Over the last 12 years, Brian has watched while a number of his peers were promoted to management positions. Brian has been considered for several of these positions but never has been selected. Last month, a management position became available for which Brian felt he was qualified. He applied for this position, believing he had a good chance of being promoted. However, when the announcement was made, the position had been given to a younger man who had been with the company only 5 years. Brian seemed to accept the decision, but over the last few weeks he has become increasingly withdrawn. He speaks to very few people at the office and is becoming seriously behind in his work. At home, he eats very little, talks to family members only when they ask a direct question, withdraws to his bedroom very early in the evening, and does not come out until it is time to leave for work the next morning. Today, he refused to get out of bed or to go to work. His wife convinced him to talk to their family doctor, who admitted him to the hospital.

CLIENT'S PERCEPTION OF THE STRESSOR

Brian states that all his life he has "not been good enough at anything. I could never please my father. Now I can't seem to please my boss. What's the use of trying? I came to the hospital because my wife and my doctor are afraid I might try to kill myself. I must admit the thought has crossed my mind more than once. I seem to have very little motivation for living. I just don't care anymore."

DIAGNOSES AND OUTCOME IDENTIFICATION

The following nursing diagnoses were formulated for Sam:

1. Risk for suicide related to depressed mood and expression of having nothing to live for
2. Chronic low self-esteem related to lack of positive feedback and learned helplessness evidenced by a sense of worthlessness, lack of eye contact, social isolation, and negative/pessimistic outlook

The following may be used as criteria for measurement of outcomes in the planning of care for Brian:

THE CLIENT WILL:

1. Not harm self
2. Express hope for the future
3. Demonstrate increased self-esteem and perception of self as a worthwhile person

CASE STUDY—cont'd

PLANNING AND IMPLEMENTATION

Table 19–4 presents a nursing care plan for Brian employing techniques associated with cognitive therapy that are within the scope of psychiatric nursing practice. These include providing psychoeducation, use of the therapeutic relationship, and counseling interventions (American Nurses' Association, American Psychiatric Nurses Association, & International Society of Psychiatric-Mental Health Nurses, 2014). Rationales are presented for each intervention.

EVALUATION

Reassessment is conducted to determine if the nursing interventions have been successful in achieving the objectives of Brian's care. Evaluation can be facilitated by gathering information using the following questions:

1. Has self-harm to Brian been avoided?
2. Have Brian's suicidal ideations subsided?
3. Does Brian know where to seek help in a crisis situation?
4. Has Brian discussed the recent loss with staff and family?
5. Is Brian able to verbalize personal hope for the future?
6. Can Brian identify positive attributes about himself?
7. Does Brian demonstrate motivation to move on with his life without a fear of failure?

Table 19–4 | CARE PLAN FOR "BRIAN" (AN EXAMPLE OF INTERVENTION WITH COGNITIVE THERAPY)

NURSING DIAGNOSIS: RISK FOR SUICIDE

RELATED TO: Depressed mood

OUTCOME CRITERIA	NURSING INTERVENTIONS*	RATIONALE*
Brian will not harm himself.	1. Acknowledge Brian's feelings of despair.	1. Cognitive therapy focuses on pursuing client's point of view.
	2. Convey warmth, accurate empathy, and genuineness.	2. Establishing a therapeutic alliance is foundational to a therapeutic, problem-solving relationship
	3. Collaborate with the client in conducting a thorough assessment of suicide risk. (See Chapter 17, Suicide Prevention, for more information.)	3. Developing a collaborative assessment and plan for suicide prevention is foundational to working with any client at risk for suicide.
	4. Through Socratic questioning, challenge irrational pessimism. Ask Brian to discuss what problems suicide would solve. Then try to get him to think of reasons for *not* attempting suicide.	4. These techniques help the suicidal client think beyond the immediate cognition.
	5. Begin a serious discussion of alternatives.	5. Exploring alternatives initiates the process of cognitive reevaluation by looking at all possible alternatives.

NURSING DIAGNOSIS: CHRONIC LOW SELF-ESTEEM

RELATED TO: Lack of positive feedback and learned helplessness

EVIDENCED BY: A sense of worthlessness, lack of eye contact, social isolation, and negative/pessimistic outlook

OUTCOME CRITERIA	NURSING INTERVENTIONS*	RATIONALE*
Brian demonstrates increased self-esteem and perception of	1. Ask Brian to keep a three-column automatic thought recording.	1. This technique encourages clients to develop insight into their cognitive responses.

Continued

Table 19–4 | CARE PLAN FOR "BRIAN" (AN EXAMPLE OF INTERVENTION WITH COGNITIVE THERAPY)—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS*	RATIONALE*
himself as a worthwhile person.	2. Help Brian to recognize that his worth as a person is not tied to his promotion at work. The world will go on and he can survive this loss.	2. The technique of decatastrophizing is designed to help clients put cognitions into a more balanced perspective.
	3. Help Brian to identify ways in which he could feel better about himself. For example, Sam states that he would like to update his computer skills, but he is afraid he is too old. Challenge his negative thinking about his age by incorporating the technique of "examining the evidence."	3. Generating alternatives helps clients recognize that a broader range of possibilities may exist than may be evident at the moment. Examining the evidence may help Brian understand that self-improvement is worthwhile at any age.
	4. Ask Brian to expand on his three-column automatic thought recording and make a daily record of dysfunctional thoughts (DRDT).	4. Cognitive therapists use this tool to help clients identify their automatic thoughts and modify them by coming up with more rational responses.
	5. Discourage Brian's ruminating about his failures. May need to withdraw attention if he persists. Focus on past accomplishments and offer support in undertaking new tasks. Offer recognition of successful endeavors and positive reinforcement of attempts made.	5. Lack of attention to undesirable behavior may discourage its repetition. Recognition and positive reinforcement enhance self-esteem and encourage repetition of desirable behaviors.

*Interventions and rationale for the diagnosis Risk for suicide are adapted from Beck, A.T., & Weishaar, M.E. (2011). Cognitive therapy. In R.J. Corsini and D. Wedding (Eds.), *Current psychotherapies* (9th ed., pp. 276-309). Belmont, CA: Brooks/Cole; Harvard Medical School. (2003). Confronting suicide—part II. *Harvard Mental Health Letter, 19*(12), 1-5.

Summary and Key Points

- Cognitive therapy is founded on the premise that how people think significantly influences their feelings and behavior.
- The concept was initiated in the 1960s by Aaron Beck in his work with depressed clients. Since that time, it has been expanded for use with a number of emotional illnesses.
- Cognitive therapy is short-term, highly structured, and goal-oriented therapy that consists of three major components: didactic, or educational, aspects; cognitive techniques; and behavioral interventions.
- The therapist teaches the client about the relationship between his or her illness and the distorted thinking patterns. Explanation about cognitive therapy and how it works is provided.
- The therapist helps the client to recognize his or her negative automatic thoughts (sometimes called *cognitive errors*).
- Once these automatic thoughts have been identified, various cognitive and behavioral techniques are used to assist the client to modify the dysfunctional thinking patterns.
- Independent homework assignments are an important part of the cognitive therapist's strategy.
- Many of the cognitive therapy techniques are within the scope of psychiatric-mental health nursing practice.
- As the role of the psychiatric nurse continues to expand, the knowledge and skills associated with a variety of therapies will need to be broadened. Cognitive therapy is likely to be one in which nurses will become more involved.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Janet failed her first test in nursing school. She thinks, "Well, that's it! I'll never be a nurse." What automatic thought does this statement represent?
   a. Overgeneralization
   b. Magnification
   c. Catastrophic thinking
   d. Personalization

2. When Jack is not accepted at the law school of his choice, he thinks, "I'm so stupid. No law school will ever accept me." What automatic thought does this statement represent?
   a. Overgeneralization
   b. Magnification
   c. Selective abstraction
   d. Minimization

3. Nancy's new in-laws came to dinner for the first time. When Nancy's mother-in-law left some food on her plate, Nancy thought, "I must be a lousy cook." What automatic thought does this statement represent?
   a. Dichotomous thinking
   b. Overgeneralization
   c. Minimization
   d. Personalization

4. Barbara burned the toast. She thinks, "I'm a totally incompetent person." What automatic thought does this statement represent?
   a. Selective abstraction
   b. Magnification
   c. Minimization
   d. Personalization

5. Opal is a 43-year-old woman who is suffering from depression and suicidal ideation. Opal says, "I'm such a worthless person. I don't deserve to live." The therapist responds, "I would like for you to think about what problems committing suicide would solve." The therapist is using which of the following cognitive therapy techniques?
   a. Imagery
   b. Role play
   c. Problem-solving
   d. Thought recording

6. The thought recording (two-column and three-column) cognitive therapy techniques help clients:
   a. Identify automatic thoughts.
   b. Modify automatic thoughts.
   c. Identify rational alternatives.
   d. All of the above.

7. The daily record of dysfunctional thoughts (DRDT) is used in cognitive therapy to help clients:
   a. Identify automatic thoughts.
   b. Modify automatic thoughts.
   c. Identify rational alternatives.
   d. All of the above.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. A client tells the therapist, "I thought I would just die when my husband told me he was leaving me. If I had been a better wife, he wouldn't have fallen in love with another woman. It's all my fault." The therapist asks the client to explore what responsibilities the husband may have in the breakup. What cognitive therapy technique is the therapist using?
   a. Reattribution
   b. Role-play
   c. Decatastrophizing
   d. Thought recording

9. A client tells the therapist, "I thought I would just die when my husband told me he was leaving me. If I had been a better wife, he wouldn't have fallen in love with another woman. It's all my fault." The therapist wants to use the technique of "examining the evidence." Which of the following statements reflects this technique?
   a. "How do you think you could have been a better wife?"
   b. "Okay, you say it's all your fault. Let's discuss why it might be your fault, and then we will look at why it may not be."
   c. "Let's talk about what would make you a happier person."
   d. "Would you have wanted him to stay if he didn't really want to?"

10. The therapist teaches a client that when the idea of herself as a worthless person starts to form in her mind, she should immediately start to whistle the tune of "Dixie." What cognitive therapy technique is the therapist using?
    a. Behavioral rehearsal
    b. Social skills training
    c. Distraction
    d. Generating alternatives

20 Electroconvulsive Therapy

KEY TERMS

insulin coma therapy

pharmacoconvulsive therapy

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *electroconvulsive therapy.*
2. Discuss historical perspectives related to electroconvulsive therapy.
3. Discuss indications, contraindications, mechanism of action, and side effects of electroconvulsive therapy.
4. Identify risks associated with electroconvulsive therapy.
5. Describe the role of the nurse in the administration of electroconvulsive therapy.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Mr. J. says to the nurse, "This consent form says there is a possibility of permanent memory loss with ECT. I don't want to lose my memory!" How should the nurse respond to Mr. J.?
2. What medication is commonly given before the ECT treatment to decrease secretions?
3. Why is the client given oxygen during the procedure?

Electroconvulsive therapy (ECT) has long had a negative reputation. In the iconic depiction of this treatment in the movie *One Flew Over the Cuckoo's Nest,* it is a physically and emotionally brutal procedure imposed on unwilling clients in order to calm them. Today, ECT remains one of the most controversial treatments for psychological disorders and remains the subject of impassioned debate among various factions within both the professional and lay communities. One of the most recent debates stems from the U.S. Food and Drug Administration (FDA)'s (2016) proposed rule that categorizes ECT machines as low risk, a downgrade from their long-held high-risk classification. Critics of the procedure take offense to this proposal, with some even threatening to sue the FDA.

Despite its controversial image, ECT has been used continuously for more than 50 years, longer than any other physical treatment for mental illness. Kellner (2010) identifies that it has achieved this longevity because, when administered properly for the right illness, it can help as much as or more than any other treatment (Kellner, 2010).

This chapter explores the historical perspectives, indications and contraindications, mechanism of action, side effects, and risks associated with ECT. The role of the nurse in the care of the client receiving ECT is presented in the context of the nursing process.

Electroconvulsive Therapy, Defined

CORE CONCEPT
Electroconvulsive Therapy
The induction of a grand mal (generalized) seizure through the application of electrical current to the brain.

With ECT, seizure is induced by administering a dose of electrical current through electrodes placed either bilaterally (in the bifrontal or bifrontotemporal areas) or unilaterally on the right side of the frontotemporal area. Right unilateral ECT is associated with fewer cognitive side effects, and its efficacy can be ensured with adequate dosing strategies (Sadock, Sadock, & Ruiz, 2015). Although unilateral treatments were once conducted on the hemisphere of the nondominant hand, Sadock and associates (2015) note that the right hemisphere is involved in sustaining depressed mood regardless of handedness. The dose of electrical current is carefully controlled through the use of an ECT machine.

The amount of electrical stimulus applied is a point of controversy among clinicians. The dose of electrical stimulation must be strong enough to reach the patient's seizure threshold, but this threshold is highly variable among individuals. Further, a patient's seizure threshold may increase 25 to 200 percent during the course of ECT treatments. In this mechanism of action, ECT itself acts as an anticonvulsant because the seizure threshold increases as treatment progresses (Sadock et al., 2015).

Observing the patient for seizure activity is not always the best indicator. Movements are minimal because of the administration of a muscle relaxant before treatment. The tonic phase of the seizure usually lasts 10 to 15 seconds and may be identified by a rigid plantar extension of the feet. The clonic phase follows and is usually characterized by rhythmic movements of the muscles that decrease in frequency and finally disappear. Because of the muscle relaxant, movements may be observed merely as a rhythmic twitching of the toes. Monitoring EEG activity during the treatment provides evidence of grand mal seizure activity.

Most clients require an average of 6 to 12 treatments, but some may require up to 20 treatments (Sadock et al., 2015). Treatments are usually administered every other day, three times per week. Treatments are performed on an inpatient basis for those who require close observation and care (e.g., clients who are suicidal, agitated, delusional, catatonic, or acutely manic). Those at less risk may receive therapy at an outpatient treatment facility.

Historical Perspectives

Inducing convulsions to treat psychiatric illness was reported as early as the 16th century, although the mechanism of induction at that time was the administration of camphor. In the early 1900s, Hungarian neuropsychiatrist Ladislas Meduna observed that individuals with epilepsy had more than the average number of glial cells and that people with schizophrenia had fewer than average, sparking interest and further study into the clinical benefits of seizure induction. The first electroconvulsive therapy treatment was performed in April 1938 by Italian psychiatrists Ugo Cerletti and Lucio Bini in Rome. Other somatic therapies were tried before that time, including **insulin coma therapy** and **pharmacoconvulsive therapy.**

Insulin coma therapy was introduced by the German psychiatrist Manfred Sakel in 1933. His therapy was used for clients with schizophrenia. The insulin injection treatments induced a hypoglycemic coma, which Sakel claimed was effective in alleviating schizophrenic symptoms. This therapy required vigorous medical and nursing intervention through the stages of induced coma. Some fatalities occurred when clients failed to respond to efforts directed at termination of the coma. The efficacy of insulin coma therapy has been questioned, and its use has been discontinued in the treatment of mental illness.

Pharmacoconvulsive therapy was introduced in Budapest in 1934 by Ladislas Meduna (Fink, 2009). He induced convulsions with intramuscular injections of camphor in oil in clients with schizophrenia. He based his treatment on clinical observation and theorized the existence of a biological antagonism between schizophrenia and epilepsy. Thus, by inducing seizures he hoped to reduce schizophrenic symptoms. Because he discovered that camphor was unreliable

for inducing seizures, he began using pentylenetetrazol (Metrazol). Some successes were reported in terms of reduction of psychotic symptoms, and until the advent of ECT in 1938, pentylenetetrazol was the most frequently used method for producing seizures in clients with psychosis. There was a brief resurgence of pharmacoconvulsive therapy in the late 1950s, when flurothyl (Indoklon), a potent inhalant convulsant, was introduced as an alternative for individuals who were unwilling to consent to ECT for the treatment of depression and schizophrenia. Pharmacoconvulsive therapy is no longer used in psychiatry.

Periodic recognition of the important contribution of ECT in the treatment of mental illness has been evident in the United States. An initial acceptance was observed from 1940 to 1960, followed by a 20-year period during which ECT was considered objectionable by both the psychiatric profession and the public. A second wave of acceptance began around 1980 and has been increasing to the present. The period of nonacceptability coincided with the introduction of tricyclic and monoamine oxidase inhibitor antidepressant drugs and ended with the realization among many psychiatrists that the widely heralded replacement of ECT with these chemical agents had failed to materialize (Abrams, 2002). Some individuals showed improvement with ECT after failing to respond to other forms of therapy.

Currently, an estimated 100,000 people in the United States and about 2 million people worldwide receive ECT treatments each year (Kalapatapu, 2015; Mathew, Amiel, & Sackeim, 2013). The typical client is white, female, middle aged, and from a middle- to upper-income background, receiving treatment in a private or university hospital for major depression, usually after drug therapy has proved ineffective. Largely because of the expense involved and the need for a team of highly skilled medical specialists, many public hospitals are unable to offer this service to their clients.

Indications

Major Depression

ECT has been shown to be effective in the treatment of severe depression, particularly among depressed clients who are also experiencing psychotic symptoms, catatonia, psychomotor retardation, and neurovegetative changes, such as disturbances in sleep, appetite, and energy. ECT is typically considered only after a trial of therapy with antidepressant medication has proved ineffective. It may be considered the treatment of choice when the need for treatment response is urgent, such as in patients who are extremely suicidal or are refusing food and are nutritionally compromised (Kalapatapu, 2015).

Mania

ECT is indicated in the treatment of acute manic episodes and is at least as effective as lithium (Sadock et al., 2015). At present, it is rarely used for this purpose because lithium and other pharmacotherapies are so effective in the short and long term. However, ECT has been shown to be effective in the treatment of manic clients who do not tolerate or fail to respond to lithium or other drug treatment or when life is threatened by dangerous behavior or exhaustion. ECT should not be used while a patient is receiving lithium because lithium lowers the seizure threshold and may cause prolonged seizures when combined with ECT (Sadock et al., 2015).

Recent evidence has supported the use of ECT in the treatment of bipolar disorders with mixed states (concurrent depressive and manic features). This is especially beneficial, since this type of bipolar disorder is often more severe than other types, with lower interepisode remission and higher risk for suicide (Palma et al., 2016). Nonetheless, it is still used only when the patient has failed to respond to medication.

Schizophrenia

ECT can induce a remission in some clients who present with acute schizophrenia, particularly those who have marked positive, catatonic, or affective (depression or mania) symptomatology (Sadock et al., 2015). It does not appear to be of value to individuals with chronic schizophrenic illness.

Other Conditions

ECT has been reported as useful in episodic psychosis, atypical psychosis, obsessive-compulsive disorder, delirium, and medical conditions such as neuroleptic malignant syndrome, hypopituitarism, intractable seizure disorders, and Parkinson's disease, particularly when there is comorbid depression (Kalapatapu, 2015; Sadock et al., 2015). For pregnant women and elderly individuals who are unable to take medication, ECT may be a safer alternative. Oztav and associates (2015) reported that although the literature on safety of ECT in pregnancy is scarce, their research supported others' findings that it can be used safely. They also note that 40 percent of pregnant patients treated with ECT in their study demonstrated full recovery. ECT is not effective in somatization disorders (unless there is comorbid depression), personality disorders, and anxiety disorders (Sadock et al., 2015).

Contraindications

There are no absolute contraindications for ECT. However, some patients may be considered at higher risk for adverse events that require attention and closer monitoring (Black & Andreasen, 2014; Eisendrath &

Lichtmacher, 2013; Sadock et al., 2015). High-risk conditions are largely cardiovascular and include myocardial infarction or cerebrovascular accident within the preceding 3 to 6 months, aortic or cerebral aneurysm, severe underlying hypertension, and congestive heart failure. Clients with cardiovascular problems are placed at risk because of the body's response to the seizure itself. The initial vagal response results in a sinus bradycardia and drop in blood pressure. This is followed immediately by tachycardia and a hypertensive response. These changes can be life threatening to an individual with an already compromised cardiovascular system.

Patients with intracranial lesions may be at risk for edema or brain herniation after ECT, but these risks can be decreased by pretreatment with dexamethasone in cases in which the lesion is small (Sadock et al., 2015). Patients with increased intracranial pressure are at increased risk related to increased cerebral blood flow during seizures, but Sadock and associates (2015) note that risk can be lessened by controlling the patient's blood pressure during the treatment.

Other factors that place clients at risk during ECT include severe osteoporosis, acute and chronic pulmonary disorders, and high-risk or complicated pregnancy. Because oxytocin levels increase after ECT, there is an increased risk of intrauterine contractions and premature birth with an incidence of around 3 to 6 percent (Oztav et al., 2015).

Mechanism of Action

Both therapeutic and adverse effects may result from inducing a bilateral generalized seizure, but the exact mechanism by which ECT effects a therapeutic response is unknown. Many parts of the central nervous system are affected by ECT, including hormones, neuropeptides, neurotrophic factors, and nearly every neurotransmitter (Kalapatapu, 2015). Affected neurotransmitters include serotonin, norepinephrine, and dopamine, the same biogenic amines that are affected by antidepressant drugs. Research studies on serotonin, however, have yielded such mixed results that their impact in the efficacy of ECT remains controversial (Sadock et al., 2015). Other possible mechanisms of action, based on changes that occur during ECT, include an increase of GABA transmission and an increase of endogenous opioids, both of which may raise the seizure threshold (Kalapatapu, 2015).

Several recent studies have identified an increase in gray matter, particularly in the hippocampal and amygdala areas, following ECT (Depping et al., 2016; Pirnia et al., 2016; Sartorius et al., 2015). Because these areas of the brain show a decrease in volume in major depression, the study findings are being looked at with interest as an indication of neuroplasticity and the neurorestorative effects of ECT.

One recent study revealed that the therapeutic response from ECT may be related to the modulation of white matter microstructure in pathways connecting frontal and limbic areas, which are altered in major depression (Lyden et al., 2014). The results of studies relating to the mechanism underlying the effectiveness of ECT are still ongoing and continue to bear mixed results. It may be a complex dynamic of several effects interacting with one another.

Side Effects

The most common side effects of ECT are temporary memory loss and confusion. Critics of the therapy argue that these changes represent irreversible brain damage. Proponents insist they are temporary and reversible. In one recent study that looked at long-term outcomes of ECT in clients with bipolar I disorder (Haghighi et al., 2016), the evidence supported that 2 years following ECT, cognitive skills and short-term memory were not impaired, while mood symptom recurrence had improved regardless of the level of mania. It has been argued that bilateral electrode placement may be more effective than right unilateral (RUL) placement but is associated with more cognitive side effects. However, evidence supports that a more aggressive stimulus in RUL placement improves its efficacy (Pulia et al., 2013).

Risks Associated With Electroconvulsive Therapy

Mortality

In 2011, the American Psychiatric Nurses Association (APNA) advanced a position statement in support of ECT for "severe depression that has been shown to be refractory to medication administration" (American Psychiatric Nurses Association, 2015). The APNA cites a mortality rate less than that of childbirth. Studies indicate that the mortality rate from ECT is about 0.002 percent per treatment and 0.01 percent for each patient (Sadock et al., 2015). Although the occurrence is rare, the major cause of death with ECT is from cardiovascular complications (e.g., acute myocardial infarction or cerebrovascular accident), usually in individuals with previously compromised cardiac status. Assessment and management of cardiovascular disease *prior* to treatment is vital in the reduction of morbidity and mortality rates associated with ECT.

Memory Loss

Memory impairment almost always occurs to some degree during the course of ECT treatments, but follow-up studies indicate that most patients return to their cognitive baselines after 6 months (Sadock

et al., 2015). Some clients do report persistent memory impairment, and in most cases, this impairment occurs among patients who showed little improvement with ECT (Sadock et al., 2015).

Sackeim and associates (2007) reported on the results of a longitudinal study of clinical and cognitive outcomes in patients with major depression treated with ECT at seven facilities in the New York City metropolitan area. Participants were evaluated shortly following the ECT course and 6 months later. Data revealed that cognitive deficits at the 6-month interval were directly related to type of electrode placement and electrical waveform used. Bilateral electrode placement resulted in more severe and persisting (as evaluated at the 6-month follow-up) retrograde amnesia than unilateral placement. The extent of the amnesia was directly related to the number of ECT treatments received. The researchers also found that stimulation produced by sine wave (continuous) current resulted in greater short- and long-term deficits than that produced by short-pulse wave (intermittent) current.

Black and Andreasen (2014) suggested that all clients receiving ECT should be informed of the possibility for some degree of permanent memory loss. Although the potential for these effects appears to be minimal, the client must be made aware of the risks involved before consenting to treatment.

Brain Damage

The question of brain damage secondary to ECT treatments has been advanced as a concern by critics of the procedure. The subject has been studied using a variety of brain imaging modalities, and virtually all conclude there is no evidence of brain damage caused by ECT treatments (McClintock & Husain, 2011; Sadock et al., 2015). Previously cited studies on the neurorestorative effects of ECT have argued that this, too, is evidence in contradiction to ideas about brain-damaging effects of ECT.

The Role of the Nurse in Electroconvulsive Therapy

Nurses play an integral role in education and preparation for and administration of ECT. They provide support before, during, and after the treatment to the client and family and assist the medical professionals who are conducting the therapy. The nursing process provides a systematic approach to the provision of care for the client receiving ECT.

Assessment

A complete physical examination must be conducted by the appropriate medical professional prior to the initiation of ECT. This evaluation should include a thorough assessment of cardiovascular and pulmonary status as well as laboratory blood and urine studies. A skeletal history and x-ray assessment should also be considered.

The nurse may be responsible for ensuring that informed consent has been obtained from the client. "No patient who has the capacity to give voluntary consent should be given ECT without his or her written consent" and clinicians should be aware of local, state, and federal laws governing the use of ECT (Kalapatapu, 2015). If the depression is severe, the client is clearly unable to consent to the procedure, and relevant laws allow it, permission may be obtained from family or another legally responsible individual. Consent is secured only after the client or responsible individual acknowledges understanding of the procedure, including possible side effects and potential risks involved.

Client and family must also understand that ECT is voluntary and that consent may be withdrawn at any time (American Psychiatric Association, 2001; Fetterman & Ying, 2011; Vera, 2012). This kind of education supports patient-centered care.

Nurses may also be required to assess the following:

- The client's mood and level of interaction with others
- Evidence of suicidal ideation, plan, and means
- Level of anxiety and fears associated with receiving ECT
- Thought and communication patterns
- Baseline memory for short- and long-term events
- Client and family knowledge of indications for, side effects of, and potential risks associated with ECT
- Current and past use of medications
- Baseline vital signs and history of allergies
- The client's ability to carry out activities of daily living

Diagnosis and Outcome Identification

Selection of appropriate nursing diagnoses for the client undergoing ECT is based on continual assessment before, during, and after treatment. Selected potential nursing diagnoses with outcome criteria for evaluation are presented in Table 20–1.

Planning and Implementation

ECT treatments are usually performed in the morning. The client is given nothing by mouth (NPO) for 6 to 8 hours before the treatment. Some institutional policies require that the client be placed on NPO status at midnight prior to the treatment day. The treatment team routinely consists of the psychiatrist, anesthesiologist, and two or more nurses.

Nursing interventions before the treatment include

- Ensuring that the physician and the anesthesiologist have obtained informed consent and that a signed permission form is on the chart.

TABLE 20–1 Potential Nursing Diagnoses and Outcome Criteria for Client Receiving ECT	
NURSING DIAGNOSES	**OUTCOME CRITERIA**
Anxiety (moderate to severe) related to impending therapy	Client verbalizes a decrease in anxiety following explanation of procedure and expression of fears.
Deficient knowledge related to necessity for and side effects or risks of ECT	Client verbalizes understanding of need for and side effects/risks of ECT following explanation.
Risk for injury related to risks associated with ECT	Client undergoes treatment without sustaining injury.
Risk for aspiration related to altered level of consciousness immediately following treatment	Client experiences no aspiration during ECT.
Decreased cardiac output related to vagal stimulation occurring during the ECT	Client demonstrates adequate tissue perfusion during and after treatment (absence of cyanosis or severe change in mental status).
Impaired memory/acute confusion related to side effects of ECT	Client maintains reality orientation following ECT treatment.
Self-care deficit related to incapacitation during postictal stage	Client's self-care needs are fulfilled at all times.
Risk for activity intolerance related to post-ECT confusion and memory loss	Client gradually increases participation in therapeutic activities to the highest level of personal capability.

■ Ensuring that the most recent laboratory reports (complete blood count, urinalysis) and results of electrocardiogram (ECG) and x-ray examination are available.

■ Approximately 1 hour before treatment is scheduled, taking and recording vital signs. Have the client void and remove dentures, eyeglasses or contact lenses, jewelry, and hairpins. Following institutional requirements, the client should change into hospital gown or, if permitted, into his or her own loose clothing or pajamas. At this point, it is best for the client to remain in bed. Side rails may be raised unless prohibited by institutional policy or assessed as unsafe for the individual client.

■ Approximately 30 minutes before treatment, administering the pretreatment medication as prescribed by the physician. The usual order is for atropine sulfate or glycopyrrolate (Robinul) given intramuscularly. Either of these medications may be ordered to decrease secretions (to prevent aspiration) and counteract the effects of vagal stimulation (bradycardia) induced by the ECT.

■ Staying with the client to help allay fears and anxiety. Maintain a positive attitude about the procedure, and encourage the client to verbalize feelings.

In the treatment room, the client is placed on the treatment table in a supine position, and the anesthesiologist intravenously administers a short-acting anesthetic. The two most commonly used anesthetic agents for ECT in the United States are methohexital and propofol (Kellner & Bryson, 2012). Some studies have identified methohexital (Brevital) as preferable because it increases the duration of the seizure (Pulia et al., 2013) and because of its established safety record, effectiveness, and low cost (Kalapatapu, 2015). The duration of the seizure is significant only in the sense that if it is less than 20 seconds, restimulation may be required to achieve a fully generalized seizure. Restimulation may be associated with an increase in cognitive side effects (Pulia et al., 2013). A muscle relaxant, usually succinylcholine chloride, is given intravenously to prevent severe muscle contractions during the seizure, thereby reducing the possibility of fractured or dislocated bones. Because succinylcholine paralyzes respiratory muscles as well, the client is oxygenated with pure oxygen during and after the treatment, except for the brief interval of electrical stimulation, until spontaneous respirations return (Kellner & Bryson, 2012). A blood pressure cuff may be placed on the lower leg and inflated above systolic pressure prior to the injection of the succinylcholine. This is to ensure that the seizure activity can be observed in one limb that is unaffected by the muscle relaxant.

An airway/bite block is placed in the client's mouth, and he or she is positioned to facilitate airway patency. Electrodes are placed (either bilaterally or unilaterally) on the temples to deliver the electrical stimulation.

Nursing interventions during the treatment include

■ Ensuring patency of airway. Provide suctioning if needed.

■ Assisting anesthesiologist with oxygenation as required.

■ Observing readouts on machines monitoring vital signs and cardiac functioning.

■ Providing support to the client's arms and legs during the seizure.

■ Observing and recording the type and amount of movement induced by the seizure.

After the treatment, the anesthesiologist continues to oxygenate the client with pure oxygen until spontaneous respirations return. Most clients awaken within 10 or 15 minutes of the treatment and are confused and disoriented; however, some clients will sleep for 1 to 2 hours following the treatment. All clients require close observation in this immediate posttreatment period.

Nursing interventions in the posttreatment period include

■ Monitoring pulse, respirations, and blood pressure every 15 minutes for the first hour, during which time the client should remain in bed.

■ Positioning the client on side to prevent aspiration.

■ Orienting the client to time and place.

■ Describing what has occurred.

■ Providing reassurance that confusion and memory loss will subside and memories should return following the course of ECT therapy.

■ Allowing the client to verbalize fears and anxieties related to receiving ECT.

■ Staying with the client until he or she is fully awake, oriented, and able to perform self-care activities without assistance.

■ Providing the client with a highly structured schedule of routine activities in order to minimize confusion.

Evaluation

Evaluation of the effectiveness of nursing interventions is based on the achievement of the projected outcomes. Reassessment may be based on answers to the following questions:

■ Was the client's anxiety maintained at a manageable level?

■ Was the client/family teaching completed satisfactorily?

■ Did the client/family verbalize understanding of the procedure, its side effects, and risks involved?

■ Did the client undergo treatment without experiencing injury or aspiration?

■ Has the client maintained adequate tissue perfusion during and following treatment? Have vital signs remained stable?

■ With consideration to the individual client's condition and response to treatment, is the client reoriented to time, place, and situation?

■ Have all of the client's self-care needs been fulfilled?

■ Is the client participating in therapeutic activities to his or her maximum potential?

■ What is the client's level of social interaction?

Careful documentation is an important part of the evaluation process. Some routine observations may be evaluated on flow sheets specifically identified for ECT. However, progress notes with detailed descriptions of client behavioral changes are essential to evaluate improvement and help determine the number of treatments that will be administered. Continual reassessment, planning, and evaluation ensure that the client receives adequate and appropriate nursing care throughout the course of therapy. In some cases, maintenance ECT (either weekly, biweekly, or monthly) is recommended and has been reported as effective for relapse prevention, although more evidence is needed to support the benefits of this practice (Sadock et al., 2015). Other brain stimulation treatments, such as transcranial magnetic stimulation, cranial electrical stimulation, magnetic seizure therapy, and vagal nerve stimulation, provide alternatives that may also be beneficial in treatment-resistant cases, but more research is needed to clearly identify effectiveness and best practices for their use.

Studies such as one previously cited (Pulia et al., 2013) found that changes in anesthetic agent (from propofol to methohexital) and increasing the dose of electric stimulus demonstrated improvements in the quality of their ECT procedures and efficacy. Pulia, the nurse involved in the research, highlights the active role that nurses can play when collaborating with other members of the health-care team to pursue quality improvement.

Summary and Key Points

■ ECT is the induction of a grand mal seizure through the application of electrical current to the brain.

■ ECT is a safe and effective treatment alternative for individuals with depression, mania, or schizoaffective disorder who do not respond to other forms of therapy.

■ There are no absolute contraindications for ECT, but some conditions have associated increased risks and require close monitoring and attention. Individuals with cardiovascular problems are at high risk for complications from ECT. Increased intracranial pressure and intracranial lesions impose higher risks for adverse events.

■ Other factors that place clients at risk include severe osteoporosis, acute and chronic pulmonary disorders, and high-risk or complicated pregnancy.

■ The exact mechanism of action of ECT is unknown, but there are multiple effects on central

nervous system activity, including hormones, neuropeptides, neurotrophic factors, and nearly every neurotransmitter. Studies demonstrating an increase in gray matter, particularly in the hippocampal and amygdala areas, suggest neuroplasticity and a possibly neurorestorative effect of ECT.

■ The most common side effects with ECT are temporary memory loss and confusion.

■ Although it is rare, death must be considered a risk associated with ECT. When it does occur, the most common cause is cardiovascular complications.

■ There is virtually no evidence supporting the idea that ECT causes permanent brain damage.

■ The nurse assists with ECT using the steps of the nursing process before, during, and after treatment.

■ Important nursing interventions include ensuring client safety, managing client anxiety, and providing adequate client education.

■ Nursing input into the ongoing evaluation of client behavior is an important factor in determining the therapeutic effectiveness of ECT.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Electroconvulsive therapy is most commonly prescribed for which of the following?
   a. Bipolar disorder, manic
   b. Paranoid schizophrenia
   c. Major depression
   d. Obsessive-compulsive disorder

2. Which of the following best describes the average number of ECT treatments given and the timing of administration?
   a. One treatment per month for 6 to 12 months
   b. One treatment every other day, three times a week for a total of 6 to 12 treatments
   c. One treatment three times per week for 6 to 12 months
   d. One treatment every day for a total of 10 to 20 treatments

3. Which of the following conditions increases the risk of adverse events associated with ECT? (Select all that apply.)
   a. Increased intracranial pressure
   b. Recent myocardial infarction
   c. Severe underlying hypertension
   d. Congestive heart failure
   e. Breast cancer

4. A patient has been ordered ECT and asks the nurse, "Exactly how does ECT work?" Which of the following is the most accurate response by the nurse?
   a. "I'm not allowed to tell you that because that would be informed consent."
   b. "The exact mechanism is unknown, but there are several ways that ECT may have antidepressant effects."
   c. "The administration of a shock to the brain induces memory loss, which will make you forget you are depressed."
   d. "The neuroplasticity affected by seizure activity prevents further brain damage."

5. The most common side effects of ECT are:
   a. Permanent memory loss and brain damage.
   b. Fractured and dislocated bones.
   c. Myocardial infarction and cardiac arrest.
   d. Temporary memory loss and confusion.

Review Questions—cont'd
Self-Examination/Learning Exercise

6. Sam has a diagnosis of major depression. After an unsuccessful trial of antidepressant medication, Sam's physician has hospitalized him for a course of ECT treatments. Sam says to the nurse on admission, "I don't want to end up like McMurphy in *One Flew Over the Cuckoo's Nest!* I'm scared!" What is Sam's priority nursing diagnosis at this time?
   a. Anxiety related to deficient knowledge about ECT
   b. Risk for injury related to risks associated with ECT
   c. Deficient knowledge related to negative media presentation of ECT
   d. Acute confusion related to side effects of ECT

7. Sam, who has been hospitalized for ECT treatments, says to the nurse on admission, "I don't want to end up like McMurphy in *One Flew Over the Cuckoo's Nest!* I'm scared!" Which of the following statements would be most appropriate by the nurse in response to Sam's expression of concern?
   a. "I guarantee you won't end up like McMurphy, Sam."
   b. "The doctor knows what he is doing. There's nothing to worry about."
   c. "I know you are scared, Sam, and we're going to talk about what you can expect from the therapy."
   d. "I'm going to stay with you as long as you are scared."

8. What is the priority nursing intervention before starting ECT therapy?
   a. Take vital signs and record.
   b. Have the patient void.
   c. Administer succinylcholine.
   d. Ensure that the consent form has been signed.

9. Atropine sulfate is administered to a client receiving ECT for what purpose?
   a. To alleviate anxiety
   b. To decrease secretions
   c. To relax muscles
   d. As a short-acting anesthetic

10. Succinylcholine is administered to a client receiving ECT for what purpose?
   a. To alleviate anxiety
   b. To decrease secretions
   c. To relax muscles
   d. As a short-acting anesthetic

The Recovery Model

CHAPTER OUTLINE

KEY TERMS

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *recovery*.
2. Discuss the 10 guiding principles of recovery as delineated by the Substance Abuse and Mental Health Services Administration.
3. Describe three models of recovery: Tidal Model, WRAP Model, and Psychological Recovery Model.
4. Identify nursing interventions to assist individuals with mental illness in the process of recovery.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What is the basic concept of a recovery model?
2. How is recovery supported by peer groups?
3. What is the focus of the Tidal Model of Recovery?
4. What is the intended outcome in the Psychological Recovery Model?

For many years, the belief was that individuals with mental illnesses do not recover. Optimistically, the course of the illness was viewed in terms of maintenance, and pessimistically, with the expectation for deterioration. The medical model has primarily focused on treatment of symptoms, largely with psychotropic medications, but as Jacobs (2015) notes, in spite of these available treatments, people with severe mental illness "continue to have residual positive symptoms, negative symptoms and marked cognitive deficits"

and as a result have difficulty "getting their lives back on track." But research suggests that striving for and achieving recovery is in fact realistic for many individuals. While critics of the recovery model argue that it is in contradiction to the scientific medical model, other literature highlights the complementary and integrative potential of both models working collaboratively (Duckworth, 2015; Jacobs, 2015).

The concept of recovery is not new. It originally began in the addictions field, referring to a person

recovering from a substance-related disorder. The term has more recently been adopted by mental health professionals who believe that recovery from mental illness is also possible.

> ## CORE CONCEPT
> **Recovery**
> A process of movement toward improvement in health and quality of life.

What Is Recovery?

A number of definitions of recovery as it applies to mental illness have been proposed. The Substance Abuse and Mental Health Services Administration (SAMHSA, 2012) suggests the following:

> Recovery from mental health disorders and substance use disorders is a process of change through which individuals improve their health and wellness, live a self-directed life, and strive to reach their full potential.

Essential to understanding recovery definitions and models is the focus on recovery as an ongoing process rather than a set of interventions with a distinct endpoint.

SAMHSA suggests that a life in recovery is supported by four major dimensions:

1. **Health:** Overcoming or managing one's disease as well as living in a physically and emotionally healthy way
2. **Home:** A stable and safe place to live
3. **Purpose:** Meaningful daily activities, such as a job, school, volunteerism, family caretaking, or creative endeavors, and the independence, income, and resources to participate in society
4. **Community:** Relationships and social networks that provide support, friendship, love, and **hope.**

William A. Anthony (1993), executive director of the Center for Psychiatric Rehabilitation at Boston University, offers this definition:

> Recovery is described as a deeply personal, unique process of changing one's attitudes, values, feelings, goals, skills, and/or roles. It is a way of living a satisfying, hopeful, and contributing life even with limitations caused by illness. Recovery involves the development of new meaning and purpose in one's life as one grows beyond the catastrophic effects of mental illness. (p. 13)

The President's New Freedom Commission on Mental Health (2003) proposed to transform the mental health system by shifting the paradigm of care of persons with serious mental illness from traditional medical psychiatric treatment toward the concept of recovery, and the American Psychiatric Association has endorsed a recovery model from a psychiatric services perspective (Sharfstein, 2005).

In a systematic review and synthesis of the various approaches to what has become known as the recovery model, Leamy and associates (2011) identified five recovery processes that form a common foundation for this model: connectedness, hope, optimism about the future, identity, meaning in life, and empowerment. The consumer is empowered to take primary control over decisions about his or her own care. The National Association of Social Workers (NASW, 2006) states, "Consumers need to be as fully informed as possible about the potential benefits and consequences of each decision. They also need to know the possible results if they become a danger to themselves or others."

Guiding Principles of Recovery

As part of its Recovery Support Strategic Initiative, a year-long effort by SAMHSA and a wide range of partners in the behavioral health-care community and other fields, a working definition of recovery from mental health and substance use disorders (previously stated) was developed. In addition, guiding principles that support the recovery definition were delineated. These principles include the following (SAMHSA, 2012):

- **Recovery emerges from hope:** The belief that recovery is real provides the essential and motivating message of a better future—that people can and do overcome the internal and external challenges, barriers, and obstacles that confront them. Hope is internalized and can be fostered by peers, families, providers, allies, and others. Hope is the catalyst of the recovery process.
- **Recovery is person driven:** Self-determination and self-direction are the foundations for recovery as individuals define their own life goals and design their unique paths toward those goals. Individuals optimize their autonomy and independence to the greatest extent possible by leading, controlling, and exercising choice over the services and supports that assist their recovery and resilience. In so doing, they are empowered and provided the resources to make informed decisions, initiate recovery, build on their strengths, and gain or regain control over their lives.
- **Recovery occurs via many pathways:** Individuals are unique with distinct needs, strengths, preferences,

goals, culture, and backgrounds (including trauma experiences) that affect and determine their pathways to recovery. Recovery is built on the multiple capacities, strengths, talents, coping abilities, resources, and inherent value of each individual. Recovery pathways are highly personalized. They may include professional clinical treatment, use of medications, support from families and in schools, faith-based approaches, peer support, and other approaches. Recovery is nonlinear, characterized by continual growth and improved functioning that may involve setbacks. Because setbacks are a natural, though not inevitable, part of the recovery process, it is essential to foster resilience for all individuals and families. Abstinence is the safest approach for those with substance use disorders. Use of tobacco and nonprescribed or illicit drugs is not safe for anyone. In some cases, recovery pathways can be enabled by creating a supportive environment. This is especially true for children, who may not have the legal or developmental capacity to set their own course.

■ **Recovery is holistic:** Recovery encompasses an individual's whole life, including mind, body, spirit, and community. This holistic view includes addressing self-care practices, family, housing, employment, education, clinical treatment for mental and substance use disorders, services and supports, primary health care, dental care, complementary and alternative services, faith, spirituality, creativity, social networks, transportation, and community participation. The array of services and supports available should be integrated and coordinated.

■ **Recovery is supported by peers and allies:** Mutual support and mutual aid groups, including the sharing of experiential knowledge and skills as well as social learning, play an invaluable role in recovery. Peers encourage and engage other peers and provide each other with a vital sense of belonging, supportive relationships, valued roles, and community. Through helping others and giving back to the community, one helps oneself, too. Peer-operated supports and services provide important resources to assist people along their journeys of recovery and wellness. In addictions recovery, peer support has long been recognized as foundational, especially in 12-step programs such as Alcoholics Anonymous. In mental health treatment, although formal peer support is a newer approach, the premises are similar. These individuals, sometimes called *peer support specialists,* may be trained and/or certified in supportive skills but all share the experience of living with mental illness and, as such, can provide a unique perspective for support and trust in ongoing relationships. In a fully implemented recovery model, peer support specialists should be considered equal members of the treatment team (Getty, 2015). Professionals can also play an important role in the recovery process by providing clinical treatment and other services that support individuals in their chosen recovery paths. While peers and allies play an important role for many in recovery, their role for children and youth may be slightly different. Peer supports for families are very important for children with behavioral health problems and can also play a supportive role for youth in recovery.

■ **Recovery is supported through relationships and social networks:** An important factor in the recovery process is the presence and involvement of people who believe in the person's ability to recover; who offer hope, support, and encouragement; and who suggest strategies and resources for change. Family members, peers, providers, faith groups, community members, and other allies form vital support networks. Through these relationships, people leave unhealthy and/or unfulfilling life roles behind and engage in new roles (e.g., partner, caregiver, friend, student, employee) that lead to a greater sense of belonging, personhood, empowerment, autonomy, social inclusion, and community participation.

■ **Recovery is culturally based and influenced:** "Characteristics such as race or ethnicity, religion, low socioeconomic status, gender, age, mental health, disability, sexual orientation or gender identity, geographic location, or other characteristics historically linked to exclusion or discrimination are known to influence health status" (SAMHSA, 2015). The diverse representations of culture and cultural background (including values, traditions, and beliefs) are keys to determining a person's journey and unique pathway to recovery. Further, SAMHSA (2015) clarifies that "what may work for adults in recovery may be very different for youth or older adults in recovery. For example, the promotion of resiliency in young people, and the nature of social supports, peer mentors, and recovery coaching for adolescents and transitional age youth are different than recovery support services for adults and older adults." Services should be culturally grounded, attuned, sensitive, congruent, and competent, as well as personalized to meet each individual's unique needs.

■ **Recovery is supported by addressing trauma:** The experience of trauma (such as physical or sexual abuse, domestic violence, war, disaster, and other events) is often a precursor to or associated with alcohol and drug use, mental health problems, and related issues. Services and supports should be trauma informed to foster safety (physical and

emotional) and trust and should promote choice, empowerment, and collaboration.

■ **Recovery involves individual, family, and community strengths and responsibility:** Individuals, families, and communities have strengths and resources that serve as a foundation for recovery. In addition, individuals have personal responsibility for their own self-care and journeys of recovery and should be supported in speaking for themselves. Families and significant others have responsibilities to support their loved ones, especially children and youth in recovery. Communities have responsibilities to provide opportunities and resources to address discrimination and to foster social inclusion and recovery. Individuals in recovery also have a social responsibility and should have the ability to join with peers to speak collectively about their strengths, needs, wants, desires, and aspirations.

■ **Recovery is based on respect:** Community, systems, and societal acceptance and appreciation for people affected by mental health and substance use problems—including protecting their rights and eliminating discrimination—are crucial in achieving recovery. There is a need to acknowledge that taking steps toward recovery may require great courage. Self-acceptance, developing a positive and meaningful sense of identity, and regaining belief in one's self are particularly important.

The recovery model integrates services provided by professionals (e.g., medication, therapy, case management), services provided by consumers (e.g., advocacy, peer support programs, hotlines, mentoring), and services provided in collaboration (e.g., recovery education, crisis planning, community integration, consumer rights education) (Jacobson & Greenley, 2001). Jacobson and Greenley state:

> Although many of these services may sound similar to services currently being offered in many mental health systems, it is important to recognize that no service is recovery-oriented unless it incorporates the attitude that recovery is possible and has the goal of promoting hope, healing, empowerment, and connection. (p. 485)

The concepts of consumer-driven care and empowerment are closely related to the concept of patient-centered care that has been advanced by the Institute of Medicine (2003) (now the National Academy of Medicine) as one of the key elements to improving the quality of health care in the future. As this cultural shift evolves, nurses will need to be thoughtful about language and attitudes that support patient-centered recovery models. For example, a traditional goal for a patient has been described as, "Patient will comply with prescribed medication regime." In a patient-centered recovery model, a more appropriate goal might be stated as, "Patient will discuss preferences, advantages, and disadvantages of psychotropic medication in the management of his or her illness."

Models of Recovery

There are many evidence-based models of recovery. SAMHSA lists these in a database at the National Registry for Evidence-Based Programs and Practices (www.nrepp.samhsa.gov). Three of these models, the Tidal Model, the Wellness Action Recovery Plan (WRAP), and the Psychological Recovery Model, are discussed in this chapter.

The Tidal Model

The **Tidal Model** was developed in the late 1990s by Phil Barker and Poppy Buchanan-Barker of Newcastle, United Kingdom. It is a mental health nursing recovery model that may be used as the basis for interdisciplinary mental health care (Barker & Buchanan-Barker, 2012). The authors use the power of metaphor to engage with the person in distress. The metaphor of *water* is used to describe how individuals in distress can become emotionally, physically, and spiritually *shipwrecked* (Barker & Buchanan-Barker, 2005). The Tidal Model was the first recovery model to be developed by nurses in practice, drawing largely on nursing research, and in collaboration with users and consumers of mental health services (Barker & Buchanan-Barker, 2005; Brookes, 2006).

The Tidal Model uses a person-centered approach to help people deal with their problems of human living. Focus is on the individual's personal story, which is where his or her problems first appeared and where any growth, benefit, or recovery will be found (Barker & Buchanan-Barker, 2000).

Barker and Buchanan-Barker (2005) developed a set of essential values upon which the model is based. These values, which they call the *10 Tidal Commitments,* provide practitioners with a philosophical focus for empowering people to make their own life changes rather than health-care professionals trying to manage or control "patient symptoms" (Buchanan-Barker & Barker, 2008). From these commitments, the authors developed the following Tidal Competencies, which reflect the ways the commitments are practiced in the clinical setting:

1. **Value the voice:** The person is encouraged to tell his or her story. "The person's story represents the beginning and endpoint of the helping encounter, embracing not only an account of the person's distress, but also the hope for its resolution" (p. 95). Practitioner competencies include a capacity to actively listen to the person's story

and to help the person record the story in his or her own words.

2. **Respect the language:** Individuals are encouraged to speak their own words in their own unique way. "The language of the story—complete with its unusual grammar and personal metaphors—is the ideal medium for illuminating the way to recovery. We encourage people to speak their own words in their distinctive voice" (pp. 95–96). Practitioner competencies include helping individuals express in their own language their understanding of personal experiences through use of stories, anecdotes, and metaphors.

3. **Develop genuine curiosity:** Nurses and other caregivers "need to express genuine interest in the story so that they can better understand the storyteller and the story. Genuine curiosity reflects an interest in the person and the person's unique experience" (p. 96). Practitioner competencies include showing interest in the person's story, asking for clarification of certain points, and assisting the person to unfold the story at his or her own pace.

4. **Become the apprentice:** The individual is the expert on his or her life story, and he or she must be the leader in deciding what needs to be done. "Professionals may learn something of the power of that story, but only if they apply themselves diligently and respectfully to the task by becoming apprentice-minded" (p. 96). Practitioner competencies include developing a plan of care for the individual based on his or her expressed needs or wishes and helping the individual identify specific problems and ways to address them.

5. **Use the available toolkit:** Concentration is given to the individual's strengths, which are the major tools in the recovery process. "The story contains examples of 'what has worked' for the person in the past or beliefs about 'what might work' for this person in the future. These represent the main tools that need to be used to unlock or build the story of recovery" (p. 96). Practitioner competencies include helping individuals identify what efforts may be successful in relation to solving identified problems and which persons in the individual's life may be able to provide assistance.

6. **Craft the step beyond:** The individual and the practitioner decide together what needs to be done immediately. "Any 'first step' is a crucial step, revealing the power of change and potentially pointing towards the ultimate goal of recovery" (p. 96). Practitioner competencies include helping the individual determine what kind of change would represent a step toward recovery and what he or she needs to do to take that first step in the progress toward that goal.

7. **Give the gift of time:** Change happens when the individual and practitioner spend quality time in a therapeutic relationship. "The challenge is using time for things that are important" (Young, 2010, p. 573). Practitioner competencies include acknowledging (and helping the individual understand) the importance of time dedicated to addressing the needs of the individual and the planning and implementing of care.

8. **Reveal personal wisdom:** People often do not realize their own personal wisdom, strengths, and abilities. "A key task for the professional is to help the person reveal and come to value that wisdom, so that it might be used to sustain the person throughout the voyage of recovery" (Buchanan-Barker & Barker, 2008, p. 97). Practitioner competencies include helping individuals identify personal strengths and weaknesses and develop self-confidence in their ability to help themselves.

9. **Know that change is constant:** Because change is a constant in everyone's life, important decisions and choices must be made along the path to recovery in order for growth to occur. Professional competencies include helping the individual develop awareness of the changes that are occurring and how he or she has influenced these changes. "The task of the professional helper is to develop awareness of how change is happening and to support the person in making decisions regarding the course of the recovery voyage" (p. 97).

10. **Be transparent:** Transparency is important in the teambuilding process between the individual and the professional helper. "Professionals are in a privileged position and should model confidence by being transparent at all times, helping the person understand exactly what is being done and why" (p. 97). Professional competencies include ensuring that the individual is aware of the significance of all interventions and that he or she receives copies of all documents related to the plan of care.

Young (2010) states:

> The Tidal Model is not a typical boxes-and-arrows diagram to use and follow. Instead, it is way of thinking, a paradigm for giving person-centered care that is strength-based, empowering, and relational. (p. 574)

The Wellness Recovery Action Plan (WRAP)

The **WRAP Model** was developed in 1997 by a group of 30 individuals attending a mental health recovery skills seminar conducted by Mary Ellen Copeland in Vermont. This group (which included persons

with psychiatric symptoms, family members, and care providers) determined the need for a system to incorporate the skills and strategies they were learning in the seminar into their everyday lives. Copeland (2001) states:

> [WRAP] is a structured system for monitoring uncomfortable and distressing symptoms and, through planned responses, reducing, modifying or eliminating those symptoms. It also includes plans for responses from others when a person's symptoms have made it impossible to continue to make decisions, take care of him/herself and keep him/herself safe. (p. 129)

Copeland suggests that all a person needs to begin the program is a system for storing information (e.g., a notebook, computer, or tape recorder), and possibly a friend, health-care provider, or other supporter to give assistance and feedback. The program is a stepwise process through which an individual is able to monitor and manage distressing symptoms that occur in daily life. Individuals may be assisted in the process by others (e.g., health-care professionals, significant others, friends), "but to be effective and empowering, the person experiencing the symptoms must develop the plan for himself/herself" (p. 129). Steps of the WRAP process are described in the following sections.

Step 1. Developing a Wellness Toolbox

In this first step, the individual creates a list of tools, strategies, and skills that he or she has used in the past (or has heard of in the past that he or she would like to try) to assist in relieving disturbing symptoms. Copeland (2001) offers a number of examples:

■ Talking to a friend or health-care professional
■ Peer counseling or exchange listening
■ Relaxation and stress reduction exercises
■ Guided imagery
■ Journaling
■ Physical exercise
■ Attending a support group
■ Doing something special for someone else
■ Listening to music

Step 2. Daily Maintenance List

This list is divided into three parts. In part 1, the individual writes a description of how he or she feels (or would like to feel) when experiencing wellness (e.g., bright, cheerful, talkative, happy, optimistic, capable). This information is used as a reference point. In part 2, using the wellness toolbox as a reference, the individual makes a list of things he or she needs to do every day to maintain wellness. This is an important part of the plan and must be realistic so as not to set the individual up for failure or create additional frustration.

Example items for part 2 may include the following (Copeland, 2001):

■ Eat three healthy meals and three healthy snacks
■ Drink at least six 8-ounce glasses of water
■ Avoid caffeine, sugar, junk foods, and alcohol
■ Exercise for at least 30 minutes
■ Have 20 minutes of relaxation or meditation time
■ Write in my journal for at least 15 minutes
■ Take medications and vitamin supplements
■ Spend at least 30 minutes enjoying a fun, affirming, and/or creative activity

In part 3 of this step, the individual keeps a list of things that need to be done. The individual reads this list daily as a reminder, and items may be considered for accomplishment on any given day at the individual's discretion. For part 3, Copeland (2001) suggests items such as the following:

■ Spend time with counselor or case manager
■ Make an appointment with health-care professional
■ Spend time with friend or partner
■ Be in touch with my family
■ Spend time with children or pets
■ Buy groceries
■ Do the laundry
■ Write some letters
■ Remember someone's birthday or anniversary

Step 3. Triggers

This step is divided into two parts. In part 1, the individual lists events or circumstances that, should they occur, would cause distress or discomfort. These triggers are situations to which the individual is susceptible or that have triggered or increased symptoms in the past. Copeland (2001) lists the following examples:

■ The anniversary dates of losses or trauma
■ Being exhausted
■ Work stress
■ Family friction
■ A relationship ending
■ Being judged, criticized, or teased
■ Financial problems
■ Physical illness
■ Sexual harassment or inappropriate sexual behavior
■ Substance abuse

In part 2, the individual uses items from the wellness toolbox to develop a plan for what to do if triggers interfere with wellness.

Step 4. Early Warning Signs

This step is divided into two parts. Part 1 involves identification of subtle signs that indicate a possible worsening of the situation. Copeland (2001) states, "Recognizing early warning signs and reviewing them regularly will help the person to become more aware

of these early warning signs, allowing the person to take action before the signs worsen" (p. 136). Some types of early warning signs include anxiety, forgetfulness, lack of motivation, avoiding others or isolating, increased irritability, increase in smoking, using substances, or feeling worthless and inadequate. In part 2, the individual develops a plan for responding to the early warning signs that result in relief or in preventing them from escalating. The plan may include items such as consulting a supporter or counselor, increasing focus on peer counseling, increasing time spent in relaxation exercises, or utilizing other interventions from the wellness toolbox until warning signs diminish.

Step 5. Things Are Breaking Down or Getting Worse

This step is divided into two parts. In part 1, the individual lists symptoms that indicate that the situation has worsened. In this stage, the symptoms are producing great discomfort, but the individual is still able to take some action on his or her own behalf. Immediate action is required to prevent a crisis from developing. Symptoms at this stage differ greatly from person to person, and Copeland (2001) states, "What may mean 'things are breaking down' to one person may mean 'crisis' to another" (p. 137). She lists a number of examples of symptoms, which may include the following:

■ Irrational responses to events and the actions of others
■ Inability to sleep or sleeping all the time
■ Headaches
■ Not eating or overeating
■ Social isolation
■ Thoughts of self-harm
■ Substance abuse or chain smoking
■ Bizarre behaviors
■ Seeing things that are not there
■ Paranoia

In part 2, the individual makes a plan that he or she thinks will help when the symptoms have worsened to this degree. The plan must be very specific and direct, with clear instructions. Some examples include the following (Copeland, 2001):

■ Call my health-care professional; ask for and follow directions.
■ Arrange for someone to stay with me around the clock until my symptoms subside.
■ Take action so that I cannot hurt myself if my symptoms get worse, such as giving my medication, checkbook, credit cards, and car keys to a previously designated friend for safe keeping.
■ Make sure I do everything on my daily check list.
■ Have at least two peer counseling sessions daily.

■ Increase use of items from wellness toolbox (e.g., relaxation exercises, physical exercises, creative activities).

Step 6. Crisis Planning

This stage identifies symptoms indicating that individuals can no longer care for themselves, make independent decisions, or keep themselves safe. This stage is multifaceted and meant for use by caregivers on behalf of the individual who developed the plan. It is composed of the following parts (Copeland, 2001, p. 130):

■ Part 1: Gathers information that describes what the person is like when well.
■ Part 2: Identifies the symptoms that indicate when others need to take responsibility for the person's care.
■ Part 3: Provides names of supporters previously identified by the individual to speak on his or her behalf.
■ Part 4: Includes the name of health-care providers and phone numbers; medications currently using; allergies to medications; medications the individual would prefer to take, if additional medication is necessary; medications that the individual refuses to take.
■ Part 5: Includes the individual's preferred treatments and treatments that he or she wishes to avoid.
■ Part 6: Identifies the individual's preferences in treatment facilities (e.g., home, community care, respite center).
■ Part 7: Identifies acceptable facilities if previous preferences cannot be executed. Facilities to avoid are also indicated.
■ Part 8: Includes an extensive description of what the individual expects from identified supporters who are acting on his or her behalf during a crisis situation.
■ Part 9: Consists of a list of indicators, developed by the individual, that communicates to supporters when their services are no longer required. The individual should update this plan periodically when he or she learns new information or changes his or her mind about certain situations. Assurance of the use of the crisis plan may be increased if it is notarized and signed in the presence of two witnesses. To further increase its potential for use, the person may appoint a durable power of attorney, although because of the variability of the legality of these documents from state to state, there is no guarantee that the plan will be followed.

Copeland states:

WRAP is a systematic method for developing skills in self-management and empowerment. It provides a means for individuals with a mental illness to work

more collaboratively with healthcare providers. It is highly individualized and addresses the unique needs of the person and his/her situation. It is applicable to most any long-term illness/disability or problem situation. These benefits suggest that it can be used more widely and should be introduced as an option for individuals in need of a self-management system. (p. 149)

The Psychological Recovery Model

Andresen, Oades, and Caputi (2011) define psychological recovery as "the establishment of a fulfilling, meaningful life and a positive sense of identity founded on hopefulness and self-determination. Psychological recovery is necessary whether mental illness is biologically based or the result of the exacerbation of emotional problems caused by stress" (p. 40). The **Psychological Recovery Model** does not emphasize the absence of symptoms but focuses on the person's self-determination in the course of his or her recovery process.

In examining a number of studies, Andresen and associates (2011) identified four components that were consistently evident in the recovery process:

■ **Hope:** Finding and maintaining hope that recovery can occur
■ **Responsibility:** Taking responsibility for one's life and well-being
■ **Self and identity:** Renewing the sense of self and building a positive identity
■ **Meaning and purpose:** Finding purpose and meaning in life

Andresen and associates (2011) conceptualized a five-stage model of recovery, which they define by integrating into each stage the four components of the recovery process. An explanation of these stages is presented in the following paragraphs.

Stage 1. Moratorium

This stage is identified by dark despair and confusion. "It is called moratorium, because it seems 'life is on hold'" (p. 47).

■ **Hope:** In the moratorium stage, hopelessness prevails. Consumers may even perceive feelings of hopelessness from practitioners when treatment plans emphasize stabilization and maintenance, thereby conveying messages of no hope for recovery.
■ **Responsibility:** In the moratorium stage, the individual feels out of control and powerless to change.
■ **Self and identity:** In the moratorium stage, individuals feel "as though they no longer know who they are as a person" (p. 59). An individual's sense of identity as a valuable and functional member of society can be lost with a diagnosis of mental illness.

■ **Meaning and purpose:** The diagnosis of severe mental illness is a traumatic event that can challenge an individual's fundamental beliefs, creating a loss of meaning and purpose in life.

Stage 2. Awareness

In this stage, the individual comes to a realization that a possibility for recovery exists. Andresen and associates state, "It involves an awareness of a possible self other than that of 'sick person': a self that is capable of recovery" (p. 47).

■ **Hope:** In the awareness stage, there is a dawn of hope that indeed "life is not over." This feeling of hope may emanate from significant others, professionals, or family members. Individuals may also be inspired by others who have recovered. Hope may also be derived from strong inner determination and from personal faith and spirituality.
■ **Responsibility:** In this stage, the individual develops an awareness of the need to take control of his or her life. Feelings of control and responsibility lead to a sense of personal empowerment that paves the way for recovery.
■ **Self and identity:** In the awareness stage, the individual comes to realize that he or she is a person independent of the illness. "The person realizes that there still exists an 'intact self' capable of taking action on one's own behalf" (p. 72).
■ **Meaning and purpose:** In the awareness stage, the individual strives for a personal comprehension of the illness, why it occurred, and what the implications of the illness are for his or her future. "Seeking a meaning of the illness can be explained by theories of cognitive control, in which one tries to understand unexplainable negative events by finding a reason for them" (p. 74).

Stage 3. Preparation

This stage begins with the individual's resolve to begin the work of recovery.

■ **Hope:** In the preparation stage, hope is manifested in the mobilization of personal and external resources to foster self-care and find pathways to goals. This includes identifying strengths and weaknesses, gathering knowledge and information, and seeking out available support systems.
■ **Responsibility:** Taking responsibility in the preparation stage involves learning about the effects of the illness and how to recognize, monitor, and manage symptoms. Taking charge of one's life also includes the ability to be independent and take care of basic needs.
■ **Self and identity:** Andresen and associates state, "During the preparation stage, the person takes

stock of his or her skills and strengths in order to build on them to rediscover a positive sense of identity" (p. 81). The person is willing to take risks and try new activities to reestablish a sense of self. Lost aspects of self are rediscovered, new aspects are identified, and both are incorporated into a new self-identity.

■ **Meaning and purpose:** The basis for a meaningful life lies in solid core values. "Living according to one's valued directions gives meaning to the work of recovery, and for this reason, some people hold on tenaciously to their goals" (p. 83). Each individual must live by certain tenets that make life personally valuable and enriching. Individuals living with a severe mental illness may require a reordering of priorities and setting of new goals as part of their recovery.

Rebuilding

The hard work of recovery takes place in the rebuilding stage. The individual "takes the necessary steps to work towards his or her goals in rebuilding a meaningful life" (p. 87).

■ **Hope:** In the rebuilding stage, the individual has hope for and looks forward to a more fulfilling life. Realistic goals are set, and the individual is encouraged to pursue the recovery process at his or her own pace. With each success, hope is renewed.

■ **Responsibility:** "Through setting and working towards goals, the person begins to actively take control of his or her life; not only management of symptoms, but also enlisting social support, improvement of self-image, handling social pressures, and building social competence" (p. 90). Assuming control of treatment decisions and illness management is an essential part of the recovery process.

■ **Self and identity:** The individual elaborates and enhances his or her sense of identity, having succeeded in previous stages in developing a positive self-identity separate from the illness and a new sense of self-confidence by succeeding at new activities. In the rebuilding stage, the work of examining core values and working toward value-congruent goals reinforces a positive sense of identity and a commitment to recovery.

■ **Meaning and purpose:** Having realistic goals and a positive sense of identity provides a sense of purpose in life. Individuals need a reason to start each day. Andresen and associates state, "Finding meaning [in life] is more than finding a valued occupation, but rather is more akin to finding a way to live. This may include, but is not limited to, vocational goals. It includes examining one's spirituality or philosophy of life. The journey is, in itself, a source of meaning for many" (p. 99).

Growth

The outcome of the psychological recovery process is growth. Although it is called the *final* stage of the psychological recovery model, it is important to remember that this is a dynamic stage and that personal growth is a continuing life process.

■ **Hope:** In the growth stage, the individual feels a sense of optimism and hope of a rewarding future. Skills that have been nurtured in the previous stages are applied with confidence, and the individual strives for higher levels of well-being.

■ **Responsibility:** "Achieving control requires sustained commitment in the face of set-backs" (p. 106). In the growth phase, individuals exhibit confidence in managing their illnesses and are resilient when relapses occur. They are empowered by personal input and decision-making regarding their treatment.

■ **Self and identity:** The individual in the growth stage has developed a strong, positive sense of self and identity. Andresen and associates state, "Many consumers have reported feeling that they are a better person as a result of their struggle with the illness. [In one research study] participants reported developing personal qualities, including strength and courage; more confidence in the self; resourcefulness and responsibility; a new philosophy of life; compassion and empathy; a sense of self-worth; and being happier and more carefree" (pp. 108–109).

■ **Meaning and purpose:** Individuals who have reached the growth stage often report a more profound sense of meaning. Some describe having achieved a sense of serenity and peace, and for others it takes the form of a spiritual awakening. Some individuals find reward in educating others about the experience of mental illness and recovery.

Andresen and associates (2011) state:

Recovery from serious mental illness is more than staying out of the hospital or a return to some arbitrary level of functioning. It is more than merely coping with the illness. In [the growth] stage, the notion of wellbeing replaces that of wellness. While wellness implies the absence of illness, wellbeing refers to a more holistic psychological experience of fulfilling life. Although we may not expect everyone (including those who do not have a mental illness) to reach the highest levels of self-actualization, we can expect that all people have the opportunity to develop a positive sense of self and identity and to live a meaningful life filled with purpose and hope for the future. (p. 113)

Nursing Interventions That Assist With Recovery

It is within the scope of nursing to assist individuals in many aspects of the mental health recovery process. Caldwell and associates (2010) state:

> Professional nurses must play an active role in client recovery because they are employed in all aspects of service delivery systems, and most times professional nurses are responsible for the delivery and coordination of care. The professional nurse must be center stage in the development and implementation of any action plan involving client recovery. (p. 44)

Nurses have historically held the promotion of wellness within a collaborative nurse-client relationship as a primary goal. Peplau (1991) described nursing as "a human relationship between an individual who is sick, or in need of health services, and a nurse especially educated to recognize and to respond to the need for help" (pp. 5–6). As previously noted, recovery models are inherently collaborative in that services are provided by professionals, by consumers, and cooperatively by both. Examples of interventions and activities in which nurses and consumers may collaborate in the client's journey to recovery are outlined in Table 21–1.

TABLE 21–1 **Nurse-Client Collaboration in the Mental Health Recovery Process**			
	THE TIDAL MODEL	**THE WRAP MODEL**	**PSYCHOLOGICAL RECOVERY MODEL**
Assessment	■ Client tells his or her personal story ■ Nurse actively listens and expresses interest in the story ■ Nurse helps client record story in client's own language ■ Client identifies specific problems he or she wishes to address ■ Nurse and client identify client's strengths and weaknesses	■ Client develops a wellness toolbox by creating a list of tools, strategies, and skills that have been helpful in the past ■ Client identifies strengths and weaknesses ■ Nurse provides assistance and feedback	■ Client is feeling hopeless and powerless ■ Client seeks meaning of the illness ■ Nurse helps by offering hope ■ Client begins to develop an awareness of the need to take control of and responsibility for his or her life
Interventions	■ Nurse and client determine what has worked in the past ■ Client suggests new tools he or she would like to try ■ Client decides what changes he or she would like to make and sets realistic goals ■ Nurse and client decide what must be done as the first step ■ Nurse gives positive feedback for client's efforts to make life changes and for successes achieved ■ Nurse encourages client to be as independent as possible but offers assistance when required ■ Nurse gives the "gift of time"	■ Client creates a daily maintenance list: 　■ How he or she feels at best 　■ What must be done daily to maintain wellness 　■ Reminder list of other things that need to be accomplished ■ Client identifies triggers that cause distress or discomfort and identifies what to do if triggers interfere with wellness ■ Client identifies signs of worsening of symptoms and develops a plan to prevent escalation ■ Client identifies when symptoms have worsened and help is needed ■ Client identifies when he or she can no longer care for self and makes decisions (in writing) about treatment issues (what type, who will provide, who will represent client's interests) ■ Nurse offers support and provides feedback and assistance when needed	■ Client resolves to begin work of recovery ■ Client and nurse identify strengths and weaknesses ■ Nurse assists client to learn about effects of the illness and how to recognize, monitor, and manage symptoms ■ Client identifies changes he or she wishes to occur and sets realistic goals to rebuild a meaningful life ■ Client examines personal spirituality and philosophy of life in search of a meaning and purpose—one that gives him or her a "reason to start each day"

TABLE 21–1	**Nurse-Client Collaboration in the Mental Health Recovery Process—cont'd**		
	THE TIDAL MODEL	THE WRAP MODEL	PSYCHOLOGICAL RECOVERY MODEL
Outcomes	■ Client acknowledges that change has occurred and is ongoing ■ Client feels empowered to manage own self-care ■ Nurse is available for support	■ Client develops skills in self-management ■ Client develops self-confidence and hope for a brighter future	■ Client develops a positive self-identity separate from the illness ■ Client maintains commitment to recovery in the face of setbacks ■ Client feels a sense of optimism and hope of a rewarding future

If the proposals from the President's New Freedom Commission on Mental Health become fully realized, it would mean improvement in the promotion of mental health and the care of individuals with mental illness. Many nurse leaders see this period of health-care reform as an opportunity for nurses to expand their roles and assume key positions in education, prevention, assessment, and referral. Nurses are and will continue to be paramount in helping individuals with mental illness remain as independent as possible, manage their illnesses within the community setting, and strive to minimize the number of hospitalizations required. A vision of recovery from mental illness exists, and hope, trust, and self-determination should be incorporated into all treatment models.

Summary and Key Points

- Recovery is the restoration to a former and/or better state or condition.
- SAMHSA identifies four major dimensions that support a life in recovery: health, home, purpose, and community.
- The President's New Freedom Commission on Mental Health proposes to transform the mental health system by shifting the paradigm of care of persons with serious mental illness from traditional medical psychiatric treatment toward the concept of recovery.
- SAMHSA outlines 10 guiding principles that support recovery:
  - Recovery emerges from hope
  - Recovery is person driven
  - Recovery occurs via many pathways
  - Recovery is holistic
  - Recovery is supported by peers and allies

- Recovery is supported through relationship and social networks
  - Recovery is culturally based and influenced
  - Recovery is supported by addressing trauma
  - Recovery involves individual, family, and community strengths and responsibility
  - Recovery is based on respect
- Many models of recovery exist. Three models were discussed in this chapter: the Tidal Model, the Wellness Recovery Action Plan (WRAP) Model, and the Psychological Recovery Model.
- Nurses work in key positions to assist individuals with mental illness in the recovery process. Interventions based on the three previously mentioned recovery models were included in this chapter.

Communication Exercises

1. Joshua comes to his appointment at the mental health clinic and states, "I can't sit still when I take those medications, so I don't want to take them anymore." Using principles of the recovery model, what are some options for responding to this client?

2. Kelly is a war veteran who was admitted to inpatient hospitalization with depression, alcohol addiction, and complaints of troubling nightmares. She states, at the admission assessment, "I don't trust any 'mental health gurus.' You can't possibly understand what I've been through." How will you respond, and what principles of the recovery model will guide your response?

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Which of the following is a true statement about mental health recovery? (Select all that apply.)
   a. Mental health recovery applies only to severe and persistent mental illnesses.
   b. Mental health recovery serves to provide empowerment to the consumer.
   c. Mental health recovery is based on the medical model.
   d. Mental health recovery is a collaborative process.

2. A nurse is assisting an individual with mental illness recovery using the Tidal Model. Which of the following is a component of this model?
   a. The wellness toolbox
   b. The daily maintenance list
   c. The individual's personal story
   d. Triggers

3. A nurse is assisting an individual with mental illness recovery using the Psychological Recovery Model. The client says to the nurse, "I have schizophrenia. Nothing can be done. I might as well die." In which stage of the Psychological Recovery Model would the nurse assess this individual to be?
   a. The awareness stage
   b. The preparation stage
   c. The rebuilding stage
   d. The moratorium stage

4. A nurse who is helping a client in the preparation stage of the Psychological Recovery Model might include which of the following interventions?
   a. Teach about effects of the illness and how to recognize, monitor, and manage symptoms.
   b. Help the client identify triggers that cause distress or discomfort.
   c. Help the client establish a daily maintenance list.
   d. Listen actively while the client composes his or her personal story.

5. A nurse who is helping a client with mental illness recovery using the WRAP Model says to the client, "First you must create a wellness toolbox." She explains to the client that a wellness toolbox is which of the following?
   a. A list of words that describe how the individual feels when he or she is feeling well
   b. A list of things the client needs to do every day to maintain wellness
   c. A list of strategies the client has used in the past that help relieve disturbing symptoms
   d. A list of the client's favorite health-care providers and phone numbers

Nursing Care of Clients With Alterations in Psychosocial Adaptation

22

Neurocognitive Disorders

KEY TERMS

aphasia
apraxia

ataxia
confabulation

pseudodementia
sundowning

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define and differentiate among various neurocognitive disorders (NCDs).
2. Discuss predisposing factors implicated in the etiology of NCDs.
3. Describe clinical symptoms and use the information to assess clients with NCDs.
4. Identify nursing diagnoses common to clients with NCDs and select appropriate nursing interventions for each.

5. Identify topics for client and family teaching relevant to NCDs.
6. Discuss criteria for evaluating nursing care of clients with NCDs.
7. Describe various treatment modalities relevant to care of clients with NCDs.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. An alteration in which neurotransmitter is most closely associated with the etiology of Alzheimer's disease?
2. How does vascular neurocognitive disorder differ from NCD caused by Alzheimer's disease?
3. What is pseudodementia?
4. What is the primary concern for nurses working with clients with NCDs?

Neurocognitive disorders (NCDs) include those in which a clinically significant deficit in cognition or memory exists, representing a significant change from a previous level of functioning. These disorders were previously identified in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* (American Psychiatric Association [APA], 2000) as "Dementia, Delirium, Amnestic, and Other Cognitive Disorders." In the *DSM-5,* NCDs include delirium and the syndromes called major NCD or minor NCD which are then specified according to the underlying cause (such as Alzheimer's disease, Parkinson's disease or others).

This chapter presents predisposing factors, clinical symptoms, and nursing interventions for care of clients with NCDs. The objective is to provide quality care, respect the client's dignity, and promote quality of life while offering guidance and support to their families or primary caregivers.

CORE CONCEPT

Delirium

Delirium is a mental state characterized by an acute disturbance of cognition, manifested by short-term confusion, excitement, disorientation, and clouded consciousness. Hallucinations and illusions are common.

Delirium

Clinical Findings and Course

Delirium is characterized by a disturbance in attention and awareness and a change in cognition that develop rapidly over a short period (APA, 2013). Symptoms of delirium include difficulty sustaining and shifting attention. The person is extremely distractible and must be repeatedly reminded to focus attention. Disorganized thinking prevails and is reflected by speech that is rambling, irrelevant, pressured, and incoherent, unpredictably switching from subject to subject. Reasoning ability and goal-directed behavior are impaired. Disorientation to time and place is common, and impairment of recent memory is invariably evident. Misperceptions of the environment (illusions) and false perceptions (hallucinations) prevail. Disturbances in the sleep–wake cycle occur.

The state of awareness may range from that of hypervigilance (heightened awareness to environmental stimuli) to stupor or semicoma. Sleep may fluctuate between hypersomnolence (excessive sleepiness) and insomnia. Vivid dreams and nightmares are common.

Psychomotor activity may fluctuate between agitated, purposeless movements (e.g., restlessness, hyperactivity, striking out at nonexistent objects) and a vegetative state resembling catatonic stupor. Various forms of tremor are frequently present.

Emotional instability may be manifested by fear, anxiety, depression, irritability, anger, euphoria, or apathy. These emotions may be evidenced by crying, calls for help, cursing, muttering, moaning, acts of self-destruction, fearful attempts to flee, or attacks on others who are falsely viewed as threatening. Autonomic manifestations, such as tachycardia, sweating, flushed face, dilated pupils, and elevated blood pressure, are common.

The symptoms of delirium usually begin quite abruptly (e.g., following a head injury or seizure). At other times, they may be preceded by several hours or days of prodromal symptoms (e.g., restlessness, difficulty thinking clearly, insomnia or hypersomnolence, and nightmares). The slower onset is more common if the underlying cause is systemic illness or metabolic imbalance.

The duration of delirium is usually brief (e.g., 1 week; rarely more than 1 month) and, upon elimination of the underlying causes, symptoms usually diminish over a 3- to 7-day period but in some instances may take as long as 2 weeks (Sadock, Sadock, & Ruiz, 2015). The age of the client and duration of the delirium influence rate of symptom resolution. Delirium may transition into a more permanent cognitive disorder (e.g., major NCD) and is associated with a high mortality rate because of the seriousness of the medical conditions that precipitate delirium.

Predisposing Factors

Delirium

Individuals most predisposed to delirium include those with serious medical, surgical, or neurological conditions. People older than age 65 are considered a high-risk group, and geriatric syndromes such as dementia, depression, falls, and elder abuse are often precipitating factors (Kalish, Gillham, & Unwin, 2014). Some examples of conditions known to precipitate delirium include the following (Black & Andreasen, 2014; Sadock et al., 2015):

■ Systemic infections
■ Febrile illness
■ Metabolic disorders, such as electrolyte imbalances, hypercarbia, or hypoglycemia
■ Hypoxia and chronic obstructive pulmonary disease
■ Hepatic failure or renal failure
■ Head trauma
■ Seizures
■ Migraine headaches
■ Brain abscess or brain neoplasms
■ Stroke
■ Nutritional deficiency
■ Uncontrolled pain
■ Burns
■ Heat stroke
■ Orthopedic and cardiac surgeries
■ Social isolation

Other Etiological Implications

Substance Intoxication Delirium

In this subtype, the symptoms of delirium are attributed to intoxication from certain substances, such as alcohol, amphetamines, cannabis, cocaine, hallucinogens, inhalants, opioids, phencyclidine, sedative, hypnotic, and anxiolytics, or other or unknown substances (APA, 2013).

Substance Withdrawal Delirium

Withdrawal from certain substances can precipitate symptoms of delirium that are sufficiently severe to warrant clinical attention. These substances include

alcohol; opioids; sedatives, hypnotics, or anxiolytics; and others.

Medication-Induced Delirium

Medications that have been known to precipitate delirium include anticholinergics, antihypertensives, corticosteroids, anticonvulsants, cardiac glycosides, analgesics, anesthetics, antineoplastic agents, antiparkinson drugs, H_2-receptor antagonists (e.g., cimetidine), and others (Puri & Treasaden, 2012; Sadock et al., 2015).

Delirium Due to Another Medical Condition or to Multiple Etiologies

There may be evidence from the history, physical examination, or laboratory findings that symptoms of delirium are associated with another medical condition or can be attributable to more than one cause. The current evidence supports that delirium is usually the result of many factors rather than one (Kalish et al., 2014).

CORE CONCEPT

Neurocognitive
Cognitive functions closely linked to particular areas of the brain that have to do with thinking, reasoning, memory, learning, and speaking.

Neurocognitive Disorder

NCD is classified in the *DSM-5* (APA, 2013) as either mild or major, distinguished primarily by severity of symptomatology. Mild NCD has been known in some settings as mild cognitive impairment and is particularly critical because it can be a focus of early intervention to prevent or slow progression of the disorder. Major NCD constitutes what was previously described as dementia in the *DSM-IV-TR* (APA, 2000). In progressive neurodegenerative conditions, these two diagnoses may identify earlier and later stages of the same disorder. Either diagnosis may be appropriate (depending on severity of symptoms) for certain other NCDs that are the result of reversible or temporary conditions. *DSM-5* criteria for these disorders are presented in Box 22–1.

CORE CONCEPT

Dementia (Major Neurocognitive Disorder)
A disease process in which there is progressive decline in cognitive ability in the presence of clear consciousness. It involves many cognitive deficits and significantly impairs social and occupational functioning (Sadock et al., 2015).

BOX 22–1 A Comparison of Diagnostic Criteria

Mild Neurocognitive Disorder

A. Evidence of modest cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
   1. Concern of the individual, a knowledgeable informant, or the clinician that there has been a mild decline in cognitive function; and
   2. A modest impairment in cognitive performance, preferably documented by standardized neuropsychological testing, or, in its absence, another quantified clinical assessment.
B. The cognitive deficits do not interfere with capacity for independence in everyday activities (i.e., complex instrumental activities of daily living such as paying bills or managing medications are preserved, but greater effort, compensatory strategies, or accommodation may be required).
C. The cognitive deficits do not occur exclusively in the context of a delirium.
D. The cognitive deficits are not better explained by another mental disorder (e.g., major depressive disorder, schizophrenia).

Major Neurocognitive Disorder

A. Evidence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
   1. Concern of the individual, a knowledgeable informant, or the clinician that there has been a significant decline in cognitive function; and
   2. A substantial impairment in cognitive performance, preferably documented by standardized neuropsychological testing, or, in its absence, another quantified clinical assessment.
B. The cognitive deficits interfere with independence in everyday activities (i.e., at a minimum, requiring assistance with complex instrumental activities of daily living such as paying bills or managing medications).
C. The cognitive deficits do not occur exclusively in the context of a delirium.
D. The cognitive deficits are not better explained by another mental disorder (e.g., major depressive disorder, schizophrenia).

BOX 22–1 A Comparison of Diagnostic Criteria—cont'd

Specify whether due to:

- Alzheimer's disease
- Frontotemporal lobar degeneration
- Lewy body disease
- Vascular disease
- Traumatic brain injury
- Substance/medication use
- HIV infection
- Prion disease
- Parkinson's disease
- Huntington's disease
- Another medical condition
- Multiple etiologies
- Unspecified

Specify:

Without behavioral disturbance: If the cognitive disturbance is not accompanied by any clinically significant behavioral disturbance.

With behavioral disturbance *(specify disturbance):* If the cognitive disturbance is accompanied by a clinically significant behavioral disturbance (e.g., psychotic symptoms, mood disturbance, agitation, apathy, or other behavioral symptoms).

Specify whether due to:

- Alzheimer's disease
- Frontotemporal lobar degeneration
- Lewy body disease
- Vascular disease
- Traumatic brain injury
- Substance/medication use
- HIV infection
- Prion disease
- Parkinson's disease
- Huntington's disease
- Another medical condition
- Multiple etiologies
- Unspecified

Specify:

Without behavioral disturbance: If the cognitive disturbance is not accompanied by any clinically significant behavioral disturbance.

With behavioral disturbance *(specify disturbance):* If the cognitive disturbance is accompanied by a clinically significant behavioral disturbance (e.g., psychotic symptoms, mood disturbance, agitation, apathy, or other behavioral symptoms).

Specify current severity:

Mild: Difficulties with instrumental activities of daily living (e.g., housework, managing money)

Moderate: Difficulties with basic activities of daily living (e.g., feeding, dressing)

Severe: Fully dependent

Clinical Findings, Epidemiology, and Course

NCD constitutes a large and growing public health problem. A meta-analysis conducted in 2010 identified 35.6 million people worldwide living with some form of dementia (major NCD) (National Institute on Aging [NIA], 2015a). An estimated 5.1 million people older than age 65 (81 percent of whom are older than 75) in the United States currently have Alzheimer's disease (AD), the most common form of NCD. The prevalence of the disease doubles for every 5-year age group beyond age 65 with one of three seniors eventually dying from Alzheimer's or another form of dementia (Alzheimer's Association, 2016; NIA, 2015a). The Alzheimer's Association (2015a) reports that of those with AD, an estimated 200,000 are younger than age 65 and almost two-thirds are women. By 2050, the number of individuals aged 65 and older with AD is projected to nearly triple if current population trends continue and no preventive treatments become available (Alzheimer's Association, 2015a). Health-care costs for end-stage patients with dementia have now been identified as greater than the costs for any other disease, including cancer and heart disease (NIA, 2015b).

This proliferation is not the result of an "epidemic." The greatest risk factor for AD is age, and the population of older adults in the United States continues to grow. Survival after diagnosis typically ranges from 3 to 12 years with most of that time spent in the severest stage of the disease (Mitchell, 2015). In spite of these alarming statistics about AD, recent studies have indicated that dementia in general has been on the decline in the United States over the past few years. This trend could be a temporary change or may be related to improved treatment and education for risk factors associated with heart disease and stroke (NIA, 2015a).

NCDs can be classified as either primary or secondary. Primary NCDs are those such as AD, in which the

NCD itself is the major sign of an organic brain disease not directly related to any other organic illness. Secondary NCDs are caused by or related to another disease or condition, such as HIV disease or a cerebral trauma.

In NCD, impairment is evident in abstract thinking, judgment, and impulse control. The conventional rules of social conduct are often disregarded. Behavior may be uninhibited and inappropriate. Personal appearance and hygiene are often neglected.

Language may or may not be affected. Some individuals may have difficulty naming objects, or the language may seem vague and imprecise. In severe forms of NCD, the individual may not speak at all **(aphasia).** The client may know his or her needs but may not know how to communicate those needs to a caregiver.

Personality change is common in NCD and may be manifested by either an alteration or accentuation of premorbid characteristics. For example, an individual who was previously very socially active may become apathetic and socially isolated. A previously neat person may become markedly untidy in his or her appearance. Conversely, an individual who had difficulty trusting others prior to the illness may exhibit extreme fear and paranoia as manifestations of the disorder.

The reversibility of NCD is dependent on the basic etiology of the disorder. Truly reversible NCD occurs in only a small percentage of cases and might be more appropriately termed *temporary.* Reversible causes of NCD (dementia or dementia-like symptoms) include some brain tumors, subdural hematomas, depression, medication reactions, normal pressure hydrocephalus, vitamin/nutritional deficiencies (especially B_6 and B_{12}), central nervous system (CNS) infections, thyroid disorders, and metabolic disorders (hypoglycemia) (Mayo Clinic, 2016a). In most clients, NCD runs a progressive, irreversible course.

As the disease progresses, **apraxia,** the inability to carry out motor activities despite intact motor function, may develop. The individual may be irritable, moody, or exhibit sudden outbursts over trivial issues. The ability to work or care for personal needs independently will no longer be possible. These individuals can no longer be left alone because they do not comprehend their limitations and are therefore at serious risk for accidents. Wandering away from the home or care setting often becomes a problem. In advanced dementia, clinical features include profound memory deficits, minimal verbal communication, loss of ambulatory ability, inability to perform activities of daily living (ADLs), and incontinence. The most common clinical complications are eating problems and infections (Mitchell, 2015).

Several causes have been described for NCD (see section "Predisposing Factors"), but AD accounts for 50 to 60 percent of all cases (Black & Andreasen, 2014). The progressive nature of symptoms associated with AD has been described according to stages (Alzheimer's Association, 2015a; NIA, 2013; Stanley, Blair, & Beare, 2005):

Stage 1. No apparent symptoms: In the first stage of the illness, there is no apparent decline in memory despite changes that are beginning to occur in the brain.

Stage 2. Forgetfulness: The individual begins to lose things or forget names of people. Losses in short-term memory are common. The individual is aware of the intellectual decline and may feel ashamed, becoming anxious and depressed, which in turn may worsen the symptoms. Maintaining organization with lists and a structured routine provide some compensation. These symptoms often are not observed by others.

Stage 3. Mild cognitive decline: In this stage, interference with work performance becomes noticeable to coworkers. The individual may get lost when driving his or her car. Concentration may be interrupted. Difficulty recalling names or words becomes noticeable to family and close associates. A decline occurs in the ability to plan or organize.

Stage 4. Mild to moderate cognitive decline: At this stage, the individual may forget major events in personal history, such as his or her own child's birthday; experience declining ability to perform tasks, such as shopping and managing personal finances; or be unable to understand current news events. He or she may deny that a problem exists by covering up memory loss with **confabulation** (creating imaginary events to fill in memory gaps). Depression and social withdrawal are common.

Stage 5. Moderate cognitive decline: At this stage, individuals lose the ability to independently perform some ADLs, such as hygiene, dressing, and grooming, and require some assistance to manage these on an ongoing basis. They may forget addresses, phone numbers, and names of close relatives. They may become disoriented about place and time, but they maintain knowledge about themselves. Frustration, withdrawal, and self-absorption are common.

Stage 6. Moderate to severe cognitive decline: At this stage, the individual may be unable to recall recent major life events or even the name of his or her spouse. Disorientation to surroundings is common, and the person may be unable to recall the day, season, or year. The person is unable to manage ADLs

without assistance. Urinary and fecal incontinence are common. Sleeping becomes a problem. Psychomotor symptoms include wandering, obsessiveness, agitation, and aggression. Symptoms seem to worsen in the late afternoon and evening—a phenomenon termed **sundowning.** Communication becomes more difficult, with increasing loss of language skills. Institutional care is usually required at this stage.

Stage 7. Severe cognitive decline: In the end stages of AD, the individual is unable to recognize family members. He or she most commonly is bedfast and aphasic. Problems of immobility, such as decubiti and contractures, may occur.

Stanley and associates (2005) have described the late stages of the disorder as follows:

> During late-stage [NCD], the person becomes more chairbound or bedbound. Muscles are rigid, contractures may develop, and primitive reflexes may be present. The person may have very active hands and repetitive movements, grunting, or other vocalizations. There is depressed immune system function, and this impairment coupled with immobility may lead to the development of pneumonia, urinary tract infections, sepsis, and pressure ulcers. Appetite decreases and dysphagia is present; aspiration is common. Weight loss generally occurs. Speech and language are severely impaired, with greatly decreased verbal communication. The person may no longer recognize any family members. Bowel and bladder incontinence are present and caregivers need to complete most ADLs for the person. The sleep-wake cycle is greatly altered, and the person spends a lot of time dozing and appears socially withdrawn and more unaware of the environment or surroundings. Death may be caused by infection, sepsis, or aspiration, although there are not many studies examining cause of death. (p. 358)

Predisposing Factors

NCDs are differentiated by their etiology, although they share common symptom presentation.

Categories include NCDs due to:

- Alzheimer's disease
- Frontotemporal lobar degeneration
- Lewy body disease
- Vascular disease
- Traumatic brain injury
- Substance/medication use
- HIV infection
- Prion disease
- Parkinson's disease
- Huntington's disease
- Another medical condition
- Multiple etiologies
- Unspecified

Neurocognitive Disorder Due to Alzheimer's Disease

AD is characterized by the syndrome of symptoms identified as mild or major NCD and in the seven stages described previously. The onset of symptoms is slow and insidious, and the course of the disorder is generally progressive and deteriorating. Memory impairment is an early and prominent feature.

Refinement of diagnostic criteria now enables clinicians to use specific clinical features to identify the disease with considerable accuracy. Examination by computerized tomography (CT) scan or magnetic resonance imagery (MRI) reveals a degenerative pathology of the brain that includes atrophy, widened cortical sulci, and enlarged cerebral ventricles (Figs. 22–1 and 22–2). Microscopic examinations reveal numerous neurofibrillary tangles and senile plaques in the brains of clients with AD. These changes occur as a part of the normal aging process. However, in clients with AD, they are found in dramatically increased numbers, and their profusion is concentrated in the hippocampus and certain parts of the cerebral cortex.

Etiology

The exact cause of AD is unknown, but experts believe that with the exception of rare cases in which

NEUROTRANSMITTERS

A decrease in the neurotransmitter acetylcholine has been implicated in the etiology of Alzheimer's disease. Cholinergic sources arise from the brainstem and the basal forebrain to supply areas of the basal ganglia, thalamus, limbic structures, hippocampus, and cerebral cortex.

Cell bodies of origin for the serotonin pathways lie within the raphe nuclei located in the brainstem. Those for norepinephrine originate in the locus ceruleus. Projections for both neurotransmitters extend throughout the forebrain, prefrontal cortex, cerebellum, and limbic system. Dopamine pathways arise from areas in the midbrain and project to the frontal cortex, limbic system, basal ganglia, and thalamus. Dopamine neurons in the hypothalamus innervate the posterior pituitary.

Glutamate, an excitatory neurotransmitter, has largely descending pathways with highest concentrations in the cerebral cortex. It is also found in the hippocampus, thalamus, hypothalamus, cerebellum, and spinal cord.

AREAS OF THE BRAIN AFFECTED

Areas of the brain affected by Alzheimer's disease and associated symptoms include the following:
• Frontal lobe: Impaired reasoning ability; inability to solve problems and perform familiar tasks; poor judgment; inability to evaluate the appropriateness of behavior; aggressiveness.
• Parietal lobe: Impaired orientation ability; impaired visuospatial skills (unable to remain oriented within own environment).
• Occipital lobe: Impaired language interpretation; inability to recognize familiar objects.
• Temporal lobe: Inability to recall words; inability to use words correctly (language comprehension). In late stages, some clients experience delusions and hallucinations.
• Hippocampus: Impaired memory. Short-term memory is affected initially. Later, the individual is unable to form new memories.
• Amygdala: Impaired emotions–depression, anxiety, fear, personality changes, apathy, paranoia.
• Neurotransmitters: Alterations in acetylcholine, dopamine, norepinephrine, serotonin, and others may play a role in behaviors such as restlessness, sleep impairment, mood, and agitation.

MEDICATIONS AND THEIR EFFECTS ON THE BRAIN

1. Cholinesterase inhibitors (e.g., donepezil, rivastigmine, and galantamine) act by inhibiting acetylcholinesterase, which slows the degradation of acetylcholine, thereby increasing concentrations of the neurotransmitter in the brain. Most common side effects include dizziness, gastrointestinal upset, fatigue, and headache.
2. *N*-methyl-D-aspartate (NMDA) receptor antagonists (e.g., memantine) act by blocking NMDA receptors from excessive glutamate, preventing continuous influx of calcium into the cells and ultimately slowing down neuronal degradation. Possible side effects include dizziness, headache, and constipation.

genetic mutations cause AD, multiple factors rather than a single cause influence the development of this illness (Alzheimer's Association, 2015a). These may include a combination of genetic predisposition, lifestyle, and environmental factors that influence changes in the brain over time (Mayo Clinic, 2016b). Several findings in research studies have led to hypotheses about contributing or causative factors:

■ **Neurotransmitter alterations:** Research has indicated that in the brains of those with AD, the enzyme required to produce acetylcholine is dramatically reduced. The reduction seems to be greatest in the nucleus basalis of the inferior medial forebrain area (Sadock et al., 2015). The decrease in production of acetylcholine reduces the amount of the neurotransmitter that is released to cells in the cortex and hippocampus, resulting in cognitive process disturbances. Other neurotransmitters believed to be disrupted in AD include norepinephrine, serotonin, dopamine, and the amino acid glutamate. It has been proposed that in NCD, excess glutamate leads to overstimulation of the *N*-methyl-D-aspartate (NMDA) receptors, causing increased intracellular calcium and subsequent neuronal degeneration and cell death. Decreased levels of somatostatin and corticotropin have also been found in individuals with AD.

■ **Plaques and tangles:** As mentioned previously, an overabundance of structures called *plaques* and *tangles* appear in the brains of individuals with AD. The plaques are made of a peptide called amyloid beta (Aβ), derived from a larger protein called amyloid precursor protein (APP) (NIA, 2011). Plaques are formed when Aβ peptides clump together and mix with molecules and other cellular matter. Tangles are formed from a special kind of cellular protein called *tau protein* that provides stability to the neuron. In AD, the tau protein is chemically altered (NIA, 2011). Strands of the protein become tangled together, interfering with the neuronal transport system. It is unknown whether the plaques and tangles cause AD or are a consequence of the disease; it should be noted that both are seen in other disorders as well as in the normal brain with age (Sadock et al., 2015). Plaques and tangles are thought to contribute to the destruction and death of neurons, leading to memory failure, personality changes, inability to carry out ADLs, and other features of the disease. The number and density of senile plaques (also called *amyloid plaques*) found in postmortem studies have been correlated with the disease severity (Sadock et al., 2015).

■ **Head trauma:** Individuals who have a history of head trauma are at risk for AD (Black & Andreasen, 2014). Studies have shown that some individuals who experienced head trauma subsequently (after years) developed AD. This hypothesis is being investigated as a possible cause. The greatest risks are among those who experience traumatic head injury and have other risk factors for AD (Smith, 2014).

■ **Genetic factors:** As many as 40 percent of clients with AD have a family history of the disease, and some families exhibit a pattern of inheritance that suggests possible autosomal-dominant gene transmission (Sadock et al., 2015). Some studies indicate that early-onset cases are more likely than late-onset cases to be familial and that between one-third and one-half of those cases may be the genetic form. Some research indicates a link between AD and gene mutations found on chromosomes 21, 14, and 1 (Alzheimer's Disease Education & Referral [ADEAR], 2015a). Mutations on chromosome 21 cause the formation of abnormal APP. Mutations on chromosome 14 cause abnormal presenilin 1 *(PS-1)* to be made, and mutations on chromosome 1 leads to the formation of abnormal presenilin 2 *(PS-2).* Each of these mutations results in an increased amount of the Aβ protein that is a major component of the plaques associated with AD. Individuals with Down syndrome (who carry an extra copy of chromosome 21) also have an overabundance of amyloid plaques and have been found to develop a clinical syndrome of dementia almost identical to AD (Alvarez, 2016).

Two genetic variants have been identified as risk factors for late-onset AD. The apolipoprotein E epsilon 4 *(ApoE ε4)* gene, found on chromosome 19, was identified in 1993. Its exact role in the development of AD is not yet clear (ADEAR, 2015a), but it has been associated with an increase in amyloid plaques, which, as previously discussed, may contribute to neuron death and progressive symptoms of the disease (NIH, 2016). A second genetic variant, the *SORL1* gene, was identified in 2007 (Rogaeva et al., 2007). The researchers believe that the altered gene function results in increasing production of the toxic Aβ protein and subsequently the plaques associated with AD.

While much of the research has focused on toxic amyloid and tau proteins as correlated with AD, current research is exploring other molecular and cellular pathways that may be involved in the development of this disease, including glial cell activation, inflammation, glucose transport systems, and

abnormal neuronal circuit activity. Since previous research has demonstrated that ketone bodies have a protective effect on neurons, some studies are focused on the impact of ketones in improving memory and learning. One recent study demonstrated that ketone-rich diets were accompanied by a reduction in toxic proteins that have been associated with development of AD (ADEAR, 2015b).

Vascular Neurocognitive Disorder

In vascular NCD, cognitive symptoms are caused by significant cerebrovascular disease. When blood flow in the brain is impaired, progressive intellectual deterioration occurs. Impairment may be located in large vessels or microvascular networks, so symptoms vary depending on the type, extent, and location of vascular lesion (APA, 2013). Vascular NCD is the second-most common form of NCD after AD (Sadock et al., 2015).

Vascular NCD differs from AD in that it has a more abrupt onset and runs a highly variable course. In vascular NCD, progression of the symptoms occurs in steps rather than as a gradual deterioration; at times, the symptoms seem to subside and the individual exhibits fairly lucid thinking. Memory may seem better and the client may become optimistic that improvement is occurring, only to experience further decline of functioning in a fluctuating pattern of progression. This irregular pattern of decline appears to be an intense source of anxiety for the client with this disorder.

In vascular NCD, clients suffer the equivalent of small strokes that destroy many areas of the brain. The pattern of deficits is variable depending on which regions of the brain have been affected. Certain focal neurological signs commonly seen with vascular NCD include weaknesses of the limbs, small-stepped gait, and difficulty with speech. The disorder is more common in men than in women.

Etiology

Vascular NCD is directly related to an interruption of blood flow to the brain. Symptoms result from death of nerve cells in regions nourished by diseased vessels. Various diseases and conditions that interfere with blood circulation have been implicated.

High blood pressure is thought to be one of the most significant factors in the etiology of multiple small strokes or cerebral infarcts. Hypertension leads to damage to the lining of blood vessels, which can result in rupture of the blood vessel with subsequent hemorrhage or an accumulation of fibrin in the vessel with intravascular clotting and inhibited blood flow. NCD also can result from infarcts related to occlusion of blood vessels by particulate matter that travels through the bloodstream to the brain. These emboli may be solid (e.g., clots, cellular debris, platelet aggregates), gaseous (e.g., air, nitrogen), or liquid (e.g., fat, following soft tissue trauma or fracture of long bones).

Cognitive impairment can occur with multiple small infarcts (sometimes called *silent strokes*) over time or with a single cerebrovascular event in a strategic area of the brain. An individual may have both vascular NCD and AD simultaneously. This is referred to as a *mixed* disorder, the prevalence of which is likely to increase as the population ages.

Frontotemporal Neurocognitive Disorder

Symptoms of frontotemporal NCD occur as a result of shrinking of the frontal and temporal anterior lobes of the brain (National Institute of Neurological Disorders and Stroke [NINDS], 2015). This type of NCD was identified as Pick's disease in the *DSM-IV-TR*. The cause of frontotemporal NCD is unknown, but a genetic factor appears to be involved. Symptoms tend to fall into two clinical patterns: (1) behavioral and personality changes and (2) speech and language problems. Common behavioral changes include increasingly inappropriate actions, lack of judgment and inhibition, and repetitive compulsive behavior. There may be a marked impairment or loss of speech or increasing difficulty in using and understanding written and spoken language (Mayo Clinic, 2014). Because of the several behavioral and personality symptoms, it may be misdiagnosed as a different mental illness. The disease progresses steadily and often rapidly, ranging from less than 2 years in some individuals to more than 10 years in others (NINDS, 2015).

Neurocognitive Disorder Due to Traumatic Brain Injury

DSM-5 criteria state that this disorder "is caused by an impact to the head or other mechanisms of rapid movement or displacement of the brain within the skull, with one or more of the following: loss of consciousness, posttraumatic amnesia, disorientation and confusion, or neurological signs (e.g., positive neuroimaging demonstrating injury, a new onset of seizures or a marked worsening of a preexisting seizure disorder, visual field cuts, anosmia, hemiparesis)" (APA, 2013). Amnesia is the most common neurobehavioral symptom following head trauma. Other symptoms may include confusion and changes in speech, vision, and personality. Depending on the severity of the injury, these symptoms may eventually subside or may become permanent (Smith, 2014). Repeated head trauma, such as the type experienced by boxers, can result in *dementia*

pugilistica, a syndrome characterized by emotional lability, dysarthria, ataxia, and impulsivity (Sadock et al., 2015).

Neurocognitive Disorder Due to Lewy Body Dementia

Clinically, Lewy body NCD is fairly similar to AD; however, it tends to progress more rapidly, with earlier appearance of visual hallucinations and Parkinsonian features. Depression and delusions are also common symptoms in this population. Lewy body dementia recently gained public attention when an autopsy of famous comedian Robin Williams revealed that he was suffering from this disease. His widow reported that he had been seeking neurocognitive testing because he was aware of a decline in his mental capacities. He was also manifesting symptoms of depression and ultimately took his own life.

This disorder is distinguished by the presence of Lewy bodies—eosinophilic inclusion bodies—seen in the cerebral cortex and brainstem (Black & Andreasen, 2014). Acetylcholinesterase (ACh) concentrations are reduced in the brains of people with Lewy body NCD, and consequently, cholinesterase inhibitors are likely to be more effective for this population than for those with Alzheimer's dementia (Crystal & Jacobs, 2014). These patients are highly sensitive to extrapyramidal effects of antipsychotic medications. The disease is progressive and irreversible and may account for as many as 25 percent of all NCD cases.

Neurocognitive Disorder Due to Parkinson's Disease

NCD is observed in as many as 75 percent of clients with Parkinson's disease (APA, 2013). This disease is characterized by a loss of nerve cells in the substantia nigra and diminished dopamine activity, resulting in involuntary muscle movements, slowness, and rigidity along with tremor in the upper extremities. In some instances, the cerebral changes that occur in NCD due to Parkinson's disease closely resemble those of AD.

Neurocognitive Disorder Due to HIV Infection

Infection with the human immunodeficiency virus-type 1 (HIV-1) can result in an NCD called *HIV-1-associated cognitive/motor complex.* A less severe form, known as *HIV-1-associated minor cognitive/motor disorder,* also occurs. The severity of symptoms is correlated to the extent of brain pathology. The immune dysfunction associated with HIV disease can lead to brain infections by other organisms, and HIV-1 also appears to cause NCD directly. In the early stages, neuropsychiatric symptoms may be manifested by barely perceptible changes in a person's normal psychological presentation. Severe cognitive changes, particularly confusion, changes in behavior, and sometimes psychoses, are not uncommon in the later stages.

With the advent of the highly active antiretroviral therapies (HAART), incidence rates of NCD due to HIV infection have been on the decline. However, it is possible that the prolonged life span of HIV-infected patients taking medications may actually increase the number of individuals living with HIV-associated NCD.

Substance/Medication-Induced Neurocognitive Disorder

NCD can occur as the result of substance reactions, overuse, or abuse (Hale & Frank, 2015). Symptoms are consistent with major or mild neurocognitive disorder and persist beyond the usual duration of intoxication and acute withdrawal (APA, 2013). Substances that have been associated with the development of NCDs include alcohol, sedatives, hypnotics, anxiolytics, and inhalants. Drugs that cause anticholinergic side effects and toxins such as lead and mercury have also been implicated.

Neurocognitive Disorder Due to Huntington's Disease

Huntington's disease is transmitted as a Mendelian dominant gene. Damage is seen in the areas of the basal ganglia and the cerebral cortex. The onset of symptoms (i.e., involuntary twitching of the limbs or facial muscles, mild cognitive changes, depression, and apathy) usually occurs between age 30 and 50 years. The client usually declines into a profound state of cognitive impairment and **ataxia** (muscular incoordination). The average duration of the disease is 10 to 20 years depending on the severity of symptoms. (Huntington's Disease Society of America [HDSA], 2016).

Neurocognitive Disorder Due to Prion Disease

Prion disease is a group of disorders caused by infectious agents called *prions* and characterized by its insidious onset and rapid progression. Manifestations include problems with coordination and other movement disturbances along with rapidly progressing dementia. This type of NCD is diagnosed when there is evidence of characteristic biomarkers, including recognized lesions in the brain, specific types of proteins in the cerebrospinal fluid, and distinctive triphasic waves on electroencephalograms (APA, 2013). Five to 15 percent of cases of prion disease have a genetic component. Symptoms may develop at any age in adults but typically occur between ages 40 and 60 years.

The clinical course is extremely rapid, with the progression from diagnosis to death in less than 2 years (Rentz, 2008). The most common form of prion disease in humans is Creutzfeldt-Jakob's disease (Johns Hopkins Medicine, no date).

Neurocognitive Disorder Due to Another Medical Condition

A number of other medical conditions can cause NCD, including hypothyroidism, hyperparathyroidism, pituitary insufficiency, uremia, encephalitis, brain tumor, pernicious anemia, thiamine deficiency, pellagra, uncontrolled epilepsy, cardiopulmonary insufficiency, fluid and electrolyte imbalances, CNS and systemic infections, systemic lupus erythematosus, and multiple sclerosis (Black & Andreasen, 2014; Puri & Treasaden, 2012). The etiological factors associated with delirium and NCD are summarized in Box 22–2.

Application of the Nursing Process

Assessment

Nursing assessment of the client with delirium or mild or major NCD is based on knowledge of the symptomatology associated with the disorders previously described in this chapter. Subjective and objective data are gathered by various members of the health-care team. Clinicians report use of a variety of methods for obtaining assessment information.

Client History

Nurses play a significant role in acquiring the client history, including the specific mental and physical changes that have occurred and the age at which the changes began. If the client is unable to relate information adequately, the data should be obtained from family members or others who would be aware of the client's physical and psychosocial history.

From the client history, nurses should assess the following areas of concern: (1) type, frequency, and severity of mood swings, personality and behavioral changes, and catastrophic emotional reactions; (2) cognitive changes, such as problems with attention span, thinking process, problem-solving, and memory (recent and remote); (3) language difficulties; (4) orientation to person, place, time, and situation; and (5) appropriateness of social behavior.

The nurse also should obtain information regarding current and past medication usage, history of other drug and alcohol use, and possible exposure to toxins. Knowledge regarding the history of related symptoms or specific illnesses (e.g., Huntington's disease, AD, Pick's disease, or Parkinson's disease) in other family members might be useful.

BOX 22–2 Etiological Factors Implicated in the Development of Delirium and/or Mild or Major Neurocognitive Disorder

Biological Factors

Hypoxia: Any condition leading to a deficiency of oxygen to the brain

Nutritional deficiencies: Vitamins (particularly B and C); protein; fluid and electrolyte imbalances

Metabolic disturbances: Porphyria; encephalopathies related to hepatic, renal, pancreatic, or pulmonary insufficiencies; hypoglycemia

Endocrine dysfunction: Thyroid, parathyroid, adrenal, pancreas, pituitary

Cardiovascular disease: Stroke, cardiac insufficiency, atherosclerosis

Primary brain disorders: Epilepsy, Alzheimer's disease, Pick's disease, Huntington's chorea, multiple sclerosis, Parkinson's disease

Infections: Encephalitis, meningitis, pneumonia, septicemia, neurosyphilis (dementia paralytica), HIV disease, acute rheumatic fever, Creutzfeldt-Jakob disease

Intracranial neoplasms

Congenital defects: Prenatal infections, such as first-trimester maternal rubella

Exogenous Factors

Birth trauma: Prolonged labor, damage from use of forceps, other obstetric complications

Cranial trauma: Concussion, contusions, hemorrhage, hematomas

Volatile inhalant compounds: Gasoline, glue, paint, paint thinners, spray paints, cleaning fluids, typewriter correction fluid, varnishes, and lacquers

Heavy metals: Lead, mercury, manganese

Other metallic elements: Aluminum

Organic phosphates: Various insecticides

Substance abuse/dependence: Alcohol, amphetamines, caffeine, cannabis, cocaine, hallucinogens, inhalants, nicotine, opioids, phencyclidine, sedatives, hypnotics, anxiolytics

Other medications: Anticholinergics, antihistamines, antidepressants, antipsychotics, antiparkinsonians, antihypertensives, steroids, digitalis

Physical Assessment

Assessment of physical systems by both the nurse and the physician has two main emphases: signs of damage to the nervous system and evidence of diseases of other organs that could affect mental function. Diseases of various organ systems can induce confusion, loss of memory, and behavioral changes. These causes must be considered in diagnosing cognitive disorders. In the neurological examination, the client is asked to perform maneuvers or answer questions that are designed to elicit information about the condition of specific parts of the brain or peripheral nerves. Testing will assess mental status and alertness, muscle strength, reflexes, sensory perception, proprioception, language skills, and coordination. Physical assessment should include looking for signs of abuse or neglect, screening for hearing or vision impairments, and conducting a mental status examination (Moussa, 2016). An example of a mental status examination for a client with NCD is presented in Box 22–3.

BOX 22–3 Mental Status Examination for Neurocognitive Disorder

Patient Name_____ Date_____

Age_____ Sex_____ Diagnosis_____

	Maximum	**Client's Score**
1. VERBAL FLUENCY Ask client to name as many animals as he/she can. (Time: 60 seconds) (Score 1 point/2 animals)	10 points	_____
2. COMPREHENSION a. Point to the ceiling b. Point to your nose and the window c. Point to your foot, the door, and ceiling d. Point to the window, your leg, the door, and your thumb	1 point 1 point 1 point 1 point	_____ _____ _____ _____
3. NAMING AND WORD FINDING Ask the client to name the following as you point to them: a. Watch stem (winder) b. Teeth c. Sole of shoe d. Buckle of belt e. Knuckles	 1 point 1 point 1 point 1 point 1 point	 _____ _____ _____ _____ _____
4. ORIENTATION a. Date b. Day of week c. Month d. Year	2 points 2 points 1 point 1 point	_____ _____ _____ _____

5. NEW LEARNING ABILITY
Tell the client: "I'm going to tell you four words, which I want you to remember." Have the client repeat the four words after they are initially presented, and then say that you will ask him/her to remember the words later. Continue with the examination, and at intervals of 5 and 10 minutes, ask the client to recall the words. Three different sets of words are provided here.

		5 min.	10 min.
a. Brown (Fun) (Grape)	2 points each:	_____	_____
b. Honesty (Loyalty) (Happiness)	2 points each:	_____	_____
c. Tulip (Carrot) (Stocking)	2 points each:	_____	_____
d. Eyedropper (Ankle) (Toothbrush)	2 points each:	_____	_____

6. VERBAL STORY FOR IMMEDIATE RECALL
Tell the client: "I'm going to read you a short story, which I want you to   13 points   _____
remember. Listen closely to what I read because I will ask you to tell me
the story when I finish." Read the story slowly and carefully, but without
pausing at the slash marks. After completing the paragraph, tell the client
to retell the story as accurately as possible. Record the number of correct

Continued

BOX 22–3 Mental Status Examination for Neurocognitive Disorder—cont'd

memories (information within the slashes) and describe confabulation if
it is present. (1 point = 1 remembered item [13 maximum points])
It was July / and the Rogers family, mom, dad, and four children /
were packing up their station wagon / to go on vacation.
They were taking their yearly trip / to the beach at Gulf Shores.
This year they were making a special 1-day stop / at The Aquarium
in New Orleans. After a long day's drive they arrived at the motel /
only to discover that in their excitement / they had left the twins /
and their suitcases / in the front yard.

7. **VISUAL MEMORY (HIDDEN OBJECTS)**
   Tell the client that you are going to hide some objects around the
   office (desk, bed) and that you want him/her to remember where
   they are. Hide four or five common objects (e.g., keys, pen, reflex
   hammer) in various places in the client's sight. After a delay of several
   minutes, ask the client to find the objects. (1 point per item found)

a. Coin	1 point	_____
b. Pen	1 point	_____
c. Comb	1 point	_____
d. Keys	1 point	_____
e. Fork	1 point	_____

8. **PAIRED ASSOCIATE LEARNING**
   Tell the client that you are going to read a list of words two at a time.
   The client will be expected to remember the words that go together
   (e.g., big–little). When he/she is clear on the directions, read the first
   list of words at the rate of one pair per second. After reading the first list,
   test for recall by presenting the first recall list. Give the first word of a pair
   and ask for the word that was paired with it. Correct incorrect responses
   and proceed to the next pair. After the first recall has been completed,
   allow a 10-second delay and continue with the second presentation
   and recall lists.

   Presentation Lists

1	**2**
a. High–Low	a. Good–Bad
b. House–Income	b. Book–Page
c. Good–Bad	c. High–Low
d. Book–Page	d. House–Income

   Recall Lists

1	**2**		
a. House _____	a. High _____	2 points	_____
b. Book _____	b. Good _____	2 points	_____
c. High _____	c. House _____	2 points	_____
d. Good _____	d. Book _____	2 points	_____

9. **CONSTRUCTIONAL ABILITY**
   Ask client to reconstruct this drawing and to draw the other 2 items: 3 points   _____
BOX 22–3 Mental Status Examination for Neurocognitive Disorder–cont'd

Draw a daisy in a flowerpot	3 points	_____
Draw a clock with all the numbers and set the clock at 2:30.	3 points	_____

10. WRITTEN COMPLEX CALCULATIONS

a. Addition	108 + 79	1 point	_____
b. Subtraction	605 − 86	1 point	_____
c. Multiplication	108 × 36	1 point	_____
d. Division	559 ÷ 43	1 point	_____

11. PROVERB INTERPRETATION
Tell the client to explain the following sayings. Record the answers.

a. Don't cry over spilled milk.	2 points	_____
_____		
b. Rome wasn't built in a day.	2 points	_____
_____		
c. A drowning man will clutch at a straw.	2 points	_____
_____		
d. A golden hammer can break down an iron door.	2 points	_____
_____		
e. The hot coal burns, the cold one blackens.	2 points	_____
_____		

12. SIMILARITIES
Ask the client to name the similarity or relationship between each of the two items.

a. Turnip.. Cauliflower	2 points	_____
b. Car... Airplane	2 points	_____
c. Desk... Bookcase	2 points	_____
d. Poem.. Novel	2 points	_____
e. Horse.. Apple	2 points	_____
	Maximum: 100 points	_____

Normal Individuals		Clients with Alzheimer's Disease	
Age Group	**Mean Score (standard deviation)**	**Stage**	**Mean Score (standard deviation)**
40-49	80.9 (9.7)	I	57.2 (9.1)
50-59	82.3 (8.6)	II	37.0 (7.8)
60-69	75.5 (10.5)	III	13.4 (8.1)
70-79	66.9 (9.1)		
80-89	67.9 (11.0)		

Adapted from Strub, R.L., & Black, F. W. (2000). The mental status examination in neurology, 4th ed., Philadelphia: F.A. Davis. With permission.

A battery of psychological tests may be ordered as part of the diagnostic examination. The results of these tests may be used to make a differential diagnosis between NCD and **pseudodementia** (depression). Depression is one of the most common mental illnesses in the elderly, but it is often misdiagnosed and treated inadequately. Cognitive symptoms of depression may mimic NCD, and because of the prevalence of NCD in the elderly, providers are often too eager to make this diagnosis. A comparison of symptoms of NCD and pseudodementia (depression) is presented in Table 22–1. Nurses can assist in this assessment by carefully observing and documenting these sometimes subtle differences.

Diagnostic Laboratory Evaluations

The nurse also may be required to help the client fulfill the physician's orders for special diagnostic laboratory evaluations. Many of these tests are conducted to rule out other factors associated with dementia, such as evaluation of blood and urine samples to test for various infections, liver function studies to rule out hepatic disease, glucose tests to rule out diabetes or hypoglycemia, electrolytes to rule out imbalances, thyroid tests to rule out hypothyroidism, vitamin B_{12} test to rule out nutritional deficiencies, and drug and alcohol screening to rule out the presence of toxic substances. A rapid plasma reagin (RPR) test for syphilis and HIV testing should be included if the patient is at higher risk for these conditions (Moussa, 2016). CT scanning produces an image of the size and shape of the brain, and MRI produces a computerized image of soft tissue in the brain. Both CT and MRI scans are useful in identifying areas of atrophy such as those seen in AD and may identify other pathological processes needed for differential diagnosis. A lumbar puncture may be performed to examine the cerebrospinal fluid for evidence of CNS infection or hemorrhage if this is suspected. Positron emission tomography (PET) is used to reveal the metabolic activity of the brain, an evaluation some researchers believe is important for early diagnosis of AD. Moussa (2016) cautions that routine brain imaging is controversial and some believe it is overutilized. He adds that while there are genotyping tests that identify genetic markers for apolipoprotein E (which could suggest risk for development of AD), these tests are not indicated for clinical use.

Nursing Diagnosis and Outcome Identification

Using information collected during the assessment, the nurse completes the client database, from which the selection of appropriate nursing diagnoses is determined. Table 22–2 presents a list of client behaviors and the NANDA-I nursing diagnoses that correspond to those behaviors, which may be used in planning care for the client with an NCD.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with an NCD.

TABLE 22–1 **A Comparison of Neurocognitive Disorder (NCD) and Pseudodementia (Depression)**		
SYMPTOM ELEMENT	NCD	PSEUDODEMENTIA (DEPRESSION)
Progression of symptoms	Slow	Rapid
Memory	Progressive deficits; recent memory loss greater than remote; may confabulate for memory "gaps"; no complaints of loss	More like forgetfulness; no evidence of progressive deficit; recent and remote loss equal; complaints of deficits; no confabulation (will more likely answer "I don't know")
Orientation	Disoriented to time and place; may wander in search of the familiar	Oriented to time and place; no wandering
Task performance	Consistently poor performance but struggles to perform	Performance is variable; little effort is put forth
Symptom severity	Worse as the day progresses	Better as the day progresses
Affective distress	Appears unconcerned	Communicates severe distress
Appetite	Unchanged	Diminished
Attention and concentration	Impaired	Intact

TABLE 22–2 Assigning Nursing Diagnoses to Behaviors Commonly Associated With Neurocognitive Disorders	
BEHAVIORS	NURSING DIAGNOSES
Falls, wandering, poor coordination, confusion, misinterpretation of the environment (illusions, hallucinations), lack of understanding of environmental hazards, memory deficits	Risk for trauma
Disorientation, confusion, memory deficits, inaccurate interpretation of the environment, suspiciousness, paranoia	Disturbed thought processes;* Impaired memory
Having hallucinations (hears voices, sees visions, feels crawling sensation on skin)	Disturbed sensory perception*
Aggressiveness, assaultiveness (hitting, scratching, or kicking)	Risk for other-directed violence
Inability to name objects/people, loss of memory for words, difficulty finding the right word, confabulation, incoherent, screaming and demanding verbalizations	Impaired verbal communication
Inability to perform activities of daily living: feeding, dressing, hygiene, toileting	Self-care deficit (specify)
Expressions of shame and self-degradation, progressive social isolation, apathy, decreased activity, withdrawal, depressed mood	Situational low self-esteem; Grieving

*These nursing diagnoses have been resigned from the NANDA-I list of approved diagnoses, but are used for purposes of this text.

The client:

- Has not experienced physical injury
- Has not harmed self or others
- Has maintained reality orientation to the best of his or her capability
- Is able to communicate with consistent caregiver
- Fulfills ADLs with assistance (or for client who is unable, has needs met as anticipated by caregiver)
- Discusses positive aspects about self and life

Planning and Implementation

Care for an individual with an NCD must focus on immediate needs and keeping the individual safe from harm.

Risk for Trauma

Because the individual has impairments in cognitive and psychomotor functioning, it is important to ensure that the environment is as safe as possible to prevent injury. NANDA-I defines *Risk for trauma* as "vulnerable to accidental tissue injury (e.g., wound, burn, fracture) which may compromise health" (Herdman & Kamitsuru, 2014). Table 22–3 presents this nursing diagnosis in care plan format.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

- Client will call for assistance when ambulating or conducting other activities (if it is within his or her cognitive ability).

- Client will maintain a calm demeanor, with minimal agitated behavior.
- Client will not experience physical injury.

Long-term goal

- Client will not experience physical injury.

Interventions

Interventions for preventing injury in the cognitively impaired client include the following:

- Arrange the furniture and other items in the room to accommodate the client's disabilities. Ensure that frequently used items are stored within easy access.
- Keep the bed in its lowest position. If allowed by hospital regulation or accrediting body, limited use of bedrails may provide a measure of safety.
- A room near the nurse's station may be helpful to ensure that the client has close observation. In some instances, one-to-one observation may be necessary, particularly for the delirious client.
- If the client is a smoker, ensure that cigarettes and lighter are kept at the nurse's station and dispensed only when someone is available to stay with the client while he or she is smoking.
- Assist the client with ambulation. Provide cane or walker for balance and instruct client in its proper use. Transport client in wheelchair when longer excursions are necessary.
- Teach client to hold on to hand railing if one is available or to call for assistance when ambulating if he or she is cognitively able.

Table 22–3 | CARE PLAN FOR THE CLIENT WITH A NEUROCOGNITIVE DISORDER

NURSING DIAGNOSIS: RISK FOR TRAUMA

RELATED TO: Impairments in cognitive and psychomotor functioning

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals • Client calls for assistance when ambulating or carrying out other activities (if it is within his or her cognitive ability). • Client maintains a calm demeanor, with minimal agitated behavior. • Client does not experience physical injury. **Long-Term Goal** • Client does not experience physical injury.	The following measures may be instituted: a. Arrange furniture and other items in the room to accommodate client's disabilities. b. Store frequently used items within easy access. c. Keep the bed in the lowest position from the floor when the client is not being immediately attended to. Pad siderails and headboard if client has history of seizures. Keep bedrails up when client is in bed (if regulations permit). d. Assign room near nurses' station; observe frequently. e. Assist client with ambulation. f. Keep a dim light on at night. g. If client is a smoker, cigarettes and lighter or matches should be kept at the nurses' station and dispensed only when someone is available to stay with client while he or she is smoking. h. Frequently orient client to place, time, and situation. i. If client is prone to wander, provide an area within which wandering can be carried out safely. j. Soft restraints may be required if client is very disoriented and hyperactive.	To ensure client safety

For the Agitated Client

■ Maintain an environment of low stimulation for an individual with disruptions in cognitive processes. Irritability, hostility, aggression, and psychotic behaviors are troublesome symptoms that require management in individuals with cognitive disorders. These behaviors often make it difficult for family to care for their loved ones and is a common cause for placement in an institution. In the United States, 16 percent of patients with dementia die in hospitals, and the majority die in nursing homes (Mitchell, 2015). This issue requires further exploration, since many families struggle with the idea of institutionalization but are not equipped to deal with the overwhelming burden of caring for a client with an NCD.

■ Antipsychotics have historically been used to help manage behavioral symptoms in patients with NCD. Treatment of nonpsychotic behavior with antipsychotics, however, is an off-label use and could have legal implications; this is a difficult treatment issue because behavioral symptoms occur in 90 percent

of patients with NCD at some point during progression of the illness (Rice & Humphries, 2014). The conventional antipsychotics are also problematic because of their tendency to induce extrapyramidal side effects. The newer atypical antipsychotics have shown some effectiveness in treating these symptoms. Although antipsychotic medications are still used for this purpose by some physicians, the U.S. Food and Drug Administration (FDA) has issued black-box warnings against their use in elderly patients with NCD-related psychosis. They have been associated with increased mortality in this patient population.

■ Remain calm and undemanding, and avoid pressing the individual to perform activities that he or she is refusing. Reasoning with some clients with NCDs may only increase the possibility for agitation. Practicing relaxation exercises and walking with the client may be of some help.

■ Recent nursing literature has highlighted novel, evidence-based interventions to reduce anxiety and agitation, including dance and other rhythmic movement therapy (Lapum & Bar, 2016) and doll therapy (Shin, 2015).

For the Client Who Wanders

A number of reasons have been proposed as to why individuals with NCD wander. Some clinicians associate wandering behavior with increased stress and anxiety or restless agitation. Others relate the behavior to stages of cognitive decline. When memory diminishes and fear sets in, individuals may wander in search of something that seems familiar to them. Increased walking at night corresponds with disruption of diurnal rhythm. In any event, wandering behavior in NCD can cause great problems for caregivers. Wandering is often a problem in midstage NCD and less so in later stages. Clients new to a nursing home may wander in an attempt to become oriented to new surroundings. Wandering behavior can also be attributed to physical causes, such as hunger, thirst, and urinary or fecal urgency. When the wandering behavior begins after a long period of stability, it is likely that a new complication may be occurring—medical, psychiatric, or cognitive. Delirium may produce the abrupt onset of wandering behavior. The goals of wandering therapy are to keep the individual safe, to prevent intrusion into others' rooms, and to try to determine contributing factors to the behavior. When caring for a client who wanders, it is important to keep the following interventions in mind:

■ Keep the individual on a structured schedule of recreational activities and a strict feeding and toileting schedule.

■ Provide a safe, enclosed place for pacing and wandering.

■ Walk with the individual for a while and gently redirect him or her back to the care unit.

■ Ensure that outdoor exits are electronically controlled.

Disturbed Thought Processes/Impaired Memory and Disturbed Sensory Perception

Disturbed thought processes and sensory perception have been resigned as nursing diagnoses by NANDA-I, but they are retained in this text because of their appropriateness in describing specific behaviors. In this instance, they are evidenced by disorientation, confusion, and inaccurate interpretation of the environment, including illusions, delusions, and hallucinations. *Disturbed thought processes* has been defined as disruptions in cognitive operations and activities. *Disturbed sensory perception* is defined as a "change in the amount or patterning of incoming stimuli accompanied by a diminished, exaggerated, distorted, or impaired response to such stimuli" (NANDA-I, 2012, p. 490). *Impaired memory* is defined as the "inability to remember or recall bits of information or behavioral skills" (Herdman & Kamitsuru, 2014, p. 259).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ Client utilizes measures provided (e.g., clocks, calendars, room identification) to maintain reality orientation.

■ Client experiences fewer episodes of acute confusion.

Long-term goal

■ Client maintains reality orientation to the best of his or her cognitive ability.

Interventions

For the Client Who Is Disoriented

■ Try to keep the client as oriented to reality as possible.

■ Use clocks and calendars with large numbers that are easy to read.

■ Place large, colorful signs on the doors to identify clients' rooms, bathrooms, activity rooms, dining rooms, and chapel.

■ Allow the client to have as many of his or her personal items as possible. Even an old familiar chair in the room can provide a degree of comfort.

■ If at all possible, encourage family and close friends to be a part of the client's care, to promote feelings of security and orientation.

■ Provide the client with radio, television, and music if they are diversions the client enjoys; these may add a feeling of familiarity to the environment.

■ Ensure that noise level is controlled to prevent excess stimulation. One study found that use of earplugs at night decreased risk for delirium by 53 percent and patients reported improved sleep (Van Rompaey et al., 2012)

■ Allow the client to view old photograph albums and utilize reminiscence therapy. These are excellent ways to provide orientation to reality.

■ Maintain consistency of staff and caregivers to the best extent possible. Familiarity promotes comfort and feelings of security.

■ Continuously monitor for medication side effects. Physiological changes in the elderly can alter the body's response to certain medications. Toxic effects may intensify altered cognitive processes.

■ There has been criticism about reality orientation of individuals with NCD (particularly those with moderate to severe disease process), suggesting that constant relearning of material contributes to problems with mood and self-esteem (Spector et al., 2000). See Box 22–4, Validation Therapy, for more information.

For the Client With Delusions and Hallucinations

■ Minimize focus on delusional thinking. Do not disagree with made-up stories. Instead, gently correct the client, offer reassurance that he or she is safe, and guide the conversation toward topics about real events and real people.

BOX 22–4 **Validation Therapy**

Some people believe it is not helpful (and sometimes even cruel) to try to insist that a person with moderate to severe NCD continually try to grasp what we know as the "real world." Allen (2000) states,

There is no successful alternative but to accept whatever the dementia person claims as their reality, no matter how untrue it is to us. There is no successful way to "force" a person with dementia to join the "real" world. The most frustrated caregivers are the ones who do not accept this simple fact: the world of dementia is defined by the dementia victim.

Validation therapy (VT) was originated by Naomi Feil, a gerontological social worker, who describes the process as "communicating with a disoriented elderly person by validating and respecting their feelings in whatever time or place is real to them at the time, even though this may not correspond with our 'here and now' reality" (Day, 2013). Feil suggests that the validation principle is truthful to the person with NCD because people live on several levels of awareness (Feil, 2013). She suggests that if an individual asks to see his or her spouse, and the spouse has been dead for many years, that on some level of awareness, that person knows the truth. To keep reminding the person that the spouse is dead may only serve to cause repeated episodes of grief and distress, as he or she receives the information "anew" each time it is presented (Allen, 2000).

Validation therapy validates the feelings and emotions of a person with NCD. It often also integrates redirection techniques. Allen (2000) states, "The key is to 'agree' with what they want but by conversation and 'steering' get them to do something else without them realizing they are actually being redirected. This is both validation and redirection therapy."

EXAMPLES

Mrs. W. (agitated): That old lady stole my watch! I know she did. She goes into people's rooms and takes our things. We call her "sticky fingers"!

Nurse: That watch is very important to you. Have you looked around the room for it?

Mrs. W.: My husband gave it to me. He will be so upset that it is gone. I'm afraid to tell him.

Nurse: I'm sure you miss your husband very much. Tell me what it was like when you were together. What kinds of things did you do for fun?

Mrs. W.: We did a lot of traveling. To Italy, and England, and France. We ate wonderful food.

Nurse: Speaking of food, it is lunch time, and I will walk with you to the dining room.

Mrs. W.: Yes, I'm getting really hungry.

In this situation, the nurse validated Mrs. W.'s feelings about not being able to find her watch. She did not deny that it had been stolen, nor did she remind Mrs. W. that her husband was deceased. *(Remember: a concept of VT is that, on some level, Mrs. W. knows that her husband is dead*.) The nurse validated the emotions Mrs. W. was feeling about missing her husband. She brought up special times that Mrs. W. and her husband had spent together, which served to elevate Mrs. W.'s mood and self-esteem. Finally, she redirected Mrs. W. to the dining room to have her lunch. (The watch was eventually found in Mrs. W.'s medicine cabinet, where she had hidden it for safekeeping.)

BOX 22–4 **Validation Therapy—cont'd**

Feil (2013) presents another example:

When a resident asks for his wife who is dead, caregivers reply, "She'll be here to see you later." The resident may not remember much, but he clings to that statement. He continues to ask for his wife on a daily basis, and the caregivers continue to lie. Eventually, he loses trust in the caregivers, knowing that what they say is not true. With VT, the caregivers would encourage the resident to talk about his wife. They would validate his emotions and encourage him to express his needs, accepting the fact that there is a reason behind his behavior. He has not simply "forgotten that his wife died"; he needs to grieve for her. This is unfinished business. When the emotion is expressed and someone listens with empathy, it is relieved. The old man no longer needs to search for his wife. He feels safe with the caregiver, whom he trusts. He always knew on a deep level of awareness that his wife had died. (pp. 3, 4)

■ Never argue a point with the client; to do so only serves to increase his or her anxiety and agitation.

■ Do not ignore reports of hallucinations when it is clear that the client is experiencing them. It is important for the nurse to hear an explanation of the hallucination from the client. These perceptions are very real and often very frightening to the client. Unless they are appropriately managed, hallucinations can escalate into disturbing and even hostile behaviors. Visual and auditory hallucinations are the most common type in NCD. The physician may treat these manifestations with antipsychotic medication.

■ Assess for side effects of medications as a potential contributing factor to sensory perception disturbances.

■ Check to ensure that hearing aid is working properly and to ensure that faulty sounds are not being emitted.

■ Check eyeglasses to ensure that the individual is indeed wearing his or her own glasses.

■ Assess for other possible contributing factors to illusions or visual hallucination. Clients often see faces in patterns on fabrics or in pictures on the wall. A mirror can also be the culprit of false perceptions. These may need to be moved or covered.

■ Provide reassurance that the client is safe. It may be necessary to stay with the client for a while until he or she is calm.

■ Never argue that the hallucination is not real. Try to let the client know that, although you are not sharing the experience, you understand how very distressing it is for him or her.

■ Distract the client. Hallucinations are less likely to occur when the person is occupied or involved in what is going on around him or her. Focus on real situations and real people.

■ Assess whether or not the hallucinations are problematic for the patient. Not all hallucinations are upsetting.

EXAMPLE

An elderly woman approaches the nurses' station and says, "I'm so perturbed. The woman in my room refuses to turn down my bed so that I can go to sleep." The nurse may respond, "I will walk to your room with you and see that your bed is turned down." The nurse chats with the client about something that occurred during the day, and by the time they arrive at her room, there is no further mention of a woman in her room.

Impaired Verbal Communication

When individuals who are cognitively impaired begin to lose the ability to process verbal communication, the way that words are expressed becomes as important as what is said. NANDA-I defines *Impaired verbal communication* as "decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols" (Herdman & Kamitsuru, 2014).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ Client is able to make needs known to primary caregiver.

■ Client is able to understand basic communications in interactions with primary caregiver.

Long-term goal

■ In latter stages of the illness when client is unable to communicate, needs are anticipated and fulfilled by primary caregiver.

Interventions

■ Use a calm and reassuring approach when interacting with the client.

■ Use simple words, speak slowly and distinctly, and keep face-to-face contact with the client.

■ Always identify yourself to the client and call him or her by name at each meeting.

- Use nonverbal gestures to help the client understand what you want him or her to accomplish, if appropriate.
- Ask only one question (or give only one direction) at a time, and give the client plenty of time to process the information and respond. The question may need to be rephrased if it is clear that the client has not understood the meaning.
- Always try to approach the client from the front. An unexpected approach or touch from behind may startle and upset the client and may even promote aggressive behavior.
- Maintain consistency of staff and caregivers to the best extent possible. This facilitates comfort and security and promotes an effective communication process with the client.
- Should the client become verbally aggressive, remain calm and provide validation for his or her feelings: "I know this is a hard time for you. You were always so busy and so active, and you took care of so many people. Maybe you could tell me about some of those people."
- When it is clearly appropriate, use touch and affection to communicate. Sometimes clients will respond to a hug or to a hand reaching for theirs when they will respond to nothing else.

Self-Care Deficit

It is important for clients to remain as independent as possible for as long as possible. They should be encouraged to accomplish ADLs to the best of their ability. NANDA-I defines *Self-care deficit* as "impaired ability to perform or complete activities" (Herdman & Kamitsuru, 2014).

Client Goals

Outcome criteria include short- and long-term goals. Time-lines are individually determined.

Short-term goal

- Client participates in ADLs with assistance from caregiver.

Long-term goals

- Client accomplishes ADLs to the best of his or her ability.
- Unfulfilled needs are met by caregiver.

Interventions

- Provide a simple, structured environment for the client, identify self-care deficits, and offer assistance as required.
- Allow plenty of time for the client to complete tasks.
- Provide guidance and support for independent actions by talking the client through the task one step at a time.

- Provide a structured schedule of activities that does not change from day to day.
- Ensure that ADLs follow the client's usual routine as closely as possible.
- Minimize confusion by providing for consistency in assignment of daily caregivers.
- Perform an ongoing assessment of the client's ability to fulfill his or her nutritional needs, ensure personal safety, follow the medication regimen, and communicate the need for assistance with activities that he or she cannot accomplish independently. Anticipate needs that are not verbally communicated.
- If the client is to be discharged to family caregivers, assess those caregivers' ability to anticipate and fulfill client's unmet needs. Provide information to assist caregivers with this responsibility. Ensure that caregivers are aware of available community support systems from which they may seek assistance when required. Examples include adult day care centers, housekeeping and homemaker services, respite care services, and the local chapter of a national support organization. Following are two helpful resources:
  - For AD information:
    Alzheimer's Association

Concept Care Mapping

The concept map care plan (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and interventions. An example of a concept map care plan for a client with an NCD is presented in Figure 22–3.

Client and Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client/family education relevant to NCDs is presented in Box 22–5.

Evaluation

In the final step of the nursing process, reassessment occurs to determine if the nursing interventions have been effective in achieving the intended goals of care. Evaluation of the client with an NCD is based on a series of short-term goals rather than on long-term

Clinical Vignette: Sarah, age 82, a widow of many years, has been admitted to a long-term care facility with a diagnosis of NCD due to Alzheimer's disease. She is confused about her whereabouts and says to the nurse, "I think I've been here long enough now. It's time for me to go home. I'll just call my husband to come get me." She wanders around the unit and cannot find her room. She attempts to go out the locked door to the outside and sets off the alarm. With much reluctance, she allows the nurse to help her get ready for bed. The nurse discovers her awake in the middle of the night and wandering into other patients' rooms. She appears in the dining room the next morning barefoot and wearing her pajamas. The nurse develops the following concept map care plan for Sarah.

Signs and Symptoms
- Impairments in cognitive and psychomotor functioning

Signs and Symptoms
- Disorientation
- Confusion
- Memory deficits
- Inaccurate interpretation of the environment

Signs and Symptoms
- Unable to fulfill activities of daily living

Nursing Diagnosis

Risk for trauma

Nursing Diagnosis

Disturbed thought processes

Nursing Diagnosis

Self-care deficit

Nursing Actions
- Arrange furniture to facilitate movement.
- Keep bed in low position.
- Assist with ambulation.
- Provide nightlight.
- Provide safe place for wandering.
- Keep level of stimuli in the environment low.

Nursing Actions
- Display clocks and calendars with large numbers.
- Put signs on doors to identify specific rooms.
- Allow client to have personal belongings.
- Speak slowly and distinctly, in face-to-face contact.
- Distract from delusions and hallucinations.

Nursing Actions
- Allow time to do tasks.
- Provide step-by-step instructions.
- Provide simple, structured environment.
- Provide for consistency of caregivers.
- Anticipate and fulfill unmet needs.

Medical Rx:
Aricept 5 mg q HS

Outcomes
- Has not experienced physical injury
- Has not harmed self or others

Outcomes
- Interprets environment accurately
- Maintains reality orientation to best of personal ability
- Discusses positive aspects about self and life

Outcomes
- Assists with own dressing
- Feeds self
- Finds way to bathroom with some assistance
- Assists with shower

FIGURE 22–3 Concept map care plan for client with major neurocognitive disorder.

goals. Outcomes are measured in terms of slowing down the process rather than stopping or curing the problem. Evaluation questions may include the following:

- Has the client experienced injury?
- Does the client maintain orientation to time, person, place, and situation to the best of his or her cognitive ability?

- Is the client able to fulfill basic needs? Have those needs unmet by the client been fulfilled by caregivers?
- Is confusion minimized by familiar objects and structured, routine schedule of activities?
- Do the prospective caregivers have information regarding the progression of the client's illness?

BOX 22–5 Topics for Client/Family Education Related to Neurocognitive Disorders

1. Nature of the illness
   a. Possible causes
   b. What to expect
   c. Symptoms

2. Management of the illness
   a. Ways to ensure client safety
   b. How to maintain reality orientation
   c. Providing assistance with ADLs
   d. Nutritional information
   e. Difficult behaviors
   f. Medication administration
   g. Matters related to hygiene and toileting

3. Support services
   a. Financial assistance
   b. Legal assistance
   c. Caregiver support groups
   d. Respite care
   e. Home health care

■ Do caregivers have information regarding where to go for assistance and support in the care of their loved one?

■ Have the prospective caregivers received instruction in how to promote the client's safety, minimize confusion and disorientation, and cope with difficult client behaviors (e.g., hostility, anger, depression, agitation)?

■ Has the client been able to maintain the best quality of life within the limitations posed by his or her illness?

Quality and Safety Education for Nurses (QSEN)

The Institute of Medicine (now the National Academy of Medicine), in its report *Health Professions Education: A Bridge to Quality* (Greiner, Knebel, & Institute of Medicine, 2003), challenged faculties of medicine, nursing, and other health professions to ensure that their graduates have achieved a core set of competencies in order to meet the needs of the 21st-century health-care system. These competencies include *providing patient-centered care, working in interdisciplinary teams, employing evidence-based practice, applying quality improvement, maintaining safety,* and *utilizing informatics.* A QSEN teaching strategy is included in Box 22–6. The use of this type of activity is intended to arm the instructor and student with guidelines for attaining the knowledge, skills, and attitudes necessary for achievement of quality and safety competencies in nursing.

Medical Treatment Modalities

Delirium

The first step in the treatment of delirium should be the determination and correction of the underlying causes. Additional attention must be given to fluid and electrolyte status, hypoxia, anoxia, and diabetic problems. Staff members should remain with the client at all times to monitor behavior and provide reorientation and assurance. The room should maintain a low level of stimuli.

Some physicians prefer not to prescribe medications for the client with delirium, reasoning that additional agents may only compound the syndrome of brain dysfunction. However, psychosis with agitation and aggression demonstrated by the client with delirium may require chemical and/or mechanical restraint for his or her personal safety. Choice of specific therapy is made with consideration for the client's clinical condition and the underlying cause of the delirium. Low-dose antipsychotics are the most common medications used in delirium management. However, two recent meta-analyses have found mixed results. One analysis of 15 studies concluded that second-generation antipsychotics are beneficial (and preferable to haloperidol) in treatment of delirium (Kishi et al., 2015), but a second meta-analysis of 19 studies concluded that the evidence does not support use of antipsychotics for prevention or treatment of delirium (Neufeld et al., 2016). Haloperidol (Haldol) is still used to treat psychotic features, but because it has been associated with prolongation of QT intervals, nurses must monitor the client's cardiac status (Sadock et al., 2015). A benzodiazepine (e.g., lorazepam) is commonly used when the etiology is substance withdrawal (Eisendrath & Lichtmacher, 2012). Melatonin, an over-the-counter supplement, and ramelteon (Rozerem), a prescription medication for treatment of insomnia, have both been identified as potentially beneficial in prevention and treatment of delirium, since melatonin levels were found to be altered in patients with delirium (Alagiakrishnan, 2016).

Neurocognitive Disorder

Once a definitive diagnosis of NCD has been made, a primary consideration in the treatment of the disorder is the etiology. Focus must be directed to the identification and resolution of potentially reversible processes. Sadock and colleagues (2015) note that once dementia is apparent, it is essential to complete a clinical workup to identify the syndrome and its causes because "approximately 15% of people with dementia have reversible illnesses if treatment is initiated before irreversible damage takes place" (p. 704).

BOX 22–6 QSEN TEACHING STRATEGY

Assignment: Linking Evidence-Based Practice With a Nursing Procedure
Reality Orientation of Clients With Neurocognitive Disorder

Competency Domain: Evidence-Based Practice

Learning Objectives: Student will:
- Locate an evidence-based practice article on protocols for reality orientation in patients with NCDs and compare and contrast this information with the protocols established by the hospital or other assigned facility for clinical experience.
- Identify whether evidence-based practice is utilized with this protocol, and identify barriers or challenges with implementing evidence-based practice in the clinical setting.

Strategy Overview:
1. Research the nursing intervention of reality orientation of clients with NCD. Identify the pros and cons and ethical issues associated with this intervention (particularly with clients who have advanced NCD).
2. Find an evidence-based practice journal article about the intervention.
3. Locate the facility's protocol for reality orientation of clients with NCD.
4. Compare and contrast the facility's protocol with how unit staff carry out this intervention. If there are deviations from the written protocol, what are they, and why do they occur?
5. Compare and contrast the hospital's protocol with the information found in the evidence-based practice article.
6. At postconference, summarize the article on evidence-based practice to the clinical group, and report information gathered throughout the clinical day. Discuss any ethical dilemmas associated with the intervention.
7. Write a paper discussing personal reflections and feelings about this intervention.

Adapted from teaching strategy submitted by Chris Tesch, Instructor, University of South Dakota, Sioux Falls, SD. © 2009 QSEN; http://qsen.org. With permission.

The need for general supportive care with provisions for security, stimulation, patience, and nutrition, has been recognized and accepted. A number of pharmaceutical agents have been tried with varying degrees of success in the treatment of clients with NCD. Some of these drugs are described in the following sections according to symptomatology for which they are indicated. A summary of medications for clients with NCD is provided in Table 22–4.

Cognitive Impairment

Cholinesterase inhibitors are often used for treatment of mild to moderate cognitive impairment in AD and have demonstrated efficacy in treating patients

TABLE 22–4	**Selected Medications Used in the Treatment of Clients With NCD**			
MEDICATION	CLASSIFICATION	FOR TREATMENT OF	DAILY DOSAGE RANGE (mg)	SIDE EFFECTS
Donepezil (Aricept)	Cholinesterase inhibitor	Cognitive impairment	5–10	Insomnia, dizziness, gastrointestinal (GI) upset, headache
Rivastigmine (Exelon)	Cholinesterase inhibitor	Cognitive impairment	6–12	Dizziness, headache, GI upset, fatigue
Galantamine (Razadyne)	Cholinesterase inhibitor	Cognitive impairment	8–24	Dizziness, headache, GI upset
Memantine (Namenda)	NMDA receptor antagonist	Cognitive impairment	5–20	Dizziness, headache, constipation
Memantine, extended release + donepezil (Namzaric)	Anti-Alzheimer's agent	Moderate to severe Alzheimer's type dementia	Memantine ER, 14–28 mg, and donepezil 10 mg, once daily	Headache, nausea, vomiting, dizziness, diarrhea, decreased appetite

Continued

TABLE 22–4 Selected Medications Used in the Treatment of Clients With NCD–cont'd

MEDICATION	CLASSIFICATION	FOR TREATMENT OF	DAILY DOSAGE RANGE (mg)	SIDE EFFECTS
Risperidone* (Risperdal)	Antipsychotic	Agitation, aggression, hallucinations, thought disturbances, wandering	1–4 (increase dosage cautiously)	Agitation, insomnia, headache, insomnia, extrapyramidal symptoms
Olanzapine* (Zyprexa)	Antipsychotic	Agitation, aggression, hallucinations, thought disturbances, wandering	5 (increase dosage cautiously)	Hypotension, dizziness, sedation, constipation, weight gain, dry mouth
Quetiapine* (Seroquel)	Antipsychotic	Agitation, aggression, hallucinations, thought disturbances, wandering	Initial dose 25 (titrate slowly)	Hypotension, tachycardia, dizziness, drowsiness, headache, constipation, dry mouth
Haloperidol* (Haldol)	Antipsychotic	Agitation, aggression, hallucinations, thought disturbances, wandering	1–4 (increase dosage cautiously)	Dry mouth, blurred vision, orthostatic hypotension, extrapyramidal symptoms, sedation
Pimavanserin (Nuplazid)	Antipsychotic	Hallucinations and delusions specifically associated with Parkinson's disease psychosis. *Note:* Pimavanserin is not approved for dementia-related psychosis unrelated to Parkinson's disease psychosis	34 mg daily (17 mg, twice daily)	Peripheral edema, nausea, confusion, hallucinations, constipation, gait disturbance
Sertraline (Zoloft)	Antidepressant (SSRI)	Depression	50–100	Fatigue, insomnia, sedation, GI upset, headache, dizziness
Paroxetine (Paxil)	Antidepressant (SSRI)	Depression	10–40	Dizziness, headache, insomnia, somnolence, GI upset
Nortriptyline (Pamelor)	Antidepressant (tricyclic)	Depression	30–50	Anticholinergic, orthostatic hypotension, sedation, arrhythmia
Lorazepam** (Ativan)	Antianxiety (benzodiazepine)	Anxiety	1–2	Drowsiness, dizziness, GI upset, hypotension, tolerance, dependence
Oxazepam** (Serax)	Antianxiety (benzodiazepine)	Anxiety	10–30	Drowsiness, dizziness, GI upset, hypotension, tolerance, dependence
Temazepam** (Restoril)	Sedative/Hypnotic (benzodiazepine)	Insomnia	15	Drowsiness, dizziness, GI upset, hypotension, tolerance, dependence
Zolpidem (Ambien)	Sedative-hypnotic (nonbenzodiazepine)	Insomnia	5	Headache, drowsiness, dizziness, GI upset
Zaleplon (Sonata)	Sedative-hypnotic (nonbenzodiazepine)	Insomnia	5	Headache, drowsiness, dizziness, GI upset
Eszopiclone (Lunesta)	Sedative-hypnotic (nonbenzodiazepine)	Insomnia	1–2	Headache, drowsiness, dizziness, GI upset, unpleasant taste
Ramelteon (Rozerem)	Sedative-hypnotic (nonbenzodiazepine)	Insomnia	8	Dizziness, fatigue, drowsiness, GI upset

TABLE 22–4 Selected Medications Used in the Treatment of Clients With NCD—cont'd				
MEDICATION	**CLASSIFICATION**	**FOR TREATMENT OF**	**DAILY DOSAGE RANGE (mg)**	**SIDE EFFECTS**
Trazodone	Antidepressant (heterocyclic)	Depression and insomnia	50	Dizziness, drowsiness, dry mouth, blurred vision, GI upset
Mirtazapine (Remeron)	Antidepressant (tetracyclic)	Depression and insomnia	7.5–15	Somnolence, dry mouth, constipation, increased appetite

*Although clinicians may still prescribe these medications in low-risk patients, no antipsychotics have been approved by the FDA for the treatment of patients with NCD-related psychosis. All antipsychotics include black-box warnings about increased risk of death in elderly patients with NCD.
**Benzodiazepines should be used only for short-term treatment.

with Lewy body dementia (Crystal & Jacobs, 2014). (Higher-dose donepezil has also been approved for moderate to severe AD.) Some of the clinical manifestations of AD are thought to result from a deficiency of the neurotransmitter acetylcholine. In the brain, acetylcholine is inactivated by the enzyme acetylcholinesterase. Donepezil (Aricept), rivastigmine (Exelon), and galantamine (Razadyne) act by inhibiting acetylcholinesterase, which slows the degradation of acetylcholine, thereby increasing concentrations of the neurotransmitter in the cerebral cortex. Because their action relies on functionally intact cholinergic neurons, the effects of these medications may lessen as the disease process advances, and there is no evidence that these medications alter the course of the underlying degenerative process.

Another medication, an NMDA receptor antagonist, was approved by the FDA in 2003. The medication, memantine (Namenda), was approved for the treatment of moderate to severe AD. Studies on the use of memantine for Parkinson's disease and dementia with Lewy bodies have been inconclusive (Schwarz, Froelich, & Burns, 2012). High levels of glutamate in the brains of AD patients are thought to contribute to the symptomatology and decline in functionality. These high levels are caused by a dysfunction in glutamate transmission. In normal neurotransmission, glutamate plays an essential role in learning and memory by triggering NMDA receptors to allow a controlled amount of calcium to flow into a nerve cell. This creates the appropriate environment for information processing. In AD, there is a sustained release of glutamate, which results in a continuous influx of calcium into the nerve cells. This increased intracellular calcium concentration ultimately leads to disruption and death of the neurons. Memantine may protect cells against excess glutamate by partially blocking NMDA receptors. Memantine has been shown in clinical trials to be effective in improving cognitive function and the ability to perform ADLs in clients with moderate to severe AD. Although it does not stop or reverse the effects of the disease, it

has been shown to slow down the progression of the decline in cognition and function (Salloway & Correia, 2009). Because memantine's action differs from that of the cholinesterase inhibitors, consideration is being given to possible coadministration of these medications. However, combination therapy with acetylcholinesterase inhibitors and memantine remains controversial because research findings have demonstrated conflicting results (Schwarz et al., 2012). In 2014, the FDA approved one such drug (Namzaric), which is a combination of memantine and donepezil.

Current drug trials are underway to test for a vaccine against AD. One study led by the Karolinska Institutet in Sweden reported positive use with CAD106, a vaccine designed to trigger the body's immune defense against Aβ (Winblad et al., 2012). So far, active vaccines have not demonstrated effectiveness in humans and in some cases have proved dangerous, so research efforts have moved to a focus on passive vaccines (McDonald, 2014). Vaccine trials have continued for the last several years without major breakthroughs. However, in 2016, a group of American and Australian researchers reported a "very promising" vaccine that they claim impacts amyloid and tau proteins, both of which are implicated in AD. It is clear that interest in such research is high, with government funding for AD research exceeding $1 billion in 2016 (LaVigne, 2016). The researchers believe that the vaccine will have both preventive and treatment benefits (Davtyan et al., 2016). They expect (pending successful clinical trials in humans) to have a treatment available within 3 to 5 years (LaVigne, 2016).

In a study funded by the National Institute on Aging and others, three drugs were evaluated in the prevention of a rare and aggressive form of autosomal-dominant AD (Bateman et al., 2012). These clinical trials included individuals who are mutation carriers and therefore genetically destined to develop AD at a young age, typically in their 30s, 40s, or 50s. To date, there have been no medications clearly identified or approved as preventive for this condition. Genotyping and genetic counseling are available options

for evaluation and management (National Center for Advancing Translational Sciences, 2015). Antipsychotics have been associated with increased mortality in patients with dementia, and Moussa (2016) recommends that prescribers use low doses of quetiapine or olanzapine only "in patients with severe, disabling symptoms after informing families of the mortality risk."

Gingko biloba is a popular over-the-counter supplement advanced as having benefits for improving cognitive impairment and symptoms of dementia. Its actions include dilating blood vessels, thinning blood, modifying neurotransmitters, and reducing the density of oxygen free radicals (Birks & Grimley, 2009). But in a systematic review of 36 trials, Birks and Grimley conclude that evidence for benefits in cognitive impairment or dementia is inconsistent and unreliable.

More recent research has focused on the chemical resveratrol, found in grape skins, cacao, and other foods. It has been advanced as having anti-aging properties and neuroprotective functions, as well as possibly reducing the buildup of amyloid plaques associated with AD. The most recent of these studies (Turner et al., 2015) found promising evidence that high doses of resveratrol (up to 2000 mg daily) has CNS effects on biomarkers for AD. The researchers caution that more research is needed to fully understand the impact of these changes on the trajectory of AD.

With regard to nonpharmacologic treatments for cognitive impairment in patients with NCD, cognitive rehabilitation (which includes education about cognitive strengths and weaknesses, cognitive retraining, and compensatory strategies) has demonstrated some evidence of modest improvement in cognitive domains, although research is in the early stages (Dancis & Cotter, 2015). Recent studies have also supported that mindfulness meditation results in observable changes in brain structures related to memory and emotional responses and therefore may have benefits in the treatment of NCDs (Sorrell, 2015).

Agitation, Aggression, Hallucinations, Thought Disturbances, and Wandering

Historically, physicians have prescribed antipsychotic medications to control agitation, aggression, hallucinations, thought disturbances, and wandering in clients with NCD. The atypical antipsychotic medications, such as risperidone, olanzapine, quetiapine, and ziprasidone, were often favored because of their lessened propensity to cause anticholinergic and extrapyramidal side effects. In 2005, however, following review of a number of studies, the FDA ordered black-box warnings on drug labels of all the atypical antipsychotics, noting that the drugs are associated with an increased risk of death in elderly patients who display psychotic behaviors associated with NCD. Most of the

deaths appeared to be cardiovascular related. In July 2008, based on the results of several studies, the FDA extended this warning to include all first-generation antipsychotics as well, such as haloperidol and perphenazine. This poses a clinical dilemma for physicians who have found these medications to be helpful to their clients, and some have chosen to continue to use them in patients without significant cerebrovascular disease, in which previous behavioral programs have failed, and with consent from relatives or guardians who are clearly aware of the risks and benefits.

In 2016, a new drug, pimavanserin (Nuplazid), was approved by the FDA specifically for treatment of hallucinations and delusions in Parkinson's disease psychosis. The mechanism of action is unknown, but it is thought to provide benefit through its serotonin agonist and antagonist activities.

Anticholinergic Effects

Many antipsychotic, antidepressant, and antihistaminic medications produce anticholinergic side effects, which include confusion, blurred vision, constipation, dry mouth, dizziness, and difficulty urinating. Older people, and especially those with NCD, are particularly sensitive to these effects because of decreased cholinergic reserves. Many elderly individuals are also at increased risk for developing an anticholinergic toxicity syndrome because of the additive anticholinergic effects of multiple medications (Hall, Hall, & Chapman, 2009).

Depression

It is estimated that up to 40 percent of people with AD also suffer from major depression (Alzheimer's Association, 2015b). Recognizing the symptoms of depression in these individuals is often a challenge. Depression—which affects thinking, memory, sleep, and appetite and interferes with daily life—is sometimes difficult to distinguish from NCD. Clearly, the existence of depression in the client with NCD complicates and worsens the individual's functioning.

Antidepressant medication is sometimes used in treatment of depression in those with NCD. The selective serotonin reuptake inhibitors (SSRIs) are considered by many to be the first-line drug treatment for depression in the elderly because of their favorable side-effect profile, although patients should be assessed for hyponatremia, since this is a risk associated with SSRIs. Tricyclic antidepressants are often avoided because of cardiac and anticholinergic side effects. Trazodone may be a good choice when used at bedtime for depression and insomnia.

Not only is depression common among those with AD, but research has suggested that it may be a risk factor for the disease (Caraci et al., 2010; Geerlings

et al., 2008; Wilson et al., 2014). Several theories have been advanced about the causes for this correlation, including one theory that depression directly damages the brain through the effects of stress and chronic inflammation, another that depression may decrease brain volume, and a third that depression may be an early sign of dementia (Bowers, 2014). Whatever the causes, Wilson and associates (2014) found that depression is an independent risk factor for the development of dementia. Although antidepressant medication may be prescribed for patients with dementia, a review of the research indicated that the efficacy of antidepressants in this population remains unproven (Schwarz et al., 2012).

Anxiety

The progressive loss of mental functioning is a significant source of anxiety in the early stages of NCD. It is important that clients be encouraged to verbalize their feelings and fears associated with this loss. These interventions may be useful in reducing the anxiety of clients with NCD.

Antianxiety medications may be helpful but should not be used routinely or for prolonged periods. The least toxic and most effective of the antianxiety medications are the benzodiazepines. Examples include diazepam (Valium), chlordiazepoxide (Librium), alprazolam (Xanax), lorazepam (Ativan), and oxazepam (Serax). Studies have been conducted to evaluate the concern that long-term benzodiazepine use may actually contribute to the development of dementia, but the results have been mixed (Billioti de Gage et al., 2014; Gray et al., 2016). The drugs with shorter half-lives (e.g., lorazepam and oxazepam) are preferred to longer-acting medications (e.g., diazepam), which promote a higher risk of oversedation and falls. Barbiturates are not appropriate as antianxiety agents because they frequently induce confusion and paradoxical excitement in elderly individuals.

Sleep Disturbances

Sleep problems are common in clients with NCD and often intensify as the disease progresses. Wakefulness and nighttime wandering create much distress and anguish in family members who are charged with protection of their loved one. Indeed, sleep disturbances are among the problems that most frequently initiate the need for client placement in a long-term care facility.

Some physicians treat sleep problems with sedative-hypnotic medications. The benzodiazepines may be useful for some clients but are indicated for relatively brief periods only. Examples include flurazepam (Dalmane), temazepam (Restoril), and triazolam (Halcion). Daytime sedation, cognitive impairment, risk for falls, and paradoxical agitation in elderly clients are of particular concern with these medications. The nonbenzodiazepine sedative-hypnotics zolpidem (Ambien), zaleplon (Sonata), eszopiclone (Lunesta), and ramelteon (Rozerem) and the antidepressants trazodone (Desyrel) and mirtazapine (Remeron) may also be prescribed. Daytime sedation is a potential problem with these medications, too. As previously stated, barbiturates should not be used in elderly clients. Sleep problems are usually ongoing, and most clinicians prefer to use medications only to help an individual through a short-term stressful situation. Rising at the same time each morning; minimizing daytime sleep; participating in regular physical exercise no later than 4 hours before bedtime; getting proper nutrition; avoiding alcohol, caffeine, and nicotine; and retiring at the same time each night are behavioral approaches to sleep problems that may eliminate the need for sleep aids, particularly in the early stages of NCD. Because of the tremendous potential for adverse drug reactions in the elderly, many of whom are already taking multiple medications, pharmacological treatment of insomnia should be considered only after attempts at nonpharmacological strategies have failed.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Carmen is an 81-year-old widow who lives in the same small town in the same house that she shared with her husband until his death 16 years ago. She and her husband reared two daughters, Joan and Nancy, who live with their husbands in a large city about 2 hours away from Carmen. They have always visited Carmen every 1 or 2 months. She has four grown grandchildren who live in distant states and who see their grandmother on holidays.

About a year ago, Carmen's daughters began to receive reports from friends and other family members about incidents in which Carmen was becoming forgetful (e.g., forgetting to go to a cousin's birthday party, taking a wrong turn and getting lost on the way to a niece's house [where she had driven many times], returning to church to search for something she thought she had forgotten [although she could not explain what it was], sending birthday gifts to people at the wrong times). During visits, the elder daughter, Joan, found bills left

CASE STUDY AND SAMPLE CARE PLAN—cont'd

unpaid, sometimes months overdue. Housekeepers and yard workers reported to Joan that Carmen would forget she had paid them and try to pay them again, sometimes even a third time. She became very confused when she would attempt to fill her weekly pillboxes, a task she had completed in the past without difficulty. Hundreds of dollars would disappear from her wallet, and she could not tell Joan what happened to it.

Joan and her husband subsequently moved to the small town where Carmen lived. They bought a home, and Joan visited her mother every day, took care of finances, and ensured that Carmen took her daily medications, although the daughter worked in a job that required occasional out-of-town travel. As the months progressed, Carmen's cognitive abilities deteriorated. She burned food on the stove, left the house with the oven on, forgot to take her medication, got lost in her car, missed appointments, and forgot the names of neighbors she had known for many years. She began to lose weight because she was forgetting to eat her meals.

Carmen was evaluated by a neurologist, who diagnosed her with neurocognitive disorder due to Alzheimer's disease. Because they believed that Carmen needed 24-hour care, Joan and Nancy made the painful decision to place Carmen in a long-term nursing facility. In the nursing home, her condition has continued to deteriorate. Carmen wanders up and down the halls (day and night) and has fallen twice, once while attempting to get out of bed. She requires assistance to shower and dress and has become incontinent of urine. The nurses found her attempting to leave the building, saying, "I'm going across the street to visit my daughter." One morning at breakfast, she appeared in her pajamas in the communal dining room, not realizing that she had not dressed. She is unable to form new memories and sometimes uses confabulation to fill in the blanks. She asks the same questions repeatedly, sometimes struggling for the right word. She can no longer provide the correct names of items in her environment. She has no concept of time.

Joan visits Carmen daily and Nancy visits weekly, each offering support to the other in person and by phone. Carmen always seems pleased to see them but can no longer call either of them by name. They are unsure if she knows who they are.

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Carmen:

1. **Risk for trauma** related to impairments in cognitive and psychomotor functioning; wandering; falls
   a. **Outcome criteria:** Carmen will remain injury free during her nursing home stay.
   b. **Short-term goals:**
      ■ Carmen will not fall while wandering the halls.
      ■ Carmen will not fall out of bed.

2. **Disturbed thought processes** related to cerebral degeneration evidenced by disorientation, confusion, and memory deficits
   a. **Outcome criteria:** Carmen will maintain reality orientation to the best of her cognitive ability.
   b. **Short-term goals:**
      ■ Carmen will be able to find her room.
      ■ Carman will be able to communicate her needs to staff.

3. **Self-care deficit** related to cognitive impairments, disorientation, confusion, and memory deficits
   a. **Outcome criteria:** Carmen will accomplish ADLs to the best of her ability.
   b. **Short-term goals:**
      ■ Carmen will assist with dressing herself.
      ■ Carmen will cooperate with trips to the bathroom.
      ■ Carmen will wash herself in the shower with help from the nurse.

PLANNING AND IMPLEMENTATION

RISK FOR TRAUMA

The following nursing interventions may be implemented *to ensure client safety:*

1. Arrange the furniture in Carmen's room so that it will accommodate free movement.
2. Store frequently used items within her easy reach.
3. Provide a "low bed," or possibly move her mattress from the bed to the floor, to prevent falls from bed.
4. Attach a bed alarm to alert the nurse's station when Carmen has alighted from her bed.
5. Keep a dim light on in her room at night.
6. During the day and evening, provide a well-lighted area where Carmen can safely wander.
7. Ensure that all outside doors are electronically controlled.
8. Play soft music and maintain a low level of stimuli in the environment.

DISTURBED THOUGHT PROCESSES

The following nursing interventions may be implemented *to help maintain orientation and aid in memory and recognition:*

1. Use clocks and calendars with large numbers that are easy to read.
2. Put a sign on Carmen's door with her name on it, and hang a personal item of hers on the door.
3. Ask Joan to bring some of Carmen's personal items for her room, even a favorite comfy chair if possible. Ask for some old photograph albums if they are available.
4. Keep the number of staff and caregivers to a minimum to promote familiarity.
5. Speak slowly and clearly while looking into Carmen's face.
6. Use reminiscence therapy with Carmen. Ask her to share happy times from her life with you. This technique helps decrease depression and boost self-esteem.

CASE STUDY AND SAMPLE CARE PLAN—cont'd

7. Mention the date and time in casual conversation. Refer to "spring rain," "summer flowers," "fall leaves." Emphasize holidays.
8. Correct misperceptions gently and matter-of-factly, and focus on real events and real people if false ideas should occur. Validate her feelings associated with current and past life situations.
9. Monitor for medication side effects, because toxic effects from certain medications can intensify altered thought processes.

SELF-CARE DEFICIT

The following nursing interventions may be implemented *to ensure that all Carmen's needs are fulfilled.*

1. Assess what Carmen can do independently and with which tasks she needs assistance.
2. Allow plenty of time for her to accomplish tasks that are within her ability. Clothing with easy removal or replacement, such as Velcro, facilitates independence.
3. Provide guidance and support for independent actions by talking her through tasks one step at a time.
4. Provide a structured schedule of activities that does not change from day to day.

5. Ensure that Carmen has snacks between meals.
6. Take Carmen to the bathroom regularly (according to her usual pattern, e.g., after meals, before bedtime, on arising).
7. To minimize nighttime wetness, offer fluid every 2 hours during the day and restrict fluid after 6 p.m.
8. To promote more restful nighttime sleep and less wandering at night, reduce naps during late afternoon and encourage sitting exercises, walking, and ball toss. Carbohydrate snacks at bedtime may also be helpful.

EVALUATION

The outcome criteria identified for Carmen have been met. She has experienced no injury. She has not fallen out of bed. She continues to wander in a safe area. She can find her room by herself but occasionally requires some assistance when she is anxious and confused. She has some difficulty communicating her needs to the staff, but those who work with her on a consistent basis are able to anticipate her needs. All ADLs are being fulfilled, and Carmen assists with dressing and grooming, accomplishing about half on her own. Nighttime wandering has been minimized. Soft bedtime music helps to relax her.

Summary and Key Points

- NCDs constitute a large and growing public health concern.
- Delirium is a disturbance of awareness and change in cognition that develop rapidly over a short period. Level of consciousness is often affected, and psychomotor activity may fluctuate between agitated purposeless movements and a vegetative state resembling catatonic stupor.
- The symptoms of delirium usually begin quite abruptly and often are reversible and brief.
- Delirium may be caused by a general medical condition, substance intoxication or withdrawal, or ingestion of a medication or exposure to a toxin. NCD is a syndrome of acquired, persistent intellectual impairment ranging from mild to major, with compromised function in multiple spheres of mental activity, such as memory, language, visuospatial skills, emotion or personality, and cognition.
- Dementia (also described as major NCD in the *DSM-5*) is a progressive decline of cognitive abilities in the presence of clear consciousness.
- Symptoms of NCD are insidious and develop slowly over time. In most clients, the disorder runs a progressive, irreversible course.
- NCD may be caused by genetics, cardiovascular disease, infections, neurophysiological disorders, and other medical conditions.

- Nursing care of the client with an NCD is presented around the six steps of the nursing process.
- Objectives of care for the client experiencing an acute syndrome are aimed at eliminating the etiology, promoting client safety, and facilitating a return to the highest possible level of functioning.
- Objectives of care for the client experiencing a chronic, progressive disorder are aimed at preserving the dignity of the individual, promoting deceleration of the symptoms, maximizing functional capabilities, and maintaining the best quality of life within the limitations posed by illness.
- Nursing interventions are also directed toward helping the client's family or primary caregivers learn about and cope with the changes expected in a chronic, progressive neurocognitive disorder.
- Education is provided about the disease process, expectations of client behavioral changes, methods for facilitating care, and sources of assistance and support as they struggle, both physically and emotionally, with the demands brought on by a disease process that is slowly taking their loved one away from them.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. An example of a treatable (reversible) form of NCD is one that is caused by which of the following? (Select all that apply.)
   a. Multiple sclerosis
   b. Huntington's disease
   c. Electrolyte imbalance
   d. HIV disease
   e. Folate deficiency

2. Mrs. G. has been diagnosed with NCD due to Alzheimer's disease. The cause of this disorder is which of the following?
   a. Multiple small brain infarcts
   b. Chronic alcohol abuse
   c. Cerebral abscess
   d. Unknown

3. Mrs. G. has been diagnosed with NCD due to Alzheimer's disease. The *primary* nursing intervention in working with Mrs. G. is which of the following?
   a. Ensuring that she receives food she likes to prevent hunger
   b. Ensuring that the environment is safe to prevent injury
   c. Ensuring that she meets the other patients to prevent social isolation
   d. Ensuring that she takes care of her own ADLs to prevent dependence

4. Which of the following medications have been indicated for improvement in cognitive functioning in mild to moderate Alzheimer's disease? (Select all that apply.)
   a. Donepezil (Aricept)
   b. Rivastigmine (Exelon)
   c. Risperidone (Risperdal)
   d. Sertraline (Zoloft)
   e. Galantamine (Razadyne)

5. Mrs. G., who has NCD due to Alzheimer's disease, says to the nurse, "I have a date tonight. I always have a date on Christmas." Which of the following is the most appropriate response?
   a. "Don't be silly. It's not Christmas, Mrs. G."
   b. "Today is Tuesday, October 21, Mrs. G. We will have supper soon, and then your daughter will come to visit."
   c. "Who is your date with, Mrs. G.?"
   d. "I think you need some more medication, Mrs. G. I'll bring it to you now."

6. In addition to disturbances in cognition and orientation, individuals with Alzheimer's disease may also show changes in which of the following? (Select all that apply.)
   a. Personality
   b. Vision
   c. Speech
   d. Hearing
   e. Mobility

7. Mrs. G., who has NCD due to Alzheimer's disease, has trouble sleeping and wanders around at night. Which of the following nursing actions would be *best* to promote sleep in Mrs. G.?
   a. Ask the doctor to prescribe flurazepam (Dalmane).
   b. Ensure that Mrs. G. gets an afternoon nap so she will not be overtired at bedtime.
   c. Make Mrs. G. a cup of tea with honey before bedtime.
   d. Ensure that Mrs. G. gets regular physical exercise during the day.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. The night nurse finds Mrs. G., a client with Alzheimer's disease, wandering the hallway at 4 a.m. and trying to open the door to the side yard. Which statement by the nurse probably reflects the most accurate assessment of the situation?
   a. "That door leads out to the patio, Mrs. G. It's nighttime. You don't want to go outside now."
   b. "You look confused, Mrs. G. What is bothering you?"
   c. "This is the patio door, Mrs. G. Are you looking for the bathroom?"
   d. "Are you lonely? Perhaps you'd like to go back to your room and talk for a while."

9. Which of the following factors is *not* associated with increased incidence of NCD due to Alzheimer's disease?
   a. Multiple small strokes
   b. Family history of Alzheimer's disease
   c. Head trauma
   d. Advanced age

10. Mr. Stone is a client in the hospital with a diagnosis of vascular NCD. In explaining this disorder to Mr. Stone's family, which of the following statements by the nurse is correct?
   a. "He will probably live longer than if his disorder was of the Alzheimer's type."
   b. "Vascular NCD shows stepwise progression. This is why he sometimes seems okay."
   c. "Vascular NCD is caused by plaques and tangles that form in the brain."
   d. "The cause of vascular NCD is unknown."

11. Which of the following interventions is most appropriate in helping a client with Alzheimer's disease with her ADLs? (Select all that apply.)
   a. Perform ADLs for her while she is in the hospital.
   b. Provide her with a written list of activities she is expected to perform.
   c. Assist her with step-by-step instructions.
   d. Tell her that if her morning care is not completed by 9 a.m., it will be performed for her by the nurse's aide so that she can attend group therapy.
   e. Encourage her and give her plenty of time to perform independently as many of her ADLs as possible.

TEST YOUR CRITICAL THINKING SKILLS

Joe, a 62-year-old accountant, began having difficulty remembering details necessary to perform his job. He was also having trouble at home, failing to keep his finances straight, and forgetting to pay bills. It became increasingly difficult for him to function properly at work, and eventually he was forced to retire. Cognitive deterioration continued and behavioral problems soon began. He became stubborn, verbally and physically abusive, and suspicious of most everyone in his environment. His wife and son convinced him to see a physician, who recommended hospitalization for testing.

At Joe's initial evaluation, he was fully alert and cooperative but obviously anxious and fidgety. He thought he was at his accounting office, and he could not state what year it was. He could not say the names of his parents or siblings, nor did he know who was currently the president of the United States. He could not perform simple arithmetic calculations, write a proper sentence, or copy a drawing. He interpreted proverbs concretely and had difficulty stating similarities between related objects.

Laboratory serum studies revealed no abnormalities, but a CT scan showed marked cortical atrophy. The physician's diagnosis was neurocognitive disorder due to Alzheimer's disease.

Answer the following questions related to Joe:

1. Identify the pertinent assessment data from which nursing care will be devised.
2. What is the primary nursing diagnosis for Joe?
3. How would outcomes be identified?

💬 Communication Exercises

1. Mrs. B. is a patient on the Alzheimer's unit. The nurse hears her yelling, "Waitress! Waitress! Why can't I get some service around here?"
   • How would the nurse respond appropriately to this statement by Mrs. B.?
2. Mrs. B., who had breakfast an hour ago, says to the nurse, "I've been waiting and waiting for my breakfast. On the farm, we always had breakfast by 6 o'clock. Those were the good old days."
   • How would the nurse respond appropriately to this statement by Mrs. B?

🎬 MOVIE CONNECTIONS

The Notebook (Alzheimer's disease)
Away From Her (Alzheimer's disease)
Iris (Alzheimer's disease)

Substance-Related and Addictive Disorders

23

CORE CONCEPTS

Addiction

Intoxication

Withdrawal

KEY TERMS

Alcoholics Anonymous

amphetamines

ascites

cannabis

codependency

detoxification

disulfiram

dual diagnosis

esophageal varices

Gamblers Anonymous

hepatic encephalopathy

Korsakoff's psychosis

opioids

peer assistance programs

phencyclidine

substitution therapy

Wernicke's encephalopathy

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *addiction, intoxication,* and *withdrawal*.
2. Discuss predisposing factors implicated in the etiology of substance-related and addictive disorders.
3. Identify symptomatology and use the information in assessment of clients with various substance-related and addictive disorders.
4. Identify nursing diagnoses common to clients with substance-related and addictive disorders, and select appropriate nursing interventions for each.
5. Identify topics for client and family teaching relevant to substance-related and addictive disorders.
6. Describe relevant outcome criteria for evaluating nursing care of clients with substance-related and addictive disorders.
7. Discuss the issue of substance-related and addictive disorders within the nursing profession.
8. Define *codependency,* and identify behavioral characteristics associated with the disorder.
9. Discuss treatment of codependency.
10. Describe various modalities relevant to treatment of individuals with substance-related and addictive disorders.

399

Substance-related disorders comprise two groups: substance-use disorders (addiction) and substance-induced disorders (intoxication, withdrawal, delirium, neurocognitive disorder, psychosis, bipolar disorder, depressive disorder, obsessive-compulsive disorder, anxiety disorder, sexual dysfunction, and sleep disorders). This chapter discusses addiction, intoxication, and withdrawal. The remainder of the substance-induced disorders are included in the chapters with which they share symptomatology (e.g., substance-induced depressive disorder is included in Chapter 25, Depressive Disorders; substance-induced anxiety disorder is included in Chapter 27, Anxiety, Obsessive-Compulsive, and Related Disorders). Also included in this chapter is a discussion of gambling disorder, a non-substance addiction disorder.

Drugs are a pervasive part of our society. Certain mood-altering substances, such as alcohol, caffeine, and nicotine, are socially acceptable and used moderately by many adult Americans. Society has even developed a relative indifference to an occasional abuse of these substances despite documentation of their negative impacts on health.

In addition, countless substances are produced for medicinal purposes. These include central nervous system (CNS) stimulants (e.g., **amphetamines**), CNS depressants (e.g., sedatives, tranquilizers), and numerous over-the-counter preparations designed to relieve nearly every kind of human ailment, real or imagined.

Some illegal substances have achieved a degree of social acceptance by certain societal subcultures. These drugs, such as marijuana and hashish, are by no means harmless, even though they are becoming legalized in some states. The long-term effects of use are still being studied, whereas the dangerous effects of other illegal substances (e.g., lysergic acid diethylamide [LSD], **phencyclidine,** cocaine, and heroin) have been well documented.

This chapter discusses the physical and behavioral manifestations and personal and social consequences related to the abuse of or addiction to alcohol, other CNS depressants, CNS stimulants, **opioids,** hallucinogens, and/or cannabis and those related to the non-substance addiction to gambling. Variations in attitudes regarding substance consumption and patterns of use are explored. For example, drinking alcohol is considered by many to be a part of the culture of college life, while at the same time, substance abuse is especially prevalent among individuals between the ages of 18 and 24. Substance-related disorders are diagnosed more commonly in men than in women, but the gender ratios vary with the class of the substance.

Codependency is described in this chapter, along with substance abuse treatment. The issue of substance impairment within the nursing profession is also explored. Nursing care for individuals with substance use and addictive disorders is presented in the context of the six steps of the nursing process. Various medical and other treatment modalities are also discussed.

Substance Use Disorder, Defined

CORE CONCEPT
Addiction
A primary chronic disease of brain reward, motivation, memory, and related circuitry where a dysfunction in these circuits is connected to an individual pathologically pursuing reward and or relief by substance use and other behaviors. (American Society of Addiction Medicine [ASAM], 2015)

Substance Addiction

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (American Psychiatric Association [APA], 2013) lists diagnostic criteria for addiction to specific substances, including alcohol, cannabis, hallucinogens, inhalants, opioids, sedative-hypnotics, stimulants, and tobacco. Individuals are considered to have a substance use disorder when use interferes with the ability to fulfill role obligations at work, school, or home. Often, the individual would like to control use of the substance, but attempts to do so fail and use

continues to increase. Intense cravings lead to excessive time spent trying to procure more of the substance or recover from the effects of its use. Use of the substance causes problems with interpersonal relationships, and the individual may become socially isolated. Individuals with substance use disorders often participate in hazardous activities when they are impaired by the substance, and they continue to use the substance despite knowing that its use is contributing to a physical and/or psychological problem. Addiction is evident when tolerance develops and the amount required to achieve the desired effect continually increases. Symptoms characteristic of the specific substance occur when the individual with the addiction attempts to discontinue use.

Substance-Induced Disorders, Defined

CORE CONCEPT
Intoxication
A physical and mental state of exhilaration and emotional frenzy or lethargy and stupor.

Substance Intoxication

Substance intoxication is defined as the development of a reversible syndrome of symptoms following excessive use of a substance. The symptoms are drug specific and occur during or shortly after ingestion of the substance. There is a direct effect on the CNS, and disruption in physical and psychological functioning occurs. Judgment is disturbed, resulting in inappropriate and maladaptive behavior, and social and occupational functioning are impaired.

CORE CONCEPT
Withdrawal
The physiological and mental readjustment that accompanies the discontinuation of an addictive substance.

Substance Withdrawal

Substance withdrawal occurs upon abrupt reduction or discontinuation of a substance that has been used regularly over a prolonged period of time. The substance-specific syndrome includes clinically significant physical signs and symptoms as well as psychological changes such as disturbances in thinking, feeling, and behavior. Classes of psychoactive substances are defined in Box 23–1.

> **BOX 23–1 Classes of Psychoactive Substances**
>
> The following classes of psychoactive substances are associated with substance use and substance-induced disorders:
>
> 1. Alcohol
> 2. Caffeine
> 3. Cannabis
> 4. Hallucinogens
> 5. Inhalants
> 6. Opioids
> 7. Sedatives, hypnotics, anxiolytics
> 8. Stimulants
> 9. Tobacco

Predisposing Factors to Substance-Related Disorders

A number of factors have been implicated in the predisposition to abuse of substances. At present, no single theory can adequately explain the etiology of this problem. The interaction between various elements forms a complex collection of determinants that influence a person's susceptibility to abuse substances.

Biological Factors
Genetics

Hereditary factors appear to be involved in the development of substance use disorders, especially alcoholism. Children of alcoholics are four times more likely than other children to become alcoholics (American Academy of Child and Adolescent Psychiatry, 2015). Twin studies have demonstrated that monozygotic (one egg, genetically identical) twins have a higher rate for concordance of alcoholism than dizygotic (two eggs, genetically nonidentical) twins (Black & Andreasen, 2014). Further, biological offspring of alcoholic parents have a significantly greater incidence of alcoholism than offspring of nonalcoholic parents whether the child was reared by the biological parents or by nonalcoholic adoptive parents (Puri & Treasaden, 2011). Research continues to discover genetic influences in addiction, but currently scientists estimate that genetics account for 40 to 60 percent of a person's vulnerability (National Institute on Drug Abuse [NIDA], 2014).

Biochemistry

Although evidence shows that changes in brain structure and brain neurochemistry occur in the process of developing addiction, whether these changes wholly

explain etiology remains controversial. Neurotransmitters believed to be involved in substance abuse include opioid, catecholamine (especially dopamine), and gamma-aminobutyric acid (GABA) systems (Sadock, Sadock, & Ruiz, 2015). Neuronal pathways that sense pleasure and reward, once activated, are believed responsible for pleasurable sensations associated with the substance as well as creating a "memory" that triggers desire for repeated use of the drug. These pathways are referred to as the brain-reward circuitry. Over time, the brain tries to compensate for this excessive activation by lowering levels of these neurotransmitters, resulting in the physical discomfort associated with drug withdrawal. At this point, the substance user may continue use of the substance simply to alleviate illness.

Skeptics of biochemical theories of addiction argue that since drug-dependent individuals have the capacity to change their behavior, addiction is more likely a complex interaction of several factors rather than a single biochemical process. While ongoing research will continue to shed light on specific mechanisms in addiction, both the American Society of Addiction Medicine (2015) and the Surgeon General (in a landmark report on addiction in the United States) (U.S. Department of Health and Human Services [HHS], 2016), agree that addiction is a disease of the brain.

Psychological Factors

Developmental Influences

The psychodynamic approach to the etiology of substance abuse focuses on a punitive superego and fixation at the oral stage of psychosexual development (Sadock et al., 2015). Individuals with punitive superegos turn to drugs to diminish unconscious anxiety and increase feelings of power and self-worth. Sadock and associates (2015) state, "As a form of self-medication, alcohol may be used to control panic, opioids to diminish anger, and amphetamines to alleviate depression" (pp. 619–620).

Personality Factors

Certain personality traits have been associated with an increased tendency toward addictive behavior. Some clinicians believe low self-esteem, frequent depression, passivity, antisocial personality traits, the inability to relax or to defer gratification, and the inability to communicate effectively are common in individuals who abuse substances. These personality characteristics are not necessarily *predictive* of addictive behavior, yet for reasons not completely understood, they often accompany addiction. In some cases, the substance user may be self-medicating to treat symptoms of depression or anxiety.

Cognitive Factors

Irrational thinking patterns have long been identified as a central problem in addiction. Whether these thought patterns contribute to the development of or simply perpetuate an existing addiction is unclear, but the influence they hold is widely accepted. Twerski (1997) describes these thought patterns as "addictive thinking" and suggests that when unchallenged, they may culminate in additional addictions even when a person stops using the drug to which they first became addicted. Some examples of irrational thinking patterns often associated with addiction include denial ("I'm not really addicted"), projection ("It's my wife's fault that I take drugs"), and rationalization ("I have to take drugs because I am in pain"). Exploring these thought patterns and their influence on problematic behavior, which is the basis of cognitive-behavioral therapy, has been identified as beneficial in addictions treatment (NIDA, 2012).

Sociocultural Factors

Social Learning

The effects of modeling, imitation, and identification on behavior can be observed from early childhood onward. The family appears to be an important influence in relation to substance use. Studies have shown that children and adolescents are more likely to use substances if their parents provide a model for substance use. Peers often exert substantial influence on the child or adolescent who is being encouraged to use substances for the first time. Modeling may continue to be a factor in substance use once the individual enters the workforce, particularly if the setting provides plenty of leisure time with coworkers and drinking is valued as a way to express group cohesiveness.

Conditioning

Conditioning is a term describing a learned response that occurs after repeated exposure to a stimulus. Substance abuse can become a learned response from the substance itself and from the environment where use occurs. Many substances create a pleasurable experience that encourages the user to repeat it; thus, it is the intrinsically reinforcing properties of addictive drugs that "condition" the individual to repeatedly seek out their use.

The environment in which the substance is taken also contributes to the reinforcement. If the environment is pleasurable, substance use usually increases. Further, as the substance induces a state of pleasure, the user often associates that environment with these feelings and thus with drug use. Aversive stimuli within an environment are thought to be associated with a decrease in substance use within that environment.

Cultural and Ethnic Influences

Factors within an individual's culture help establish patterns of substance use by molding attitudes, influencing patterns of consumption based on cultural acceptance, and determining the availability of the substance. For centuries, the French and Italians have considered wine an essential part of the family meal, even for children. The incidence of alcohol addiction is low, and acute intoxication from alcohol is not common. However, the possibility of chronic physiological effects associated with lifelong alcohol consumption cannot be ignored.

Historically, a high incidence of alcohol addiction has existed within the American Indian/Alaska Native (AI/AN) culture. Alcohol-related deaths among AI/AN people occur at rates 514 percent higher than that of the overall U.S. population (Purnell, 2014). Veterans Administration records show that 45 percent of AI/AN veterans are addicted to alcohol, a rate twice that of non-AI/AN veterans. Theories that attempt to explain the prevalence of alcohol abuse among this community include difficulty metabolizing alcohol, children modeling their parents' drinking habits, unemployment and poverty, and an attempt to fill the spiritual gap left by the loss of the traditional AI/AN religion.

The incidence of alcohol addiction is higher among northern Europeans than among southern Europeans. Alcohol problems in Ireland are among the highest internationally (Wilson, 2013), and drinking alcohol is a part of the social culture, as pubs are considered a hub for social activity.

Incidence of alcohol addiction among Asians is relatively low, possibly a result of genetic intolerance for the substance. Some Asians develop unpleasant symptoms when they drink alcohol, such as flushing, headaches, nausea, and palpitations. Research indicates an isoenzyme variant that quickly converts alcohol to acetaldehyde, as well as the absence of an isoenzyme that is needed to oxidize acetaldehyde, result in a rapid accumulation of acetaldehyde, which produces the unpleasant symptoms (Hanley, 2017). Some American Indians also report similar symptoms, and yet the rate of alcoholism is higher in this ethnic group (Hanley, 2017), so the role of this physical variation is unclear.

The Dynamics of Substance-Related Disorders

Alcohol Use Disorder

A Profile of the Substance

Alcohol is a natural substance formed by the reaction of fermenting sugar with yeast spores. Although there are many types of alcohol, the kind in alcoholic beverages is known scientifically as ethyl alcohol and chemically as C_2H_5OH. Its abbreviation, ETOH, is sometimes seen in medical records and other documents and publications.

By strict definition, alcohol is classified as a food because it contains calories; however, it has no nutritional value. Different alcoholic beverages are produced by using different sources of sugar for the fermentation process. For example, beer is made from malted barley, wine from grapes or berries, whiskey from malted grains, and rum from molasses. Distilled beverages (e.g., whiskey, scotch, gin, vodka, and other "hard" liquors) derive their names from further concentration of the alcohol through a process called *distillation*.

The alcohol content varies by type of beverage. For example, most American beers contain 3 to 6 percent alcohol, wines average 10 to 20 percent, and distilled beverages range from 40 to 50 percent alcohol. The average-sized drink, regardless of beverage, contains a similar amount of alcohol: 12 ounces of beer, 3 to 5 ounces of wine, and a cocktail with 1 ounce of whiskey all measure approximately 0.5 ounce. If consumed at the same rate, all would have an equal effect on the body.

Alcohol exerts a depressant effect on the CNS, resulting in behavioral and mood changes proportional to the alcoholic concentration in the blood. Most states consider legal intoxication as a blood alcohol level of 0.08 percent.

The body burns alcohol at the rate of about 0.5 ounce per hour, so behavioral changes would not be expected to occur in an individual who slowly consumed only one average-sized drink per hour. Other factors do influence these effects, however, such as an individual's physical size and whether or not the stomach contains food at the time of alcohol consumption. Alcohol is also thought to have a more profound effect when an individual is emotionally stressed or fatigued.

Historical Aspects

The use of alcohol can be traced back to the Neolithic age, with known consumption of beer and wine around 6400 BC. With the introduction of distillation by the Arabs in the Middle Ages, alchemists believed that alcohol was the answer to all of their ailments. The word *whiskey,* meaning "water of life," became widely known.

In America, AI/AN people drank beer and wine prior to the arrival of the first white immigrants. Refinement of the distillation process made beverages with high alcohol content readily available. By the early 1800s, one renowned physician of the time, Benjamin Rush, began to identify the widespread excessive, chronic alcohol consumption as a disease

and an addiction. The strong religious mores on which this country was founded soon led to a driving force to prohibit the sale of alcoholic beverages. By the middle of the 19th century, 13 states had passed prohibition laws. The most notable prohibition of alcohol in the United States was from 1920 to 1933. The mandatory restrictions on national social habits resulted in the creation of profitable underground markets that led to flourishing criminal enterprises. Further, millions of dollars in federal, state, and local revenues from taxes and import duties on alcohol were lost. It is difficult to measure the value of this dollar loss against the human devastation and social costs that occur as a result of alcohol abuse in the United States today.

Patterns of Use

About two-thirds (66.6%) of Americans aged 12 years and older report being current drinkers of alcohol, and 6.4 percent met criteria for alcohol use disorder (Substance Abuse and Mental Health Services Administration [SAMHSA], 2015).

Why do people drink? In the United States, patterns show that people use alcoholic beverages to enhance the flavor of food with meals; at social gatherings to encourage relaxation and conviviality among the guests; and to promote a feeling of celebration at special occasions such as weddings, birthdays, and anniversaries. An alcoholic beverage (wine) is also used as part of the sacred ritual in some religious ceremonies. Therapeutically, alcohol is the major ingredient in many over-the-counter and prescription medicines that are prepared in concentrated form. Therefore, alcohol can be harmless and enjoyable—sometimes even beneficial—if it is used responsibly and in moderation.

Like any other mind-altering drug, however, alcohol has the potential for abuse. Indeed, it is identified as the third-largest drug problem the United States today, second only to misuse of prescription drugs followed by marijuana (SAMHSA, 2015). Annually, 88,000 deaths are related to excessive alcohol use, and it is the third-leading lifestyle-related cause of death in the United States (National Council on Alcoholism and Drug Dependence, 2017). In addition, alcohol use is a factor in more than half of all homicides, suicides, and traffic accidents. Incidents of domestic violence are commonly alcohol related. Heavy drinking contributes to illness in each of the top three causes of death: heart disease, cancer, and stroke. At any given time, up to 40 percent of hospital beds in the United States are being used to treat health conditions related to alcohol consumption. Fetal alcohol syndrome, caused by prenatal exposure to alcohol, is the leading known cause of mental retardation in the United States (Vaux, 2016).

Jellinek (1952) outlined four phases through which the alcoholic's pattern of drinking progresses. Some variability among individuals is to be expected within this model of progression.

Phase I. The Prealcoholic Phase

This phase is characterized by the use of alcohol to relieve the everyday stress and tensions of life. As a child, the individual may have observed parents or other adults drinking alcohol and enjoying the effects. The child learns that use of alcohol is an acceptable method of coping with stress. Tolerance develops, and the amount required to achieve the desired effect steadily increases.

Phase II. The Early Alcoholic Phase

This phase begins with blackouts—brief periods of amnesia that occur during or immediately following a period of drinking. Now the alcohol is no longer a source of pleasure or relief for the individual but rather a drug that is *required* by the individual. Common behaviors include sneaking drinks or secret drinking, preoccupation with drinking and maintaining the supply of alcohol, rapid gulping of drinks, and further blackouts. The individual feels enormous guilt and becomes very defensive about his or her drinking. Excessive use of denial and rationalization is evident.

Phase III. The Crucial Phase

In this phase, the individual has lost control of his or her use, and physiological addiction is clearly evident. This loss of control has been described as the inability to choose whether or not to drink. Binge drinking, lasting from a few hours to several weeks, is common. These episodes are characterized by sickness, loss of consciousness, squalor, and degradation. In this phase, the individual is extremely ill. Anger and aggression are common manifestations. Drinking is the total focus, and he or she is willing to risk losing everything that was once important in an effort to maintain the addiction. By this phase of the illness, it is not uncommon for the individual to have experienced the loss of job, marriage, family, friends, and most especially, self-respect.

Phase IV. The Chronic Phase

This phase is characterized by emotional and physical disintegration. The individual is usually intoxicated more often than he or she is sober. Emotional disintegration is evidenced by profound helplessness and self-pity. Impairment in reality testing may result in psychosis. Life-threatening physical manifestations may be evident in virtually every system of the body. Unmanaged withdrawal from alcohol results in a terrifying syndrome of symptoms that include

hallucinations, tremors, convulsions, severe agitation, and panic. Depression and suicidal ideation are not uncommon. For long-term heavy drinkers, abrupt withdrawal of alcohol can be fatal.

Effects on the Body

Alcohol can induce a general, nonselective, reversible depression of the CNS. About 20 percent of the alcohol content in a single drink is absorbed directly and immediately into the bloodstream through the stomach wall. Unlike other "foods," it does not have to be digested. The blood carries the alcohol directly to the brain where it acts on the brain's central control areas, depressing brain activity. The other 80 percent of the drink's alcohol content is processed slightly more slowly through the upper intestinal tract and into the bloodstream. Only moments after alcohol is consumed, it can be found in all tissues, organs, and secretions of the body. Rapidity of absorption is influenced by various factors. For example, absorption is delayed when the drink is sipped rather than gulped, when the stomach contains food, and when the drink is wine or beer rather than a distilled beverage.

At low doses, alcohol produces relaxation, loss of inhibition, lack of concentration, drowsiness, slurred speech, and sleep. Chronic abuse results in multisystem physiological impairments. These complications include, but are not limited to, those outlined in the following sections.

Peripheral Neuropathy

Peripheral neuropathy, characterized by nerve damage, results in pain, burning, tingling, or prickly sensations of the extremities. Researchers believe it is the direct result of deficiency in the B vitamins, particularly thiamine. Nutritional deficiencies are common in chronic alcoholics because of insufficient intake of nutrients and because the toxic effect of alcohol results in malabsorption of nutrients. The process is reversible with abstinence from alcohol and restoration of required nutrients. Otherwise, permanent muscle wasting and paralysis can occur.

Alcoholic Myopathy

Alcoholic myopathy may occur as an acute or chronic condition. In the acute condition, also called *acute alcoholic necrotizing myopathy* or *alcoholic rhabdomyolysis,* the individual experiences a sudden onset of muscle pain, swelling, and weakness along with myoglobinuria, evidenced by a red tinge in the urine. Creatine kinase may be elevated before appearance of symptoms. Experimental studies have suggested that alcohol use and malnourishment are necessary to produce this syndrome (Lanska, 2016). Muscle symptoms are usually generalized, but pain and swelling may selectively involve the calves or other muscle groups. Laboratory studies show elevations of the enzymes creatine phosphokinase (CPK), lactate dehydrogenase (LDH), aldolase, and aspartate aminotransferase (AST). The symptoms of chronic alcoholic myopathy include a gradual wasting and weakness in skeletal muscles. Neither the pain and tenderness nor the elevated muscle enzymes seen in acute myopathy are evident in the chronic condition.

Alcoholic myopathy is thought to be a result of the same B vitamin deficiency that contributes to peripheral neuropathy. Improvement is observed with abstinence from alcohol and the return to a nutritious diet with vitamin supplements.

Wernicke's Encephalopathy

Wernicke's encephalopathy represents the most serious form of thiamine deficiency in alcoholics. Symptoms include paralysis of the ocular muscles, diplopia, ataxia, somnolence, and stupor. If thiamine replacement therapy is not undertaken quickly, death will ensue.

Korsakoff's Psychosis

Korsakoff's psychosis is identified by a syndrome of confusion, loss of recent memory, and confabulation in alcoholics. It is frequently encountered in clients recovering from Wernicke's encephalopathy. In the United States, the two disorders are usually considered together and are called *Wernicke-Korsakoff syndrome.* Treatment involves parenteral or oral thiamine replacement.

Alcoholic Cardiomyopathy

The effect of alcohol on the heart is an accumulation of lipids in the myocardial cells, resulting in enlargement and a weakened condition. The clinical findings of alcoholic cardiomyopathy generally relate to congestive heart failure or arrhythmia. Symptoms include decreased exercise tolerance, tachycardia, dyspnea, edema, palpitations, and nonproductive cough. Laboratory studies may show elevation of the enzymes CPK, AST, alanine aminotransferase (ALT), and LDH. Changes may be observed by electrocardiogram, and congestive heart failure may be evident on chest x-ray films.

The treatment is total permanent abstinence from alcohol. Treatment of the congestive heart failure may include rest, oxygen, digitalization, sodium restriction, and diuretics. Prognosis is encouraging if treated in the early stages. The death rate is high for individuals with advanced symptomatology.

Esophagitis

Esophagitis—inflammation and pain in the esophagus—occurs because of the toxic effects of alcohol on the esophageal mucosa and because of frequent vomiting associated with alcohol abuse.

Gastritis

The effects of alcohol on the stomach include inflammation of the stomach lining characterized by epigastric distress, nausea, vomiting, and distention. Alcohol breaks down the stomach's protective mucosal barrier, allowing hydrochloric acid to erode the stomach wall. Damage to blood vessels may result in hemorrhage.

Pancreatitis

Pancreatitis may be categorized as *acute* or *chronic.* Acute pancreatitis usually occurs a day or two after a binge of excessive alcohol consumption. Symptoms include constant, severe epigastric pain, nausea and vomiting, and abdominal distention. The chronic condition leads to pancreatic insufficiency resulting in steatorrhea, malnutrition, weight loss, and diabetes mellitus.

Alcoholic Hepatitis

Alcoholic hepatitis is inflammation of the liver caused by long-term heavy alcohol use. Clinical manifestations include an enlarged and tender liver, nausea and vomiting, lethargy, anorexia, elevated white blood cell count, fever, and jaundice. **Ascites** (fluid accumulation in the abdomen) and weight loss may be evident in more severe cases. With treatment—which includes strict abstinence from alcohol, proper nutrition, and rest—the individual can experience complete recovery. Severe cases can lead to cirrhosis or **hepatic encephalopathy.**

Cirrhosis of the Liver

Cirrhosis of the liver may be caused by anything that results in chronic injury to the liver. It is the end stage of alcoholic liver disease and results from long-term chronic alcohol abuse. There is widespread destruction of liver cells, which are replaced by fibrous (scar) tissue. Clinical manifestations include nausea and vomiting, anorexia, weight loss, abdominal pain, jaundice, edema, anemia, and blood coagulation abnormalities. Treatment includes abstention from alcohol, correction of malnutrition, and supportive care to prevent complications of the disease. Complications of cirrhosis include the following:

- **Portal hypertension:** Elevation of blood pressure through the portal circulation results from defective blood flow through the cirrhotic liver.
- **Ascites:** This condition, in which an excessive amount of serous fluid accumulates in the abdominal cavity, occurs in response to portal hypertension. The increased pressure results in the seepage of fluid from the surface of the liver into the abdominal cavity.
- **Esophageal varices:** Esophageal varices are veins in the esophagus that become distended because of excessive pressure from defective blood flow through the cirrhotic liver. As this pressure increases, these varicosities can rupture, resulting in hemorrhage and sometimes death.
- **Hepatic encephalopathy:** This serious complication occurs in response to the inability of the diseased liver to convert ammonia to urea for excretion. The continued rise in serum ammonia results in progressively impaired mental functioning, apathy, euphoria or depression, sleep disturbance, increasing confusion, and progression to coma and eventual death. Treatment includes complete abstention from alcohol, reduction of protein in the diet, and reduction of intestinal ammonia using neomycin or lactulose (National Library of Medicine, 2015).

Leukopenia

The production, function, and movement of the white blood cells are impaired in chronic alcoholics. This condition, called *leukopenia,* places the individual at high risk for contracting infectious diseases and for complicated recovery.

Thrombocytopenia

Platelet production and survival are impaired as a result of the toxic effects of alcohol. This places the alcoholic at risk for hemorrhage. Abstinence from alcohol rapidly reverses this deficiency.

Sexual Dysfunction

Alcohol interferes with the normal production and maintenance of female and male hormones, and long-term alcohol use can interfere with the liver's ability to metabolize estrogenic compounds (Sadock et al., 2015). For women, this can mean changes in the menstrual cycle and a decrease in or loss of fertility. For men, the altered hormone levels result in a diminished libido, decreased sexual performance, and impaired fertility. Gynecomastia may develop secondary to testicular atrophy.

Use During Pregnancy

Fetal Alcohol Syndrome

Prenatal exposure to alcohol can result in a broad range of disorders to the fetus, known as *fetal alcohol spectrum disorders* (FASDs), the most common of which is fetal alcohol syndrome (FAS). FAS includes physical, mental, behavioral, and/or learning disabilities with lifelong implications. There may be problems with learning, memory, attention span, communication, vision, hearing, or a combination of these (Centers for Disease Control and Prevention [CDC], 2016a). Other FASDs include alcohol-related neurodevelopmental disorder (ARND) and alcohol-related birth defects (ARBD).

There is no safe amount and no safe time to drink alcohol during pregnancy because alcohol can damage a fetus at any stage of development (CDC, 2016a; Vaux, 2016). Therefore, alcohol consumption should be avoided by women who are pregnant or trying to become pregnant. Estimates of the prevalence of FAS range from 0.2 to 1.5 per 1,000 live births (CDC, 2016a). Vaux (2016) adds that FAS crosses all racial and ethnic groups but regardless of race or ethnicity, the common feature in the development of fetal alcohol syndrome is women who drink heavily during pregnancy. Maier and West (2013) stated:

> The number of women who engage in heavy alcohol consumption during pregnancy surpasses the total number of children diagnosed with either FAS or ARND, meaning that not every child whose mother drank alcohol during pregnancy develops FAS or ARND. Moreover, the degree to which people with FAS or ARND are impaired differs from person to person. Several factors may contribute to this variation in the consequences of maternal drinking.

These factors include, but are not limited to, the following:

- Maternal drinking pattern
- Differences in maternal metabolism
- Differences in genetic susceptibility
- Timing of the alcohol consumption during pregnancy
- Variation in the vulnerability of different brain regions

Sadock and associates (2015) report that women with alcohol-related disorders have a 35 percent risk of having a child with defects. Children with FAS may have the following characteristics or exhibit the following behaviors (CDC, 2016a):

- Abnormal facial features (see Fig. 23–1)
- Small head size
- Shorter-than-average height
- Low body weight
- Poor coordination
- Hyperactive behavior
- Difficulty paying attention
- Poor memory
- Difficulty in school
- Learning disabilities
- Speech and language delays
- Intellectual disability or low IQ
- Poor reasoning and judgment skills
- Sleep and sucking problems as a baby
- Vision or hearing problems
- Problems with the heart, kidneys, or bones

Neuroimaging of children with FAS shows abnormalities in brain size and shape. The frontal lobes and cerebellum are often smaller than normal, and the
FIGURE 23–1 Facial features of fetal alcohol syndrome. (From the National Institute of Alcohol Abuse and Alcoholism of the National Institutes of Health, Washington, DC.)

corpus callosum and basal ganglia are commonly affected. Studies show that children with FAS are often at risk for psychiatric disorders, most commonly attention-deficit/hyperactivity disorder (Vaux, 2016). FAS may also co-occur with mood disorders, anxiety disorders, eating disorders, reactive attachment disorder, and conduct disorder (Elias, 2013).

Children with FAS require lifelong care and treatment. There is no cure for FAS, but it can be prevented. The Surgeon General's Advisory on Alcohol Use in Pregnancy states:

> Health professionals should inquire routinely about alcohol consumption by women of childbearing age, inform them of the risks of alcohol consumption during pregnancy, and advise them not to drink alcoholic beverages during pregnancy. (Carmona, 2005, p. 1)

Alcohol Intoxication

Symptoms of alcohol intoxication include disinhibition of sexual or aggressive impulses, mood lability, impaired judgment, impaired social or occupational functioning, slurred speech, incoordination, unsteady gait, nystagmus, and flushed face. Intoxication usually occurs at blood alcohol levels between 100 and 200 mg/dL. Death has been reported at levels ranging from 400 to 700 mg/dL.

Alcohol Withdrawal

Within 4 to 12 hours of cessation of or reduction in heavy and prolonged alcohol use (several days or longer), the following withdrawal symptoms may appear: coarse tremor of hands, tongue, or eyelids; nausea or vomiting; malaise or weakness; tachycardia; sweating; elevated blood pressure; anxiety; depressed mood or irritability; transient hallucinations or illusions; headache; and insomnia. In about 1 percent of alcoholic patients, complicated withdrawal syndrome may progress to *alcohol withdrawal delirium* (Sadock et al., 2015). Concomitant medical problems may increase this risk. Onset of delirium is usually on the

second or third day following decrease or discontinuation of alcohol use. Symptoms include those described under the syndrome of delirium (Chapter 22, Neurocognitive Disorders).

Sedative, Hypnotic, or Anxiolytic Use Disorder

A Profile of the Substance

The sedative, hypnotic, anxiolytic compounds are drugs of diverse chemical structures that are capable of inducing varying degrees of CNS depression, from tranquilizing relief of anxiety to anesthesia, coma, and even death. They are generally categorized as (1) barbiturates, (2) nonbarbiturate hypnotics, and (3) antianxiety agents. Effects produced by these substances depend on size of dose and potency of drug administered.

Table 23–1 presents a selected list of drugs included in these categories. Generic names are followed in parentheses by the trade names. Common street names for each category are also included.

Several principles have been identified that are fairly typical among all CNS depressants:

1. **The effects of CNS depressants are additive with one another and with the behavioral state of the user.** For example, when these drugs are used in combination with each other or with alcohol, the depressive effects are compounded. These intense depressive effects are often unpredictable and can even be fatal. Similarly, a person who is mentally depressed or physically fatigued may have an exaggerated response to a dose of the drug that would only slightly affect a person in a normal or excited state.

2. **CNS depressants are capable of producing physiological addiction.** If large doses of CNS depressants are repeatedly administered over a prolonged duration, a period of CNS hyperexcitability occurs upon withdrawal of the drug. The response can be quite severe, even leading to convulsions and death.

3. **CNS depressants are capable of producing psychological addiction.** CNS depressants have the potential to generate a psychic drive for periodic or continuous administration of the drug to achieve maximum functioning or feeling of well-being.

4. **Cross-tolerance and cross-dependence may exist between various CNS depressants.** Cross-tolerance is exhibited when one drug results in a lessened response to another drug. Cross-dependence is a condition in which one drug can prevent withdrawal symptoms associated with physical addiction to a different drug (Julien, 2014).

TABLE 23–1 **Sedative, Hypnotic, and Anxiolytic Drugs**		
CATEGORIES	**GENERIC (TRADE) NAMES**	**COMMON STREET NAMES**
Barbiturates	Amobarbital (Amytal) Pentobarbital (Nembutal) Secobarbital (Seconal) Butabarbital (Butisol) Phenobarbital	Blue birds, blue angels (amobarbital); yellow jackets, yellow birds (pentobarbital); GBs, red birds, red devils (secobarbital)
Nonbarbiturate hypnotics	Chloral hydrate Estazolam Flurazepam Temazepam (Restoril) Triazolam (Halcion) Quazepam (Doral) Eszopiclone (Lunesta) Ramelteon (Rozerem) Zaleplon (Sonata) Zolpidem (Ambien)	Peter, Mickey (chloral hydrate); sleepers
Antianxiety agents	Alprazolam (Xanax) Chlordiazepoxide (Librium) Clonazepam (Klonopin) Clorazepate (Tranxene) Diazepam (Valium) Lorazepam (Ativan) Oxazepam (Serax) Meprobamate (Miltown)	Green and whites, roaches (Librium); candy, downers (the benzodiazepines); Vs (Valium; color designates strength); dolls, dollies (meprobamate)
Club drugs	Flunitrazepam (Rohypnol) Gamma hydroxybutyric acid (gamma hydroxybutyrate; GHB)	Date rape drug, roofies, R-2, rope (Rohypnol); G, liquid X, grievous bodily harm, easy lay (GHB)

Historical Aspects

Anxiety and insomnia, two of the most common human afflictions, were treated during the 19th century with opiates, bromide salts, chloral hydrate, paraldehyde, and alcohol (Julien, 2014). Because opiates were known to produce physical addiction, the bromides carried the risk of chronic bromide poisoning, and chloral hydrate and paraldehyde had an objectionable taste and smell, alcohol became the prescribed depressant drug of choice. However, some people refused to use alcohol either because they did not like the taste or for moral reasons, and others tended to take more than prescribed. Therefore, a search for a better sedative drug continued.

Although barbituric acid was first synthesized in 1864, it was not until 1912 that phenobarbital was introduced into medicine as a sedative drug, the first of the structurally classified group of drugs called barbiturates (Julien, 2014). Since that time, more than 2,500 barbiturate derivatives have been synthesized, but fewer than a dozen remain in medical use. Illicit use of these drugs for recreational purposes grew throughout the 1930s and 1940s.

Efforts to create depressant medications that were not barbiturate derivatives accelerated. By the mid-1950s, the market for depressants had been expanded by the appearance of the nonbarbiturates glutethimide, ethchlorvynol, methyprylon, and meprobamate. Introduction of the benzodiazepines occurred around 1960 with the marketing of chlordiazepoxide (Librium), followed shortly by its derivative diazepam (Valium). The use of these drugs and others within their group grew rapidly, and they are prescribed widely in medical practice. Their margin of safety is greater than that of barbiturates and the other nonbarbiturates. However, prolonged use of even moderate doses is likely to result in physical and psychological addiction, with a characteristic syndrome of withdrawal that can be severe.

Patterns of Use

Of all the drugs used in clinical practice, the sedative, hypnotic, anxiolytic drugs are among the most widely prescribed. Sadock and associates (2015) reported that about 15 percent of all persons in the United States have had a benzodiazepine prescribed by a physician.

Two patterns of addiction are described. The first pattern begins with an individual whose physician originally prescribed the CNS depressant as treatment for anxiety or insomnia. Independently, the individual increases the dosage or frequency from that which was prescribed. Use of the medication is justified on the basis of treating symptoms, but as tolerance grows, increasingly more drug is required to produce the desired effect. Substance-seeking behavior is evident as the individual seeks prescriptions from several physicians in order to maintain sufficient supplies.

The second pattern involves people in their teens or early 20s who use illegally obtained substances in the company of their peers. The initial objective is to achieve a feeling of euphoria. The drug is usually used intermittently during recreational gatherings. This pattern of intermittent use leads to regular use and extreme levels of tolerance. Combining use with other substances is not uncommon. Physical and psychological addiction leads to intense substance-seeking behaviors, most often through illegal channels.

Effects on the Body

The sedative, hypnotic, anxiolytic compounds depress the activity of the brain, nerves, muscles, and heart tissue. The primary action of sedatives, hypnotics, and anxiolytics is on nervous tissue. However, large doses may have an effect on other organ systems. They reduce the rate of metabolism in a variety of tissues throughout the body and depress any system that uses energy (Julien, 2014). Large doses are required to produce these effects. In lower doses, these drugs appear more selective in their depressant actions by exerting their action on the centers within the brain that are concerned with arousal (e.g., the ascending reticular activating system, in the reticular formation, and the diffuse thalamic projection system).

As stated previously, these drugs are capable of producing all levels of CNS depression—from mild sedation to death. The level is determined by dosage and potency of the drug used. In Figure 23-2, a continuum demonstrates how increasing doses of these drugs affect the level of CNS depression.

Following is a discussion of the physiological effects of these medications.

Effects on Sleep and Dreaming

Barbiturate use decreases the amount of sleep time spent dreaming. During drug withdrawal, dreaming becomes vivid and excessive. Rebound insomnia and increased dreaming (termed *REM rebound*) are not uncommon with abrupt withdrawal from long-term use of these drugs as sleeping aids (Julien, 2014).

Respiratory Depression

Barbiturates are capable of inhibiting the reticular activating system, resulting in respiratory depression that may lead to lethal overdose (Sadock et al., 2015). In addition, additive effects can occur with the concurrent use of other CNS depressants, also effecting a life-threatening situation.
FIGURE 23–2 Continuum of CNS depression with increasing doses of sedative, hypnotic, or anxiolytic drugs.

Cardiovascular Effects

Hypotension may be a problem with large doses. Only a slight decrease in blood pressure is noted with normal oral dosage. High doses of barbiturates may result in decreased cardiac output, decreased cerebral blood flow, and direct impairment of myocardial contractility (Lafferty & Abdel-Kariem, 2014).

Renal Function

In doses high enough to produce anesthesia, barbiturates may suppress urine function. At the usual sedative-hypnotic dosage, however, there is no evidence of direct action on the kidneys.

Hepatic Effects

Barbiturates may result in jaundice with doses large enough to produce acute intoxication. These drugs stimulate the production of liver enzymes, resulting in a decrease in the plasma levels of both the barbiturates and other drugs metabolized in the liver. Preexisting liver disease may predispose an individual to additional liver damage with excessive barbiturate use.

Body Temperature

High doses of barbiturates can greatly decrease body temperature. It is not significantly altered with normal dosage levels.

Sexual Function

CNS depressants tend to produce a biphasic response. There is an initial increase in libido, presumably from the primary disinhibitory effects of the drug, followed by impaired sexual pleasure. In men, this initial response is followed by decreased ability to maintain an erection.

Sedative, Hypnotic, or Anxiolytic Intoxication

The *DSM*-5 (APA, 2013) describes sedative, hypnotic, or anxiolytic intoxication as the presence of clinically significant maladaptive behavioral or psychological changes that develop during, or shortly after, use of one of these substances. These maladaptive changes may include inappropriate sexual or aggressive behavior, mood lability, impaired judgment, or impaired social or occupational functioning. Other symptoms that may develop with excessive use of CNS depressants include slurred speech, incoordination, unsteady gait, nystagmus, impairment in attention or memory, and stupor or coma.

"Club drugs" in this category include gamma hydroxybutyric acid (GHB) and flunitrazepam (Rohypnol). Like all depressants, they can produce a state of disinhibition, excitement, drunkenness, and amnesia. They have been widely implicated as "date rape" drugs, since their presence is easily disguised in drinks and they produce anterograde amnesia, the inability to remember events experienced while under their influence (Walton-Moss et al., 2013).

Sedative, Hypnotic, or Anxiolytic Withdrawal

Withdrawal from sedatives, hypnotics, or anxiolytics produces a characteristic syndrome of symptoms that develops after a marked decrease in or cessation of heavy or prolonged intake (APA, 2013). Onset of symptoms depends on the drug from which the individual is withdrawing. With short-acting sedative-hypnotics (e.g., alprazolam, lorazepam), symptoms may begin between 12 and 24 hours after the last dose, reach peak intensity between 24 and 72 hours, and subside in 5 to 10 days. Withdrawal symptoms from substances with longer half-lives (e.g., diazepam, phenobarbital, chlordiazepoxide) may begin within 2 to 7 days, peak on the fifth to eighth day, and subside in 10 to 16 days.

Severe withdrawal is most likely to occur when a substance has been used at high dosages for prolonged periods. However, withdrawal symptoms also have been reported with moderate dosages taken over a relatively short duration. Withdrawal symptoms include autonomic hyperactivity (e.g., sweating or pulse rate greater than 100), increased hand tremor, insomnia, nausea or vomiting, hallucinations, illusions, psychomotor agitation, anxiety, or grand mal seizures.

Stimulant Use Disorder
A Profile of the Substance

CNS stimulants are identified by the behavioral stimulation and psychomotor agitation they induce. They differ widely in molecular structures and mechanisms of action. The amount of CNS stimulation caused by a certain drug depends on both the area in the brain or

spinal cord that is affected by the drug and the cellular mechanism fundamental to the increased excitability. The *DSM-5* (APA, 2013) categorizes caffeine-related disorders and tobacco-related disorders as separate and distinct diagnoses. For purposes of this text, these substances are discussed with the stimulant-related disorders.

Groups within this category are classified according to similarities in mechanism of action. The *psychomotor stimulants* induce stimulation by augmentation or potentiation of the neurotransmitters norepinephrine, epinephrine, or dopamine. The *general cellular stimulants* (caffeine and nicotine) exert their action directly on cellular activity. Caffeine inhibits the enzyme phosphodiesterase, allowing increased levels of adenosine 3',5'-cyclic phosphate (cAMP), a chemical substance that promotes increased rates of cellular metabolism. Nicotine stimulates ganglionic synapses. This results in increased acetylcholine, which stimulates nerve impulse transmission to the entire autonomic nervous system. A selected list of drugs included in these categories is presented in Table 23–2.

The two most prevalent and widely used stimulants are caffeine and nicotine. Caffeine is readily available in every supermarket and grocery store as a common ingredient in coffee, tea, colas, and chocolate. Nicotine is the primary psychoactive substance found in tobacco products. When used in moderation, these stimulants tend to relieve fatigue and increase alertness. They are a generally accepted part of our culture; however, with increased social awareness regarding the health risks associated with tobacco products, their use has become stigmatized in some circles.

The more potent stimulants, because of their potential for physiological addiction, are under regulation by the Controlled Substances Act. These controlled stimulants are available for therapeutic purposes by prescription only; however, they are also clandestinely manufactured and widely distributed on the illicit market. More recently, the synthetic stimulants mephedrone, 3,4-methylenedioxypyrovalerone (MDPV), methylone, and others have surfaced; because their chemical structures have been altered, they were not initially identifiable as a controlled substance or regulated by the federal government. Known as "bath salts," street names include blue silk, cloud 9, ivory wave, vanilla sky, white knight, stardust, and purple wave. In October 2011, the U.S. Drug Enforcement Administration (DEA) issued emergency scheduling of these substances to make their possession

TABLE 23–2 **CNS Stimulants**		
CATEGORIES	**GENERIC (TRADE) NAMES**	**COMMON STREET NAMES**
Amphetamines	Dextroamphetamine (Dexedrine) Methamphetamine (Desoxyn) 3,4-methylenedioxyamphetamine (MDMA)* Amphetamine + dextroamphetamine (Adderall)	Dexies, uppers, truck drivers Meth, speed, crystal, ice, crank, chalk fire, glass Adam, ecstasy, Eve, XTC Beanies, pep pills, speed, uppers, study buddies, smart pills
Synthetic stimulants	3,4-methylenedioxypyrovalerone* (MDPV) 4-methylmethcathinone (mephedrone, 4-MMC)* Methylone* Ethylone Dibutylone Alpha-PVP	Bath salts (also called blue silk, cloud 9, ivory wave, vanilla sky, white lightning, and others), flakka, gravel
Nonamphetamine stimulants	Phendimetrazine (Bontril) Benzphetamine (Didrex) Diethylpropion (Tenuate) Phentermine (Adipex-P; Ionamin) Sibutramine (Meridia)† Methylphenidate (Ritalin) Dexmethylphenidate (Focalin) Modafinil (Provigil)	Diet pills Speed, uppers
Cocaine	Cocaine hydrochloride	Coke, blow, toot, snow, lady, flake, crack
Caffeine	Coffee, tea, colas, chocolate	Java, mud, brew, cocoa
Nicotine	Cigarettes, cigars, pipe tobacco, snuff	Weeds, fags, butts, chaw, cancer sticks

*Cross-listed with the hallucinogens.
†No longer marketed in the United States.

and sales illegal (except as authorized by law). They are currently designated as Schedule I substances, the most restrictive category under the Controlled Substances Act. This action was taken in response to reports of episodes of violent behavior associated with use of the substance.

Since then, yet another synthetic cathinone, alpha-PVP (α-pyrrolidinopentiophenone, commonly known as *flakka, gravel,* or *$5 insanity*), whose chemical structure is similar but not identical to bath salts, began to surface in the United States. This drug can be snorted, injected, eaten, and vaporized for inhalation in e-cigarettes. Vaporization is a particularly dangerous route because of its immediate absorption, and deaths have been reported secondary to overdose, suicide, and heart attack. But although flakka was a significant health hazard in 2014 and 2015, no deaths were reported in 2016, since China (the singular provider of this drug) banned the production and exportation of alpha-PVP (Storrs, 2016). Storrs additionally reports, however, that when one synthetic stimulant is banned, it is often replaced by another. For example, when China banned methylone (a drug similar to flakka) in 2014, it was replaced by ethylone; after ethylone was banned, a similar drug called dibutylone surfaced. This pattern creates an ongoing battle for the FDA and DEA to identify and take action on each new synthetic variant as it comes to public attention (usually through significant health consequences or deaths).

Historical Aspects

Cocaine is the most potent stimulant derived from nature. It is extracted from the leaves of the coca plant, which has been cultivated in the Andean highlands of South America since prehistoric times. Natives of the region chew the leaves of the plant for refreshment and relief from fatigue.

Coca leaves must be mixed with lime to release the cocaine alkaloid. The chemical formula for the pure form of the drug was developed in 1960. Physicians began using the drug as an anesthetic in eye, nose, and throat surgeries, and it was used in the United States in a morphine-cocaine elixir designed to relieve the suffering associated with terminal illness. These therapeutic uses are now obsolete.

Cocaine has achieved a degree of acceptability within some social circles. It is illicitly distributed as a white crystalline powder, often mixed with other ingredients to increase its volume and create more profit. The drug is most commonly "snorted," and chronic users may manifest symptoms that resemble the congested nose of a common cold. The intensely pleasurable effects of the drug create the potential for extraordinary psychological addiction.

Another form of cocaine commonly used in the United States is made by processing powdered cocaine with ammonia or sodium bicarbonate and water and heating it to remove the hydrochloride (Publishers Group, 2012). The term *crack,* the street name for this form of the drug, refers to the crackling sound heard when the mixture is smoked. Because this type of cocaine can be easily vaporized and inhaled, its effects have an extremely rapid onset. See "Real People, Real Stories" for Alan's experience with crack cocaine and alcohol addiction.

Real People, Real Stories: Alan Brunner on Substance Use Disorder

Substance use disorders often follow a progressive pattern that develops over a long period of time. Alan's story is an example of that process. See also Chapter 8, Therapeutic Communication, for an interaction with Alan that incorporates motivational interviewing. Reflect on important issues for primary prevention education. Consider examples of interventions that are ineffective or unhealthy for the user and the care provider. Incorporate an understanding of codependency in this reflection.

Karyn: Tell me about when you first used drugs or alcohol.

Alan: I was 15 years old when I first started smoking pot and 16 when I had my first drink. The pot use went from occasional use to several times a week by the time I was a senior in high school. I knew that was a problem, but the drinking progressed much more gradually. For years, I only drank on weekends. For a while, my buddy and I would share a quart on the weekend. Eventually, we each had our own quart, then two quarts each. I only drank beer. Once when I was teenager, I drank a fifth of vodka and

Real People, Real Stories: Alan Brunner on Substance Use Disorder—cont'd

I got extremely sick. My mom didn't try to rescue me or help me feel better or cover for me. I just had to live through the consequences, and that was probably a good thing; I never drank vodka again. But the beer drinking became more often and at higher amounts. Even so, it took another 35 years to recognize that it was a problem!

Karyn: Was there any history of alcoholism in your family?

Alan: Oh yeah . . . several relatives. My dad had a drinking problem, and that led to my parents divorcing when I was 14 years old. When I was 19, I moved in with my dad, and then I started drinking during the week, too—because he did. My dad always worked and had a strong work ethic, even though he was a heavy drinker, so I thought, "As long as I'm able to drink and it's not interfering with work, then it's not a problem." I also remember thinking, "It's just beer, and I would never use the 'strong' or 'bad' drugs, like cocaine—I would NEVER do that."

Karyn: So your beer drinking increased while you were living with your father?

Alan: Initially, yes, but then I was surrounding myself with people and friends who liked to drink. I moved in with a friend, and we usually drank a case of beer each night. Then I started an auto repair business with a friend who was a heavy drinker, and we had beer at the shop. Pretty soon we weren't leaving the shop until all the beer was gone. Then I got involved with auto racing, and that was an environment with lots of alcohol and cocaine.

Karyn: I remember you said you were using cocaine. Is that when the use started?

Alan: No, actually I had become friends with a deacon at my church, probably because we both liked to drink. He was the one that introduced me to cocaine.

Karyn: So you started using cocaine along with drinking?

Alan: Yeah, even though I had said I would never do that. But I discovered that if I did cocaine, I had a lot more energy and I could stay awake longer, so I could be a much "better" drinker. (chuckles)

Karyn: Tell me about when you recognized that your use was a problem.

Alan: Well, eventually, I was drinking at home because it was a waste of "good drinking time" to get together with other people. So largely, I was sitting at home in the dark drinking by myself, and the beer never even made it into the fridge. The cocaine was putting me in the company of some very bad people. I knew I had to somehow get away from that . . . and when I started using cocaine, I said, "One thing I'll never do is crack," but then I started doing that, and that's when things completely fell apart.

Karyn: Fell apart?

Alan: I was racking up a lot of legal problems. I had some DUIs and reckless operation charges before that, but now I'm getting drug possession charges, paraphernalia charges, driving with a suspended license, driving with expired license plates, more DUIs, disorderly conduct charges. And the crack—that drug rips out your soul! You're always chasing the high that you got the first time you used it, and you never find that, so you keep using more. That's why one of my friends called crack "gotta" because you gotta have it. . . . And you don't care about ANYTHING else—you don't care if you die.

Karyn: You told me you've been clean and sober for seven years. How did you turn the corner?

Alan: I had such a huge legal mess that my lawyer was recommending I just accept the jail time (3 to 10 days) and be done with it, but the judge offered treatment in lieu of jail, and I told him that's what I wanted because I knew I needed it. I was told, though, that if I violated the treatment program, I would spend a year in jail, so I knew I was taking a big risk by going into treatment. But I knew it was the only way out—and I knew I needed it.

Karyn: So what is your relapse prevention plan?

Alan: I have an AA sponsor, and I go to meetings sometimes, but not as often as I used to. I never allow myself to become too proud about my sobriety because I know all it would take is one drink. As long as I remember that, I'm vulnerable. . . . I don't get too cocky. I've also had a lot of support from family, especially my mom. She supported me every step of the way in treatment. Having supportive people around you is essential. The relationship I had been in for many years broke up largely because she was telling my counselors that she wanted me to cut down but she wasn't in favor of abstinence—she was quite a partier, too. Staying in that relationship, I believed (and my counselors believed), was putting my sobriety at risk.

Karyn: What do you think is important for health-care providers to know or to do to help someone who has a substance use problem?

Alan: First of all, a person has to want help. You can't fix another person, and you can't help someone who doesn't want help.

Karyn: I agree, that is so important. I think health-care providers (and family caregivers) are vulnerable sometimes to thinking they can fix any health problem, which can culminate in interventions that are ineffective and unhealthy for the user and for the care provider.

Alan: Yes, and I would also say that health-care providers need to know how to recognize symptoms of problematic substance use.

Karyn: Like?

Alan: Like someone having "the shakes," someone not looking at you when they are answering questions, blaming other people for their circumstances and consequences, talking in circles. Don't ever ask someone, "Are you an alcoholic or a drug addict?" because we'll always say no unless we're in recovery—the denial is so strong. I also think not being too judgmental is important so you can find ways to open the door to discuss the issues. If someone is

too "hard-nosed" and judgmental, I think it reinforces the denial. Asking a question like "Have you ever been drinking and couldn't remember events around that time?" is good because having blackouts is a good indication of an alcohol problem. You may not be able to "fix" someone but you can "plant seeds" and hope that the information and education will have an impact at some point. I think

that's why people who are recovering themselves can be so effective as health-care providers because they can share their own story of addiction and, since most people think they are completely unique, hearing someone else's story about having been in the same place you are now may turn on a light switch and help people recognize their own need for treatment.

Amphetamine was first prepared in 1887. Various derivatives of the drug soon followed, and clinical use of the drug began in 1927. Amphetamines were used quite extensively for medical purposes through the 1960s, but recognition of their abuse potential has sharply decreased clinical use. Today, they are prescribed only to treat narcolepsy (a rare disorder resulting in an uncontrollable desire for sleep), hyperactivity disorders in children, and certain cases of obesity. Clandestine production of amphetamines for distribution on the illicit market has become a thriving business. Methamphetamine can be smoked, snorted, injected, or taken orally. The effects include an intense rush from smoking or intravenous injection and a slower onset of euphoria as a result of snorting or oral ingestion. Another form of the drug, crystal methamphetamine, is produced by slowly recrystallizing powder methamphetamine from a solvent such as methanol, ethanol, isopropanol, or acetone (Publishers Group, 2012). This colorless, odorless, large-crystal form of D-methamphetamine is commonly called *glass* or *ice* because of its appearance. Crystal meth is usually smoked in a glass pipe like crack cocaine.

The earliest history of caffeine is unknown and is shrouded by legend and myth. Caffeine was first discovered in coffee in 1820 and in tea 7 years later. Both beverages have been widely accepted and enjoyed as a "pick-me-up" by many cultures.

Tobacco use has a long history; Mayan carved drawings dated between 600 and 1000 AD are the earliest evidence that appears to depict smoking tobacco. Introduced in Europe in the mid-16th century, its use grew rapidly and soon became prevalent in the Orient. Tobacco came to America with the settlement of the earliest colonies. Today, it is grown in many countries of the world, and although smoking is decreasing in most industrialized nations, it continues to be a serious problem in developing areas.

Patterns of Use

Because of their pleasurable effects, CNS stimulants have a high abuse potential. In 2014, about 1.5 million Americans were current cocaine users (SAMHSA, 2015). Use was highest among Americans aged 18 to 25.

Many individuals who abuse or are addicted to CNS stimulants began using the substance for the appetite-suppressant effect in an attempt at weight control. Increasingly higher doses are consumed in an effort to maintain the pleasurable effects. With continued use, these effects diminish as dysphoric effects increase. A persistent craving for the substance remains even in the face of unpleasant adverse effects from continued use.

CNS stimulant use is usually characterized by either episodic or chronic daily or near-daily use. Individuals who use the substances on an episodic basis often "binge" on the drug with consumption of very high dosages followed by a day or two of recuperation. This recuperation period is characterized by extremely intense and unpleasant symptoms and is thus often called a "crash."

The daily user may take large or small doses and may use the drug several times a day or only at a specific time during the day. The amount consumed usually increases over time as tolerance develops. Chronic users tend to rely on CNS stimulants to feel more powerful, more confident, and more decisive. They often fall into a pattern of taking "uppers" in the morning and "downers," such as alcohol or sleeping pills, at night.

The average American consumes two cups of coffee (about 200 mg of caffeine) per day. Caffeine is consumed in various amounts by about 90 percent of the population. At a level of 500 to 600 mg of daily caffeine consumption, symptoms of anxiety, insomnia, and depression are not uncommon, and caffeine dependence and withdrawal can occur. Caffeine consumption is prevalent among children as well as adults. Table 23–3 lists some common sources of caffeine.

Nicotine, an active ingredient in tobacco, is the most widely used psychoactive substance in U.S. society after caffeine. Based on 2014 statistics, 55.2 million people are current smokers of tobacco, 12 million smoke cigars, and 8.7 million use smokeless tobacco (SAMHSA, 2015). Since 1964, when the results of the first public health report on smoking were issued, the

TABLE 23–3 **Common Sources of Caffeine**	
SOURCE	CAFFEINE CONTENT (mg)
FOOD AND BEVERAGES	
5–6 oz brewed coffee	90–125
5–6 oz instant coffee	60–90
5–6 oz decaffeinated coffee	3
5–6 oz brewed tea	70
5–6 oz instant tea	45
8 oz green tea	15–30
8–12 oz cola drinks	60
12 oz Red Bull energy drink	115
2 oz high-energy drink	215–240
5–6 oz cocoa	20
8 oz chocolate milk	2–7
1 oz chocolate bar	22
PRESCRIPTION MEDICATIONS APCs (aspirin, phenacetin, caffeine)	32
Cafergot	100
Fiorinal	40
Migralam	100
OVER-THE-COUNTER ANALGESICS Anacin, Empirin, Midol, Vanquish,	32
Excedrin Migraine (aspirin, acetaminophen, caffeine)	65
OVER-THE-COUNTER STIMULANTS NoDoz tablets	100
Vivarin	200
Caffedrine	250

percentage of total smokers has been on the decline. However, the percentage of women and teenage smokers has declined more slowly than that of adult men. Even though tobacco use is on the decline, people with severe mental illness and those in addiction treatment continue to have higher rates of use than the general population; as many as 93 percent of people in addictions treatment and 40 percent of those with severe mental illness report using tobacco (SAMHSA, 2015).

The dangers of secondhand smoke continue to be identified as a significant health hazard. The CDC (2016b) reports that, annually, secondhand smoke claims the lives of over 49,000 nonsmokers from heart disease, stroke, and lung cancer, and 1,000 babies from the effects associated with the mother smoking during pregnancy. Additionally, smoking increases the risk of infant mortality from sudden infant death syndrome.

Effects on the Body

CNS stimulants are a group of pharmacological agents that are capable of exciting the entire nervous system. This is accomplished by increasing the activity or augmenting the capability of the neurotransmitter agents directly involved in bodily activation and behavioral stimulation. Physiological responses vary according to the potency and dosage of the drug.

Central Nervous System Effects

Stimulation of the CNS results in tremor, restlessness, anorexia, insomnia, agitation, and increased motor activity. Amphetamines, nonamphetamine stimulants, and cocaine produce increased alertness, decreased fatigue, elation and euphoria, and subjective feelings of greater mental agility and muscular power. Chronic use of these drugs may result in compulsive behavior, paranoia, hallucinations, and aggressive behavior (Publishers Group, 2012).

Cardiovascular/Pulmonary Effects

Amphetamines can induce increased systolic and diastolic blood pressure, increased heart rate, and cardiac arrhythmias (Publishers Group, 2012). These drugs also relax bronchial smooth muscle.

Cocaine intoxication typically produces a rise in myocardial demand for oxygen and an increase in heart rate. Severe vasoconstriction may occur and can result in myocardial infarction, ventricular fibrillation, and sudden death. Inhaled cocaine can cause pulmonary hemorrhage, chronic bronchiolitis, and pneumonia. Nasal rhinitis is a result of chronic cocaine snorting.

Caffeine ingestion can result in increased heart rate, palpitations, extrasystoles, and cardiac arrhythmias. Caffeine induces dilation of pulmonary and general systemic blood vessels and constriction of cerebral blood vessels.

Nicotine stimulates the sympathetic nervous system, resulting in an increase in heart rate, blood pressure, and cardiac contractility, thereby increasing myocardial oxygen consumption and demand for blood flow. Contractions of gastric smooth muscle associated with hunger are inhibited, thereby producing a mild anorectic effect.

Gastrointestinal and Renal Effects

Gastrointestinal (GI) effects of amphetamines are somewhat unpredictable; however, a decrease in GI tract motility commonly results in constipation.

Contraction of the bladder sphincter makes urination difficult. Caffeine exerts a diuretic effect on the kidneys. Nicotine stimulates the hypothalamus to release antidiuretic hormone, reducing the excretion of urine. Because nicotine increases the tone and activity of the bowel, it may occasionally cause diarrhea.

Most CNS stimulants induce a small rise in metabolic rate and various degrees of anorexia. Amphetamines and cocaine can cause a rise in body temperature.

Sexual Function

CNS stimulants appear to increase sexual urges in both men and women. Women, more frequently than men, report that stimulants make them feel sexier and have more orgasms. In fact, some men may experience sexual dysfunction with the use of stimulants. For the majority of individuals, however, these drugs exert a powerful aphrodisiac effect.

Stimulant Intoxication

Stimulant intoxication produces maladaptive behavioral and psychological changes that develop during or shortly after use of these drugs. Amphetamine and cocaine intoxication typically produces euphoria or affective blunting; changes in sociability; hypervigilance; interpersonal sensitivity; anxiety, tension, or anger; stereotyped behaviors; or impaired judgment. In severe amphetamine intoxication, symptoms may include memory loss, psychosis, and violent aggression. Physical effects include tachycardia or bradycardia, pupillary dilation, elevated or lowered blood pressure, perspiration or chills, nausea or vomiting, weight loss, psychomotor agitation or retardation, muscular weakness, respiratory depression, chest pain, cardiac arrhythmias, confusion, seizures, dyskinesias, dystonias, or coma (APA, 2013).

Intoxication from caffeine usually occurs following consumption in excess of 250 mg. Symptoms include restlessness, nervousness, excitement, insomnia, flushed face, diuresis, GI disturbance, muscle twitching, rambling flow of thought and speech, tachycardia or cardiac arrhythmia, periods of inexhaustibility, and psychomotor agitation (APA, 2013).

Stimulant Withdrawal

Stimulant withdrawal is the presence of a characteristic withdrawal syndrome that develops within a few hours to a few days after cessation of or reduction in heavy and prolonged use (APA, 2013). This syndrome is often referred to as crashing, an apt description because the symptoms include fatigue, cramps, depression, headaches, and nightmares. The dysphoria can be intense enough to result in increased risk for suicide. Peak withdrawal symptoms usually occur within 2 to 4 days of abstinence (Black & Andreasen, 2014).

The *DSM-5* (APA, 2013) states that a withdrawal syndrome can occur with abrupt cessation of caffeine intake after prolonged daily use. The symptoms begin within 24 hours after last consumption and may include headache, fatigue, drowsiness, dysphoric mood, irritability, difficulty concentrating, flu-like symptoms, nausea, vomiting, and/or muscle pain and stiffness.

Withdrawal from nicotine results in dysphoric or depressed mood; insomnia; irritability, frustration, or anger; anxiety; difficulty concentrating; restlessness; decreased heart rate; and increased appetite or weight gain (APA, 2013). A mild syndrome of nicotine withdrawal can appear when a smoker switches from regular cigarettes to low-nicotine cigarettes (Sadock et al., 2015).

Inhalant Use Disorder

Profile of the Substance

Inhalant disorders are induced by inhaling the aliphatic and aromatic hydrocarbons found in substances such as fuels, solvents, adhesives, aerosol propellants, and paint thinners. Specific examples of these substances include gasoline, varnish remover, lighter fluid, airplane glue, rubber cement, cleaning fluid, spray paint, shoe conditioner, and typewriter correction fluid. Toluene (methylbenzene, toluol, phenylmethane), a common ingredient in many inhaled substances including paints, glues, and gasoline, is responsible for the mind-altering effects that occur after inhalation.

Historical Aspects

Use of inhalants for altered consciousness or for religious rituals dates back to ancient times. In the early 19th century, ether, chloroform, and nitrous oxide were inhaled for recreational purposes. By the 1960s, the inhaling of substances for recreational effects had spread to a wide range of products, including shoe polish, paints and paint thinners, lighter fluid, and gasoline. Inhalant use among children and adolescents is widespread in the United States today.

Patterns of Use

Inhalant substances are readily available, legal, and inexpensive, three factors that make them attractive to children, teens, and young adults. Highest usage is by youths aged 12 to 17, and this is the only class of drugs used more frequently by younger than by older teens (NIDA, 2015). A national government survey of drug use in 2014 revealed that 8 percent of people in the United States aged 12 years or older acknowledged having used inhalants (NIDA, 2015). A encouraging update (NIDA, 2016) identifies a decline of drug use among teens over the past 5 years for many substances, including inhalants. Younger teens more commonly inhale glue, gasoline, and spray paints. In

older teens, nitrous oxide (also known as "whippets") use is more common, and in adults, nitrites such as amyl nitrites (also called "poppers") are the most common inhalants used for mind-altering effects (NIDA, 2015).

Methods of use include "huffing"—a procedure in which a rag soaked with the substance is applied to the mouth and nose and the vapors inhaled. Another common method is called "bagging," in which the substance is placed in a paper or plastic bag from which it is inhaled by the user. The substance may also be inhaled directly from the container or sprayed in the mouth or nose.

Sadock and associates (2015) reported that

> inhalant use among adolescents may be most common in those whose parents or older siblings use illegal substances. Inhalant use among adolescents is also associated with an increased likelihood of conduct disorder or antisocial personality disorder. (p. 657)

Tolerance to inhalants has been reported with heavy use. A mild withdrawal syndrome has been documented but does not appear to be clinically significant. Among children with inhalant disorder, the products may be used several times a week, often on weekends and after school. Adults with inhalant addiction may use the substance at varying times each day or binge on the substance over a period of several days.

Effects on the Body

Inhalants are absorbed through the lungs and reach the CNS very rapidly. Inhalants generally act as CNS depressants (Black & Andreasen, 2014). The effects are relatively brief, lasting from several minutes to a few hours depending on the specific substance and amount consumed.

Central Nervous System Effects

Inhalants can cause both central and peripheral nervous system damage. Symptoms of neurological damage such as ataxia, peripheral and sensorimotor neuropathy, speech problems, and tremor can occur. Other CNS effects that have been reported with heavy inhalant use include ototoxicity, encephalopathy, parkinsonism, and damage to the protective sheath around certain nerve fibers in the brain and peripheral nervous system (Walton-Moss et al., 2013).

Respiratory Effects

Respiratory effects of inhalant use range from coughing and wheezing to dyspnea, emphysema, and pneumonia. There is increased airway resistance due to inflammation of the passages. Walton-Moss and associates (2013) note additionally that suffocation can occur as a result of inhaling substances from paper or plastic bags.

Gastrointestinal Effects

Abdominal pain, nausea, and vomiting may occur. A rash may be present around the individual's nose and mouth. Unusual breath odors are common. Long-term use has resulted in reports of liver toxicity.

Renal System Effects

Acute and chronic renal failure and hepatorenal syndrome may occur. Renal toxicity from toluene exposure has been reported, manifesting in renal tubular acidosis, hypokalemia, hypophosphatemia, hyperchloremia, azotemia, sterile pyuria, hematuria, and proteinuria (McKeown, 2015).

Inhalant Intoxication

The *DSM-5* defines inhalant intoxication as "clinically significant problematic behavioral or psychological changes that developed during or shortly after exposure to inhalants" (APA, 2013). Symptoms are similar to alcohol intoxication and may include the following (APA, 2013; Black & Andreasen, 2014):

- Dizziness; ataxia
- Euphoria; excitation; disinhibition
- Nystagmus; blurred vision; double vision
- Slurred speech
- Hypoactive reflexes
- Psychomotor retardation; lethargy
- Generalized muscle weakness
- Stupor or coma (at higher doses)

Opioid Use Disorder

Profile of the Substance

The term *opioid* refers to a group of compounds that includes opium, opium derivatives, and synthetic substitutes. Opioids exert both a sedative and an analgesic effect, and their major medical uses are pain relief, treatment of diarrhea, and relief of coughing. These drugs have addictive qualities in that they are capable of inducing tolerance and physiological and psychological addiction. The United States is currently struggling to respond to an unprecedented opiate abuse epidemic.

Opioids are popular drugs of abuse because they desensitize an individual to both psychological and physiological pain and induce a sense of euphoria. Lethargy and indifference to the environment are common manifestations.

Opioid abusers usually spend much of their time nourishing the habit. Individuals who are addicted to opioids are seldom able to hold a steady job that will support their need and must therefore secure funds from friends, relatives, or whomever they have not yet alienated with their addiction-related behavior. It is not uncommon for individuals addicted to opioids to

resort to illegal means of obtaining funds, such as burglary, robbery, prostitution, or selling drugs.

Methods of administration of opioid drugs include oral ingestion; snorting; smoking; and subcutaneous, intramuscular, and intravenous injection. A selected list of opioid substances is presented in Table 23–4.

Under close supervision, opioids are indispensable in the practice of medicine. They are the most effective agents known for the relief of intense pain. However, they also induce a pleasurable effect on the CNS that promotes their abuse. The physiological and psychological addiction that occurs with opioids, as well as the development of profound tolerance, contribute to the addict's ongoing quest for more of the substance, regardless of the means.

Historical Aspects

In its crude form, opium is a brownish-black gummy substance obtained from the ripened pods of the opium poppy. References to the use of opiates have been found in the Egyptian, Greek, and Arabian cultures as early as 3000 BC. The drug became widely used both medicinally and recreationally throughout Europe during the 16th and 17th centuries. Most of the opium supply came from China, where the drug was introduced by Arab traders in the late 17th century. Morphine, the primary active ingredient of opium, was isolated in 1803 by the European chemist Friedrich Sertürner. Since that time, morphine rather than crude opium has been used throughout the world for the medical treatment of pain and diarrhea. This process was facilitated in 1853 by the development of the hypodermic syringe, which made it possible to deliver undiluted morphine quickly into the body for rapid relief from pain.

This development also created a new variety of opiate user in the United States: one who was able to self-administer the drug by injection. In addition, the large influx of Chinese immigrants into the United States during this era introduced opium smoking to this country. By the early part of the 20th century, opium addiction was widespread.

In response to the concerns over the prevalence of opium addiction, in 1914 the U.S. government passed the Harrison Narcotic Act, which created strict controls on the accessibility of opiates. Until that time, these substances were freely available to the public without a prescription. The Harrison Act banned the use of opiates for nonmedicinal purposes and drove the use of heroin underground. To this day, the beneficial uses of these substances are widely acclaimed within the medical profession, but the illicit trafficking of the drugs for recreational purposes continues to resist most efforts at control.

Patterns of Use

The development of opioid addiction may follow one of two typical behavior patterns. The first occurs in the individual who has obtained the drug by prescription from a physician for the relief of a medical problem. Abuse and addiction occur when the individual increases the amount and frequency of use, justifying the behavior as symptom treatment. He or she becomes obsessed with obtaining more and more of the substance, seeking out several physicians in order to replenish and maintain supplies.

TABLE 23–4 **Opioids and Related Substances**		
CATEGORIES	**GENERIC (TRADE) NAMES**	**COMMON STREET NAMES**
Opioids of natural origin	Opium (ingredient in various antidiarrheal agents) Morphinan (Astramorph) Codeine (ingredient in various analgesics and cough suppressants) Kratom (opioid-like)	Black stuff, poppy, tar, big O M, white stuff, Miss Emma Terp, schoolboy, syrup, cody
Opioid derivatives	Heroin Hydromorphone (Dilaudid) Oxycodone (Percodan; OxyContin) Hydrocodone (Vicodin)	H, horse, junk, brown sugar, smack, skag, TNT, Harry DLs, 4s, lords, little D Perks, perkies, Oxy, O.C. Vike
Synthetic opiate-like drugs	Meperidine (Demerol) Methadone (Dolophine) Pentazocine (Talwin) Fentanyl (Fentora) Carfentanil Desomorphine U-47700	Doctors Dollies, done Ts Apache, China girl, China town, dance fever, goodfella, jackpot Krokodil Pink or pinky

The second pattern of behavior occurs among individuals who use the drugs for recreational purposes and obtain them from illegal sources. Opioids may be used alone to induce the euphoric effects or in combination with stimulants or other drugs to enhance the euphoria or counteract the substance's depressant effects. Tolerance develops and addiction occurs, leading the individual to procure the substance by whatever means is required to support the habit.

A recent government survey reported that there were 435,000 current heroin users aged 12 years and older in the United States in 2014 (SAMHSA, 2016). The same survey revealed an estimated 4.3 million persons who used prescription psychotherapeutic drugs nonmedically. Since 1999, prescription rates for painkillers and deaths from opiate overdoses have both quadrupled (CDC, 2016c). Efforts have been made in some states to exert stricter controls on opiate prescription practices, and 2012 marked the first year of a drop in prescription rates nationally. However, the longer-term trend has shown an increase from 76 million prescriptions for opiates in 1991 to 207 million in 2013 (NIDA, 2014). The CDC reports that 44 people die each day from prescription painkiller overdose. The most common drugs involved in prescription overdose deaths include hydrocodone (Vicodin), oxycodone (OxyContin), oxymorphone (Opana), and methadone.

One alarming trend is a significant increase in overdose deaths associated with fentanyl mixed with heroin. This frequently results in accidental overdose since fentanyl is 30 to 50 times more potent than pure heroin (CDC, 2016c). Even more recently, carfentanil (carfentanyl), a potent drug used mainly in the capture of wild animals (100 times more potent than fentanyl and 10,000 times more potent than morphine), has been responsible for rapid accidental overdose and often death when ingested along with heroin (National Institutes of Health [NIH], 2016).

Much like the trend with synthetic amphetamines discussed earlier in this chapter, a new synthetic opiate, U-47700, surfaced in 2015 and was responsible for 46 fatalities in 2016 before the substance was emergency classified as a Schedule I drug to allow the DEA more time to collect data on the substance (Duffy, 2016). Kratom, a plant from Southeast Asia that triggers opiate-like effects, surfaced in the United States and was subsequently banned; however, this decision was reversed when researchers argued that it might help them develop tools to overcome opiate and alcohol addiction as well as chronic pain (MPR, 2016). At present, the opioid epidemic remains out of control, but several national initiatives to address this public health crisis have been identified. A National Practice Guideline for use of medications to treat opioid use disorder has been established (ASAM, 2015), and for the first time in U.S. history, the Surgeon General declared illicit drug use and misuse of prescription drugs a national health-care priority and committed to the need for additional research and treatment options (HHS, 2016).

Effects on the Body

Opiates are sometimes classified as *narcotic analgesics*. They exert their major effects primarily on the CNS, the eyes, and the GI tract. Chronic morphine use or acute morphine toxicity is manifested by a syndrome of sedation, chronic constipation, decreased respiratory rate, and pinpoint pupils. Intensity of symptoms is largely dose dependent. The following physiological effects are common with opioid use.

Central Nervous System Effects

All opioids, opioid derivatives, and synthetic opioid-like drugs affect the CNS. Common manifestations include euphoria, mood changes, and mental clouding. Other common CNS effects include drowsiness and pain reduction. Pupillary constriction occurs in response to stimulation of the oculomotor nerve. CNS depression of the respiratory centers within the medulla results in respiratory depression. The antitussive response is caused by suppression of the cough center within the medulla. The nausea and vomiting commonly associated with opiate ingestion is related to the stimulation of the centers within the medulla that trigger this response.

Gastrointestinal Effects

These drugs exert a profound effect on the GI tract. Both stomach and intestinal tone increase, while peristaltic activity of the intestines is diminished. These effects lead to a marked decrease in the movement of food through the GI tract. This is a notable therapeutic effect in the treatment of severe diarrhea. In fact, no drugs have yet been developed that are more effective than the opioids for this purpose. However, constipation and even fecal impaction may be a serious problem for the chronic opioid user.

Cardiovascular Effects

In therapeutic doses, opioids have minimal effect on the action of the heart. Morphine is used extensively to relieve pulmonary edema and the pain of myocardial infarction in cardiac clients. At high doses, opioids induce hypotension, which may be caused by direct action on the heart or by opioid-induced histamine release.

Sexual Function

Opioid use causes decreased sexual function and diminished libido, and long-term use has been associated

with erectile dysfunction (Deyo et al., 2013). Delayed ejaculation, impotence, and orgasm failure (in both men and women) may occur.

Opioid Intoxication

Opioid intoxication constitutes clinically significant problematic behavioral or psychological changes that develop during, or shortly after, opioid use (APA, 2013). Symptoms include initial euphoria followed by apathy, dysphoria, psychomotor agitation or retardation, and impaired judgment. Physical symptoms include pupillary constriction (or dilation due to anoxia from severe overdose), drowsiness, slurred speech, and impairment in attention or memory (APA, 2013). Symptoms are consistent with the half-life of most opioid drugs and usually last for several hours. Severe opioid intoxication can lead to respiratory depression, coma, and death.

Opioid Withdrawal

Opioid withdrawal produces a syndrome of symptoms that develops after cessation of or reduction in heavy and prolonged use of an opiate or related substance. Symptoms include dysphoric mood, nausea or vomiting, muscle aches, lacrimation or rhinorrhea, pupillary dilation, piloerection, sweating, diarrhea, yawning, fever, and insomnia (APA, 2013). With short-acting drugs such as heroin, withdrawal symptoms occur within 6 to 8 hours after the last dose, peak within 1 to 3 days, and gradually subside over a period of 5 to 10 days (Walton-Moss et al., 2013). With longer-acting drugs such as methadone, withdrawal symptoms begin within 1 to 3 days after the last dose, peak between days 4 and 6, and are complete in 14 to 21 days. Withdrawal from the ultra-short-acting meperidine begins quickly, reaches a peak in 8 to 12 hours, and is complete in 4 to 5 days (Sadock et al., 2015).

Hallucinogen Use Disorder

Profile of the Substance

Hallucinogenic substances can distort an individual's perception of reality, alter sensory perception, and induce hallucinations. For this reason, they have sometimes been referred to as "mind-expanding drugs." Some of the effects of these substances have been likened to those of a psychotic break. The hallucinations experienced by an individual with schizophrenia, however, are most often auditory, whereas substance-induced hallucinations are usually visual. Perceptual distortions have been reported by some users as spiritual, as giving a sense of depersonalization (observing oneself having the experience), or as feeling at peace with self and the universe. Others, who describe their experiences as "bad trips," report feelings of panic and a fear of dying or going insane. A

common danger reported with hallucinogenic drugs is that of flashbacks, or a spontaneous reoccurrence of the hallucinogenic state without ingestion of the drug. These can occur months after the drug was last taken.

Recurrent use can produce tolerance, encouraging users to resort to increasingly higher dosages. No evidence of physical addiction is detectable when the drug is withdrawn; however, recurrent use appears to induce a psychological addiction to the insight-inducing experiences that a user may associate with episodes of hallucinogen use (Sadock et al., 2015). This psychological addiction varies according to the drug, the dose, and the individual user. Hallucinogens are highly unpredictable in the effects they may induce each time they are used.

Many hallucinogenic substances have structural similarities. Some are produced synthetically; others are natural products of plants and fungi. A selected list of hallucinogens is presented in Table 23–5.

Historical Aspects

Hallucinogens have been used throughout history in many cultures for religious and mystical experiences, including in Aztec, Mexican Indian, and Hindu ceremonies (Parish, 2015). Use of the peyote cactus as part of religious ceremonies in the southwestern part of the United States still occurs today, although this ritual use has greatly diminished.

LSD was first synthesized in 1943 by Dr. Albert Hoffman as a clinical research tool to investigate the biochemical etiology of schizophrenia. It soon reached the illicit market, and its abuse began to overshadow the research effort.

The abuse of hallucinogens reached a peak in the late 1960s, waned during the 1970s, and returned to favor in the 1980s with the so-called designer drugs (e.g., 3,4-methylenedioxyamphetamine [MDMA], also known as "Molly" or "ecstasy," and methoxyamphetamine [MDA]). Another hallucinogen, PCP, originally was developed in the 1950s as an anesthetic, but this use was discontinued because of serious adverse effects. It continues to be used illegally and is often combined with cannabis. A number of deaths have been directly attributed to the use of PCP, and numerous accidental deaths have occurred as a result of overdose and of the behavioral changes the drug precipitates. A derivative of PCP, ketamine, is also used as a preoperative anesthetic and abused for its psychedelic properties. It produces effects similar to but somewhat less intense than those of PCP. Ketamine is also currently being studied for potential benefits in the treatment of depression and posttraumatic stress disorder.

Several therapeutic uses of LSD have been proposed, including the treatment of chronic alcoholism

TABLE 23–5 **Hallucinogens**		
CATEGORIES	GENERIC (TRADE) NAMES	COMMON STREET NAMES
Naturally occurring hallucinogens	Mescaline (the primary active ingredient of the peyote cactus) Psilocybin and psilocin (active ingredients of *Psilocybe* mushrooms) Ololiuqui (morning glory seeds), *Salvia divinorum*	Cactus, mesc, mescal, half moon, big chief, bad seed, peyote Magic mushroom, God's flesh, shrooms Heavenly blue, pearly gates, flying saucers, salvia
Synthetic compounds	Lysergic acid diethylamide (LSD)—synthetically produced from a fungal substance found on rye or a chemical substance found in morning glory seeds Dimethyltryptamine (DMT) and diethyltryptamine (DET)—chemical analogues of tryptamine 2,5-Dimethoxy-4-methylamphetamine (DOM) Phencyclidine (PCP) Ketamine (Ketalar) 3,4-Methylene-dioxyamphetamine (MDMA)* Methoxy-amphetamine (MDA) 3,4-methylenedioxypyrovalerone (MDPV)* 4-methylmethcathinone (mephedrone, 4-MMC)* Methylone*	Acid, cube, big D, California sunshine, microdots, blue dots, sugar, orange wedges, peace tablets, purple haze, cupcakes Businessman's trip STP (serenity, tranquility, peace) Angel dust, hog, peace pill, rocket fuel Special K, vitamin K, kit kat XTC, ecstasy, Adam, Eve Love drug Bath salts (also called blue silk, cloud 9, ivory wave, vanilla sky, white knight, and others)

*Cross-listed with the CNS stimulants.

and the reduction of intractable pain such as occurs in malignant disease. A great deal more research is required regarding the therapeutic uses of LSD. At this time, there is no real evidence of the safety and efficacy of this drug in humans.

Patterns of Use

Use of hallucinogens is usually episodic. Because cognitive and perceptual abilities are so markedly affected by these substances, the user must set aside time from normal daily activities for indulgence. According to a national study in 2014, 1.2 million people reported using hallucinogens in the prior month (SAMHSA, 2015).

LSD, like other hallucinogens, does not lead to the development of physical addiction or withdrawal symptoms (Sadock et al., 2015). However, tolerance for LSD and other hallucinogens develops quickly and to a high degree. In fact, tolerance is complete after 3 to 4 consecutive days of use. Recovery from tolerance also occurs very rapidly (in 4 to 7 days), so the individual is able to achieve the desired effect from the drug repeatedly and often.

PCP is usually taken episodically, in binges that can last for several days. However, some chronic users take the substance daily. Physical addiction does not occur with PCP; however, psychological addiction characterized by craving for the drug has been reported in chronic users, as has the development of tolerance. Tolerance apparently develops quickly with frequent use.

Psilocybin is an ingredient of the *Psilocybe* mushroom indigenous to the United States and Mexico. Ingestion of these mushrooms produces an effect similar to that of LSD but of a shorter duration. This hallucinogenic chemical can now be produced synthetically.

Mescaline is the only hallucinogenic compound used legally for religious purposes today by members of the Native American Church of the United States. It is the primary active ingredient of the peyote cactus. Neither physical nor psychological addiction occurs with the use of mescaline, although as with other hallucinogens, tolerance can develop quickly with frequent use.

Salvia is an herb from the mint family that has hallucinogenic effects when dried leaves are chewed, extracted juices are consumed, or smoke from the leaves is inhaled. This particular hallucinogen is advertised and sold over the Internet, since it is not currently regulated by the Controlled Substances Act, but some states and countries have limited or banned its use (NIDA, 2015).

Among the most potent hallucinogens of the current drug culture are those categorized as amphetamine derivatives. These include 2,5-dimethoxy-4-methylamphetamine (DOM, STP), MDMA, and MDA. At lower doses, these drugs produce the "high" associated with CNS stimulants. At higher doses, hallucinogenic effects occur. These drugs have existed for many years but were rediscovered in the mid-1980s. Because of the rapid increase in recreational use, the DEA imposed an emergency classification of MDMA as a

Schedule I drug in 1985. MDMA, or ecstasy, is a synthetic drug with both stimulant and hallucinogenic qualities. It has a chemical structure similar to methamphetamine and mescaline and has become widely available throughout the world. Because of its growing popularity, the demand for this drug has led to tablets and capsules being sold as ecstasy that are not pure MDMA. Many contain drugs such as methamphetamine, PCP, amphetamine, ketamine, and *p*-methoxyamphetamine (PMA, a stimulant with hallucinogenic properties; more toxic than MDMA). This practice has increased the dangers associated with MDMA use.

Effects on the Body

The effects produced by the various hallucinogenics are highly unpredictable. The variety of effects may be related to dosage, the mental state of the individual, and the environment in which the substance is used. Some common effects have been reported (APA, 2013; Julien, 2014; Sadock et al., 2015).

Physiological Effects

- Nausea and vomiting
- Chills
- Pupil dilation
- Increased pulse, blood pressure, and temperature
- Mild dizziness
- Trembling
- Loss of appetite
- Insomnia
- Sweating
- A slowing of respirations
- Elevation in blood sugar

Psychological Effects

- Heightened response to color, texture, and sounds
- Heightened body awareness
- Distortion of vision
- Sense of slowed time
- All feelings magnified: love, lust, hate, joy, anger, pain, terror, despair
- Fear of losing control
- Paranoia, panic
- Euphoria, bliss
- Projection of self into dreamlike images
- Serenity, peace
- Depersonalization
- Derealization
- Increased libido

The effects of hallucinogens are not always pleasurable for the user. Two types of toxic reactions are known to occur. The first is the *panic reaction,* or "bad trip." Symptoms include intense anxiety, fear, and stimulation. The individual hallucinates and fears going insane. Paranoia and acute psychosis may be evident.

The second type of toxic reaction to hallucinogens is the flashback. This phenomenon refers to the transient, spontaneous repetition of a previous LSD-induced experience that occurs without taking the substance. The *DSM*-5 (APA, 2013) refers to this as *Hallucinogen Persisting Perception Disorder.* Various studies have reported that 15 to 80 percent of hallucinogen users report having experienced flashbacks (Sadock et al., 2015). These episodes typically last for a few minutes or less.

Hallucinogen Intoxication

Symptoms of hallucinogen intoxication develop during or shortly after hallucinogen use. Maladaptive behavioral or psychological changes include marked anxiety or depression, ideas of reference (a type of delusional thinking that all activity within one's environment is "referred to" [about] one's self), fear of losing one's mind, paranoid ideation, and impaired judgment (APA, 2013). Perceptual changes occur while the individual is fully awake and alert and include intensification of perceptions, depersonalization, derealization, illusions, hallucinations, and synesthesias (APA, 2013). Because hallucinogens are sympathomimetics, they can cause tachycardia, hypertension, sweating, blurred vision, papillary dilation, and tremors (Black & Andreasen, 2014).

Symptoms of PCP intoxication are unpredictable. Specific symptoms are dose related and may be manifested by impulsiveness, impaired judgment, assaultiveness, and belligerence, or the individual may appear calm, stuporous, or comatose. Physical symptoms include vertical or horizontal nystagmus, hypertension, tachycardia, ataxia, diminished pain sensation, muscle rigidity, and seizures. Symptoms of ketamine intoxication appear similar to those of PCP.

General effects of MDMA (ecstasy) include increased heart rate, blood pressure, and body temperature; dehydration; confusion; insomnia; and paranoia. Overdose can result in panic attacks, hallucinations, severe hyperthermia, dehydration, and seizures. Death can occur from kidney or cardiovascular failure.

Cannabis Use Disorder
Profile of the Substance

Cannabis is the most commonly used illicit drug in the United States (NIDA, 2015) and the fourth-most commonly used psychoactive substance after caffeine, alcohol, and nicotine (Sadock et al., 2015). Cannabis has been legalized in some states for recreational and/or medicinal use. The major psychoactive ingredient of this class of substances is delta-9-tetrahydrocannabinol (THC). It occurs naturally in the plant *Cannabis sativa,* which grows readily in warm climates. Marijuana, the

most prevalent type of cannabis preparation, is composed of the dried leaves, stems, and flowers of the plant. Hashish is a more potent concentrate of the resin derived from the flowering tops of the plant. Hash oil is a very concentrated form of THC made by boiling hashish in a solvent and filtering out the solid matter (Publishers Group, 2012). Cannabis products are usually smoked in the form of loosely rolled cigarettes or may be inhaled through the use of vaporizers to reduce the irritants and toxins associated with smoking. Cannabis can also be taken orally when it is prepared in food, but about two to three times the amount of cannabis must be ingested orally to equal the potency obtained by the inhalation of its smoke (Sadock et al., 2015).

At moderate dosages, cannabis produces effects resembling alcohol and other CNS depressants. By depressing higher brain centers, they release lower centers from inhibitory influences. There has been some controversy in the past over the classification of these substances. They are not narcotics, although they are legally classified as controlled substances. They are not hallucinogens, although in very high dosages they can induce hallucinations. They are not sedative-hypnotics, although they most closely resemble these substances. Like sedative-hypnotics, their action occurs in the ascending reticular activating system.

Psychological addiction has been shown to occur with cannabis, and tolerance can occur. Controversy has existed about whether physiological addiction occurs with cannabis. In the past, symptoms of cannabis withdrawal were not considered clinically significant enough for inclusion in the *DSM*. However, the *DSM-5* Substance-Related Work Group determined that subsequent research has provided significant data to support cannabis withdrawal as a valid and reliable syndrome that can negatively impact abstinence attempts of heavy cannabis users. The diagnosis of Cannabis Withdrawal has been included in the *DSM-5*.

Common cannabis preparations are presented in Table 23–6.

Historical Aspects

Products of *Cannabis sativa* have been used therapeutically for nearly 5,000 years (Julien, 2014). Cannabis was first employed in China and India as an antiseptic and an analgesic. Its use later spread to the Middle East, Africa, and Eastern Europe.

In the United States, medical interest in the use of cannabis arose during the early part of the 19th century. Many articles were published espousing its use for varied reasons. The drug was almost as commonly used for medicinal purposes as aspirin is today and could be purchased without a prescription in any

TABLE 23–6 **Cannabinoids**		
CATEGORY	COMMON PREPARATIONS	STREET NAMES
Cannabis	Marijuana	Joint, weed, pot, grass, Mary Jane, Texas tea, locoweed, MJ, hay, stick
	Hashish	Hash, bhang, ganja, charas
Synthetic Cannabinoids	NPS (new psychoactive substances) powders or liquids To be inhaled	K2, Spice, Black Mamba, Joker, Kush

drug store. It was purported to have antibacterial and anticonvulsant capabilities, to decrease intraocular pressure, decrease pain, help in the treatment of asthma, increase appetite, and generally raise one's morale.

The drug fell out of favor primarily because of the huge variation in potency within batches of medication caused by the variations in the THC content of different plants. Other medications were favored for their greater degree of solubility and faster onset of action than cannabis products. A federal law put an end to its legal use in 1937, after an association between marijuana and criminal activity became evident. In the 1960s, marijuana became the symbol of the "antiestablishment" generation and reached its peak as a drug of abuse.

Research continues in regard to the possible therapeutic uses of cannabis. It has been shown to be effective for relieving the nausea and vomiting associated with cancer chemotherapy when other antinausea medications fail. It has also been used in the treatment of chronic pain, glaucoma, multiple sclerosis, acquired immune deficiency syndrome, and epilepsy (Sadock et al., 2015).

Advocates who praise the therapeutic usefulness and support the legalization of cannabis persist within the United States today. Such groups as the Alliance for Cannabis Therapeutics (ACT) and the National Organization for the Reform of Marijuana Laws (NORML) have lobbied extensively to allow disease sufferers easier access to the drug. The medical use of marijuana has been legalized by a number of states. The U.S. Drug Enforcement Agency (2013) has stated:

The DEA supports ongoing research into potential medicinal uses of marijuana's active ingredients. As of January 2013 there are 125 researchers registered

with the DEA to perform studies with marijuana, marijuana extracts, and non-tetrahydrocannabinol marijuana derivatives that exist in the plant, such as cannabidiol and cannabinol. Studies include evaluation of abuse potential, physical/psychological effects, adverse effects, therapeutic potential, and detection. Eighteen of the researchers are approved to conduct research with smoked marijuana on human subjects. At present, however, **the clear weight of the evidence is that smoked marijuana is harmful.** No matter what medical condition has been studied, other drugs already approved by the FDA have been proven to be safer and more effective than smoked marijuana. (p. 5)

Two medications that have components of the marijuana plant or related synthetic compounds are currently FDA approved. Dronabinol, a synthetic compound in the medication Marinol, is approved for nausea and vomiting associated with cancer treatment and for severe weight loss associated with AIDS. Nabilone, a chemical similar to THC and found in the medication Cesamet, is a similar FDA-approved drug. A third medication, Sativex, is an oromucosal spray containing THC and cannabidiol. It can be prescribed in the United States only with a special exemption from the FDA for use in select patients (Sadock et al., 2015).

Patterns of Use

In its 2014 National Survey on Drug Use and Health, SAMHSA (2015) reported that an estimated 22.2 million Americans aged 12 years or older were current illicit users of marijuana. This estimate represents almost 8.4 percent of the population ages 12 and older.

Many people incorrectly regard cannabis as a substance of low abuse potential. This lack of knowledge has promoted use of the substance by individuals who believe it is harmless. Tolerance, although it tends to decline rapidly, does occur with chronic use. As tolerance develops, physical addiction also occurs, resulting in a withdrawal syndrome upon cessation of drug use.

One controversy that exists regarding marijuana (particularly because of several statewide efforts toward legalization) is whether its use is a "gateway" to the use of other illicit drugs. DuPont (2016), the first director of the National Institute on Drug Abuse (NIDA), states that marijuana use is positively correlated with use of alcohol, tobacco, cocaine, and methamphetamine and that people addicted to marijuana are three times more likely to be addicted to heroin.

Effects on the Body

Following is a summary of some of the effects that have been attributed to marijuana usage. Undoubtedly, as research continues, evidence of additional physiological and psychological effects will be made available.

Cardiovascular Effects

Cannabis ingestion induces tachycardia and orthostatic hypotension (NIH, 2012). With the decrease in blood pressure, myocardial oxygen supply is decreased. Tachycardia in turn increases oxygen demand.

Respiratory Effects

Marijuana produces a greater amount of "tar" than its equivalent weight in tobacco. Because of the method by which marijuana is smoked—that is, the smoke is held in the lungs for as long as possible to achieve the desired effect—larger amounts of tar are deposited in the lungs, promoting deleterious effects.

Although the initial reaction to the inhalation of marijuana is bronchodilation, thereby facilitating respiratory function, chronic use results in obstructive airway disorders (NIH, 2012). Frequent marijuana users often have laryngitis, bronchitis, cough, and hoarseness. Cannabis smoke contains more carcinogens than tobacco smoke; therefore, lung damage and cancer are real risks for heavy users (NIH, 2012).

Reproductive Effects

Some studies have shown that with heavy marijuana use, men may have a decrease in sperm count, motility, and structure. In women, heavy marijuana use may result in a suppression of ovulation, disruption in menstrual cycles, and alteration of hormone levels.

Central Nervous System Effects

Acute CNS effects of marijuana are dose related. Many people report a feeling of being high—the equivalent of being "drunk" on alcohol. Symptoms include feelings of euphoria, relaxed inhibitions, disorientation, depersonalization, and relaxation. At higher doses, sensory alterations may occur, including impairment in judgment of time and distance, recent memory, and learning ability. Physiological symptoms may include tremors, muscle rigidity, and conjunctival redness. Toxic effects are generally characterized by panic reactions. Very heavy usage has been shown to precipitate an acute psychosis that is self-limited and short-lived once the drug is removed from the body (Julien, 2014).

Heavy long-term cannabis use is also associated with a condition called *amotivational syndrome*. Amotivational syndrome is defined as lack of motivation to persist in or complete a task that requires ongoing attention. Persons are described as "apathetic, anergic, usually gaining weight, and appearing slothful" (Sadock et al., 2015, p. 647). Evidence supports that long-term use also impairs cognitive functions of memory, attention, and organization; these impairments may also

contribute to some of the symptoms apparent in amotivational syndrome.

Sexual Function

Marijuana is reported to enhance the sexual experience in both men and women. The intensified sensory awareness and the slowness of time perception are thought to increase sexual satisfaction. Marijuana also enhances sexual function by releasing inhibitions for certain activities that would normally be restrained.

Cannabis Intoxication

Cannabis intoxication is evidenced by the presence of clinically significant behavioral or psychological changes that develop during or shortly after cannabis use. Symptoms include impaired motor coordination, euphoria, anxiety, a sensation of slowed time, impaired judgment and memory, and social withdrawal. Physical symptoms include conjunctival injection (red eyes), increased appetite, dry mouth, and tachycardia (APA, 2013). The impairment of motor skills lasts for 8 to 12 hours and interferes with the operation of motor vehicles. These effects are additive to those of alcohol, which is commonly used in combination with cannabis (Sadock et al., 2015). Cannabis intoxication delirium is marked by significant cognitive impairment and difficulty performing tasks. Higher doses also impair level of consciousness.

NIDA (2015) reported a recent trend in overdoses associated with synthetic cannabinoids (such as K2, Spice, and others). These chemicals are related to THC but are significantly more powerful and dangerous than marijuana. Symptoms include agitation, high blood pressure, shaking and seizures, nausea and vomiting, hallucinations and paranoia, and violent behavior.

Cannabis Withdrawal

The *DSM-5* describes a syndrome of symptoms that occurs upon cessation of heavy, prolonged cannabis use. Symptoms occur within a week following cessation of use and may include any of the following:

■ Irritability, anger, or aggression
■ Nervousness, restlessness, or anxiety
■ Sleep difficulty (e.g., insomnia, disturbing dreams)
■ Decreased appetite or weight loss
■ Depressed mood
■ Physical symptoms, such as abdominal pain, tremors, sweating, fever, chills, or headache

Tables 23–7 and 23–8 include summaries of the psychoactive substances, including symptoms of intoxication, withdrawal, use, overdose, possible therapeutic uses, and trade and common names by which they may be referred. The dynamics of substance use disorders using the transactional model of stress and adaptation are presented in Figure 23–3.

Application of the Nursing Process

Assessment

In the pre-introductory phase of relationship development, the nurse must examine his or her feelings about working with a client who abuses substances. If these behaviors are viewed by the nurse as morally wrong and he or she has internalized these attitudes from very early in life, it may be difficult to suppress judgmental feelings. The role that alcohol or other substances has played (or plays) in the life of the nurse most certainly will affect the way in which he or she interacts with a client who has a substance use disorder.

How are attitudes examined? Some individuals may have sufficient ability for introspection to recognize whether they have unresolved issues related to substance abuse. For others, it may be more helpful to discuss these issues in a group situation, where insight may be gained from feedback regarding the perceptions of others.

Whether alone or in a group, the nurse may gain a greater understanding about attitudes and feelings related to substance abuse by responding to the following types of questions. As written here, the questions are specific to alcohol, but they could be adapted for any substance.

■ What are my drinking patterns?
■ If I drink, why do I drink? When, where, and how much?
■ If I don't drink, why do I abstain?
■ Am I comfortable with my drinking patterns?
■ If I decided not to drink any more, would that be a problem for me?
■ What did I learn from my parents about drinking?
■ Have my attitudes changed as an adult?
■ What are my feelings about people who become intoxicated?
■ Does it seem more acceptable for some individuals than for others?
■ Do I ever use terms such as "sot," "drunk," or "boozer" to describe some individuals who overindulge, yet I overlook it in others?
■ Do I ever overindulge myself?
■ Has the use of alcohol (by me or others) affected my life in any way?
■ Do I see alcohol/drug abuse as a sign of weakness? A moral problem? An illness?

Unless nurses fully understand and accept their own attitudes and feelings, they cannot be empathetic toward clients' problems. Clients in recovery need to know they are accepted for themselves, regardless of past behaviors. Nurses must be able to separate the client from the behavior and to accept that individual with unconditional positive regard.

TABLE 23–7 Psychoactive Substances: A Profile Summary

CLASS OF DRUGS	SYMPTOMS OF USE	THERAPEUTIC USES	SYMPTOMS OF OVERDOSE	TRADE NAMES	COMMON NAMES
CNS DEPRESSANTS					
Alcohol	Relaxation, loss of inhibitions, lack of concentration, drowsiness, slurred speech, sleep	Antidote for methanol consumption; ingredient in many pharmacological concentrates	Nausea, vomiting; shallow respirations; cold, clammy skin; weak, rapid pulse; coma; possible death	Ethyl alcohol, beer, gin, rum, vodka, bourbon, whiskey, liqueurs, wine, brandy, sherry, champagne	Booze, alcohol, liquor, drinks, cocktails, highballs, nightcaps, moonshine, white lightning, firewater
Other (barbiturates and nonbarbiturates)	Same as alcohol	Relief from anxiety and insomnia; as anticonvulsants and anesthetics	Anxiety, fever, agitation, hallucinations, disorientation, tremors, delirium, convulsions, possible death	Seconal, Amytal, Nembutal, Valium, Librium, Noctec, Miltown	Red birds, yellow birds, blue birds, Blues/yellows, Green & whites, Mickies, Downers
CNS STIMULANTS					
Amphetamines and related drugs	Hyperactivity, agitation, euphoria, insomnia, loss of appetite	Management of narcolepsy, hyperkinesia, and weight control	Cardiac arrhythmias, headache, convulsions, hypertension, rapid heart rate, coma, possible death	Dexedrine, Didrex, Tenuate, Bontril, Ritalin, Focalin, Meridia, Provigil	Uppers, pep pills, wakeups, bennies, eye-openers, speed, black beauties, sweet As
Cocaine	Euphoria, hyperactivity, restlessness, talkativeness, increased pulse, dilated pupils, rhinitis		Hallucinations, convulsions, pulmonary edema, respiratory failure, coma, cardiac arrest, possible death	Cocaine hydrochloride	Coke, flake, snow, dust, happy dust, gold dust, girl, Cecil, C, toot, blow, crack
Synthetic stimulants	Agitation, insomnia, irritability, dizziness, decreased ability to think clearly, increased heart rate, chest pains	Depression, paranoia, delusions, suicidal thoughts, seizures, panic attacks, nausea, vomiting, heart attack, stroke	Mephedrone, MDPV (3-4 methylenedioxypyrovalerone)	Bath salts, bliss, vanilla sky, ivory wave, purple wave	Increased heart rate, increased blood pressure, nosebleeds, hallucinations, aggressive behavior
OPIOIDS	Euphoria, lethargy, drowsiness, lack of motivation, constricted pupils	As analgesics; antidiarrheals, and antitussives; methadone in substitution therapy; heroin has no therapeutic use	Shallow breathing, slowed pulse, clammy skin, pulmonary edema, respiratory arrest, convulsions, coma, possible death	Heroin, Morphine, Codeine, Dilaudid, Demerol, Dolophine, Percodan, Talwin, Opium	Snow, stuff, H, harry, horse, M, morph, Miss Emma, Schoolboy, Lords, Doctors, Dollies, Perkies, Ts, Big O, black stuff

Categories	Symptoms	Therapeutic Uses	Symptoms of Overdose	Generic (Trade)	Common/Street Names
HALLUCINOGENS	Visual hallucinations, disorientation, confusion, paranoid delusions, euphoria, anxiety, panic, increased pulse	LSD has been proposed in the treatment of chronic alcoholism, and in the reduction of intractable pain	Agitation, extreme hyperactivity, violence, hallucinations, psychosis, convulsions, possible death	LSD PCP	Acid, cube, big D Angel dust, hog, peace pill
				Mescaline DMT STP, DOM MDMA Ketamine	Mesc Businessman's trip Serenity and peace Ecstasy, XTC Special K, vitamin K, kit kat
				MDPV	Bath salts
CANNABINOLS	Relaxation, talkativeness, lowered inhibitions, euphoria, mood swings	Marijuana has been used for relief of nausea and vomiting associated with antineoplastic chemotherapy and to reduce eye pressure in glaucoma	Fatigue, paranoia, delusions, hallucinations, possible psychosis	Cannabis Hashish	Marijuana, pot, grass, joint, Mary Jane, MJ Hash, rope, Sweet Lucy

TABLE 23–8	Summary of Symptoms Associated With the Syndromes of Intoxication and Withdrawal		
CLASS OF DRUGS	INTOXICATION	WITHDRAWAL	COMMENTS
Alcohol	Aggressiveness, impaired judgment, impaired attention, irritability, euphoria, depression, emotional lability, slurred speech, incoordination, unsteady gait, nystagmus, flushed face	Tremors, nausea/vomiting, malaise, weakness, tachycardia, sweating, elevated blood pressure, anxiety, depressed mood, irritability, hallucinations, headache, insomnia, seizures	Alcohol withdrawal begins within 4–6 hr after last drink. May progress to delirium tremens on second or third day. Use of Librium or Serax is common for substitution therapy.
Amphetamines and related substances	Fighting, grandiosity, hypervigilance, psychomotor agitation, impaired judgment, tachycardia, pupillary dilation, elevated blood pressure, perspiration or chills, nausea and vomiting	Anxiety, depressed mood, irritability, craving for the substance, fatigue, insomnia or hypersomnia, psychomotor agitation, paranoid and suicidal ideation	Withdrawal symptoms usually peak within 2–4 days, although depression and irritability may persist for months. Antidepressants may be used.
Caffeine	Restlessness, nervousness, excitement, insomnia, flushed face, diuresis, gastrointestinal complaints, muscle twitching, rambling flow of thought and speech, cardiac arrhythmia, periods of inexhaustibility, psychomotor agitation	Headache	Caffeine is contained in coffee, tea, colas, cocoa, chocolate, some over-the-counter analgesics, "cold" preparations, and stimulants.
Cannabis	Euphoria, anxiety, suspiciousness, sensation of slowed time, impaired judgment, social withdrawal, tachycardia, conjunctival redness, increased appetite, hallucinations	Restlessness, irritability, insomnia, loss of appetite, depressed mood, tremors, fever, chills, headache, stomach pain	Intoxication occurs immediately and lasts about 3 hours. Oral ingestion is more slowly absorbed and has longer-lasting effects.
Cocaine	Euphoria, fighting, grandiosity, hypervigilance, psychomotor agitation, impaired judgment, tachycardia, elevated blood pressure, pupillary dilation, perspiration or chills, nausea/vomiting, hallucinations, delirium	Depression, anxiety, irritability, fatigue, insomnia or hypersomnia, psychomotor agitation, paranoid or suicidal ideation, apathy, social withdrawal	Large doses of the drug can result in convulsions or death from cardiac arrhythmias or respiratory paralysis.
Inhalants	Belligerence, assaultiveness, apathy, impaired judgment, dizziness, nystagmus, slurred speech, unsteady gait, lethargy, depressed reflexes, tremor, blurred vision, stupor or coma, euphoria, irritation around eyes, throat, and nose		Intoxication occurs within 5 minutes of inhalation. Symptoms last 60–90 minutes. Large doses can result in death from CNS depression or cardiac arrhythmia.
Nicotine		Craving for the drug, irritability, anger, frustration, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite, weight gain, tremor, headaches, insomnia	Symptoms of withdrawal begin within 24 hours of last drug use and decrease in intensity over days, weeks, or sometimes longer.
Opioids	Euphoria, lethargy, somnolence, apathy, dysphoria, impaired judgment, pupillary constriction, drowsiness, slurred speech, constipation, nausea, decreased respiratory rate and blood pressure	Craving for the drug, nausea/vomiting, muscle aches, lacrimation or rhinorrhea, pupillary dilation, piloerection or sweating, diarrhea, yawning, fever, insomnia	Withdrawal symptoms appear within 6–8 hours after last dose, reach a peak in the second or third day, and subside in 5–10 days. Times are shorter with meperidine and longer with methadone.

TABLE 23–8	**Summary of Symptoms Associated With the Syndromes of Intoxication and Withdrawal—cont'd**		
CLASS OF DRUGS	**INTOXICATION**	**WITHDRAWAL**	**COMMENTS**
Phencyclidine and related substances	Belligerence, assaultiveness, impulsiveness, psychomotor agitation, impaired judgment, nystagmus, increased heart rate and blood pressure, diminished pain response, ataxia, dysarthria, muscle rigidity, seizures, hyperacusis, delirium		Delirium can occur within 24 hours after use of phencyclidine or may occur up to a week following recovery from an overdose of the drug.
Sedatives, hypnotics, and anxiolytics	Disinhibition of sexual or aggressive impulses, mood lability, impaired judgment, slurred speech, incoordination, unsteady gait, impairment in attention or memory disorientation, confusion	Nausea/vomiting, malaise, weakness, tachycardia, sweating, anxiety, irritability, orthostatic hypotension, tremor, insomnia, seizures	Withdrawal may progress to delirium, usually within 1 week of last use. Long-acting barbiturates or benzodiazepines may be used in withdrawal substitution therapy.

Motivational Interviewing

Motivational interviewing is an approach that can be used in the assessment and intervention process for clients with any disorder, although it first gained popularity in treatment of clients with substance use disorders. It uses skills such as empathy, validation, open-ended questions, and reflection to explore the client's motivation, strengths, and readiness for change. Some of the preceding questions could easily be reframed to explore the client's attitudes and feelings. Through this process, the client is empowered to become an active partner in treatment goals while exploring reasons for resistance to behavior change. For example, rather than telling a client that he or she must abstain from alcohol and must attend 12-step meetings, the health-care professional helps the client articulate what he or she wants to achieve and then facilitates the process of exploring advantages and disadvantages of desired behavior change.

This is a patient-centered approach that encourages empowerment and active engagement, and as such, it articulates well with two current trends in psychiatric-mental health nursing care: recognizing the importance of patient-centered care as an essential nursing competency (Institute of Medicine, 2003) and the recovery model (see Chapter 21, The Recovery Model, for further discussion of this model).

Assessment Tools

Nurses often perform the admission interview. A variety of assessment tools are appropriate for use in chemical dependency units. A nursing history and assessment tool was presented in Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing. With some adaptation, it is an appropriate instrument for creating a database on clients who abuse substances. Box 23–2 presents a drug history and assessment that could be used in conjunction with the general biopsychosocial assessment.

The Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar) is an excellent tool that is used by many hospitals to assess risk and severity of withdrawal from alcohol. It may be used for initial assessment as well as ongoing monitoring of alcohol withdrawal symptoms. A copy of the CIWA-Ar is presented in Box 23–3.

Other screening tools exist for determining whether an individual has a problem with substances. Two such tools developed by the American Psychiatric Association for the diagnosis of alcoholism include the Michigan Alcoholism Screening Test and the CAGE Questionnaire (Boxes 23–4 and 23–5). Some psychiatric units administer these surveys to all admitted clients to help determine if there is a secondary alcohol problem in addition to the psychiatric problem for which the client is being admitted (sometimes called **dual diagnosis**). These tools can be adapted to use in diagnosing problems with other drugs as well.

Dual Diagnosis

If the client is diagnosed with both mental illness and a coexisting substance disorder, he or she may be assigned to a special program that targets both problems. Traditional counseling approaches use more confrontation than is considered appropriate for clients with dual diagnoses. Most dual diagnosis programs take a supportive, less confrontational approach.

Peer support groups are an important part of the treatment program. Group members offer encouragement and practical advice to each other.

Precipitating Event
(Any event sufficiently stressful to threaten an already weak ego;
the precipitating event for the dependent person may be the onset of withdrawal symptoms)

Predisposing Factors
Genetic Influences: Possible hereditary and biochemical factors
Past Experiences: Negative role modeling, positive conditioning, cultural/ethnic influences
Existing Conditions: Retarded ego development, addictive personality traits

Cognitive appraisal

* Primary *

(Perceived threat to self-concept or physical integrity)

* Secondary *

Ineffective coping mechanisms related to diminished ego strength
Defense mechanisms utilized: denial, regression, rationalization, projection

Quality of response

Adaptive   Maladaptive

Substance Abuse

Substance Dependence

1. Uses substances knowing use causes problems in one or more aspects of life
2. Uses substances in physically hazardous situations

1. Inability to control or stop use
2. Uses greater amounts to achieve effects
3. Uses substances knowing use causes problems in one or more aspects of life
4. Develops withdrawal symptoms if ceases or cuts down on use
5. Takes substances to relieve or avoid withdrawal symptoms

FIGURE 23–3 The dynamics of substance use disorders using the transactional model of stress and adaptation.

BOX 23–2 Drug History and Assessment*

1. When you were growing up, did anyone in your family drink alcohol or take other kinds of drugs?
2. If so, how did the substance use affect the family situation?
3. When did you have your first drink/drugs?
4. How long have you been drinking/taking drugs on a regular basis?
5. What is your pattern of substance use?
   a. When do you use substances?
   b. What do you use?
   c. How much do you use?
   d. Where are you and with whom when you use substances?
6. When did you have your last drink/drug? What was it and how much did you consume?
7. Does using the substance(s) cause problems for you? Describe. Include family, friends, job, school, other.
8. Have you ever experienced injury as a result of substance use?
9. Have you ever been arrested or incarcerated for drinking/using drugs?
10. Have you ever tried to stop drinking/using drugs? If so, what was the result? Did you experience any physical symptoms, such as tremors, headache, insomnia, sweating, or seizures?
11. Have you ever experienced loss of memory for times when you have been drinking/using drugs?
12. Describe a typical day in your life.
13. Are there any changes you would like to make in your life? If so, what are they?
14. What plans or ideas do you have for seeing that these changes occur?

*To be used in conjunction with general biopsychosocial nursing history and assessment tool (Chapter 9, The Nursing Process in Psychiatric/Mental Health Nursing).

BOX 23–3 Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised

Patient: Date: Time:

Pulse or heart rate, taken for one minute: Blood pressure:

NAUSEA AND VOMITING—Ask "Do you feel sick to your stomach? Have you vomited?" Observation.

0 no nausea and no vomiting
1 mild nausea with no vomiting
2
3
4 intermittent nausea with dry heaves
5
6
7 constant nausea, frequent dry heaves and vomiting

TREMOR—Arms extended and fingers spread apart. Observation.

0 no tremor
1 not visible, but can be felt fingertip to fingertip
2
3
4 moderate, with patient's arms extended
5
6
7 severe, even with arms not extended

TACTILE DISTURBANCES—Ask "Have you any itching, pins and needles sensations, any burning, any numbness, or do you feel bugs crawling on or under your skin?" Observation.

0 none
1 very mild itching, pins and needles, burning or numbness
2 mild itching, pins and needles, burning or numbness
3 moderate itching, pins and needles, burning or numbness
4 moderately severe hallucinations
5 severe hallucinations
6 extremely severe hallucinations
7 continuous hallucinations

AUDITORY DISTURBANCES—Ask "Are you more aware of sounds around you? Are they harsh? Do they frighten you? Are you hearing anything that is disturbing to you? Are you hearing things you know are not there?" Observation.

0 not present
1 very mild harshness or ability to frighten
2 mild harshness or ability to frighten
3 moderate harshness or ability to frighten
4 moderately severe hallucinations
5 severe hallucinations
6 extremely severe hallucinations
7 continuous hallucinations

BOX 23–3 Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised–cont'd

PAROXYSMAL SWEATS—Observation.

0 no sweat visible
1 barely perceptible sweating, palms moist
2
3
4 beads of sweat obvious on forehead
5
6
7 drenching sweats

ANXIETY—Ask "Do you feel nervous?" Observation.

0 no anxiety, at ease
1 mild anxious
2
3
4 moderately anxious, or guarded, so anxiety is inferred
5
6
7 equivalent to acute panic states as seen in severe delirium or acute schizophrenic reactions

AGITATION—Observation

0 normal activity
1 somewhat more than normal activity
2
3
4 moderately fidgety and restless
5
6
7 paces back and forth during most of the interview, or constantly thrashes about

The CIWA-Ar is not copyrighted and may be reproduced freely. This assessment for monitoring withdrawal symptoms requires approximately 5 minutes to administer. The maximum score is 67 (see instrument). Patients scoring less than 10 do not usually need additional medication for withdrawal. _____

VISUAL DISTURBANCES—Ask "Does the light appear to be too bright? Is its color different? Does it hurt your eyes? Are you seeing anything that is disturbing to you? Are you seeing things you know are not there?" Observation.
0 not present
I very mild sensitivity
2 mild sensitivity
3 moderate sensitivity
4 moderately severe hallucinations
5 severe hallucinations
6 extremely severe hallucinations
7 continuous hallucinations

HEADACHE, FULLNESS IN HEAD—Ask "Does your head feel different? Does it feel like there is a band around your head?" Do not rate for dizziness or lightheadedness. Otherwise, rate severity.
0 not present
1 very mild
2 mild
3 moderate
4 moderately severe
5 severe
6 very severe
7 extremely severe

ORIENTATION AND CLOUDING OF SENSORIUM—Ask "What day is this? Where are you? Who am I?"
0 oriented and can do serial additions
1 cannot do serial additions or is uncertain about date
2 disoriented for date by no more than 2 calendar days
3 disoriented for date by more than 2 calendar days
4 disoriented for place/or person

Total CIWA-Ar Score _____
Rater's Initials _____
Maximum Possible Score 67

Psychodynamic therapy can be useful for some individuals with dual diagnoses by delving into the personal history of how psychiatric disorders and substance abuse have reinforced one another and how the cycle can be broken. Cognitive and behavioral therapies are helpful in training clients to monitor moods and thought patterns that lead to substance abuse. Teaching clients about coping skills and stress management also promotes skills in maintaining abstinence and dealing with substance cravings.

BOX 23–4 Michigan Alcoholism Screening Test (MAST)

Answer the following questions by placing an X under yes or no.*	Yes	No
1. Do you enjoy a drink now and then?	0	0
2. Do you feel you are a normal drinker? (By normal we mean you drink less than or as much as most people.)		2
3. Have you ever awakened the morning after some drinking the night before and found that you could not remember a part of the evening?	2	
4. Does your wife, husband, parent, or other near relative ever worry or complain about your drinking?	1	
5. Can you stop drinking without a struggle after one or two drinks?		2
6. Do you ever feel guilty about your drinking?	1	
7. Do friends or relatives think you are a normal drinker?		2
8. Are you able to stop drinking when you want to?		2
9. Have you ever attended a meeting of Alcoholics Anonymous (AA)?	5	
10. Have you gotten into physical fights when drinking?	1	
11. Has your drinking ever created problems between you and your wife, husband, a parent, or other relative?	2	
12. Has your wife, husband, or another family member ever gone to anyone for help about your drinking?	2	
13. Have you ever lost friends because of your drinking?	2	
14. Have you ever gotten into trouble at work or school because of drinking?	2	
15. Have you ever lost a job because of drinking?	2	
16. Have you ever neglected your obligations, your family, or your work for 2 or more days in a row because you were drinking?	2	
17. Do you drink before noon fairly often?	1	
18. Have you ever been told you have liver trouble? Cirrhosis?	2	
19. After heavy drinking have you ever had delirium tremens (DTs) or severe shaking or heard voices or seen things that really were not there?	5	
20. Have you ever gone to anyone for help about your drinking?	5	
21. Have you ever been in a hospital because of drinking?	5	
22. Have you ever been a patient in a psychiatric hospital or on a psychiatric ward of a general hospital where drinking was part of the problem that resulted in hospitalization?	2	
23. Have you ever been seen at a psychiatric or mental health clinic or gone to any doctor, social worker, or clergyman for help with any emotional problem, where drinking was part of the problem?	2	
24. Have you ever been arrested for drunk driving, driving while intoxicated, or driving under the influence of alcoholic beverages? (If yes, how many times? _____)	2 ea	
25. Have you ever been arrested, or taken into custody, even for a few hours, because of other drunk behavior? (If yes, how many times? _____)	2 ea	

Items are scored under the response that would indicate a problem with alcohol.
Method of scoring:
0–3 points = no problem with alcohol
4 points = possible problem with alcohol
5 or more = indicates problem with alcohol
From Selzer, M.L. (1971) The Michigan alcohol screening test: The quest for a new diagnostic instrument. American Journal of Psychiatry, 127*(12),*
    1653-1658, with permission.

BOX 23–5 The CAGE Questionnaire

1. Have you ever felt you should **C**ut down on your drinking?
2. Have people **A**nnoyed you by criticizing your drinking?
3. Have you ever felt bad or **G**uilty about your drinking?
4. Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover (**E**ye-opener)?

Scoring: 2 or 3 "yes" answers strongly suggests a problem with alcohol.
From Mayfield, D., McLeod, G., & Hall, P. (1974). THE CAGE questionnaire: Validation of a new alcoholism screening instrument. American Journal of Psychiatry,
    131*(10), 1121-1123, with permission.*

Individuals with dual diagnoses should be educated about 12-step recovery programs (e.g., Alcoholics Anonymous or Narcotics Anonymous). Dual diagnosis clients are sometimes resistant to attending 12-step programs, and they often do better in substance abuse support groups specifically designed for people with psychiatric disorders.

Substance-abuse groups are usually integrated into regular programming for the psychiatric client with a dual diagnosis. An individual in a psychiatric facility or day treatment program will attend a substance abuse group periodically in lieu of another scheduled activity therapy. Topics are directed toward areas that are unique to clients with mental illness, such as mixing medications with other substances, as well as topics that are common to primary substance abusers. Individuals are encouraged to discuss their personal problems.

Continued attendance at 12-step group meetings is encouraged upon discharge from treatment. Family involvement is enlisted, and preventive strategies are outlined. Individual case management is common, and success is often promoted by this close supervision.

Diagnosis and Outcome Identification

The next step in the nursing process is to identify appropriate nursing diagnoses by analyzing the data collected during the assessment phase. The individual who abuses or is dependent on substances undoubtedly has many unmet physical and emotional needs. Table 23–9 presents a list of client behaviors and the NANDA-I nursing diagnoses that correspond to those behaviors, which may be used in planning care for the client with a substance use disorder.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with substance-related disorders.

The client:

■ Has not experienced physical injury
■ Has not caused harm to self or others
■ Accepts responsibility for own behavior
■ Acknowledges association between personal problems and use of substance(s)
■ Demonstrates more adaptive coping mechanisms that can be used in stressful situations (instead of taking substances)
■ Shows no signs or symptoms of infection or malnutrition
■ Exhibits evidence of increased self-worth by attempting new projects without fear of failure and by demonstrating less defensive behavior toward others
■ Verbalizes importance of abstaining from use of substances in order to maintain optimal wellness

TABLE 23–9 **Assigning Nursing Diagnoses to Behaviors Commonly Associated With Substance Use Disorders**	
BEHAVIORS	**NURSING DIAGNOSES**
Makes statements such as, "I don't have a problem with (substance). I can quit any time I want to." Delays seeking assistance; does not perceive problems related to use of substances; minimizes use of substances; unable to admit impact of disease on life pattern	Denial
Abuse of chemical agents; destructive behavior toward others and self; inability to meet basic needs; inability to meet role expectations; risk taking	Ineffective coping
Loss of weight, pale conjunctiva and mucous membranes, decreased skin turgor, electrolyte imbalance, anemia, drinks alcohol instead of eating	Imbalanced nutrition: Less than body requirements/Deficient fluid volume
Risk factors: Malnutrition, altered immune condition, failing to avoid exposure to pathogens	Risk for infection
Criticizes self and others, self-destructive behavior (abuse of substances as a coping mechanism), dysfunctional family background	Chronic low self-esteem
Denies that substance is harmful; continues to use substance in light of obvious consequences	Deficient knowledge
FOR THE CLIENT WITHDRAWING FROM CNS DEPRESSANTS: Risk factors: CNS agitation (tremors, elevated blood pressure, nausea and vomiting, hallucinations, illusions, tachycardia, anxiety, seizures)	Risk for injury
FOR THE CLIENT WITHDRAWING FROM CNS STIMULANTS: Risk factors: Intense feelings of lassitude and depression; "crashing," suicidal ideation	Risk for suicide

Planning and Implementation

Implementation with clients who abuse substances is a long-term process, often beginning with **detoxification** and progressing to total abstinence. The following sections present a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Risk for Injury

Risk for injury is defined as "vulnerable to physical damage due to environmental conditions interacting with the individual's adaptive and defensive resources, which may compromise health" (Herdman & Kamitsuru, 2014, p. 386).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

1. Client's condition will stabilize within 72 hours.

Long-term goal

2. Client will not experience physical injury.

Interventions

For the client in substance withdrawal

- Assess the client's level of disorientation to determine specific requirements for safety.
- Obtain a drug history, if possible. It is important to determine the type of substance(s) used, the time and amount of last use, the length and frequency of use, and the amount used on a daily basis.
- Because subjective history is often not accurate, obtain a urine sample for laboratory analysis of substance content.

- It is important to keep the client in as quiet an environment as possible. Excessive stimuli may increase client agitation. A private room is ideal.
- Observe client behaviors frequently. If seriousness of the condition warrants, it may be necessary to assign a staff person on a one-to-one basis.
- Accompany and assist the client when ambulating, and use a wheelchair for transporting the client long distances.
- Pad the headboard and side rails of the bed with thick towels to protect the client in case of a seizure.
- Suicide precautions may need to be instituted for the client withdrawing from CNS stimulants.
- Ensure that smoking materials and other potentially harmful objects are stored away from the client's access.
- Frequently orient the client to reality and the surroundings.
- Monitor the client's vital signs every 15 minutes initially and less frequently as acute symptoms subside.
- Follow the medication regimen as ordered by the physician. Common psychopharmacological intervention for substance intoxication and withdrawal is presented later in this chapter under the section "Treatment Modalities for Substance-Related Disorders."

Denial

Denial is defined as a "conscious or unconscious attempt to disavow the knowledge or meaning of an event to reduce anxiety and/or fear, leading to the detriment of health" (Herdman & Kamitsuru, 2014, p. 335). Table 23–10 presents this nursing diagnosis in care plan format.

Table 23–10 | CARE PLAN FOR A CLIENT WITH A SUBSTANCE USE DISORDER

NURSING DIAGNOSIS: DENIAL

RELATED TO: Lack of coping skills to manage anxiety

EVIDENCED BY: Statements indicating no problem with substance use

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client diverts attention away from external issues and focuses on behavioral outcomes associated with substance use.	1. Begin by working to develop a trusting nurse-client relationship. Be honest. Keep all promises.	1. Trust is the basis of a therapeutic relationship.
	2. Convey an attitude of acceptance to client. Ensure that he or she understands "It is not *you* but your *behavior* that is unacceptable."	2. An attitude of acceptance promotes feelings of dignity and self-worth.

Continued

Table 23–10 | CARE PLAN FOR A CLIENT WITH A SUBSTANCE USE DISORDER–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Long-Term Goal • Client verbalizes acceptance of responsibility for own behavior and acknowledges association between substance use and personal problems.	3. Provide information to correct misconceptions about substance abuse. Client may rationalize his or her behavior with statements such as "I'm not an alcoholic. I can stop drinking any time I want. Besides, I only drink beer," or "I only smoke pot to relax before class. So what? I know lots of people who do. Besides, you can't get hooked on pot."	3. Many myths abound regarding use of specific substances. Factual information presented in a matter-of-fact, nonjudgmental way explaining what behaviors constitute substance-related disorders may help client focus on his or her own behaviors as an illness that requires help.
	4. Identify recent maladaptive behaviors or situations that have occurred in client's life, and discuss how use of substances may have been a contributing factor.	4. The first step in decreasing use of denial is for client to see the relationship between substance use and personal problems.
	5. Use confrontation with caring. Do not allow client to fantasize about his or her lifestyle (e.g., "It is my understanding that the last time you drank alcohol, you . . ." or "The lab report shows that you were under the influence of alcohol when you had the accident that injured three people").	5. Confrontation interferes with client's ability to use denial; a caring attitude preserves self-esteem and avoids putting client on the defensive.
	6. Do not accept rationalization or projection as client attempts to make excuses or blame other people or situations for his or her behavior.	6. Rationalization and projection prolong denial that problems exist in client's life because of substance use.
	7. Encourage participation in group activities.	7. Peer feedback is often more accepted than feedback from authority figures. Peer pressure can be a strong factor, as can association with individuals who are experiencing or who have experienced similar problems.
	8. Offer immediate positive recognition of client's expressions of insight gained regarding illness and acceptance of responsibility for own behavior.	8. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.
	9. Employ motivational interviewing techniques to begin an exploration of client's motivations and readiness for change.	9. Using a patient-centered approach that includes techniques such as reflection, open-ended questions, clarification, and validation encourages client to actively engage in problem-solving.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will focus on behavioral outcomes associated with substance use.

Long-term goal

■ Client will verbalize acceptance of responsibility for own behavior and acknowledge association between substance use and personal problems.

Interventions

■ Begin by working to develop a trusting nurse-client relationship. Be honest and keep all promises.

■ Convey an attitude of acceptance to the client. Ensure that he or she understands "It is not *you* but your *behavior* that is unacceptable." An attitude of acceptance helps to promote the client's feelings of dignity and self-worth.

■ Provide information to correct misconceptions about substance abuse. The client may rationalize his or her behavior with statements such as, "I'm not an alcoholic. I can stop drinking any time I want. Besides, I only drink beer" or "I only smoke pot to relax before class. So what? I know lots of people who do. Besides, you can't get hooked on pot." Many myths abound regarding use of specific substances. Factual information presented in a matter-of-fact, nonjudgmental way explaining what behaviors constitute substance use disorders may help the client focus on his or her own behaviors as an illness that requires help.

■ Identify recent maladaptive behaviors or situations that have occurred in the client's life, and discuss how use of substances may have been a contributing factor. The first step in decreasing denial is for the client to see the relationship between substance use and personal problems.

■ Use confrontation with caring. Do not allow the client to fantasize about his or her lifestyle. Confrontation interferes with the client's ability to use denial; a caring attitude preserves self-esteem and avoids putting the client on the defensive.

> **CLINICAL PEARL**
>
> It is important to speak objectively and nonjudgmentally to a person in denial. Examples: "It is my understanding that the last time you drank alcohol, you . . ." or "The lab report shows that your blood alcohol level was 250 when you were involved in that automobile accident."

■ Acknowledge the use of rationalization or projection as the client attempts to make excuses for or blame his or her behavior on other people or situations. Rationalization and projection prolong the client's denial that problems exist secondary to substance use.

■ Encourage participation in group activities. Peer feedback is often more accepted than feedback from authority figures. Peer pressure from individuals who are experiencing or who have experienced similar problems can be powerfully influential in confronting denial as well.

■ Offer immediate positive recognition of the client's expressions of insight regarding illness and acceptance of responsibility for own behavior. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.

Ineffective Coping

Ineffective coping is defined as the "inability to form a valid appraisal of the stressors, inadequate choices of practiced responses, and/or inability to use available resources" (Herdman & Kamitsuru, 2014, p. 326).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will express true feelings about using substances as a method of coping with stress.

Long-term goal

■ Client will be able to verbalize use of adaptive coping mechanisms, instead of substance abuse, in response to stress.

Interventions

■ Spend time with the client and establish a trusting relationship.

■ Set limits on manipulative behavior. Be sure that the client knows what is acceptable, what is not, and the consequences for violating the limits set. Ensure that all staff maintain consistency with this intervention. Encourage the client to verbalize feelings, fears, and anxieties. Answer any questions he or she may have regarding the disorder. Verbalization of feelings in a nonthreatening environment may help the client come to terms with long-unresolved issues.

■ Explain the effects of substance abuse on the body. Emphasize that the prognosis is closely related to abstinence. Many clients lack knowledge about the deleterious effects of substance abuse on the body.

■ Explore with the client the options available to assist with stressful situations rather than resorting to substance use (e.g., contacting various members of Alcoholics Anonymous or Narcotics Anonymous, physical exercise, relaxation techniques, meditation).

The client may have persistently resorted to chemical use and thus possess little or no knowledge of adaptive responses to stress.

■ Provide positive reinforcement for evidence of gratification delayed appropriately. Encourage the client to be as independent as possible in performing his or her self-care. Provide positive feedback for independent decision-making and effective use of problem-solving skills.

Dysfunctional Family Processes

Dysfunctional family processes occur when "psychosocial, spiritual, and physiological functions of the family unit are chronically disorganized, which leads to conflict, denial of problems, resistance to change, ineffective problem solving, and a series of self-perpetuating crises" (Herdman & Kamitsuru, 2014, p. 290).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term coals

■ Family members will participate in individual family programs and support groups.
■ Family members will identify ineffective coping behaviors and consequences.
■ Family will initiate and plan for necessary lifestyle changes.

Long-term goal

■ Family members will take action to change self-destructive behaviors and alter behaviors that contribute to client's addiction.

Interventions

■ Review family history; explore roles of family members, current level of functioning, circumstances involving alcohol use, strengths, and areas of growth. Explore how family members have coped with the client's addiction (e.g., denial, repression, rationalization, hurt, loneliness, projection). Persons who enable also suffer from the same feelings as the client and use ineffective methods for dealing with the situation, necessitating help in learning new and effective coping skills.

■ Determine the extent of enabling behaviors evidenced by family members; explore these behaviors with each individual and the client. Enabling behaviors are those that inhibit rather than promote change. Family and friends may enable continued substance use because the user has convinced them that this is the most helpful way to show their love. The substance abuser often relies on others to cover up for his or her inability to cope with daily responsibilities, but this scenario is less likely to promote the need for change.

■ Provide information about enabling behavior and addictive disease characteristics for both the user and nonuser. Achieving awareness and knowledge of behaviors (e.g., avoiding and shielding, taking over responsibilities, rationalizing, and subserving) provides an opportunity for individuals to begin the process of change.

■ Identify and discuss the possibility of sabotage behaviors by family members. Even though family members may verbalize a desire for the individual to become substance free, the reality of interactive dynamics is that they may unconsciously not want the individual to recover, as this would affect the family members' own role in the relationship. Additionally, they may receive sympathy or attention from others (secondary gain).

■ Assist the client's partner to understand that the client's abstinence and drug use are not the partner's responsibility and that the client's use of substances may or may not change despite involvement in treatment. Partners must come to realize and accept that the only behavior they can control is their own.

■ Involve the family in plans for discharge from treatment. Substance abuse is a family illness. Because the family has been so involved in dealing with the substance use behavior, family members need help adjusting to the new behavior of sobriety/abstinence. Encourage involvement with self-help associations, such as Alcoholics Anonymous, Al-Anon, Alateen, CoDA, and professional family therapy. These organizations put the client and family in direct contact with support systems necessary for continued sobriety and assists with problem resolution.

Concept Care Mapping

The concept map care plan (see Chapter 9) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with a substance use disorder is presented in Figure 23–4.

Client and Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client/family education relevant to substance-related disorders is presented in Box 23–6. Sample client teaching guides are available online.

Evaluation

The final step of the nursing process involves reassessment to determine if the nursing interventions have been effective in achieving the intended goals

Clinical Vignette: John, age 56, was arrested for driving while under the influence of alcohol. He ran a red light and caused an accident in which another person was injured. He was taken to the hospital and admitted to the alcohol and drug detoxification unit. Following an unremarkable detoxification, he was transferred to the rehab unit. He says to the nurse, "I don't have a problem with alcohol. I can quit any time I want to. Besides, what does it hurt?" He tells the nurse that he has a very stressful job, and drinking alcohol helps him relax. He is pale and underweight for his height. He admits that sometimes he doesn't eat regular meals but instead drinks until he goes to sleep. His skin is dry and flaky. Laboratory results indicate evidence of malnutrition and dehydration. The nurse develops the following concept map care plan for John.

Signs and Symptoms
- "I don't have a problem with alcohol. I can quit any time I want to."

Signs and Symptoms
- Use of alcohol as a coping mechanism

Signs and Symptoms
- Dry skin
- Pale
- Underweight
- Lab reports positive for malnutrition

Signs and Symptoms
- Unable to verbalize physiological effects of alcohol abuse
- "What does it hurt?"

Nursing Diagnosis
Ineffective denial

Nursing Diagnosis
Ineffective coping

Nursing Diagnosis
Imbalanced nutrition: less than body requirements

Nursing Diagnosis
Deficient knowledge

Nursing Actions
- Accept client unconditionally.
- Identify ways in which use of alcohol has contributed to maladaptive behaviors.
- Do not allow client to blame others for behaviors associated with alcohol abuse.

Nursing Actions
- Set limits on manipulative behavior.
- Practice alternative, more adaptive coping strategies.
- Give positive feedback for delaying gratification and using adaptive coping strategies.

Nursing Actions
- Consult dietitian.
- Measure I&O and daily weights.
- Monitor protein intake of client with impaired liver function.
- Restrict sodium intake to minimize fluid retention.
- Provide small, frequent feedings of nonirritating foods.

Nursing Actions
- Assess client's level of knowledge and readiness to learn.
- Include significant others in teaching.
- Provide information about physical effects of alcohol on body.
- Teach about possibility of using disulfiram.

Outcomes
- Verbalizes correlation between use of alcohol and personal problems
- Accepts responsibility for own behaviors

Outcomes
- Verbalizes and demonstrates adaptive coping strategies as alternatives to alcohol use in response to stress

Outcomes
- Vital signs, blood pressure, and lab values are within normal limits
- Verbalizes importance of adequate nutrition

Outcomes
- Verbalizes effects of alcohol on body
- Verbalizes knowledge about use of medication to assist with abstinence

FIGURE 23–4 Concept map care plan for client with alcoholism.

of care. Evaluation of the client with a substance-related disorder may be accomplished by using information gathered from the following reassessment questions:

- Has detoxification occurred without complications?
- Is the client still in denial?
- Does the client accept responsibility for his or her own behavior? Has he or she acknowledged a personal problem with substances?

- Has a correlation been made between personal problems and the use of substances?
- Does the client still make excuses or blame others for use of substances?
- Has the client remained substance free during treatment?
- Does the client cooperate with treatment?
- Does the client refrain from manipulative behavior and violation of limits?

BOX 23–6 Topics for Client/Family Education Related to Substance Use Disorders

NATURE OF THE ILLNESS
1. Effects of (substance) on the body
   a. Alcohol
   b. Other CNS depressants
   c. CNS stimulants
   d. Hallucinogens
   e. Inhalants
   f. Opioids
   g. Cannabinols
2. Ways in which use of (substance) affects life.

MANAGEMENT OF THE ILLNESS
1. Activities to substitute for (substance) in times of stress
2. Relaxation techniques
   a. Progressive relaxation
   b. Tense and relax
   c. Deep breathing
   d. Autogenics
3. Problem-solving skills
4. The essentials of good nutrition

SUPPORT SERVICES
1. Financial assistance
2. Legal assistance
3. Alcoholics Anonymous (or other support group specific to another substance)
4. One-to-one support person

■ Is the client able to verbalize motivation toward alternative adaptive coping strategies to substitute for substance use? Has the use of these strategies been demonstrated? Does positive reinforcement encourage repetition of these adaptive behaviors?

■ Has nutritional status been restored? Does the client consume a diet adequate for his or her size and level of activity? Is the client able to discuss the importance of adequate nutrition?

■ Has the client remained free of infection during hospitalization?

■ Is the client able to verbalize the effects of substance abuse on the body?

The Chemically Impaired Nurse

Substance abuse and addiction has the potential for impairment in an individual's social, occupational, psychological, and physical functioning. This becomes an especially serious problem when the impaired person is responsible for the lives of others each day. Approximately 10 percent of the general population suffers from chemical addiction. In one study, researchers identified the prevalence of substance abuse among employed nurses to be 5.1 percent

(Monroe et al., 2013). Alcohol is the most widely abused drug, followed closely by narcotics. Nurses who abuse substances have an added vulnerability because they are often handling controlled substances when providing patient care.

For years, the impaired nurse was protected, promoted, transferred, ignored, or fired. These types of responses promoted the growth of the problem. Programs are needed that involve early reporting and treatment of chemical addiction as a disease, with a focus on public safety and rehabilitation of the nurse.

How does one identify the impaired nurse? It is easy to overlook what *might* be a problem. Denial, on the part of the impaired nurse as well as nurse colleagues, is still the strongest defense for not dealing with substance abuse problems. Some states have mandatory reporting laws that require observers to report substance-abusing nurses to the state board of nursing. These are difficult laws to enforce, and hospitals are not always compliant with mandatory reporting. Some hospitals may choose not to report to the state board of nursing if the impaired nurse is actively seeking treatment and is not placing clients in danger.

A number of clues for recognizing substance impairment in nurses have been identified (Ellis & Hartley, 2012). They are not easy to detect and will vary according to the substance used. There may be high absenteeism if the person's source is outside the work area, or the individual may rarely miss work if the substance source is at work. There may be an increase in "wasting" of drugs, higher incidences of incorrect narcotic counts, and a higher record of signing out drugs than for other nurses.

Poor concentration, difficulty meeting deadlines, inappropriate responses, and poor memory or recall usually occur late in the disease process. The person may also have problems with relationships. Some other possible signs are irritability, mood swings, tendency to isolate, elaborate excuses for behavior, unkempt appearance, impaired motor coordination, slurred speech, flushed face, inconsistent job performance, and frequent use of the restroom. He or she may frequently medicate other nurses' patients, and there may be patient complaints of inadequate pain control. Discrepancies in documentation may occur. Ideally, suspicious behavior is recognized by peers and intervention sought before the impaired nurse reaches late stages of the disease process. As uncomfortable as it may seem to tell a supervisor about suspected impairment in a colleague, it is in the interest of the nurse's health and critically important to ensuring patient safety.

If suspicious behavior occurs, it is important to keep careful, objective records. Confrontation with

the impaired nurse will undoubtedly result in hostility and denial. Confrontation should occur in the presence of a supervisor or other nurse and should include the offer of assistance in seeking treatment. If a report is made to the state board of nursing, it should be a factual documentation of specific events and actions, not a diagnostic statement of impairment.

Each case is generally decided on an individual basis. A state board may deny, suspend, or revoke a license on the basis of a report of chemical abuse by a nurse. Several state boards of nursing have passed diversionary laws that allow impaired nurses to avoid disciplinary action by agreeing to seek treatment. Some administer the treatment programs themselves, and others refer the nurse to community resources or state nurses' association assistance programs. Treatment may entail successful completion of inpatient, outpatient, group, or individual counseling treatment program(s); evidence of regular attendance at nurse support groups or a 12-step program; random negative drug screens; and employment or volunteer activities during the suspension period. When a nurse is deemed safe to return to practice, he or she may be closely monitored for several years and required to undergo random drug screenings. The nurse also may be required to practice under specifically circumscribed conditions for a designated period of time.

In 1982, the American Nurses Association (ANA) House of Delegates adopted a national resolution to provide assistance to impaired nurses. Since that time, the majority of state nurses' associations have developed (or are developing) programs for nurses who are impaired by substances or psychiatric illness. The individuals who administer these efforts are nurse members of the state associations, as well as nurses who are in recovery themselves. For this reason, they are called **peer assistance programs.**

The peer assistance programs strive to intervene early, reduce hazards to clients, and increase prospects for the nurse's recovery. Most states provide either a hotline number that the impaired nurse or intervening colleague may call or phone numbers of peer assistance committee members. Typically, a contract is drawn up detailing the method of treatment, which may be obtained from various sources, such as employee assistance programs, Alcoholics Anonymous, Narcotics Anonymous, private counseling, or outpatient clinics. Guidelines for monitoring the course of treatment are established. Peer support is provided through regular contact with the impaired nurse, usually for a period of 2 years. Peer assistance programs serve to assist impaired nurses to recognize their impairment, obtain necessary treatment, and regain accountability within their profession.

Codependency

The concept of **codependency** arose from a need to define the dysfunctional behaviors that are evident among members of the family of a chemically addicted person. The term has been expanded to include all individuals from families that harbor secrets of physical or emotional abuse or pathological conditions. Living under these conditions results in unmet needs for autonomy and self-esteem and a profound sense of powerlessness. The codependent person is able to achieve a sense of control only through fulfilling the needs of others. Personal identity is relinquished and boundaries with the other person become blurred. The codependent person disowns his or her own needs and wants in order to respond to external demands and the demands of others. Codependence has been called "a dysfunctional relationship with oneself."

The traits associated with a codependent personality are varied. In a relationship, the codependent person derives self-worth from that of the partner, whose feelings and behaviors determine how the codependent should feel and behave. In order for the codependent to feel good, his or her partner must be happy and behave in appropriate ways. If the partner is not happy, the codependent feels responsible for *making* him or her happy. The codependent's home life is fraught with stress. Ego boundaries are weak and behaviors are often enmeshed with those of the pathological partner. Denial that problems exist is common. Feelings are kept in control, and anxiety may be released in the form of stress-related illnesses or compulsive behaviors such as eating, spending, working, or use of substances.

Wesson (2013) describes the following behaviors characteristic of codependency. She stated that codependents:

■ Have a long history of focusing thoughts and behavior on other people.
■ Are "people pleasers" and will do almost anything to get the approval of others.
■ Outwardly appear very competent, but actually feel quite needy, helpless, or perhaps nothing at all.
■ Have experienced abuse or emotional neglect as a child.
■ Are outwardly focused toward others and know very little about how to direct their own lives from their own sense of self.

The Codependent Nurse

Certain characteristics of codependence have been associated with the profession of nursing. A shortage of nurses combined with the increasing ranks of seriously ill clients may result in nurses providing care to and fulfilling everyone's needs but their own. Many

health-care workers who were reared in homes with a chemically addicted person or otherwise dysfunctional family are at risk for activation of unresolved codependent tendencies. Nurses who assumed the "fixer" role in their dysfunctional families of origin during childhood may attempt to resume that role in their caregiving professions. They are attracted to a profession in which they are needed but nurture feelings of resentment for receiving so little in return. Their emotional needs go unmet, but they continue to deny that these needs exist. Instead, these unmet emotional needs may be manifested through use of compulsive behaviors, such as work or spending excessively, or addictions, such as to food or substances.

Codependent nurses have a need to be in control. They often strive for an unrealistic level of achievement. Their self-worth comes from the feeling of being needed by others and maintaining control over the environment. They nurture the dependence of others and accept the responsibility for the happiness and contentment of others. They rarely express their true feelings, and they do what is necessary to preserve harmony and maintain control. They are at high risk for physical and emotional burnout.

Treating Codependency

Cermak (1986) identified four stages in the recovery process for individuals with codependent personality:

Stage I: The Survival Stage In this first stage, codependent persons must begin to let go of the denial that problems exist or that their personal capabilities are unlimited. This initiation of abstinence from blanket denial may be a very emotional and painful period.

Stage II: The Reidentification Stage Reidentification occurs when the individuals are able to glimpse their true selves through a break in the denial system. They accept the label of codependent and take responsibility for their own dysfunctional behavior. Codependents tend to enter reidentification only after being convinced that it is more painful not to do so. They accept their limitations and are ready to face the issues of codependence.

Stage III: The Core Issues Stage In this stage, the recovering codependent must face the fact that relationships cannot be managed by force of will. Each partner must be independent and autonomous. The goal of this stage is to detach from the struggles of life that exist because of prideful and willful efforts to control things that are beyond the individual's power to control.

Stage IV: The Reintegration Stage This is a stage of self-acceptance and willingness to change when codependents relinquish the power *over others* that was not rightfully theirs but reclaim the *personal* power that

they do possess. Integrity is achieved out of awareness, honesty, and connection with one's spiritual consciousness. Control is achieved through self-discipline and self-confidence.

Self-help groups have been found helpful in the treatment of codependency. Groups developed for families of chemically addicted people, such as Al-Anon, may be of assistance. Groups specific to codependency also exist. One of these groups, which bases its philosophy on the Twelve Steps of Alcoholics Anonymous (see the section that follows) is

Co-Dependents Anonymous (CoDA)

Treatment Modalities for Substance-Related Disorders

Alcoholics Anonymous

Alcoholics Anonymous (AA) is a major self-help organization for the treatment of alcoholism. It was founded in 1935 by two alcoholics—a stockbroker, Bill Wilson, and a physician, Bob Smith—who discovered that they could remain sober through mutual support. This they accomplished not as professionals, but as peers who were able to share their common experiences. Soon they were working with other alcoholics, who in turn worked with others. The movement grew, and remarkably, individuals who had been treated unsuccessfully by professionals were able to maintain sobriety through helping one another.

Today, AA chapters exist in virtually every community in the United States. The self-help groups are based on the concept of peer support—acceptance and understanding from others who have experienced the same problems. The only requirement for membership is a desire on the part of the alcoholic person to stop drinking. Each new member is assigned a support person from whom he or she may seek assistance when the temptation to drink occurs.

A survey by the General Service Office of Alcoholics Anonymous in 2014 (Alcoholics Anonymous, 2015) revealed the following statistics: members ages 30 and younger comprised 12 percent of the membership, and the average age of AA members was 50; women comprised 38 percent; 89 percent were white, 4 percent were African American, 3 percent were Hispanic, 1 percent were Native American, and 3 percent were Asian American and other minorities. Almost half (49%) of people involved in AA were referred by a health-care professional or treatment facility. The sole purpose of AA is to help members stay sober. When sobriety has been achieved, they in turn are expected to help other

alcoholic persons. The Twelve Steps that embody the philosophy of AA provide specific guidelines on how to attain and maintain sobriety (Box 23–7).

AA accepts alcoholism as an illness and promotes total abstinence as the only cure, emphasizing that the alcoholic person can never safely return to social drinking. They encourage the members to seek sobriety, taking one day at a time. The Twelve Traditions are the statements of principles that govern the organization.

AA has been the model for various self-help groups associated with addiction problems. Some of these groups and the memberships for which they are organized are listed in Table 23–11. Nurses must be fully and accurately informed about available self-help groups and their importance as a treatment resource on the health-care continuum so that they can use them as a referral source for clients with substance use disorders.

Pharmacotherapy

Disulfiram (Antabuse)

Disulfiram (Antabuse) is a drug that can be administered as a deterrent to drinking to individuals who abuse alcohol. Ingestion of alcohol while disulfiram is in the body results in a syndrome of symptoms that produce substantial discomfort for the individual and even result in death if the blood alcohol level is high. The reaction varies according to the sensitivity of the individual and how much alcohol was ingested.

BOX 23–7 Alcoholics Anonymous

The Twelve Steps

1. We admitted we were powerless over alcohol—that our lives have become unmanageable.
2. Came to believe that a Power greater than ourselves could restore us to sanity.
3. Made a decision to turn our will and our lives over to the care of God as we understood Him.
4. Made a searching and fearless moral inventory of ourselves.
5. Admitted to God, to ourselves, and to another human being the exact nature of our wrongs.
6. Were entirely ready to have God remove all these defects of character.
7. Humbly asked Him to remove our shortcomings.
8. Made a list of all persons we had harmed and became willing to make amends to them all.
9. Made direct amends to such people wherever possible except when to do so would injure them or others.
10. Continued to take personal inventory and when we were wrong promptly admitted it.
11. Sought through prayer and meditation to improve our conscious contact with God as we understood Him, praying only for knowledge of His will for us and the power to carry that out.
12. Having had a spiritual awakening as the result of these steps, we tried to carry this message to alcoholics and to practice these principles in all our affairs.

The Twelve Traditions

1. Our common welfare should come first; personal recovery depends upon AA unity.
2. For our group purpose there is but one ultimate authority—a loving God as He may express Himself in our group conscience. Our leaders are but trusted servants; they do not govern.
3. The one requirement for AA membership is a desire to stop drinking.
4. Each group should be autonomous except in matters affecting other groups or AA as a whole.
5. Each group has but one primary purpose—to carry its message to the alcoholic who still suffers.
6. An AA group ought never endorse, finance, or lend the AA name to any related facility or outside enterprise, lest problems of money, property, and prestige divert us from our primary purpose.
7. Every AA group ought to be fully self-supporting, declining outside contributions.
8. Alcoholics Anonymous should remain forever nonprofessional, but our service centers may employ special workers.
9. Alcoholics Anonymous, as such, ought never be organized; but we may create service boards of committees directly responsible to those they serve.
10. Alcoholics Anonymous has no opinion on outside issues; hence, the Alcoholics Anonymous name ought never be drawn into public controversy.
11. Our public relations policy is based on attraction rather than promotion; we need always maintain personal anonymity at the level of press, radio, and films.
12. Anonymity is the spiritual foundation of all our traditions, ever reminding us to place principles before personalities.

The Twelve Steps and Twelve Traditions are reprinted with permission of Alcoholics Anonymous World Services, Inc. (AAWS). Permission to reprint the Twelve Steps and Twelve Traditions does not mean that AAWS has reviewed or approved the contents of this publication, or that AA necessarily agrees with the views expressed herein. AA is a program of recovery from alcoholism only. Use of the Twelve Steps and Twelve Traditions in connection with programs and activities which are patterned after AA, but which address other problems, or in any other non-AA context, does not imply otherwise.

TABLE 23–11 **Addiction Self-Help Groups**	
GROUP	MEMBERSHIP
Adult Children of Alcoholics (ACOA)	Adults who grew up with an alcoholic in the home
Al-Anon	Families of alcoholics
Alateen	Adolescent children of alcoholics
Children Are People	School-aged children with an alcoholic family member
Cocaine Anonymous	Cocaine addicts
Codependents Anonymous (CoDA)	Families of alcohol or other substance abusers
Families Anonymous	Parents of children who abuse substances
Fresh Start	Nicotine addicts
Gamblers Anonymous	Gambling addicts
Narcotics Anonymous	Narcotics addicts
Nar-Anon	Families of narcotics addicts
Overeaters Anonymous	Food addicts
Pills Anonymous	Polysubstance addicts
Pot Smokers Anonymous	Marijuana smokers
Smokers Anonymous	Nicotine addicts
Women for Sobriety	Female alcoholics

Disulfiram works by inhibiting the enzyme aldehyde dehydrogenase, thereby blocking the oxidation of alcohol at the stage when acetaldehyde is converted to acetate. This results in an accumulation of acetaldehyde in the blood, which is thought to produce the symptoms associated with the disulfiram-alcohol reaction. These symptoms persist as long as alcohol is being metabolized. The rate of alcohol elimination does not appear to be affected.

Symptoms of disulfiram-alcohol reaction can occur within 5 to 10 minutes of ingestion of alcohol. Mild reactions can occur at blood alcohol levels as low as 5 to 10 mg/dL. Symptoms are fully developed at approximately 50 mg/dL and may include flushed skin, throbbing in the head and neck, respiratory difficulty, dizziness, nausea and vomiting, sweating, hyperventilation, tachycardia, hypotension, weakness, blurred vision, and confusion. With a blood alcohol level of approximately 125 to 150 mg/dL, severe reactions can occur, including respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

Disulfiram should not be administered until it has been ascertained that the client has abstained from alcohol for at least 12 hours. If disulfiram is discontinued, it is important for the client to understand that the sensitivity to alcohol may last for as long as 2 weeks. Consuming alcohol or alcohol-containing substances during this 2-week period could result in the disulfiram-alcohol reaction.

The client receiving disulfiram therapy should be aware of the many substances that contain alcohol. These products, such as liquid cough and cold preparations, vanilla extract, aftershave lotions, colognes, mouthwash, nail polish removers, and isopropyl alcohol, are capable of producing the symptoms described if ingested or even rubbed on the skin. The individual must read labels carefully and inform any doctor, dentist, or other health-care professional from whom assistance is sought that he or she is taking disulfiram. In addition, the client must carry a card explaining participation in disulfiram therapy, possible consequences of the therapy, and symptoms that may indicate an emergency situation.

The client must be assessed carefully before beginning disulfiram therapy. A thorough medical screening is performed before therapy commences, and written informed consent is usually required. The drug is contraindicated for clients at high risk for

alcohol ingestion. It is also contraindicated for psychotic clients and clients with severe cardiac, renal, or hepatic disease.

Disulfiram therapy is not a cure for alcoholism. It provides a measure of control for the individual who desires to avoid impulse drinking. Clients receiving disulfiram therapy are encouraged to seek other assistance with their problem, such as AA or another support group, to aid in the recovery process.

Other Medications for Treatment of Alcoholism

The narcotic antagonist naltrexone (ReVia) was approved by the FDA in 1994 for the treatment of alcohol addiction. Naltrexone, which was approved in 1984 for the treatment of heroin abuse, works on the same receptors in the brain that produce the feelings of pleasure when heroin or other opiates bind to them but does not produce the same "narcotic high" and is not habit forming. Although alcohol does not bind to these brain receptors, a systematic review of the research demonstrated that naltrexone works equally well against alcohol (Garbutt et al., 1999). In comparison to the placebo-treated clients, participants on naltrexone therapy showed significantly lower overall relapse rates and fewer drinks per drinking day among those clients who did resume drinking. In another large study of veterans (mostly men), Krystal and associates (2001) concluded that evidence does not support the use of naltrexone for men with chronic severe alcohol dependence. Thus, the efficacy of selective serotonin reuptake inhibitors (SSRIs) in the decrease of alcohol craving among alcohol-dependent individuals has yielded mixed results (National Institute on Alcohol Abuse and Alcoholism, 2000). A greater degree of success was observed with moderate drinkers than with heavy drinkers.

In August 2004, the FDA approved acamprosate (Campral), which is indicated for the maintenance of abstinence from alcohol in patients with alcohol addiction who are abstinent at treatment initiation. The mechanism of action of acamprosate in maintenance of alcohol abstinence is not completely understood. It is hypothesized to restore the normal balance between neuronal excitation and inhibition by interacting with glutamate and gamma-aminobutyric acid (GABA) neurotransmitter systems. Acamprosate is ineffective in clients who have not undergone detoxification and not achieved alcohol abstinence prior to beginning treatment. It is recommended for concomitant use with psychosocial therapy.

Counseling

Counseling on a one-to-one basis is often used to help the client who abuses substances. The relationship is goal directed, and the length of the counseling may vary from weeks to years. The focus is on current reality, development of a working treatment relationship, and strengthening ego assets. The counselor must be warm, kind, and nonjudgmental yet able to set limits firmly. Research consistently demonstrates that personal characteristics of counselors are highly predictive of client outcome. In addition to technical counseling skills, many important therapeutic qualities affect the outcome of counseling, including insight, respect, genuineness, concreteness, and empathy (SAMHSA, 2014).

Counseling of the client who abuses substances passes through various phases, each of which is of indeterminate length. In the first phase, an assessment is conducted. Factual data are collected to determine whether the client does indeed have a problem with substances; that is, that substances are regularly impairing effective functioning in one or more significant life areas.

Following the assessment, in the working phase of the relationship, the counselor assists the individual to accept that the use of substances causes problems in significant life areas and that he or she is not able to prevent this from occurring. The client states a desire to make changes. The strength of the denial system is determined by the duration and extent of substance-related adverse effects in the person's life. Thus, those individuals with rather minor substance-related problems of recent origin have less difficulty with this stage than those with long-term extensive impairment. The individual also works to gain self-control and abstain from substances.

Once the problem has been identified and sobriety achieved, the client must have a concrete and workable plan for getting through the early weeks of abstinence. Anticipatory guidance through role-play helps the individual practice how he or she will respond when substances are readily obtainable and the impulse to partake is strong.

Counseling often includes the family or specific family members. In family counseling, the therapist tries to help each member see how he or she has affected, and been affected by, the substance abuse behavior. Family strengths are mobilized, and family members are encouraged to move in a positive direction. Referrals are often made to self-help groups such as Al-Anon, Nar-Anon, Alateen, Families Anonymous, and Adult Children of Alcoholics.

Group Therapy

Group therapy has long been regarded as a powerful agent of change with those who abuse substances. In groups, individuals are able to share their experiences with others going through similar problems. They are able to "see themselves in others" and thus confront

their defenses about giving up the substance. They may recognize similar attitudes and defenses in others. Groups also give individuals the capacity to communicate needs and feelings directly.

In task-oriented education groups, the leader is charged with presenting material associated with substance abuse and its effects on the person's life. Other educational groups that may be effective include assertiveness techniques and relaxation training. Teaching groups differ from psychotherapy groups, whose focus is on helping individuals understand and manage difficult feelings and situations, particularly as they relate to substance use.

Therapy groups and self-help groups such as AA are complementary to each other. Whereas the self-help group focus is on achieving and maintaining sobriety, in the therapy group the individual may learn more adaptive ways of coping, how to deal with problems that may have arisen from or were exacerbated by the former substance use, and ways to improve quality of life and function more effectively without substances.

Psychopharmacology for Substance Intoxication and Substance Withdrawal

Various medications have been used to decrease the intensity of symptoms in an individual who is withdrawing from or experiencing the effects of excessive use of alcohol and other drugs. **Substitution therapy** may be required to reduce the life-threatening effects of intoxication or withdrawal from some substances. The severity of the withdrawal syndrome depends on the particular drug used, how long it has been used, the dose used, and the rate at which the drug is eliminated from the body.

Alcohol

Benzodiazepines are the most widely used group of drugs for substitution therapy in alcohol withdrawal. Chlordiazepoxide (Librium), oxazepam (Serax), lorazepam (Ativan), and diazepam (Valium) are the most common agents. The approach to treatment with benzodiazepines for alcohol withdrawal is to start with relatively high doses and reduce the dosage by 20 to 25 percent each day until withdrawal is complete. Additional doses may be given for breakthrough signs or symptoms (Black & Andreasen, 2014). In clients with liver disease, accumulation of longer-acting agents (chlordiazepoxide and diazepam) may be problematic, and use of shorter-acting benzodiazepines (lorazepam or oxazepam) is more appropriate.

Some physicians may order anticonvulsant medication (e.g., carbamazepine, valproic acid, or gabapentin) for management of withdrawal seizures. These drugs are particularly useful in individuals who undergo repeated episodes of alcohol withdrawal, which appear to "kindle" even more serious withdrawal episodes, including the production of withdrawal seizures that can result in brain damage (Julien, 2014). These anticonvulsants have been used successfully in both acute withdrawal and longer-term craving situations.

Multivitamin therapy, in combination with daily injections or oral administration of thiamine, is common protocol. Thiamine is commonly deficient in chronic alcoholics. Replacement therapy is required to prevent neuropathy, confusion, and encephalopathy.

Opioids

Examples of drugs in the opioid classification include opium, morphine, codeine, heroin, hydromorphone, oxycodone, and hydrocodone. Synthetic opiate-like narcotic analgesics include meperidine, methadone, pentazocine, and fentanyl.

Opioid intoxication is treated with narcotic antagonists such as naloxone (Narcan), naltrexone (ReVia), or nalmefene (Revex). In 2015 the FDA approved an intranasal form of naloxone hydrochloride under a fast-track approval process in response to the increase in deaths associated with drug overdose, particularly from respiratory depression and arrest. It is reported to work within 2 minutes but must be given quickly to prevent death (Brown, 2015). Naloxone nasal spray can cause severe withdrawal in patients who are opioid dependent.

Opiate withdrawal symptoms, as discussed previously, last for varying amounts of time depending on the type of opiate (see the section entitled "Opiate Withdrawal"). Withdrawal therapy includes rest, adequate nutritional support, and methadone substitution. Methadone, if ordered, is given on the first day in a dose sufficient to suppress withdrawal symptoms. The dose is then gradually tapered over a specified time. As the dose of methadone diminishes, renewed abstinence symptoms may be ameliorated by the addition of clonidine.

In October 2002, the FDA approved two forms of the drug buprenorphine for treating opiate addiction. Buprenorphine is less powerful than methadone but is considered somewhat safer and causes fewer side effects, making it especially attractive for clients who are mildly or moderately addicted. Individuals are able to access treatment with buprenorphine in office-based settings, providing an alternative to methadone clinics. Physicians are deemed qualified to prescribe buprenorphine if they hold an addiction certification from the American Society of Addiction Medicine, the American Academy of Addiction Psychiatry, the

American Psychiatric Association, or a similar association. The number of patients to whom individual physicians may provide outpatient buprenorphine treatment was previously limited to 100, but in response to the growing opioid epidemic, a new federal rule became effective in August 2016 increasing the allowable number to 275 patients, with stipulations about necessary credentialing in addictions medicine or addictions psychiatry and allowable practice settings (SAMHSA, 2016). A sublingual formulation of a combination medication with buprenorphine and naloxone (Suboxone) is also available.

Clonidine (Catapres) also has been used to suppress opiate withdrawal symptoms. As monotherapy, it is not as effective as substitution with methadone, but it is nonaddictive and serves effectively as a bridge to enable the client to stay opiate free long enough to facilitate termination of methadone maintenance.

Depressants

Substitution therapy for CNS depressant withdrawal (particularly barbiturates) is most commonly combined with the long-acting barbiturate phenobarbital (Luminal). The dosage required to suppress withdrawal symptoms is administered. When stabilization has been achieved, the dose is gradually decreased by 30 mg/day until withdrawal is complete. Long-acting benzodiazepines are commonly used for substitution therapy when the abused substance is a nonbarbiturate CNS depressant.

Stimulants

Treatment of stimulant intoxication usually begins with minor tranquilizers such as chlordiazepoxide and progresses to major tranquilizers such as haloperidol (Haldol). Antipsychotics should be administered with caution because of their propensity to lower seizure threshold. Repeated seizures are treated with intravenous diazepam.

Withdrawal from CNS stimulants is not the medical emergency observed with CNS depressants. Treatment is usually aimed at reducing drug craving and managing severe depression. The client is placed in a quiet atmosphere and allowed to sleep and eat as much as needed or desired. Suicide precautions may need to be instituted. Antidepressant therapy may be helpful in treating symptoms of depression.

Hallucinogens and Cannabinols

Substitution therapy is not required with these drugs. When adverse reactions such as anxiety or panic occur, benzodiazepines (e.g., diazepam or chlordiazepoxide) may be prescribed to prevent harm to the client or others. Psychotic reactions may be treated with antipsychotic medications.

Non-Substance Addictions

Gambling Disorder

Gambling disorder is defined by the *DSM-5* as persistent and recurrent problematic gambling behavior leading to clinically significant impairment or distress (APA, 2013). The preoccupation with and impulse to gamble often intensifies when the individual is under stress. Many impulsive gamblers describe a physical sensation of restlessness and anticipation that can be relieved only by placing a bet. Blume (2013) states:

> In some cases the initial change in gambling behavior leading to pathological gambling begins with a "big win," bringing a rapid development of preoccupation, tolerance, and loss of control. Winning brings feelings of special status, power, and omnipotence. The gambler increasingly depends on this activity to cope with disappointments, problems, and negative emotional states, pulling away from emotional attachment to family and friends.

As the need to gamble increases, the individual is forced to obtain money by any means available. This may include borrowing money from illegal sources or pawning personal items (or items that belong to others). As gambling debts accrue, or out of a need to continue gambling, the individual may desperately resort to forgery, theft, or even embezzlement. Family relationships are disrupted, and impairment in occupational functioning may occur because of absences from work in order to gamble.

Gambling behavior usually begins in adolescence; however, compulsive behaviors rarely occur before young adulthood. The disorder generally runs a chronic course, with periods of waxing and waning that are largely dependent on psychosocial stress. Prevalence estimates for problem gambling range from 3 to 5 percent, with about 1 percent meeting the criteria for a gambling disorder (Sadock et al., 2015). This condition is more common among men than women.

Various personality disorder traits have been associated with pathological gambling. In a systematic review and meta-analysis (Dowling et al., 2015), the most prevalent included narcissistic, antisocial, avoidant, obsessive-compulsive, and borderline traits. The researchers conclude that in any treatment setting for gambling disorders, screening and treatment for these common comorbid conditions must be addressed.

Gambling problems may be episodic and increase during periods of stress or depression, or the behavior may be persistent (APA, 2013). The *DSM-5* diagnostic

criteria for pathological gambling are presented in Box 23–8.

Predisposing Factors to Gambling Disorder

Biological Influences

Genetic Familial and twin studies show an increased prevalence of pathological gambling in family members of individuals diagnosed with the disorder. Black and associates (2014) found that first-degree relatives of pathological gamblers were eight times more likely to develop the same condition, which suggests an underlying genetic predisposition.

Physiological Studies of dopamine receptor systems have implicated this neurotransmitter in the development of addictive personality traits, including pathological gambling (Weiss & Pontone, 2014). Support for this association comes from studies that demonstrated a correlation between the development of pathological gambling behaviors after individuals were treated with dopamine receptor agonist drugs (Moore, Glenmullen, & Mattison, 2014).

Biochemical theories suggest that, ironically, both winning and losing (perhaps related to the excitement of taking a risk) may stimulate the reward and pleasure centers of the brain. This could contribute to persistent and repeated desire to gamble even when one is not winning.

Psychosocial Influences

Sadock and associates (2015) report that the following may be predisposing factors to the development of pathological gambling: "loss of a parent by death, separation, divorce, or desertion before the child is 15 years of age; inappropriate parental discipline (absence, inconsistency, or harshness); exposure to and availability of gambling activities for the adolescent; a family emphasis on material and financial symbols; and a lack of family emphasis on saving, planning, and budgeting" (p. 691).

Treatment Modalities for Gambling Disorder

Because most pathological gamblers deny that they have a problem, treatment is difficult. In fact, most gamblers only seek treatment due to legal difficulties, family pressures, or other psychiatric complaints. Behavior therapy, cognitive-behavioral therapy, motivational interviewing, 12-step programs (Gamblers Anonymous)

BOX 23–8 Diagnostic Criteria for Gambling Disorder

A. Persistent and recurrent problematic gambling behavior leading to clinically significant impairment or distress, as indicated by the individual exhibiting four (or more) of the following in a 12-month period:
  1. Needs to gamble with increasing amounts of money in order to achieve the desired excitement.
  2. Is restless or irritable when attempting to cut down or stop gambling.
  3. Has made repeated unsuccessful efforts to control, cut back, or stop gambling.
  4. Is often preoccupied with gambling (e.g., persistent thoughts of reliving past gambling experiences, handicapping or planning the next venture, or thinking of ways to get money with which to gamble).
  5. Often gambles when feeling distressed (e.g., helpless, guilty, anxious, depressed).
  6. After losing money gambling, often returns another day to get even ("chasing" one's losses).
  7. Lies to conceal the extent of involvement with gambling.
  8. Has jeopardized or lost a significant relationship, job, or educational or career opportunity because of gambling.
  9. Relies on others to provide money to relieve desperate financial situations caused by gambling.
B. The gambling behavior is not better explained by a manic episode.

Specify if:

Episodic: Meeting diagnostic criteria at more than one point in time, with symptoms subsiding between periods of gambling disorder for at least several months.

Persistent: Experiencing continuous symptoms, to meet diagnostic criteria for multiple years.

Specify if:

In early remission: After full criteria for gambling disorder were previously met, none of the criteria for gambling disorder have been met for at least 3 months but for less than 12 months.

In sustained remission: After full criteria for gambling disorder were previously met, none of the criteria for gambling disorder have been met during a period of 12 months or longer.

Specify current severity:

Mild: 4–5 criteria met.

Moderate: 6–7 criteria met.

Severe: 8–9 criteria met.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

and self-help strategies such as bibliotherapy have all been used with pathological gambling with various degrees of success. About one-third of individuals with gambling disorders recover naturally without need for treatment (Rash, Weinstock, & Van Patten, 2016). Some medications have been used with effective results in the treatment of pathological gambling. SSRIs and clomipramine have been used to treat obsessive-compulsive disorders and may have benefits for those with gambling disorder who have comorbid obsessive-compulsive traits. Lithium, carbamazepine, and naltrexone have also been shown effective.

Possibly the most effective treatment of pathological gambling is participation by the individual in **Gamblers Anonymous** (GA). This organization of inspirational group therapy is modeled after Alcoholics Anonymous.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

The police bring Dan to the emergency department of the local hospital around 9 p.m. His wife, Cassandra, called 911 when Dan became violent and she began to fear for her safety. Dan was fired from his job as a foreman in a manufacturing plant for refusing to follow his supervisor's directions on a project. When cleaning up after his move, several partially used liquor bottles were found in his work area.

Cassandra reports that Dan has been drinking since he came home shortly after noon today. He bloodied her nose and punched her in the stomach when she poured the contents of a bottle he was drinking down the kitchen sink. The police responded to her call and brought Dan to the hospital in handcuffs. By the time they arrive at the hospital, Dan has calmed down and appears drugged and drowsy. His blood alcohol level measures 247 mg/dL. He is admitted to the detoxification unit of the hospital with a diagnosis of Alcohol Intoxication.

Cassandra tells the admitting nurse that she and Dan have been married for 12 years. He was a social drinker before they were married, but his drinking has increased over the years. He has been under a lot of stress at work; hates his job, his boss, and his coworkers; and is depressed a lot of the time. He never had a loving relationship with his parents, who are now deceased. For the past few years, his pattern has been to come home, start drinking immediately, and drink until he passes out for the night. She states that she has tried to get him to go for help with his drinking, but he refuses and says that he doesn't have a problem. Cassandra begins to cry and says to the nurse, "We can't go on like this. I don't know what to do!"

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Dan:

1. **Risk for injury** related to CNS agitation from alcohol withdrawal.
   a. **Short-term goal:** Dan's condition will stabilize within 72 hours.
   b. **Long-term goal:** Dan will not experience physical injury.
2. **Ineffective denial** related to low self-esteem, weak ego development, and underlying fears and anxieties.
   a. **Short-term goal:** Dan will focus immediate attention on behavioral changes required to achieve sobriety.

   b. **Long-term goal:** Dan will accept responsibility for his drinking behaviors and acknowledge the association between his drinking and personal problems.

PLANNING AND IMPLEMENTATION

RISK FOR INJURY

The following nursing interventions may be implemented *in an effort to ensure client safety:*

1. Assess Dan's level of disorientation; frequently orient him to reality and his surroundings.
2. Obtain a drug history.
3. Obtain a urine sample for analysis.
4. Place Dan in a quiet room (private, if possible).
5. Ensure that smoking materials and other potentially harmful objects are stored away.
6. Observe Dan frequently. Take vital signs every 15 to 30 minutes.
7. Monitor for signs of withdrawal within a few hours after admission. Watch for signs of
   ■ Increased heart rate
   ■ Tremors
   ■ Headache
   ■ Diaphoresis
   ■ Agitation; restlessness
   ■ Nausea
   ■ Fever
   ■ Convulsions
8. Follow medication regimen, as ordered by physician (commonly a benzodiazepine, thiamine, multivitamin).

DENIAL

The following nursing interventions may be implemented *in an effort to help Dan accept responsibility for the behavioral consequences associated with his drinking:*

1. Develop Dan's trust by spending time with him, being honest, and keeping all promises.
2. Ensure that Dan understands that it is not *him* but his *behavior* that is unacceptable.
3. Provide Dan with accurate information about the effects of alcohol. Do this in a matter-of-fact, nonjudgmental way.
4. Point out recent negative events that have occurred in Dan's life and associate the use of alcohol with these events. Help him to see the association.
5. Use confrontation with caring: "Yes, your wife called the police. You were physically abusive. She was afraid. And

CASE STUDY AND SAMPLE CARE PLAN—cont'd

your blood alcohol level was 247 when you were brought in. You were obviously not in control of your behavior at the time."

6. Don't accept excuses for his drinking. Point out rationalization and projection behaviors. These behaviors prolong denial that he has a problem. He must directly accept responsibility for his drinking (not make excuses and blame it on the behavior of others). He must come to understand that only *he* has control of his behavior.

7. Encourage Dan to attend group therapy during treatment and Alcoholics Anonymous following treatment. Peer feedback is a strong factor in helping individuals recognize their problems and ultimately remain sober.

8. Encourage Cassandra to attend Al-Anon meetings. She can benefit from the experiences of others who have experienced and are experiencing the same types of problems as she is.

9. Help Dan to identify ways that he can cope besides using alcohol, such as exercise, sports, and relaxation. He should choose what is most appropriate for him and be given positive feedback for efforts made toward change.

EVALUATION

The outcome criteria identified for Dan have been met. He experienced an uncomplicated withdrawal from alcohol and exhibits no evidence of physical injury. He verbalizes understanding of the relationship between his personal problems and his drinking and accepts responsibility for his own behavior. He verbalizes understanding that alcohol addiction is an illness that requires ongoing support and treatment, and he regularly attends AA meetings. Cassandra regularly attends Al-Anon meetings.

Summary and Key Points

- An individual is considered to be addicted to a substance when he or she is unable to control its use, even knowing that it interferes with normal functioning; when increasing amounts of the substance are required to produce the desired effects; and when characteristic withdrawal symptoms develop upon cessation or drastic decrease in use of the substance.

- Substance intoxication is defined as the development of a reversible syndrome of maladaptive behavioral or psychological changes due to the direct physiological effects of a substance on the CNS and develop during or shortly after ingestion of (or exposure to) a substance.

- Substance withdrawal is the development of a substance-specific maladaptive behavioral change, with physiological and cognitive concomitants, due to the cessation of or reduction in heavy and prolonged substance use.

- The etiology of substance use disorders is unknown. Various contributing factors have been implicated, such as genetics, biochemical changes, developmental influences, personality factors, social learning, conditioning, and cultural and ethnic influences.

- Seven classes of substances are presented in this chapter in terms of a profile of the substance, historical aspects, patterns of use and abuse, and effects on the body. They include alcohol, other CNS depressants, CNS stimulants, opioids, hallucinogens, inhalants, and cannabinols.

- The nurse uses the nursing process as the vehicle for delivery of care of the client with a substance-related disorder.

- The nurse must first examine his or her own feelings regarding personal substance use and substance use by others. Only the nurse who can be accepting and nonjudgmental of substance-use behaviors will be effective in working with these clients.

- Special care is given to clients with dual diagnoses of mental illness and substance use disorders.

- Addiction to substances is a problem for many members of the nursing profession. Most state boards of nursing and state nurses' associations have established avenues for peer assistance to provide help to impaired members of the profession.

- Individuals who are reared in families with chemically addicted persons learn patterns of dysfunctional behavior that carry over into adult life. These dysfunctional behavior patterns have been termed *codependence.* Codependent persons sacrifice their own needs for the fulfillment of others' in order to achieve a sense of control. Many nurses also have codependent traits.

- Treatment modalities for substance-related disorders include self-help groups, deterrent therapy, individual counseling, and group therapy. Substitution pharmacotherapy is frequently implemented, with clients experiencing substance intoxication or substance withdrawal. Treatment modalities are implemented on an inpatient basis or in outpatient settings, depending on the severity of the impairment.

- Gambling disorder is defined by the *DSM-5* as persistent and recurrent problematic gambling behavior leading to clinically significant impairment or distress.
- The preoccupation with and impulse to gamble intensifies when the individual is under stress. Many impulsive gamblers describe a physical sensation of restlessness and anticipation that can be relieved only by placing a bet.
- Research indicates a possible genetic component in the etiology to gambling disorder. Abnormalities in the serotonergic, noradrenergic, and dopaminergic neurotransmitter systems have also been implicated.
- A number of psychosocial influences have been implicated in the predisposition to gambling disorder, including dysfunctional family patterns.

- Behavior therapy, cognitive therapy, and psychoanalysis have been used with gambling disorder with various degrees of success. Medications such as SSRIs, clomipramine, lithium, carbamazepine, and naltrexone, have also been tried.
- Gamblers Anonymous, an organization of inspirational group therapy modeled after Alcoholics Anonymous, has been very effective in helping individuals who desire to stop gambling.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Mr. White is admitted to the hospital after an extended period of binge alcohol drinking. His wife reports that he has been a heavy drinker for a number of years. Laboratory reports reveal he has a blood alcohol level of 250 mg/dL. He is placed on the chemical addiction unit for detoxification. When would the first signs of alcohol withdrawal symptoms be expected to occur?
   a. Several hours after the last drink
   b. 2 to 3 days after the last drink
   c. 4 to 5 days after the last drink
   d. 6 to 7 days after the last drink

2. Symptoms of alcohol withdrawal include:
   a. Euphoria, hyperactivity, and insomnia.
   b. Depression, suicidal ideation, and hypersomnia.
   c. Diaphoresis, nausea and vomiting, and tremors.
   d. Unsteady gait, nystagmus, and profound disorientation.

3. Which of the following medications is the physician most likely to order for a client experiencing alcohol withdrawal syndrome?
   a. Haloperidol (Haldol)
   b. Chlordiazepoxide (Librium)
   c. Methadone (Dolophine)
   d. Phenytoin (Dilantin)

4. Dan, who has been admitted to the alcohol rehabilitation unit after being fired for drinking on the job, states to the nurse, "I don't have a problem with alcohol. I can handle my booze better than anyone I know. My boss is a jerk! I haven't missed any more days than my coworkers." What is the nurse's best response?
   a. "Maybe your boss is mistaken, Dan."
   b. "You are here because your drinking was interfering with your work, Dan."
   c. "Get real, Dan! You're a boozer and you know it!"
   d. "Why do you think your boss is a jerk, Dan?"

Review Questions—cont'd
Self-Examination/Learning Exercise

5. Dan, who has been admitted to the alcohol rehabilitation unit after being fired for drinking on the job, states to the nurse, "I don't have a problem with alcohol. I can handle my booze better than anyone I know. My boss is a jerk! I haven't missed any more days than my coworkers." Which defense mechanism is Dan using?
   a. Denial
   b. Projection
   c. Displacement
   d. Rationalization

6. Dan has been admitted to the alcohol rehabilitation unit after being fired for drinking on the job. Dan's drinking buddies come for a visit, and when they leave, the nurse smells alcohol on Dan's breath. Which of the following would be the best intervention with Dan at this time?
   a. Search his room for evidence.
   b. Ask, "Have you been drinking alcohol, Dan?"
   c. Send a urine specimen from Dan to the laboratory for drug screening.
   d. Tell Dan, "These guys cannot come to the unit to visit you again."

7. Dan begins attendance at AA meetings. Which of the statements by Dan reflects the purpose of this organization?
   a. "They claim they will help me stay sober."
   b. "I'll dry out in AA, then I can have a social drink now and then."
   c. "AA is only for people who have reached the bottom."
   d. "If I lose my job, AA will help me find another."

8. From which of the following symptoms might the nurse identify in a chronic cocaine user?
   a. Clear, constricted pupils
   b. Red, irritated nostrils
   c. Muscle aches
   d. Conjunctival redness

9. An individual who is addicted to heroin is likely to experience which of the following symptoms of withdrawal?
   a. Increased heart rate and blood pressure
   b. Tremors, insomnia, and seizures
   c. Incoordination and unsteady gait
   d. Nausea and vomiting, diarrhea, and diaphoresis

10. A polysubstance abuser makes the statement, "The green and whites do me good after speed." How might the nurse interpret the statement?
    a. The client abuses amphetamines and anxiolytics.
    b. The client abuses alcohol and cocaine.
    c. The client is psychotic.
    d. The client abuses narcotics and marijuana.

11. A client admitted to the emergency department smells strongly of alcohol, and his wife reports he has been a heavy drinker for the last 25 years. Which of the following assessment findings are consistent with long-term chronic alcohol abuse? (Select all that apply.)
    a. The client reports weak leg muscles, and his gait is unsteady.
    b. The client's abdomen is distended.
    c. The client reports he was coughing up some blood.
    d. The client reports he has double vision.
    e. Blood tests reveal a low white blood cell count.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

DESCRIPTION OF THE STUDY: This study examined social support and self-efficacy in maintaining abstinence among individuals discharged from inpatient treatment for substance use disorders. The participants ($N = 270$) were largely unemployed with an average of 6.3 prior convictions, and the majority (41.4%) reported using opiates/heroin, followed by cocaine (27.8%), alcohol (12.8%), polysubstance use (11.3%), and cannabis (6.4%).

RESULTS OF THE STUDY: The researchers found that individuals with high psychiatric severity had lower levels of self-efficacy for abstinence even though there was not a significant difference in social support. The researchers suggest that usual social support resources such as 12-step programs may not be sufficient for individuals with comorbid psychiatric illness. Abstinence self-efficacy may be inhibited by cognitive dysfunction associated with the psychiatric illness, but whatever the contributing factors, abstinence self-efficacy is highly correlated with decreasing relapse.

IMPLICATIONS FOR NURSING PRACTICE: The researchers point out that interventions related to coping skills and stress management have been shown to increase abstinence self-efficacy. Nurses play an active role in this kind of education for clients in inpatient psychiatric units. Targeting these interventions for individuals with concurrent substance abuse disorders may provide a stronger foundation for relapse prevention in this group post-discharge.

TEST YOUR CRITICAL THINKING SKILLS

Kelly, age 23, is a first-year law student engaged to a surgical resident at the local university hospital. She has been struggling to do well in law school because she wants to make her parents, two prominent local attorneys, proud of her. She had never aspired to do anything but go into law, and that is also what her parents expected her to do.

Kelly's midterm grades were not as high as she had hoped, so she increased the number of hours of study time, staying awake all night several nights a week to study. She started drinking large amounts of coffee to stay awake but still found herself falling asleep as she tried to study at the library and in her apartment. As final exams approached, she began to panic that she would not be able to continue the pace of studying she felt she needed in order to make the grades she hoped for.

One of Kelly's classmates told her that she needed some "speed" to give her that extra energy to study. Her classmate said, "All the kids do it. Hardly anyone I know gets through law school without it." She gave Kelly the name of a source.

Kelly contacted the source, who supplied her with enough amphetamines to see her through final exams. Kelly was excited, because she had so much energy, did not require sleep, and was able to study the additional hours she thought she needed for the exams. However, when the results were posted, Kelly had failed two courses and would have to repeat them in summer school if she was to continue with her class in the fall. She continued to replenish her supply of amphetamines from her contact until he told her he could not get her anymore. She became frantic and stole a prescription blank from her fiancé and forged his name for more pills.

She started taking increasing amounts of the medication in order to achieve the high she wanted to feel. Her behavior became erratic. Yesterday, her fiancé received a call from a pharmacy to clarify an order for amphetamines that Kelly had written. He insisted that she admit herself to the chemical addiction unit for detoxification.

On the unit, she appears tired and depressed, moves very slowly, and wants to sleep all the time. She keeps saying to the nurse, "I'm a real failure. I'll never be an attorney like my parents. I'm too dumb. I just wish I could die."

Answer the following questions related to Kelly:

1. What is the primary nursing diagnosis for Kelly?
2. Describe important nursing interventions to be implemented with Kelly.
3. In addition to physical safety, what would be the primary short-term goal the nurses would strive to achieve with Kelly?

💬 Communication Exercises

1. Tom is a patient on the alcohol treatment unit. He says to the nurse, "My boss and my wife ganged up on me. They think I have a drinking problem. I don't have a drinking problem! I can quit any time I want to!"
   - How would the nurse respond appropriately to this statement by Tom?
2. Tom says to the nurse, "My head hurts. I didn't sleep very well last night. I'm getting shaky and it's hot in here! I could sure use a cup of coffee and a cigarette."
   - How would the nurse respond appropriately to this statement by Tom?
3. Tom says, "Sure, I missed a couple days of work. Everyone gets sick now and then. I don't think my wife cares about what happens to me. She and my boss got together and decided I needed to be here, or I lose my job!"
   - How would the nurse respond appropriately to this statement by Tom?

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss the concepts of schizophrenia and other psychotic disorders.
2. Identify predisposing factors in the development of these disorders.
3. Describe various types of schizophrenia and other psychotic disorders.
4. Identify symptomatology associated with these disorders and use this information in client assessment.
5. Formulate nursing diagnoses and outcomes of care for clients with schizophrenia and other psychotic disorders.
6. Identify topics for client and family teaching relevant to schizophrenia and other psychotic disorders.
7. Describe appropriate nursing interventions for behaviors associated with these disorders.
8. Describe relevant criteria for evaluating nursing care of clients with schizophrenia and other psychotic disorders.
9. Discuss modalities relevant to treatment of schizophrenia and other psychotic disorders.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Describe the neurotransmitters theorized to be involved in various symptoms of schizophrenia.
2. What is schizoaffective disorder?
3. How do delusions differ from hallucinations?
4. What was the first atypical antipsychotic to be developed? Why is it no longer considered a first-line treatment for schizophrenia?

The term *schizophrenia* was coined in 1908 by the Swiss psychiatrist Eugen Bleuler, derived from the Greek *skhizo* ("split') and *phren* ("mind").

Over the years, much debate has surrounded the concept of schizophrenia. Various definitions of the disorder have evolved, and numerous treatment strategies been proposed, but none have proven to be uniformly effective or sufficient.

Although controversy lingers, two general factors appear to be gaining acceptance among clinicians. The first is that schizophrenia is probably not a homogeneous disease entity. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5),* supports this concept by describing schizophrenia as one of the schizophrenia spectrum disorders (American Psychiatric Association [APA], 2013). While current consensus points to schizophrenia as a neurodevelopmental disorder (Álvarez et al., 2015), schizophrenia spectrum disorders may have several etiological influences, including genetic predisposition, biochemical dysfunction, physiological factors, and psychosocial stress.

The second agreed-upon factor among clinicians is that there is not now and may never be a single treatment that cures schizophrenia. Effective treatment currently requires a comprehensive, multidisciplinary effort, including pharmacotherapy and various forms of psychosocial care, such as living skills and **social skills training,** rehabilitation and recovery, and family therapy. Emerging evidence indicates that a comprehensive, patient-centered approach offers hope for a recovery process and improved quality of life in this population.

Of all the mental illnesses that cause suffering in society, schizophrenia is likely responsible for longer hospitalizations, greater chaos in family life, more exorbitant costs to individuals and governments, and more fear than any other. Because it is such an enormous threat to life and happiness and because its causes are an unsolved puzzle, it has also probably been studied more than any other mental disorder.

Risk for suicide is a major concern among patients with schizophrenia. About one-third of people with schizophrenia attempt suicide, and about 1 in 10 die from the act (Black & Andreasen, 2014). This chapter explores various theories of predisposing factors implicated in the development of schizophrenia. Symptomatology associated with different diagnostic categories of the disorder is discussed. Nursing care is presented in the context of the six steps of the nursing process. Various dimensions of medical treatment are explored.

Nature of the Disorder

CORE CONCEPT
Psychosis
A severe mental condition in which there is disorganization of the personality, deterioration in social functioning, and loss of contact with, or distortion of, reality. There may be evidence of hallucinations and delusional thinking. Psychosis can occur with or without the presence of organic impairment.

Perhaps no psychological disorder is more crippling than schizophrenia. Characteristically, disturbances in thought processes, perception, and affect invariably result in a severe deterioration of social and occupational functioning.

The lifetime prevalence of schizophrenia is about 1 percent in the general population (Sadock, Sadock, & Ruiz, 2015). Symptoms generally appear in late adolescence or early adulthood, although they may occur in middle or late adult life. Early-onset schizophrenia refers to symptoms that begin in childhood and adolescence before age 18 years. This condition, although rare, is recognized as a progressive neurodevelopmental disorder with a chronic and severely symptomatic course (Sadock et al., 2015). Some studies have indicated that symptoms occur earlier in men than in women. The pattern of development of schizophrenia may be viewed in four phases: the premorbid, prodromal, active psychotic (acute schizophrenic episode), and residual phases.

Phase I: Premorbid Phase

Premorbid signs are those that occur before there is clear evidence of illness and may include distinctive personality traits or behaviors. Premorbid personality and behavioral indications may include being very shy and withdrawn, having poor peer relationships, doing poorly in school, and demonstrating antisocial behavior. Sadock and associates (2015) stated:

In the typical, but not invariable, premorbid history of schizophrenia, patients had schizoid or schizotypal personalities characterized as quiet, passive, and introverted; as children, they had few friends. Preschizophrenic adolescents may have no close friends and no dates and may avoid team sports. They may enjoy [solitary activities] to the exclusion of social activities. (p. 311)

Current research is focused on the premorbid phase in hopes that identification of potential biomarkers and at-risk individuals may prevent transition to illness or provide early intervention (Clark et al., 2016).

Phase II: Prodromal Phase

Prodromal signs more clearly manifest as signs of developing schizophrenia than do premorbid signs. The prodromal phase of schizophrenia begins with a change from premorbid functioning and extends until the onset of frank psychotic symptoms. This phase can be as brief as a few weeks or months, but most studies indicate that the average length of the prodromal phase is between 2 and 5 years. During this phase, the individual begins to show signs of significant deterioration in function. Fifty percent complain of depressive symptoms (APA, 2013). Social withdrawal is not uncommon, and signs of cognitive impairment may begin to emerge. In addition, some adolescent patients develop sudden onset of obsessive-compulsive behavior during the prodromal phase (Sadock et al., 2015).

Recognition of the behaviors associated with the prodromal phase provides an opportunity for early intervention with a possibility for improvement in long-term outcomes. Current treatment guidelines suggest therapeutic interventions that offer support with identified problems, cognitive therapies to minimize functional impairment, family interventions to improve coping, and involvement with the schools to reduce the possibility of failure. Some controversy exists as to the benefit of pharmaceutical therapy during the prodromal phase; however, evidence supports that comprehensive treatment started at the time of the first psychotic episode is associated with better outcomes (Insel, 2015).

Phase III: Active Psychotic Phase (Acute Schizophrenic Episode)

Schizophrenia is a chronic illness but is characterized by acute episodes in which symptoms are more pronounced. In the active phase of the disorder, psychotic symptoms are typically prominent. Box 24–1 describes the *DSM-5* (APA, 2013) diagnostic criteria for schizophrenia.

Phase IV: Residual Phase

Schizophrenia is characterized by periods of remission and exacerbation and consequently is described as episodic despite being a chronic illness. A residual phase usually follows the active phase of the illness, during which symptoms of the active phase are either absent or no longer prominent. Negative symptoms

(see Box 24–3) may remain, and flat affect and impairment in role functioning are common during this phase. It has long been thought that these remaining symptoms are pervasive and stable, but current research has challenged that belief with evidence that negative symptoms can improve over time (Savill et al., 2015). Residual impairment often increases with additional episodes of active psychosis.

Prognosis

Outcomes in schizophrenia are difficult to predict, but a complete return to full premorbid functioning is uncommon. However, several factors have been associated with a more positive outcome, including high-level premorbid functioning, later age at onset, female gender, abrupt onset of symptoms with obvious precipitating factor (as opposed to gradual, insidious onset of symptoms), associated mood disturbance, rapid resolution of active-phase symptoms, minimal residual symptoms, absence of structural brain abnormalities, normal neurological functioning, and no family history of schizophrenia (Black & Andreasen, 2014; Puri & Treasaden, 2011; Sadock et al., 2015).

Predisposing Factors

The cause of schizophrenia is still uncertain. Most likely, no single factor can be implicated in the etiology; rather, the disease probably results from a combination of influences including biological, psychological, and environmental factors.

Biological Factors

In addition to the factors summarized in the following sections, Chapter 3, Concepts of Psychobiology, contains a more thorough review of the biological implications of psychiatric illness.

Genetics

The body of evidence for genetic vulnerability to schizophrenia is growing. Studies show that relatives of individuals with schizophrenia have a much higher probability of developing the disease than does the general population. Whereas the lifetime risk for developing schizophrenia is about 1 percent in most population studies, the siblings of an identified client have a 10 percent risk of developing schizophrenia, and individuals with one parent who has schizophrenia have a 5 to 6 percent chance of developing the disorder (Black & Andreasen, 2014).

How schizophrenia is inherited is uncertain. Current research is focused on determining which gene or genes are important in the vulnerability to schizophrenia and what other biomarkers may predict risk for this illness. Okazaki and associates (2016) studied

BOX 24–1 DSM-V Criteria for Schizophrenia Diagnosis

A. Two (or more) of the following, each present for a significant portion of time during a 1-month period (or less if successfully treated). At least one of these must be (1), (2), or (3):
   1. **Delusions**
   2. **Hallucinations**
   3. **Disorganized speech (e.g., frequent derailment or incoherence)**
   4. Grossly disorganized or catatonic behavior
   5. Negative symptoms (i.e., diminished emotional expression or avolition)
B. For a significant portion of the time since the onset of the disturbance, level of functioning in one or more major areas, such as work, interpersonal relations, or self-care, is markedly below the level achieved prior to the onset (or when the onset is in childhood or adolescence, there is failure to achieve expected level of interpersonal, academic, or occupational functioning).
C. Continuous signs of the disturbance persist for at least 6 months. This 6-month period must include at least 1 month of symptoms (or less if successfully treated) that meet Criterion A (i.e., active-phase symptoms) and may include periods of prodromal or residual symptoms. During these prodromal or residual periods, the signs of the disturbance may be manifested by only negative symptoms or by two or more symptoms listed in Criterion A present in an attenuated form (e.g., odd beliefs, unusual perceptual experiences).
D. Schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because either (1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms; or (2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness.
E. The disturbance is not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.
F. If there is a history of autism spectrum disorder or a communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations, in addition to the other required symptoms of schizophrenia, are also present for at least 1 month (or less if successfully treated).

Specify if: First episode, currently in acute, partial, or full remission; Multiple episodes, currently in acute, partial or full remission; Continuous; Unspecified; With catatonia
Specify current severity.

gene expression in peripheral blood samples of patients admitted with acute psychosis and found that a specific combination of genes (CDK4, MCM7, and POLD 4) differentiated these patients from controls. This finding suggests that the combination could be a genetic biomarker for schizophrenia and may also clarify aspects of pathophysiology in schizophrenia. The authors conclude that the messenger ribonucleic acid (mRNA) expression changes that occur in CDK4 are potentially both trait and state biomarkers for schizophrenia. Research is ongoing to identify genetic influences in schizophrenia that will hone our understanding of the multivariate influences in the development of this disease and perhaps identify treatment implications.

In monozygotic twins, the rate of schizophrenia is four to five times greater than the rate for dizygotic (fraternal) twins and approximately 50 times that of the general population (Sadock et al., 2015). Identical twins reared apart are at the same risk for schizophrenia as those reared together. Genetic makeup alone cannot account for the development of this disease, however;

in about half of cases, only one of a pair of identical twins develops schizophrenia.

Biochemical Factors

The oldest and most thoroughly explored biological theory to explain schizophrenia attributes a pathogenic role to abnormal brain biochemistry. Notions of a "chemical disturbance" as an explanation for mental illness were suggested by some theorists as early as the mid-19th century.

The Dopamine Hypothesis

This theory suggests that schizophrenia or schizophrenia-like symptoms may be caused by an excess of dopamine-dependent neuronal activity in the brain (Fig. 24–1). This excess activity may be related to increased production or release of the substance at nerve terminals, increased receptor sensitivity, too many dopamine receptors, or a combination of these mechanisms (Sadock et al., 2015).

Pharmacological support for this hypothesis exists. Amphetamines, which increase levels of dopamine,
FIGURE 24–1 Neurobiology of schizophrenia.

NEUROTRANSMITTERS

A number of neurotransmitters have been implicated in the etiology of schizophrenia: dopamine, norepinephrine, serotonin, glutamate, and gamma-aminobutyric acid (GABA). The dopaminergic system has been most widely studied and closely linked to the symptoms associated with the disease.

AREAS OF THE BRAIN AFFECTED

Four major dopaminergic pathways (the pathways that transmit dopamine to different areas of the brain) have been identified:

- *Mesolimbic pathway:* Originates in the ventral tegmentum area (VTA) and projects to areas of the limbic system, including the nucleus accumbens, amygdala, and hippocampus. The mesolimbic pathway is associated with functions of memory, emotion, arousal, and pleasure. Excess activity in the mesolimbic tract has been implicated in the positive symptoms of schizophrenia (e.g., hallucinations, delusions). Dopamine blockade in this pathway is the target of antipsychotic medication to reduce hallucinations and delusions.
- *Mesocortical pathway:* Originates in the VTA and projects into the cortex. The mesocortical pathway is concerned with cognition, social behavior, planning, problem-solving, motivation, and reinforcement in learning. Negative symptoms of schizophrenia (e.g., flat affect, apathy, lack of motivation, and anhedonia) have been associated with diminished activity in the mesocortical tract.
- *Nigrostriatal pathway:* Originates in the substantia nigra and terminates in the striatum of the basal ganglia. This pathway is associated with the function of motor control. Degeneration in this pathway is associated with Parkinson's disease, and since typical antipsychotics may also block dopamine here, drug-induced Parkinson-like extrapyramidal side effects and tardive dyskinesia occur.
- *Tuberoinfundibular pathway:* Originates in the hypothalamus and projects to the pituitary gland. It is associated with endocrine function, digestion, metabolism, hunger, thirst, temperature control, and sexual arousal. Dopamine blockade in this pathway is associated with an increase in prolactin levels (hyperprolactinemia), which can result in galactorrhea (milk discharge from the nipples) in both men and women, erectile disorder, and anorgasmia.

ANTIPSYCHOTIC MEDICATIONS

Type	Receptor Affinity	Associated Side Effects
Conventional (typical) antipsychotics: Phenothiazines Haloperidol	Strong D$_2$ (dopamine)	Extrapyramidal symptoms (EPS), hyperprolactinemia, neuroleptic malignant syndrome
Provide relief of psychosis, improvement in positive symptoms, worsening of negative symptoms.	Varying degrees of affinity for: ACh (acetylcholine) α_1 (norepinephrine)	Anticholinergic effects Tachycardia, tremors, insomnia, postural hypotension
	H$_1$ (histamine) Weak 5-HT (serotonin)	Weight gain, sedation Low potential for ejaculatory difficulty
Novel (atypical) antipsychotics: Clozapine, olanzapine, quetiapine, aripiprazole, risperidone, iloperidone,	Strong 5-HT Low to moderate D$_2$	Sexual dysfunction, GI disturbance, headache Low potential for EPS

ANTIPSYCHOTIC MEDICATIONS–cont'd		
Type	Receptor Affinity	Associated Side Effects
ziprasidone, paliperidone, asenapine, lurasidone	Varying degrees of affinity for: ACh	Anticholinergic effects
Provide relief of psychosis, improvement in positive symptoms, improvement in negative symptoms.	α-adrenergic	Tachycardia, tremors, insomnia, postural hypotension
	H_1	Weight gain, sedation

induce symptoms that mimic those of psychosis. The antipsychotics (e.g., chlorpromazine or haloperidol) lower brain levels of dopamine by blocking dopamine receptors, thus reducing psychotic symptoms, including those induced by amphetamines.

Postmortem brain studies of individuals who had schizophrenia have revealed a significant increase in the average number of dopamine receptors in approximately two-thirds of cases. This finding suggests that an increased number of dopamine receptors may not be the central or sole issue in all individuals with schizophrenia. Clients with positive symptoms such as delusions and hallucinations (referred to as *positive* symptoms because they are "added" to the clinical picture) respond with greater efficacy to dopamine-reducing drugs than do clients with negative symptoms (deficits such as apathy, poverty of ideas, and loss of drive). More information about positive and negative symptoms is listed in Box 24–3.

Thus, the current position on the dopamine hypothesis is that positive symptoms of schizophrenia may be related to increased numbers of dopamine receptors in the brain, as these symptoms are ameliorated by antipsychotic drugs that block dopamine receptors.

Other Biochemical Hypotheses

Various other biochemicals have been implicated in the predisposition to schizophrenia. Abnormalities in the neurotransmitters norepinephrine, serotonin, acetylcholine, and gamma-aminobutyric acid and in neuroregulators such as prostaglandins and endorphins have been suggested. Excess of serotonin has been hypothesized to cause both positive and negative symptoms of schizophrenia. The effectiveness of medications such as clozapine (a strong serotonin antagonist) lends support to this hypothesis (Sadock et al., 2015).

Recent research has implicated the neurotransmitter glutamate in the etiology of schizophrenia. The N-methyl-D-aspartate (NMDA) receptor is activated by the neurotransmitters glutamate and glycine. Psychopharmacological studies have shown that the drug class of glutamate antagonists (e.g., phencyclidine [PCP], ketamine) can produce schizophrenia-like symptoms in individuals who do not have the disorder (Hashimoto, 2006; Stahl, 2013). In one study,

participants experiencing ketamine-induced schizophrenia-like psychotic symptoms were treated with a drug trial of a glycine transporter-1 inhibitor (D'Souza et al., 2012). This medication was shown to reduce psychotic symptoms induced by the NMDA receptor antagonism of ketamine, so it is hoped that it may also benefit schizophrenia treatment. Despite evidence of a glutamate link to schizophrenia (Hu et al., 2014), further research is needed on the implications for treatment. Previous studies have focused on trying to reduce glutamate levels in patients who have advanced illness, but current research has identified that glutamate levels may be more important in the *transition* to psychosis. This theory is supported by the fact that first episodes of psychosis are often precipitated by stress, and glutamate increases under stress (Nauert, 2015). When glutamate levels are very high, the hippocampus becomes hypermetabolic and then begins to atrophy. Hippocampal atrophy has been identified as a significant finding in many individuals with schizophrenia. Future research may find that targeting interventions on glutamate is beneficial in high-risk individuals or those in early stages of illness to prevent onset or slow the progression of the disease (Nauert, 2015).

Current conventional antipsychotic medications largely target the dopamine receptors in the brain. Newer second-generation antipsychotics have strong affinity for serotonergic receptors. The glutamate model of schizophrenia suggests possibilities for new biomarkers signaling early illness and for new approaches to prevention and early treatment.

Physiological Factors

A number of physical factors have been identified in the medical literature. However, their specific mechanisms in the etiology of schizophrenia are unclear.

Viral Infection

Sadock and colleagues (2015) report that epidemiological data indicate a high incidence of schizophrenia after prenatal exposure to influenza. They stated:

> Other data supporting a viral hypothesis are an increased number of physical anomalies at birth, an increased rate of pregnancy and birth complications,

seasonality of birth consistent with viral infection, geographical clusters of adult cases, and seasonality of hospitalizations. (p. 305)

The effect of autoimmune antibodies in the brain is being studied within the field of psychoneuroimmunology, and evidence suggests that these antibodies may be responsible for the development of at least some cases of schizophrenia following infection from a neurotoxic virus (particularly prenatal exposure to toxoplasma gondii) (Matheson, Shepherd, & Carr, 2014). The role of cytokines in inflammation and the specific effects of these chemicals in the brain are still being explored through ongoing research.

Anatomical Abnormalities

With the use of neuroimaging technologies, structural brain abnormalities have been observed in individuals with schizophrenia. Ventricular enlargement is the most consistent finding; however, some reduction in gray matter is also reported. As previously discussed, reduction in the volume of the hippocampus observed in neuroimaging studies may signal risk for transition to a first psychotic episode (Harrisberger et al., 2016). Studies that focus on risk for a first psychotic episode are important, as early treatment is associated with better outcomes. Ultimately, it is hoped that these studies will also point to preventive strategies.

Magnetic resonance imaging has revealed reduced symmetry in lobes of the brain and reductions in size of structures within the limbic system in clients with schizophrenia. Considerable evidence from postmortem studies has shown abnormalities in the prefrontal cortex, and people who have had prefrontal lobotomies are reported to manifest with many symptoms common to schizophrenia (Sadock et al., 2015).

Diffusion tensor imaging studies have identified widespread white matter abnormalities in schizophrenia (Viher et al., 2016). These abnormalities in white matter microstructure appear to be primarily associated with negative symptoms and psychomotor behavior abnormalities.

Long-term studies of patients with schizophrenia have noted brain volume reduction, particularly in the temporal and preventricular areas (Veijola et al., 2014). It has been postulated that long-term antipsychotic medication use may contribute to this reduction, but the implications are unclear. Veijola and associates found that symptom severity, level of functional ability, and decline in cognitive abilities were not correlated with this reduction in brain volume.

Electrophysiology

Several studies have evaluated 40 Hz auditory steady-state response, a measure of electrical activity in the brain, and identified neural circuit dysfunctions in people with schizophrenia. A recent meta-analysis (Thunè, Recasens, & Uhlhaas, 2016) of these studies demonstrates robust evidence of such dysfunction in schizophrenia. The meaning of these circuit dysfunctions is not well understood but may indicate another biomarker for identifying risk or illness.

Physical Conditions

Several medical conditions are known to cause acute psychotic episodes, including but not limited to Huntington's disease, hypo- or hyperthyroidism, hypoglycemia, calcium imbalances, temporal lobe epilepsy, Wilson's disease, central nervous system (CNS) neoplasms, encephalitis, meningitis, neurosyphilis, and stroke (Mathews et al., 2013). See Table 24–2 for a more comprehensive list.

Psychological Factors

Early conceptualizations of schizophrenia focused on family relationship factors as major influences in the development of the illness, probably in light of the conspicuous absence of information related to a biological connection. These early theories implicated poor parent-child communication, particularly condemning the mother as schizophrenogenic (inducing schizophrenia in her child) related to a troublesome communication style known as *double-bind communication.* This theory no longer holds credibility. Researchers now focus their studies on schizophrenia as a brain disorder. Even though family communication patterns are no longer a credible explanation for the etiology of schizophrenia, the symptoms of the disease can contribute to significant disruption in communication and relationships among family members. For this reason, psychosocial factors should always be part of a comprehensive assessment. Further, evidence suggests that childhood trauma, and particularly multiple traumatizations, are associated (in combination with many other influences) with the development of schizophrenia (Álvarez et al., 2015; Matheson et al., 2014). Trauma-informed care should also be part of a comprehensive psychosocial assessment.

Environmental Influences

Sociocultural Factors

Many studies have attempted to link schizophrenia to social class. Epidemiological statistics have shown that more individuals from lower socioeconomic classes experience symptoms associated with schizophrenia

than do those from higher socioeconomic groups (Puri & Treasaden, 2011). This occurrence may be explained by the conditions associated with living in poverty, such as congested housing accommodations, inadequate nutrition, absence of prenatal care, few resources for dealing with stressful situations, and feelings of hopelessness for escaping the cycle of poverty.

An alternative view is that of the *downward drift hypothesis,* which suggests that because of the characteristic symptoms of the disorder, individuals with schizophrenia have difficulty maintaining gainful employment and "drift down" to a lower socioeconomic level (or fail to rise out of a lower socioeconomic group). Proponents of this view consider poor social conditions to be a consequence rather than a cause of schizophrenia.

Stressful Life Events

Studies have been conducted to determine whether psychotic episodes may be precipitated by stressful life events. No scientific evidence indicates that stress causes schizophrenia. It is probable, however, that stress may contribute to the severity and course of the illness. It is known that extreme stress can precipitate psychotic episodes, so it may also precipitate symptoms in an individual who possesses a genetic vulnerability to schizophrenia. Stressful life events also may be associated with exacerbation of schizophrenic symptoms and increased rates of relapse.

Cannabis and Genetic Vulnerability

Studies of genetic vulnerability for schizophrenia have linked certain genes (COMT and ATK1) to increased risk for psychosis, particularly for adolescents with this genetic vulnerability who use cannabinoids (Radhakrishnan, Wilkinson, & D'Souza, 2014). Both cannabis and synthetic cannabinoids can induce schizophrenia-like symptoms. In individuals with a preexisting psychosis, cannabinoids can exacerbate symptoms. More important, the increased risk for psychotic disorders such as schizophrenia when combined with cannabis use suggests the influence of lifestyle factors in the expression of genes and points to the possibility of multiple factors playing a role in the causality of this illness.

Theoretical Integration and the Transactional Model

The etiology of schizophrenia remains unclear. No single theory or hypothesis has substantiated a clearcut explanation for the disease. It seems the more research that is conducted, the more evidence is compiled to support the concept of multiple causation in the development of schizophrenia. In a systematic review of the literature on schizophrenia, Matheson and associates (2014) summarize that the most robust evidence suggests that schizophrenia is a widespread neural dysfunction accompanied by various psychological effects that respond moderately well to psychosocial and biomedical therapy:

> Patients have relatively poor cognitive functioning, and subtle, but diverse, structural brain alterations, altered electrophysiological functioning and sleep patterns, minor physical anomalies, neurological soft signs, and sensory alterations. There are markers of infection, inflammation or altered immunological parameters; and there is increased mortality from a range of causes. Risk for schizophrenia is increased with cannabis use, pregnancy and birth complications, prenatal exposure to *Toxoplasma gondii,* childhood central nervous system viral infections, childhood adversities, urbanicity, and immigration (first and second generation), particularly in certain ethnic groups. Developmental motor delays and lower intelligence quotient in childhood and adolescence are apparent. (p. 3387)

Despite the wealth of research and knowledge that we have about schizophrenia, much more is needed before we will fully understand this illness.

One way to conceptualize the pathway to acute illness is through exploring influencing factors and the individual's response to these stressors. The dynamics of schizophrenia using the transactional model of stress and adaptation are presented in Figure 24–2.

Other Schizophrenia Spectrum and Psychotic Disorders

The *DSM-5* (APA, 2013) identifies a spectrum of psychotic disorders organized to reflect a gradient of psychopathology from least to most severe. Degree of severity is determined by the level, number, and duration of psychotic signs and symptoms.

Several disorders may carry the additional specification of *With Catatonic Features,* the criteria for which are presented in Box 24–2. The disorders to which this specifier may be applied include brief psychotic disorder, schizophreniform disorder, schizophrenia, schizoaffective disorder, and substance-induced psychotic disorder. It may also be applied to neurodevelopmental disorder, major depressive disorder, and bipolar disorders I and II (APA, 2013).

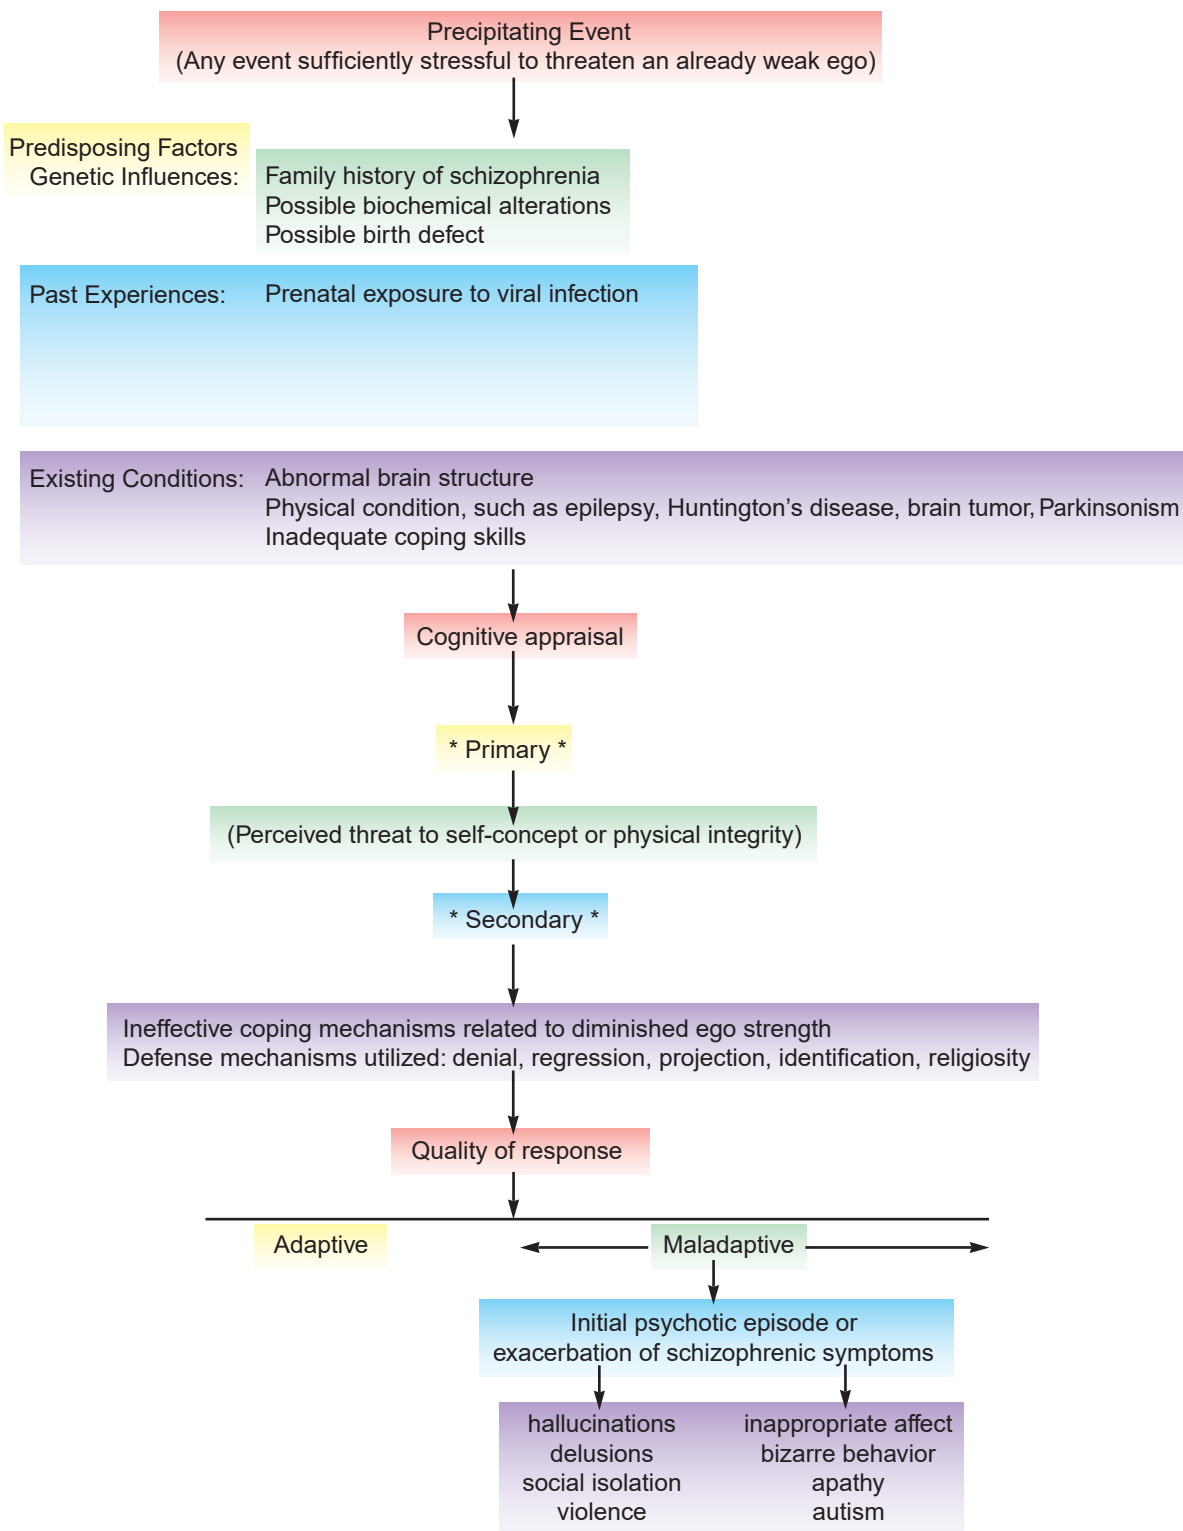
The *DSM-5* initiates the spectrum of disorders with Schizotypal Personality Disorder. For purposes of this textbook, this disorder is presented in Chapter 32, Personality Disorders.


FIGURE 24–2 The dynamics of schizophrenia using the transactional model of stress and adaptation.

Delusional Disorder

Delusional disorder is characterized by the presence of delusions experienced for at least 1 month (APA, 2013). If present at all, hallucinations are not prominent, and behavior is not bizarre. The *DSM-5* states that a specifier may be added to denote if the delusions are considered *bizarre* (i.e., if the thought is "clearly implausible, not understandable, and not derived from ordinary life experiences" [p. 91]). Subtypes of delusional disorder include the following.

Erotomanic Type

With this type of delusion, the individual believes that someone, usually of a higher status, is in love with him or her. Famous persons are often the subjects of erotomanic delusions. Sometimes the delusion is kept secret, but some individuals may follow, contact, or otherwise try to pursue the object of their delusion.

Grandiose Type

Individuals with grandiose delusions have irrational ideas regarding their own worth, talent, knowledge, or power. They may believe that they have a special relationship with a famous person or even assume the identity of a famous person (believing that the actual person is an imposter). Grandiose delusions of a religious nature may lead to assumption of the identity of a deity or religious leader.

Jealous Type

The content of jealous delusions centers on the idea that the person's sexual partner is unfaithful. The idea is irrational and without cause, but the individual with the delusion searches for evidence to justify the belief. The sexual partner is confronted (and sometimes physically attacked) regarding the imagined infidelity. The imagined lover of the sexual partner may also be the object of the attack. Attempts to restrict the autonomy of the sexual partner in an effort to stop the imagined infidelity are common.

Persecutory Type

In persecutory delusions, the most common type, individuals believe they are being persecuted or malevolently treated in some way. Frequent themes include being plotted against, cheated or defrauded, followed and spied on, poisoned, or drugged. The individual may obsess about and exaggerate a slight rebuff (either real or imagined) until it becomes the focus of a delusional system. Repeated complaints may be directed at legal authorities, lack of satisfaction from which may result in violence toward the object of the delusion.

Somatic Type

Individuals with somatic delusions have fixed, false beliefs that they have some type of medical condition or that there has been an alteration in a body organ or its function.

Mixed Type

When the disorder is *mixed,* delusions are prominent, but no single theme is predominant.

Brief Psychotic Disorder

This disorder is identified by the sudden onset of psychotic symptoms that may or may not be preceded by a severe psychosocial stressor. These symptoms last at least a day but less than a month, and there is an eventual full return to the premorbid level of functioning (APA, 2013). The individual experiences emotional turmoil or overwhelming perplexity or confusion. Evidence of impaired reality may include incoherent speech, delusions, hallucinations, bizarre behavior, and disorientation. Individuals with preexisting personality disorders (most commonly, histrionic, narcissistic, paranoid, schizotypal, and borderline personality disorders) appear to be susceptible to this disorder (Sadock et al., 2015). Catatonic features may also be associated with this disorder (see Box 24–2).

Substance/Medication-Induced Psychotic Disorder

The prominent hallucinations and delusions associated with this disorder are directly attributable to substance intoxication or withdrawal or exposure to a medication or toxin. This diagnosis is made when the symptoms

are more excessive and more severe than those usually associated with intoxication or withdrawal syndrome (APA, 2013). The medical history, physical examination, or laboratory findings provide evidence that the appearance of the symptoms occurred in association with substance intoxication or withdrawal or exposure to a medication or toxin. Substances believed to induce psychotic disorders are presented in Table 24–1. Catatonic features may also be associated with this disorder (see Box 24–2).

Psychotic Disorder Due to Another Medical Condition

The essential features of this disorder are prominent hallucinations and delusions that can be directly attributed to another medical condition (APA, 2013). The diagnosis is not made if the symptoms occur during the course of delirium. A number of medical conditions that can cause psychotic symptoms are presented in Table 24–2.

Catatonic Disorder Due to Another Medical Condition

Catatonic disorder is identified by the symptoms described in Box 24–2. This diagnosis is made when symptomatology evidenced from medical history, physical examination, or laboratory findings is directly attributable to the physiological consequences of another medical condition (APA, 2013). Types of medical conditions associated with **catatonia** include metabolic disorders (e.g., hepatic encephalopathy, diabetic ketoacidosis, hypo- and hyperthyroidism, hypo- and hyperadrenalism, hypercalcemia, and vitamin B_{12} deficiency) and neurological conditions (e.g., epilepsy, tumors, cerebrovascular disease, head

TABLE 24–1	Substances That May Cause Psychotic Disorders
Drugs of abuse	Alcohol Amphetamines and related substances Cannabis Cocaine Hallucinogens Inhalants Opioids Phencyclidine and related substances Sedatives, hypnotics, and anxiolytics
Medications	Anesthetics and analgesics Anticholinergic agents Anticonvulsants Antidepressant medication Antihistamines Antihypertensive agents Cardiovascular medications Antimicrobial medications Antineoplastic medications Antiparkinsonian agents Corticosteroids Disulfiram Gastrointestinal medications Muscle relaxants Nonsteroidal anti-inflammatory agents
Toxins	Anticholinesterase Organophosphate insecticides Nerve gases Carbon dioxide Carbon monoxide Volatile substances (e.g., fuel, paint, gasoline, toluene)

TABLE 24–2	General Medical Conditions That May Cause Psychotic Symptoms

Acute intermittent porphyria
Brain abscesses
Cerebrovascular disease
CNS infections
CNS trauma
Cushing's syndrome
Deafness
Encephalitis
Fluid or electrolyte imbalances
Hepatic disease
Herpes encephalitis
Huntington's disease
Hypoadrenocorticism
Hypo- or hyperparathyroidism
Hypo- or hyperthyroidism
Meningitis
Metabolic conditions (e.g., hypoxia; hypercarbia; hypoglycemia)
Migraine headache
Neoplasms
Neurosyphilis
Normal pressure hydrocephalus
Renal disease
Systemic lupus erythematosus
Temporal lobe epilepsy
Vitamin deficiency (e.g., B_{12})
Wilson's disease

(2015). *Synopsis of psychiatry: Behavioral sciences/clinical psychiatry* (11th ed.). Philadelphia: Lippincott Williams & Wilkins.

trauma, and encephalitis) (APA, 2013; Mathews et al., 2013).

Schizophreniform Disorder

The essential features of this disorder are identical to those of schizophrenia except that the duration, including prodromal, active, and residual phases, is at least 1 month but less than 6 months (APA, 2013). If the diagnosis is made while the individual is still symptomatic but has been so for less than 6 months, it is qualified as "provisional." The diagnosis is changed to schizophrenia if the clinical picture persists beyond 6 months. Schizophreniform disorder often has a good prognosis if the individual's affect is not blunted or flat, if there is a rapid onset of psychotic symptoms from the time the unusual behavior is noticed, or if premorbid social and occupational functioning was satisfactory (APA, 2013). Catatonic features may also be associated with this disorder (see Box 24–2).

Schizoaffective Disorder

This disorder is manifested by signs and symptoms of schizophrenia along with a strong element of symptomatology associated with the mood disorders (depression or mania). The client may appear depressed, with psychomotor retardation and suicidal ideation, or symptoms may include euphoria, grandiosity, and hyperactivity. The decisive factor in the diagnosis of schizoaffective disorder is the presence of hallucinations and/or delusions that occur for at least 2 weeks in the absence of a major mood episode (APA, 2013). However, prominent mood disorder symptoms must be evident for a majority of the time. The prognosis for schizoaffective disorder is generally better than that for other schizophrenic disorders but worse than that for mood disorders alone (Black & Andreasen, 2014). Catatonic features may also be associated with this disorder (see Box 24–2).

Application of the Nursing Process

Schizophrenia—Background Assessment Data

The diagnostic criteria for schizophrenia were presented earlier in this chapter. As previously stated, symptoms may present in phases, with schizophrenia representing the active phase of the disorder. Symptoms associated with the active phase are discussed in this section.

In the first step of the nursing process, the nurse gathers a database from which nursing diagnoses are derived and a plan of care is formulated. This step of the nursing process is extremely important because problem identification, objectives of care, and outcome criteria cannot be accurately determined without an accurate assessment.

Assessment of the client with schizophrenia is a complex process based on information gathered from a number of sources. Clients in an acute episode of their illness are seldom able to make significant contributions to their history. Data may be obtained from family members, if possible; from old medical records, if available; or from other individuals who have been in a position to report on the progression of the client's behavior.

The nurse must be familiar with behaviors common to the disorder to obtain an adequate assessment of the client with schizophrenia. Symptoms of schizophrenia are commonly described as positive or negative. Positive symptoms are those present in a person with schizophrenia that would not be present in a person without the illness, sometimes described as features that are "added." In contrast, negative symptoms are those that reflect a decrease in normal functions (functions that have been "taken away" by the illness). Most but not all clients exhibit a mixture of both types of symptoms.

Positive symptoms are associated with normal brain structures on computed tomography scan and respond relatively well to treatment. Sadock and associates (2015) identify that positive symptoms tend to become less severe over time, whereas the negative or "deficit" symptoms are socially debilitating and may increase in severity. Atypical antipsychotics have been advanced as more effective in treating negative symptoms, but researchers continue to search for medications that will specifically treat the several cognitive deficits that are most problematic for patients with schizophrenia. These deficits include memory, attention, language, and executive functions, and they can dramatically impact an individual's overall functional ability (Fioravanti, Bianchi, & Cinti, 2012).

The positive and negative symptoms associated with schizophrenia are described next. It is important to note that not all patients with schizophrenia experience all of these symptoms. Bora (2015) notes that in individuals who develop cognitive deficits, the age of onset is variable, and MacCabe and associates (2012) identify that a subgroup of individuals with schizophrenia have no cognitive impairment even in adulthood. Many factors contribute to functional impairment and decline beyond the symptoms themselves, including comorbid metabolic conditions, chronic substance use, stress, frequency and intensity of episodes, residual symptoms, and social defeat (Bora, 2015). A summary of positive and negative symptoms is presented in Box 24–3.

BOX 24–3 Positive and Negative Symptoms of Schizophrenia

POSITIVE SYMPTOMS

Delusions (Fixed, False Beliefs)

Persecutory—belief that one is going to be harmed by other(s)

Referential—belief that cues in the environment are specifically referring to them

Grandiose—belief that they have exceptional greatness

Somatic—beliefs that center on one's body functioning

Hallucinations (sensory perceptions without external stimuli)

Auditory (most common in schizophrenia)

Visual

Tactile

Olfactory

Gustatory

(Note: Hallucinations may be a normal part of religious experience in cultural contexts)

Disorganized Thinking (Manifested in Speech)

Loose association

Tangentiality

Circumstantiality

Incoherence (includes word salad)

Neologisms

Clang associations

Echolalia

Grossly Disorganized or Abnormal Motor Behavior (Including Catatonia)

Hyperactivity

Hypervigilance

Hostility

Agitation

Childlike silliness

Catatonia (ranging from rigid or bizarre posture and decreased responsivity to complete lack of verbal or behavioral response to the environment)

Catatonic excitement (excessive and purposeless motor activity)

Stereotyped, repetitive movements

Unusual mannerisms or postures

NEGATIVE SYMPTOMS

Lack of Emotional Expression

Blunted affect

Lack of movement in head and hands that add expression in communication

Lack of intonation in speech

Decreased or Lack of Motivation to Complete Purposeful Activities (Avolition)

Neglect of activities of daily living

Decreased Verbal Communication (Alogia)

Decreased Interest in Social Interaction and Relationship (Asociality)

Withdrawal

Poor rapport

Diminished Ability for Abstract Thinking

Concrete interpretation of events and communication from others

Positive symptoms refer to symptoms that are present ("added") in people with schizophrenia and not typically present in people without the disease. Negative symptoms are referred to as deficits or impairments (things "taken away" by the illness) in individuals with schizophrenia.
SOURCES: American Psychiatric Association (APA). (2013). Diagnostic and statistical manual of mental disorders (5th ed.) Washington, DC: APA. Kay, S.R., Fiszbein, A., & Opler, L.A. (1987). The positive and negative syndrome scale (PANSS) for schizophrenia. Schizophrenia Bulletin,13(2), 261-276.

Positive Symptoms

Disturbances in Thought Content

Delusions **Delusions** are false personal beliefs inconsistent with the person's intelligence or cultural background. The individual continues to have the belief despite obvious proof that it is false or irrational.

Delusions are subdivided according to their content. Some of the more common ones are listed here.

■ **Delusion of persecution:** The individual feels threatened and believes that others intend harm or persecution toward him or her in some way (e.g., "The FBI has bugged my room and intends

to kill me"; "I can't take a shower in this bathroom; the nurses have put a camera in there so that they can watch everything I do").

- **Delusion of grandeur:** The individual has an exaggerated feeling of importance, power, knowledge, or identity (e.g., "I am Jesus Christ").
- **Delusion of reference:** Events within the environment are referred by the psychotic person to himself or herself (e.g., "Someone is trying to get a message to me through the articles in this magazine [or newspaper or TV program]; I must break the code so that I can receive the message"). Delusions of reference are fixed false beliefs and are adhered to in spite of evidence to the contrary. *Ideas* of reference are less rigid than delusions of reference. For example, an individual with ideas of reference may think that other people in the room who are giggling must be laughing about him, but with additional information can acknowledge that there could be other explanations for their behavior.
- **Delusion of control or influence:** The individual believes certain objects or persons have control over his or her behavior (e.g., "The dentist put a filling in my tooth; I now receive transmissions through the filling that control what I think and do").
- **Somatic delusion:** The individual has a false idea about the functioning of his or her body (e.g., "I'm 70 years old, and I will be the oldest person ever to give birth. The doctor says I'm not pregnant, but I know I am").
- **Nihilistic delusion:** The individual has a false idea that the self, a part of the self, others, or the world is nonexistent or has been destroyed (e.g., "The world no longer exists"; "I have no heart").

Paranoia Individuals with **paranoia** have extreme suspiciousness of others and of their actions or perceived intentions (e.g., "I won't eat this food. I know it has been poisoned").

Magical Thinking With **magical thinking,** the person believes that his or her thoughts or behaviors have control over specific situations or people (e.g., the mother who believed if she scolded her son in any way he would be taken away from her). Magical thinking is common in children (e.g., "It's raining; the sky is sad"; "It snowed last night because I wished very, very hard that it would").

Disturbances in Thought Processes Manifested in Speech

Loose Associations Thinking is characterized by speech in which ideas shift from one unrelated subject to another. Typically, the individual with **loose associations** is unaware that the topics are unconnected. When the condition is severe, speech may be incoherent (e.g., "We wanted to take the bus, but the airport took all the traffic. Driving is the ticket when you want to get somewhere. No one needs a ticket to heaven. We have it all in our pockets").

Neologisms **Neologisms** are newly invented words that are meaningless to others but have symbolic meaning to the individual (e.g., "She wanted to give me a ride in her new *uniphorum*").

Clang Associations Choice of words is governed by sounds, often taking the form of rhyming, which forms a **clang association.** For instance, "It is very cold. I am cold and bold. The gold has been sold."

Word Salad A **word salad** is a group of words that appear to be put together randomly, without any logical connection (e.g., "Most forward action grows life double plays circle uniform").

Circumstantiality With **circumstantiality,** the individual delays in reaching the point of a communication because of unnecessary and tedious details. The point or goal is usually met but only with numerous interruptions by the interviewer to keep the person on track.

Tangentiality **Tangentiality** refers to a veering away from the topic of discussion and demonstrates difficulty in maintaining focus and attention.

Perseveration The individual who exhibits **perseveration** persistently repeats the same word or idea in response to different questions. It is the manifestation of a thought-processing disturbance in which the person gets stuck on a particular thought.

Echolalia **Echolalia** refers to repeating words or phrases spoken by another. In toddlers this is a normal phase in development, but in children with autism, echolalia may persist beyond the toddler years. In adulthood, echolalia is a significant neurological symptom of thought disturbance that occurs in schizophrenia, strokes, and other neurological disorders.

Disturbances in Perception

Hallucinations **Hallucinations,** or false sensory perceptions not associated with real external stimuli, may involve any of the five senses. Types of hallucinations include the following:

- **Auditory:** Auditory hallucinations are false perceptions of sound. Most commonly, these are voices, but the individual may report clicks, rushing noises, music, and other noises. Command hallucinations are "voices" that issue commands to the individual. They are potentially dangerous when the commands are for violence to self or others. Auditory hallucinations are the most common type in schizophrenia.
- **Visual:** These are false visual perceptions that may consist of formed images, such as those of people, or of unformed images, such as flashes of light. Visual hallucinations occur 27 percent of the time in individuals with schizophrenia (and 15 percent

in affective psychosis). They typically co-occur with auditory hallucinations and are associated with poorer outcomes (Waters et al., 2014).

- **Tactile:** Tactile hallucinations are false perceptions of the sense of touch, often of something on or under the skin. One specific tactile hallucination is formication, the sensation that something is crawling on or under the skin.
- **Gustatory:** This is a false perception of taste. Most commonly, gustatory hallucinations are described as unpleasant tastes.
- **Olfactory:** Olfactory hallucinations are false perceptions of the sense of smell.

Illusions **Illusions** are misperceptions or misinterpretations of real external stimuli. These may occur during the prodromal phase and persist in the residual phase as well as during the active phase.

Echopraxia The client who exhibits **echopraxia** imitates movements made by others. The mechanisms underlying echopraxia in schizophrenia are not well understood, but current evidence suggests that it may involve a disturbance in mirror neuron activity in the presence of social cognition impairments and self-monitoring deficits, culminating in imitative psychomotor behavior (Urvakhsh et al., 2014).

Negative Symptoms

Disturbances in Affect

Affect describes the visual manifestations associated with an individual's feeling state or emotional tone.

Inappropriate Affect Affect is inappropriate when the individual's emotional tone is incongruent with the circumstances (e.g., a young woman who laughs when told of the death of her mother).

Bland or Flat Affect Affect is described as bland when the emotional tone is very weak. The individual with flat affect appears to be void of emotional tone (or overt expression of feelings).

Apathy

The client with schizophrenia often demonstrates an indifference to or disinterest in the environment. The bland or flat affect is a manifestation of the emotional apathy.

Avolition

Impaired volition has to do with the inability to initiate goal-directed activity. In the individual with schizophrenia, this may take the form of inadequate interest, lack of motivation, neglect of activities of daily living including personal hygiene and appearance, or inability to choose a logical course of action in a given situation. Impairment in social functioning may be reflected in social isolation, emotional detachment, and lack of regard for social convention.

Lack of Interest or Skills in Interpersonal Interaction

Some clients with acute schizophrenia cling to others and intrude on the personal space of others, exhibiting behaviors that are not socially and culturally acceptable. Others may exhibit ambivalence in social relationships. Still others may withdraw from relationships altogether (asociality).

Lack of Insight

Some individuals lack awareness of having any illness or disorder even when symptoms appear obvious to others. The term for this is **anosognosia.** The *DSM-5* identifies this symptom as the "most common predictor of nonadherence to treatment, and it predicts higher relapse rates, increased number of involuntary treatments, poorer psychosocial functioning, aggression, and poorer course of illness" (APA, 2013, p. 101).

Anergia

Anergia is a deficiency of energy. The individual with schizophrenia may lack sufficient energy to carry out activities of daily living or to interact with others.

Anhedonia

Anhedonia is the inability to experience pleasure. This is a particularly distressing symptom that compels some clients to attempt suicide.

Lack of Abstract Thinking Ability

Concrete thinking, or literal interpretations of the environment, represents a regression to an earlier level of cognitive development. Abstract thinking becomes impaired in some individuals with schizophrenia. For example, the client with schizophrenia would have great difficulty describing the abstract meaning of sayings such as "I'm climbing the walls" or "It's raining cats and dogs."

Associated Features

Waxy Flexibility

Waxy flexibility describes a condition in which the client with schizophrenia allows body parts to be placed in bizarre or uncomfortable positions. This symptom is associated with catatonia. Once placed in position, the arm, leg, or head remains in that position for long periods, regardless of how uncomfortable it is for the client. For example, the nurse may position the client's arm in an outward position to take a blood pressure measurement. When the cuff is removed, the client maintains the arm in the position in which it was placed to take the reading.

Posturing

This symptom is manifested by the voluntary assumption of inappropriate or bizarre postures.

Pacing and Rocking

Pacing back and forth and body rocking (a slow, rhythmic, backward-and-forward swaying of the trunk from the hips, usually while sitting) are common psychomotor behaviors of the client with schizophrenia.

Regression

Regression is the retreat to an earlier level of development. This primary defense mechanism of schizophrenia may be a dysfunctional attempt to reduce anxiety. It provides the basis for many of the behaviors associated with schizophrenia.

Eye Movement Abnormalities

Eye movement abnormalities may manifest in several ways including difficulty maintaining focus on a stationary object and difficulty with smooth pursuit of a moving object. Research (Benson et al., 2012) has found that simple eye movement tests can distinguish the abnormalities common in schizophrenia with exceptional accuracy.

Diagnosis and Outcome Identification

Using information collected during the assessment, the nurse completes the client database, from which the selection of appropriate nursing diagnoses is determined. Table 24–3 presents a list of client behaviors and the NANDA nursing diagnoses that correspond to those behaviors, which may be used in planning care for clients with psychotic disorders.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with schizophrenia.

The client:

■ Demonstrates an ability to relate satisfactorily with others

---

TABLE 24–3 **Assigning Nursing Diagnoses to Behaviors Commonly Associated With Psychotic Disorders**	
BEHAVIORS	**NURSING DIAGNOSES**
Impaired communication (inappropriate responses), disordered thought sequencing, rapid mood swings, poor concentration, disorientation, stops talking in midsentence, tilts head to side as if to be listening	Disturbed sensory perception*
Delusional thinking; inability to concentrate; impaired volition; inability to problem-solve, abstract, or conceptualize; extreme suspiciousness of others; inaccurate interpretation of the environment	Disturbed thought processes*
Withdrawal; sad, dull affect; need-fear dilemma; preoccupation with own thoughts; expression of feelings of rejection or of aloneness imposed by others; uncommunicative; seeks to be alone	Social isolation
Risk factors: Aggressive body language (e.g., clenching fists and jaw, pacing, threatening stance); verbal aggression; catatonic excitement; command hallucinations; rage reactions; history of violence; overt and aggressive acts; goal-directed destruction of objects in the environment; self-destructive behavior; active, aggressive suicidal acts	Risk for violence: Self-directed or other-directed
Loose association of ideas, neologisms, word salad, clang associations, echolalia, verbalizations that reflect concrete thinking, poor eye contact, difficulty expressing thoughts verbally, inappropriate verbalization	Impaired verbal communication
Difficulty carrying out tasks associated with hygiene, dressing, grooming, eating, and toileting	Self-care deficit
Neglectful care of client in regard to basic human needs or illness treatment, extreme denial or prolonged overconcern regarding client's illness, depression, hostility and aggression	Disabled family coping
Inability to take responsibility for meeting basic health practices, history of lack of health-seeking behavior, lack of expressed interest in improving health behaviors, demonstrated lack of knowledge regarding basic health practices, anosognosia (lack of insight about illness)	Ineffective health maintenance
Unsafe, unclean, disorderly home environment; household members express difficulty in maintaining their home in a safe and comfortable condition	Impaired home maintenance

Adapted from Herdman, T.H., & Kamitsuru, S. (Eds.). (2014). *NANDA-I nursing diagnoses: Definitions and classification, 2015–2017.* Chichester, UK: Wiley Blackwell.
*These diagnoses have been resigned from the NANDA-I list of approved diagnoses. They are used in this instance because they are most compatible with the identified behaviors.

- Recognizes distortions of reality
- Has not harmed self or others
- Perceives self realistically
- Demonstrates the ability to perceive the environment correctly
- Maintains anxiety at a manageable level
- Relinquishes the need for delusions and hallucinations
- Demonstrates the ability to trust others
- Uses appropriate verbal communication in interactions with others
- Performs self-care activities independently

Planning and Implementation

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each. In general, nursing interventions should be geared toward establishing trust, since suspiciousness is a common symptom in this disorder.

Using a passive rather than a directive communication approach, which offers the client the opportunity to make his or her decisions about activities, treatment goals, and other aspects of care, is in the interest of establishing trust and incorporating a patient-centered approach.

In addition, nurses must be aware of their own attitudes in order to avoid perpetuating stigmatization of this client, since this concern has often been responsible for individuals avoiding treatment from health-care professionals. One way to reduce stigma is to become familiar with real people who suffer from this disorder rather than relying on fictitious representations (and sometimes, misrepresentations) of this population in popular media. (See the "Real People, Real Stories" introduction to Dr. Fred Frese).

Real People, Real Stories: Dr. Fred Frese
People with schizophrenia continue to be disenfranchised, misunderstood, and stigmatized. Even within health care, evidence has shown that some settings have been very hostile to people with severe mental illnesses. One way to begin combating stigmatization of people with mental illness is to get to know them personally. Dr. Fred Frese is a licensed psychologist and an internationally renowned speaker, writer, and advocate in the field of mental illness.

Karyn: Could you share a little bit about your history with schizophrenia?

Dr. Frese: I was 25 when I had my first episode. I was in the Marines and—I know I had seen the movie *The Manchurian Candidate* previously—and I began to think that the Vietnamese were using the same strategies from the movie to control us. When I let my commanding officer know my theories, I was hospitalized involuntarily, and for the next 10 years I was in and out of hospitals—mostly involuntarily—taking various medications, living many different places, and not employed.

Karyn: Were you getting any treatments or intervention that you thought were helpful to your recovery?

Dr. Frese: Well, at that time it was thought that schizophrenia was not an illness from which one could recover. Even recently, I've heard some folks who have a family member with schizophrenia say, "There's no way that anyone with this illness can get better." But that's starting to change, and now that the government, through SAMHSA [Substance Abuse and Mental Health Services Administration] is backing the recovery model approach, I think health care will improve. I remember being told that my brain was going to progressively deteriorate and that I would never be able to function on my own. All in all, I probably spent about a year of my life in hospitalizations. Once the laws changed and I knew you had to be of imminent harm to yourself or others in order to be hospitalized involuntarily, I talked some of the health professionals out of admitting me. During the last attempt to hospitalize me, I actually escaped and ran away, even though I was in pretty bad shape.

Karyn: So since you were knowledgeable about the laws, you could essentially be your own self-advocate and argue your case, so to speak?

Dr. Frese: Yes, and by that time, I was in grad school and had secured a job at what is now the Department of Mental Health and Addiction Services. I remember I was living in the hallway of some university housing, and one of the students, who saw me day after day just hanging around and not really doing anything, suggested that I might be eligible for a government job because of my military background. When I applied, the receptionist saw my history of mental health commitments and said I would never get the job, but I did. The last time I went to the hospital, I went voluntarily because I knew I needed more medication, but

Real People, Real Stories: Dr. Fred Frese—cont'd

they thought I needed to be hospitalized and I didn't; so I ran away.

Karyn: Sounds like you were managing a lot of stuff—grad school, working—and, at the same time, episodically struggling with symptoms of illness. You were working in the field of mental health, too. Was the work environment supportive?

Dr. Frese: Not always. It seemed like even among my coworkers, when something strange happened, they thought it was something wrong with me.

Karyn: What do you mean by "something strange"?

Dr. Frese: Like one time when they perceived I was spending too much time interacting with patients, they assumed I was "going off again," and next thing I knew, they called a "blue alert" and wanted to hospitalize me. But that time, the medical director just told me to take some time off. I never did find out why they called that blue alert.

Karyn: So you haven't been hospitalized for a very long time, and you are internationally renowned for all of your work and advocacy in the field of mental health. What do you think has contributed most to your recovery?

Dr. Frese: No, I haven't been hospitalized since I got married. I think that has been central in my recovery: having a person who you trust to give you feedback and let me know when I need more medication.

Karyn: What role do medications play in recovery?

Dr. Frese: It's very individual. We need more research to identify who, among people with schizophrenia, will benefit most by continuous medication versus episodic, reduced doses, or no medication. Genetic research is hopeful, but we're not there yet. It's hard to advise any individual what to do without knowing their individual circumstances, and even knowing, it can be very hard.

Karyn: What do you think is most important for future nurses to know about what they should do or say when they encounter someone with schizophrenia in a health-care setting, such as ER, for example?

Dr. Frese: Even though Freud's theories about psychoanalysis and insight-oriented therapy have been shown in research to be not only not helpful in the treatment of people with schizophrenia but potentially harmful, these ideas continue to influence the thinking of health-care professionals. I would tell nurses to wean themselves away from psychoanalytic concepts in treating people with schizophrenia. There continue to be assumptions that something bad must have happened in this patient's childhood, and the family is probably to blame. It's not a good way to forge relationships and may prejudge or isolate the people that can provide invaluable support.

So I would say to future nurses, don't make assumptions about me because you see a diagnosis or the kind of medication I'm on, and don't try to blame anyone for my symptoms. Treat me with civility and respect, don't respond to me with shock and disbelief, bullying, or laughing at me. Listening to the patient is the best way to establish and maintain a relationship. Even if the patient is saying something that doesn't make any sense to you, the best response is, "That's very interesting; tell me more."

To learn more about Dr. Frese, go to www.fredfrese.com.

Some institutions use a case management model to coordinate care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing, for more detailed explanation). In case management models, the plan of care may take the form of a critical pathway. In general, team approaches to the care of this client have been identified as essential to positive outcomes and recovery.

Nurses need to collaborate effectively with other team members (including social workers, case managers, psychiatrists, chaplains, and counselors) to identify and respond to the complex care needs of this client.

Disturbed Sensory Perception: Auditory/Visual

Disturbed sensory perception has been resigned as a nursing diagnosis by NANDA International (NANDA-I), but it is retained in this text because of its appropriateness in describing specific behaviors. The diagnosis may be defined as sensory perceptions that are inconsistent with external stimuli and may include auditory, visual, tactile, olfactory, or gustatory perceptions. The following nursing interventions speak specifically to auditory hallucinations, the most common type occurring in schizophrenia. Table 24–4 presents this nursing diagnosis in care plan format.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will discuss content of hallucinations with nurse or therapist within 1 week.

Long-term goal

■ Client will be able to define and test reality, reducing or eliminating the occurrence of hallucinations.

This goal may not be realistic for the individual with severe and persistent illness who has experienced auditory hallucinations for many years. A more realistic goal may be:

■ Client will verbalize understanding that the voices are a result of his or her illness and demonstrate ways to interrupt the hallucination.

Table 24–4 | CARE PLAN FOR THE CLIENT WITH SCHIZOPHRENIA

NURSING DIAGNOSIS: DISTURBED SENSORY PERCEPTION: AUDITORY/VISUAL

RELATED TO: Panic anxiety, extreme loneliness, and withdrawal into the self

EVIDENCED BY: Inappropriate responses, disordered thought sequencing, rapid mood swings, poor concentration, disorientation

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client discusses content of hallucinations with nurse or therapist within 1 week. Long-Term Goals • Client is able to define and test reality, reducing or eliminating the occurrence of hallucinations. *Note:* This goal may not be realistic for the individual with severe and persistent illness who has experienced auditory hallucinations for many years. A more realistic goal may be: • Client verbalizes understanding that the voices are a result of his or her illness and demonstrates ways to interrupt the hallucination.	1. Observe client for signs of hallucinations (listening pose, laughing or talking to self, stopping in midsentence). Ask, "Are you hearing the voices again?" 2. Avoid touching client without warning him or her that you are about to do so. 3. An attitude of acceptance encourages client to share the content of the hallucination with you. Ask, "What do you hear the voices saying to you?" 4. Do not reinforce the hallucination. Use "the voices" instead of words such as "they" that imply validation. Let client know that you do not share the perception. Say, "Even though I realize the voices are real to you, I do not hear any voices speaking." 5. Help client understand the connection between increased anxiety and the presence of hallucinations. 6. Try to distract client from the hallucination. 7. For some clients, auditory hallucinations persist after the acute psychotic episode has subsided. Listening to the radio or watching television helps distract some clients from attention to the voices. Others have benefited from an intervention called *voice dismissal.* With this technique, client is taught to say loudly, "Go away!" or "Leave me alone!" in a conscious effort to dismiss the auditory perception.	1. Early intervention may prevent aggressive response to command hallucinations. 2. Client may perceive touch as threatening and may respond in an aggressive manner. 3. This question is important to prevent possible injury to the client or others from command hallucinations. 4. It is important for the nurse to be honest, and client must accept the perception as unreal before hallucinations can be eliminated. 5. If client can learn to interrupt escalating anxiety, hallucinations may be prevented. 6. Involvement in interpersonal activities and explanation of the actual situation will help bring client back to reality. 7. These activities assist client to exert some conscious control over the hallucination.

Table 24–4 | CARE PLAN FOR THE CLIENT WITH SCHIZOPHRENIA–cont'd

NURSING DIAGNOSIS: IMPAIRED VERBAL COMMUNICATION

RELATED TO: Panic anxiety, regression, withdrawal, disordered, unrealistic thinking

EVIDENCED BY: Loose association of ideas, neologisms, word salad, clang association, echolalia, verbalizations that reflect concrete thinking, poor eye contact

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client demonstrates the ability to remain on one topic, using appropriate, intermittent eye contact for 5 minutes with the nurse or therapist. **Long-Term Goal** • By time of discharge from treatment, client demonstrates ability to carry on a verbal communication in a socially acceptable manner with health-care providers and peers.	1. Attempt to decode incomprehensible communication patterns. Seek validation and clarification by stating, "Is it that you mean . . . ?" or "I don't understand what you mean by that. Would you please explain it to me?" 2. Maintain staff assignments as consistently as possible. 3. The technique of verbalizing the implied is used with client who is mute (unable or unwilling to speak). Example: "That must have been a very difficult time for you when your mother left. You must have felt very alone." 4. Anticipate and fulfill client's needs until functional communication pattern returns. 5. Orient client to reality as required. Call client by name. Validate those aspects of communication that help differentiate between what is real and not real. 6. Explanations must be provided at client's level of comprehension. Example: "Pick up the spoon, scoop some mashed potatoes into it, and put it in your mouth."	1. These techniques reveal how client is being perceived by others, while the responsibility for not understanding is accepted by the nurse. 2. Consistency facilitates trust and understanding between client and nurse. 3. This approach conveys empathy and may encourage client to disclose painful issues. 4. Client safety and comfort are nursing priorities. 5. These techniques may facilitate restoration of functional communication patterns in client. 6. Because concrete thinking prevails, abstract phrases and clichés must be avoided, as they are likely to be misinterpreted.

NURSING DIAGNOSIS: SELF-CARE DEFICIT

RELATED TO: Withdrawal, regression, panic anxiety, perceptual or cognitive impairment, inability to trust

EVIDENCED BY: Difficulty carrying out tasks associated with hygiene, dressing, grooming, eating, toileting

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client verbalizes a desire to perform activities of daily living (ADLs) by end of 1 week.	1. Provide assistance with self-care needs as required. Some clients who are severely withdrawn may require total care.	1. Client safety and comfort are nursing priorities.

Continued

Table 24–4 | CARE PLAN FOR THE CLIENT WITH SCHIZOPHRENIA–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Long-Term Goal • Client is able to perform ADLs in an independent manner and demonstrates a willingness to do so by time of discharge from treatment.	2. Encourage client to perform as many activities as possible independently. Provide positive reinforcement for independent accomplishments.	2. Independent accomplishment and positive reinforcement enhance self-esteem and promote repetition of desirable behaviors.
	3. Use concrete communication to show client what is expected. Provide step-by-step instructions for assistance in performing ADLs. Example: "Take your pajamas off and put them in the drawer. Take your shirt and pants from the closet and put them on. Comb your hair and brush your teeth."	3. Because concrete thinking prevails, explanations must be provided at client's concrete level of comprehension.
	4. Creative approaches may need to be taken with client who is not eating, such as allowing client to open own canned or packaged foods; family-style serving may also be an option.	4. These techniques may be helpful with client who is paranoid and may be suspicious that he or she is being poisoned with food or medication.
	5. If toileting needs are not being met, establish a structured schedule for client.	5. A structured schedule helps client establish a pattern so that he or she can develop a habit of toileting independently.

Interventions

■ Observe the client for signs of hallucinations (listening pose, laughing or talking to self, stopping in midsentence). Ask, "Are you hearing other voices?" "Are you able to distinguish those voices from my voice?" Early intervention may prevent aggressive responses to command hallucinations (such as voices telling the client to hurt or kill himself or herself).

■ Avoid touching the client, or ask for permission before doing so. The client may perceive touch as threatening and respond in an aggressive or defensive manner.

■ An attitude of acceptance will encourage the client to share the content of the hallucination with you. Ask, "What do you hear the voices saying to you?" This information is important in order to assess for risk of injury to the client or others from command hallucinations. Ask, "Do these voices seem familiar to you, or do they seem to be unfamiliar?" This question may shed some light on who the individual is associating with as the source of the voices.

CLINICAL PEARL

Do not reinforce the hallucination. Use "the voices" instead of words such as "they" that imply validation. Let the client know that you do not share the perception. For example, say, "Even though I realize that the voices are real to you, I do not hear any voices speaking." This statement conveys honesty and respect for the client's experience as real, and it provides a foundation for exploration of management and coping strategies.

■ Assess the client's level of anxiety and help him or her understand that increased anxiety may trigger hallucinations. If the client can learn to interrupt escalating anxiety, these episodes may be minimized or prevented.

■ Try to distract the client from the hallucination. Involvement in interpersonal activities and explanation of the actual situation will help the client focus on reality.

■ For some clients, auditory hallucinations persist after the acute psychotic episode has subsided. Listening to the radio or watching television helps distract some clients from the voices. Others have benefited from an intervention called *voice dismissal*. With this

technique, the client is taught to say loudly, "Go away!" or "Leave me alone!" thereby exerting some conscious control over the behavior.

■ Assess for suicide risk. Some individuals have taken their own lives to escape from pervasive, troubling, or frightening hallucinations.

Disturbed Thought Processes

Disturbed thought processes has been resigned as a nursing diagnosis by NANDA-I, but it is retained in this text because of its appropriateness in describing specific behaviors. In this instance, it is evidenced by behaviors that indicate the presence of delusional thinking, suspiciousness, and inaccurate interpretation of the environment. The diagnosis is defined as a disruption in cognitive operations and activities.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ By the end of 2 weeks, client will recognize and verbalize that false ideas occur at times of increased anxiety.

Long-term goal

Depending on chronicity of the disease process, choose the most realistic long-term goal for the client:

■ By time of discharge from treatment, client's verbalizations will reflect reality-based thinking with no evidence of delusional ideation.

■ By time of discharge from treatment, client will be able to differentiate between delusional thinking and reality.

Interventions

■ Convey acceptance of the client's need for the false belief, but indicate that you do not share the belief. The client must understand that you do not view the idea as real.

■ Do not argue or deny the belief. Arguing with the client or denying the belief serves no useful purpose, because delusional ideas are not eliminated by this approach, and the development of a trusting relationship may be impeded.

> **CLINICAL PEARL**
>
> Use *reasonable doubt* as a therapeutic technique. For example, when a client says, "The FBI is wiretapping directly into my brain," the nurse may respond, "I understand that you believe this is true, but I personally find it hard to accept."

■ Reinforce and focus on reality. Although initially encouraging the client to describe his or her delusional thoughts may be helpful to understand the client's experience and to establish trust, discourage long ruminations about the irrational thinking. Talk about real events and real people. See Box 24–4 for a list of interventions that may be helpful when working with a client who is highly suspicious.

Risk for Violence: Self-Directed or Other-Directed

Risk for self- or other-directed violence is defined by NANDA-I as "vulnerable to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful either to self or to others" (Herdman & Kamitsuru, 2014, pp. 410–411).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ Within [a specified time], client will be able to recognize signs of increasing anxiety and agitation

---

BOX 24–4 Interventions When Working With Suspicious Clients

Clients who are prone to suspicious ideation are vulnerable to misinterpreting information and social cues in their environment, which can be a barrier to communication and relationship building. The following are some interventions to promote positive communication and establishment of trusting relationships.

- To promote the development of trust, use the same staff as much as possible; be honest and keep all promises.
- Avoid physical contact. Ask the client's permission before using touch to perform a procedure, such as taking blood pressure. Suspicious clients often perceive touch as threatening and may respond in an aggressive or defensive manner.
- Avoid laughing, whispering, or talking quietly where the client can see you but cannot hear what is being said.
- Extremely suspicious clients may believe they are being poisoned and refuse to eat food from an individually prepared tray. It may be necessary to provide canned food with a can opener or serve food family style.
- They may believe they are being poisoned with their medication and attempt to discard the tablets or capsules. Mouth checks may be necessary following medication administration to verify whether the client is actually swallowing the pills.
- Competitive activities may be threatening to suspicious clients. Activities that encourage a one-to-one relationship with the nurse or therapist are best.
- Maintain an assertive, matter-of-fact, yet genuine approach with suspicious clients. Approaches that are overly directive or cheerful may increase the patient's suspiciousness.

and report to staff (or other care provider) for assistance with intervention.

■ Client will not harm self or others.

Long-term goal

■ Client will not harm self or others.

Interventions

■ Maintain a low level of stimuli in the client's environment (low lighting, few people, simple decor, low noise level). Anxiety level rises in a stimulating environment. A suspicious, agitated client may perceive individuals as threatening.

■ Observe the client's behavior frequently while carrying out routine activities to avoid creating suspicion. Close observation is necessary so that intervention can occur if required to ensure the client's (and others') safety.

■ Assess for presence of suicidal ideation and/or command hallucinations that may be instructing the client to harm self or others, and remove all dangerous objects from the client's environment so that he or she may not use them to harm self or others.

> **CLINICAL PEARL**
>
> Intervene at the first sign of increased anxiety, agitation, or verbal or behavioral aggression. Offer empathetic response to the client's feelings: "You seem anxious [or frustrated, or angry] about this situation. How can I help?" Validation of the client's feelings conveys a caring attitude, and offering assistance reinforces trust.

■ It is important to maintain a calm attitude toward the client. As the client's anxiety increases, offer some alternatives: participating in physical activity (e.g., punching bag, exercise), talking about the situation, taking antianxiety medication. Offering alternatives gives the client a feeling of some control over the situation.

■ Have sufficient staff available to indicate a show of strength to client if it becomes necessary. This shows the client evidence of control over the situation and provides some physical security for staff.

■ If the client is not calmed by "talking down" or by medication and is posing an imminent threat to the safety of self or others, use of restraint may be necessary. The avenue of the least restrictive alternative must be selected when planning interventions for a violent client. Restraints should be used only as a last resort, after all other interventions have been unsuccessful, and only if the client is clearly at risk of harm to self or others.

■ If restraint is deemed necessary, ensure that sufficient staff is available to assist. Follow protocol established by the institution. As agitation decreases, assess the client's readiness for restraint removal or reduction. Remove one restraint at a time while assessing the client's response. This minimizes the risk of injury to the client and staff.

Impaired Verbal Communication

Impaired verbal communication is defined by NANDA-I as "decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols" (Herdman & Kamitsuru, 2014, p. 261). This care plan is also presented in Table 24–4.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will demonstrate ability to remain on one topic, using appropriate, intermittent eye contact, for 5 minutes with the nurse or therapist.

Long-term goal

■ By time of discharge from treatment, client will demonstrate ability to carry on a verbal communication in a socially acceptable manner with healthcare providers and peers.

Interventions

■ Facilitate trust and understanding by maintaining staff assignments as consistently as possible. In a nonthreatening manner, explain to the client how his or her behavior and verbalizations are viewed by and may alienate others.

> **CLINICAL PEARL**
>
> Attempt to decode incomprehensible communication patterns. Seek validation and clarification by stating, "Is it that you mean . . . ?" or "I don't understand what you mean by that. Would you please explain it to me?" These techniques reveal to the client how he or she is being perceived by others and demonstrates active listening and interest in understanding what the client is trying to communicate.

■ Anticipate and fulfill the client's needs until functional communication has been established.

■ Orient the client to reality as required. Call the client by name. Validate those aspects of communication that help differentiate between what is real and not real. These techniques may facilitate restoration of functional communication patterns in the client.

CLINICAL PEARL 💬

If the client is unable or unwilling to speak (mutism), using the technique of *verbalizing the implied* is therapeutic. For example, "That must have been very difficult for you when your mother left. You must have felt very alone." This approach conveys empathy, facilitates trust, and eventually may encourage the client to discuss painful issues.

■ Because concrete thinking may be a symptom, abstract phrases, clichés, and joking must be avoided, as they are likely to be misinterpreted. Explanations must be provided at the client's level of comprehension.

CLINICAL PEARL 💬

Speak plainly and use concrete language to minimize misinterpretation by the client. For example, "Pick up the spoon, scoop some mashed potatoes into it, and put it in your mouth."

Concept Care Mapping

The concept map care plan (see Chapter 9) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with schizophrenia is presented in Figure 24–3.

Client/Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client/family education relevant to schizophrenia is presented in Box 24–5.

Evaluation

In the final step of the nursing process, a reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client with exacerbation of schizophrenic psychosis may be facilitated by gathering information utilizing the following types of questions:

■ Has the client established trust with at least one staff member?
■ Is the anxiety level maintained at a manageable level?
■ Is delusional thinking still prevalent?
■ Is hallucinogenic activity evident? Does the client share content of hallucinations, particularly if commands are heard?
■ Is the client able to interrupt escalating anxiety with adaptive coping mechanisms?

■ Is the client easily agitated?
■ Is the client able to interact with others appropriately?
■ Does the client voluntarily attend therapy activities?
■ Is verbal communication comprehensible?
■ Is the client adhering to prescribed medications? Does the client verbalize the importance of taking medication regularly and on a long-term basis? Does he or she verbalize understanding of possible side effects and when to seek assistance from the physician?
■ Does the client spend time with others rather than isolating him or herself?
■ Is the client able to carry out all activities of daily living independently?
■ Is the client able to verbalize resources from which he or she may seek assistance outside the hospital?
■ Does the family have information regarding support groups in which they may participate and from which they may seek assistance in dealing with their family member who is ill?
■ If the client lives alone, does he or she have a source for assistance with home maintenance and health management?

Quality and Safety Education for Nurses (QSEN)

The Institute of Medicine (now the National Academy of Medicine), in its report *Health Professions Education: A Bridge to Quality* (Institute of Medicine [IOM], 2003), challenged faculties of medicine, nursing, and other health professions to ensure that their graduates have achieved a core set of competencies in order to meet the needs of the 21st-century health-care system. These competencies include *providing patient-centered care, working in interdisciplinary teams, employing evidence-based practice, applying quality improvement, maintaining safety,* and *utilizing informatics.* A QSEN teaching strategy is included in Box 24–6. The use of this type of activity is intended to arm the instructor and the student with guidelines for attaining the knowledge, skills, and attitudes necessary for achievement of quality and safety competencies in nursing.

Treatment Modalities for Schizophrenia and Other Psychotic Disorders

Psychological Treatments
Individual Psychotherapy

Individual recovery-oriented psychotherapy and cognitive therapies are evidence-based interventions in the treatment of the client with schizophrenia, but these should be adjuncts to a multifaceted team approach.

Clinical Vignette: Harry has been admitted to the psychiatric unit with a diagnosis of schizophrenia. He is socially isolated and stays in his room unless strongly encouraged by the nurse to come out. He says to the nurse, "You have to be your own boss. You can't trust anybody." He refuses to eat any food from his tray, stating that the voice of his deceased grandfather is telling him it is poisoned. His clothes are dirty, and he has an objectionable body odor. The nurse develops the following concept map care plan for Harry.

Signs and Symptoms
- Delusional thinking
- Suspiciousness

Signs and Symptoms
- Verbalizes hearing voices
- Listening pose

Signs and Symptoms
- Social withdrawal
- Expresses fear of failure

Signs and Symptoms
- Offensive body odor
- Soiled clothing
- Unkempt appearance

Nursing Diagnosis
Disturbed thought processes

Nursing Diagnosis
Disturbed sensory perception (auditory)

Nursing Diagnosis
Low self-esteem

Nursing Diagnosis
Self-care deficit (hygiene)

Nursing Actions
- Do not whisper to others in client's presence.
- Serve food family style.
- Perform mouth checks for meds.
- Be cautious with touch.
- Use same staff.
- Meet client needs and keep promises to promote trust.

Nursing Actions
- Observe for signs of hallucinations.
- Be cautious with touch.
- Use "the voices" instead of "they" when asking for content of hallucinations.
- Use distraction to bring client back to reality.

Nursing Actions
- Spend time with client and develop trust.
- Attend groups with client at first to offer support.
- Encourage simple methods of achievement.
- Teach effective communication techniques.
- Encourage verbalization of fears.

Nursing Actions
- Encourage independence in ADLs, but intervene as needed.
- Offer recognition and positive reinforcement for independent accomplishments.

Medical Rx: Risperidone 2 mg bid

Outcomes
- Demonstrates ability to trust
- Differentiates between delusional thinking and reality

Outcomes
- Discusses content of hallucinations with nurse
- Hallucinations are eliminated or recognized as non-reality

Outcomes
- Attends groups willingly and without being accompanied by nurse
- Interacts appropriately with others

Outcomes
- Performs ADLs independently
- Maintains personal hygiene at an acceptable level

FIGURE 24–3 Concept map care plan for client with schizophrenia.

The primary focus in all cases must reflect efforts to decrease anxiety and increase trust.

Establishing a relationship is often particularly difficult because the individual with schizophrenia is desperately lonely yet defends against closeness and trust. He or she is likely to respond to attempts at closeness with suspiciousness, anxiety, aggression, or regression. Successful intervention may be achieved with honesty, simple directness, and a manner that respects the client's privacy and human dignity. Exaggerated warmth and professions of friendship are likely to be met with confusion and suspicion.

Once a therapeutic interpersonal relationship has been established, reality orientation is maintained through exploration of the client's behavior within relationships. Education is provided to help the client identify sources of real or perceived danger and ways of reacting appropriately. Methods for improving interpersonal communication, emotional expression, and frustration tolerance are attempted.

BOX 24–5 Topics for Client/Family Education Related to Schizophrenia

NATURE OF THE ILLNESS
1. What to expect as the illness progresses
2. Symptoms associated with the illness
3. Ways for family to respond to behaviors associated with the illness

MANAGEMENT OF THE ILLNESS
1. Connection of exacerbation of symptoms to times of stress
2. Appropriate medication management
3. Side effects of medications
4. Importance of not stopping medications
5. When to contact health-care provider
6. Relaxation techniques
7. Social skills training
8. Daily living skills training

SUPPORT SERVICES
1. Financial assistance
2. Legal assistance
3. Caregiver support groups
4. Respite care
5. Home health care
6. Residential treatment options

Group Therapy

Group therapy for individuals with schizophrenia has been shown to be effective, particularly with outpatients and when combined with drug treatment. Sadock and associates (2015) state:

> Group therapy for persons with schizophrenia generally focuses on real-life plans, problems, and relationships. Some investigators doubt that dynamic interpretation and insight therapy are valuable for typical patients with schizophrenia. But group therapy is effective in reducing social isolation, increasing the sense of cohesiveness, and improving reality testing for patients with schizophrenia. (p. 322)

Group therapy in inpatient settings is less productive. Inpatient treatment usually occurs when symptomatology and social disorganization are at their most intense. At this time, the least possible stimuli is most beneficial for the client. Because group therapy can be intensive and highly stimulating, it may be counterproductive early in treatment.

Group therapy for schizophrenia has been most useful over the long-term course of the illness. The social interaction, sense of cohesiveness, identification, and reality testing achieved within the group

BOX 24–6 QSEN TEACHING STRATEGY

Assignment: Using Evidence to Address Clinical Problems
Intervention With a Combative Client

Competency Domain: Evidence-Based Practice

Learning Objectives: Student will:
- Differentiate clinical opinion from research and evidence summaries.
- Explain the role of evidence in determining the best clinical practice for intervening with combative clients.
- Identify gaps between what is observed in the treatment setting and what has been identified as best practice.
- Discriminate between valid and invalid reasons for modifying evidence-based clinical practice based on clinical expertise or other reasons.
- Participate effectively in appropriate data collection and other research activities.
- Acknowledge own limitations in knowledge and clinical expertise before determining when to deviate from evidence-based best practices.

Strategy Overview:
1. Investigate the research related to intervening with a combative client.
2. Identify best practices described in the literature. How were these best practices determined?
3. Compare and contrast staff intervention with best practices described in the literature.
4. Investigate staff perceptions related to intervening with a combative client. How have they developed these perceptions?
5. Do staff members view any problems associated with their practice versus best practice described in the literature? If so, how would they like to see the problem addressed?
6. Describe ethical issues associated with intervening with a combative client.
7. What is your personal perception regarding the best evidence available to date related to intervening with a combative client? Are there situations that you can think of when you might deviate from the best practice model?
8. What questions do you have about intervening with a combative client that are not being addressed by current researchers?

Adapted from teaching strategy submitted by Pamela M. Ironside, Associate Professor, Indiana University School of Nursing, Indianapolis, IN. © 2009 QSEN; http://qsen.org. With permission.

setting have proven to be highly therapeutic processes for these clients. Groups that offer a supportive environment appear to be more helpful to clients with schizophrenia than those that follow a more confrontational approach.

Behavior Therapy

Behavior modification has a history of qualified success in reducing the frequency of bizarre, disturbing, and deviant behaviors and increasing appropriate behaviors. Features that have led to the most positive results include the following:

■ Clearly defining goals and how they will be measured
■ Attaching positive, negative, and aversive reinforcements to adaptive and maladaptive behavior
■ Using simple, concrete instructions and prompts to elicit the desired behavior

Behavior therapy can be a powerful treatment tool for helping clients change undesirable behaviors. In the treatment setting, the health-care provider can use praise and other positive reinforcements to help the client with schizophrenia reduce the frequency of maladaptive or deviant behaviors. A limitation of this type of therapy is the inability of some individuals with schizophrenia to generalize what they have learned from the treatment setting to the community setting.

Social Treatments

Social Skills Training

Social skills training is used to help clients manage struggles with interpersonal relationships and communication, which are often complicated by clients' inability to accurately perceive responses in others. Mueser, Bond, and Drake (2002) describe this training as follows:

> The basic premise of social skills training is that complex interpersonal skills involve the smooth integration of a combination of simpler behaviors, including *nonverbal behaviors* (e.g., facial expression, eye contact); *paralinguistic features* (e.g., voice loudness and affect); *verbal content* (i.e., the appropriateness of what is said); and *interactive balance* (e.g., response latency, amount of time talking). These specific skills can be systematically taught, and, through the process of *shaping* (i.e., rewarding successive approximations toward the target behavior), complex behavioral repertoires can be acquired.

Social dysfunction is a hallmark of schizophrenia. Impairment in interpersonal relations is included as part of the defining diagnostic criteria for the condition in the *DSM-5* (APA, 2013). Considerable attention is now being given to enhancement of social skills in these clients.

The educational procedure in social skills training focuses on role-play. A series of brief scenarios are selected. These should be typical of situations clients experience in their daily lives and graduated in terms of level of difficulty. The health-care provider may serve as a role model for some behaviors. For example, "See how I sort of nod my head up and down and look at your face while you talk." This demonstration is followed by the client's role-playing. Immediate feedback is provided regarding the client's presentation. Only by countless repetitions does the response gradually become smooth and effortless.

Progress is geared toward the client's needs and limitations. The focus is on small units of behavior, and the training proceeds very gradually. Highly threatening issues are avoided, and emphasis is placed on functional skills that are relevant to activities of daily living. Milieu therapy, which focuses on the client's interaction within a social environment, may provide opportunities for social skills training.

Family Therapy

Schizophrenia is an illness that can puzzle, disrupt, and sometimes destroy families. Even when families appear to cope well, there is a notable impact on the mental and physical health of relatives when a family member has this illness.

The importance of the expanded role of family in the aftercare of those with schizophrenia has been recognized, thereby stimulating interest in family intervention programs designed to support the family system, prevent or delay relapse, and help to maintain the client in the community. These psychoeducational programs treat the family as a resource rather than a stressor, with the focus on concrete problem-solving and specific behaviors for coping with stress. These programs recognize the biological basis for schizophrenia and the impact that stress has on the client's ability to function. By providing the family with information about the illness and suggestions for effective coping, psychoeducational programs reduce the likelihood of the client's relapse and the possible emergence of mental illness in previously nonaffected relatives.

Mueser and associates (2002) stated that although models of family intervention with schizophrenia differ in their characteristics and methods, effective treatment programs share a number of common features:

■ All programs are long term (usually 9 months to 2 years or more).
■ They all provide the client and family with information about the illness and its management.
■ They focus on improving adherence to prescribed medications.

■ They strive to decrease stress in the family and improve family functioning.

Asen (2002) suggested the following interventions with families of individuals with schizophrenia:

- Forming a close alliance with the caregivers
- Lowering the emotional climate within the family by reducing stress and burden on relatives
- Increasing the ability of relatives to anticipate and solve problems
- Reducing the expressions of anger and guilt by family members
- Maintaining reasonable expectations for how the ill family member should perform
- Encouraging relatives to set appropriate limits while maintaining some degree of separateness
- Promoting desirable changes in the relatives' behaviors and belief systems

Family therapy typically consists of a brief program of family education about schizophrenia and a more extended program of family contact designed to reduce overt manifestations of conflict and improve patterns of family communication and problem-solving. The response to this type of therapy has been very dramatic. Studies have clearly revealed that a more positive outcome in the treatment of the client with schizophrenia can be achieved by including the family system in the program of care.

Assertive Community Treatment

Assertive community treatment (ACT) is an evidence-based program of case management that takes a team approach in providing comprehensive, community-based psychiatric treatment, rehabilitation, and support to persons with serious and persistent mental illness such as schizophrenia. Some states use other terms for this type of treatment, such as mobile treatment teams and community support programs. Assertive programs of treatment are individually tailored for each client, intended to be proactive, and include teaching basic living skills, helping clients work with community agencies, and assisting clients to develop a social support network. Vocational expectations are emphasized, and supported work settings (i.e., sheltered workshops) are an important part of the treatment program. Other services include substance abuse treatment, psychoeducational programs, family support and education, mobile crisis intervention, and attention to health-care needs.

Responsibilities are shared by multiple team members, including psychiatrists, nurses, social workers, vocational rehabilitation therapists, and substance abuse counselors. Services are provided in the person's home; within the neighborhood; in local restaurants, parks, or stores; or wherever assistance by the client is required. These services are available to the client 24 hours a day, 365 days a year, and ACT is considered a long-term intervention strategy. One recent study looked at the impact of a Housing First intervention (an intervention that prioritizes rapid re-housing for homeless individuals with schizophrenia) and found that when this type of intervention was combined with ACT, medication adherence improved from below 50 percent to 78 percent. Additionally, these combined interventions improved clients' integration in community, increased residential stability, and decreased criminal convictions (Rezansoff et al., 2016).

ACT has been shown to reduce the number of hospitalizations and decrease costs of care for these clients. Although it has been called "paternalistic" and "coercive" by its critics, ACT has provided much-needed services and increased quality of life for many clients who are unable to manage in a less-structured environment. One limitation is that treatment programs of this kind are time and labor intensive.

Recovery Model

Research provides support for recovery as an objective within reach for individuals with schizophrenia (Lysaker, Roe, & Buck, 2010). Lysaker and associates (2010) state:

> Recovery from schizophrenia, in the sense of a state in which persons experience no difficulties associated with the illness, can occur but the modal outcome seems to be one in which difficulties linked to symptoms, social function, and work appear periodically but can be successfully confronted. (p. 40)

Conceptual models of recovery from mental illness are presented in Chapter 21, The Recovery Model. The recovery model has been used primarily in caring for individuals with serious mental illness, such as schizophrenia and bipolar disorder. However, concepts of the model are amenable to use with all individuals experiencing emotional conditions that require assistance and desiring to take control and manage their lives more independently.

Weiden (2010) identifies two types of recovery with schizophrenia: functional and process. Functional recovery focuses on the individual's level of functioning in such areas as relationships, work, independent living, and other activities. He or she may or may not be experiencing active symptoms of schizophrenia.

Weiden (2010) suggests that recovery can also be considered a process. With process recovery, there is no defined end point. Recovery continues throughout the individual's life and involves collaboration between client and clinician. The individual identifies goals based on personal values or what he or she defines as giving meaning and purpose to life. The clinician and client work together to develop a treatment plan in alignment with the goals set forth by the

client. In the process recovery model, the individual may still be experiencing symptoms. Weiden (2010) states:

> Patients do not have to be in remission, nor does remission automatically have to be a desired (or likely) goal when embarking on a recovery-oriented treatment plan. As long as the patient (and family) understands that a process recovery treatment plan is not to be confused with a promise of "cure" or even "remission," then one does not overpromise.

The concept of recovery in schizophrenia remains controversial among clinicians, and many challenges lie ahead for continued study. Recovery models have similarities with ACT in that they both necessarily engage the support of multiple resources, but recovery models also highlight the dimension of active engagement and empowerment of the client in decision-making. Some argue that this approach is difficult to implement with clients who lack insight about their illness or the need for treatment. Further, there is a lack of consistency in what constitutes "recovery," and many concepts exist.

Still, the potential and hope is that as these models become better studied and more clearly defined, they will provide a treatment approach that is comprehensive, protective, and supportive of patient-centered care.

RAISE (Recovery After an Initial Schizophrenic Episode)

The RAISE approach to treatment for schizophrenia is based on a large National Institute of Mental Health (NIMH) initiative that began in 2008, and research findings published in 2015 have demonstrated several benefits of this approach. Insel (2015) describes the RAISE approach as

> coordinated specialty care for first episode psychosis. With coordinated specialty care the young person experiencing first episode psychosis works with a team of specialists to create a personal treatment plan, combining recovery-oriented psychotherapy, low-dose medication management, family education and support, case management, and work or education support. Coordinated specialty care emphasizes shared decision-making, including family members when possible.

The RAISE approach incorporates many elements from other treatment approaches, including community treatment, recovery model approaches, family approaches, and comprehensive care models. It adds the dimension of early intervention at the first episode of psychosis. The research findings after 5 years of studying this approach are promising for improving care to this population when intervention

begins at the earliest onset of psychotic symptoms. Positive outcomes have included greater adherence to treatment programs; greater improvement in symptoms, interpersonal relationships, and quality of life; more involvement in employment or educational pursuits; and less frequent hospitalizations than are seen for clients involved in more traditional treatment approaches (Insel, 2015).

The hope for this approach to treatment is that through early and comprehensive intervention, the long-term debilitating consequences of schizophrenia can be averted or minimized.

Psychopharmacological Treatment

Chlorpromazine (Thorazine) was first introduced in the United States in 1952. At that time, it was used in conjunction with barbiturates in surgical anesthesia. With increased use, the drug's psychic properties were recognized, and by 1954 it was marketed as an antipsychotic medication in the United States. The manufacture and sale of other antipsychotic drugs followed in rapid succession.

Antipsychotic medications are also called *neuroleptics,* historically referred to as major tranquilizers. They are effective in the treatment of acute and chronic manifestations of schizophrenia and in maintenance therapy to prevent exacerbation of schizophrenic symptoms. Without drug treatment, an estimated 72 percent of individuals who have experienced a psychotic episode relapse within a year. This relapse rate can be reduced to about 23 percent with continuous medication administration (Dixon, Lehman, & Levine, 2010).

The prognosis of schizophrenia has often been reported in a paradigm of thirds. One-third of individuals achieve significant and lasting improvement. They may never experience another episode of psychosis following the initial occurrence. One-third may achieve some improvement with intermittent relapses and residual disability. Their occupational level may have decreased because of their illness, or they may be socially isolated. Finally, one-third experience severe and permanent incapacity. They often do not respond to medication and remain severely ill for much of their lives. Men have poorer outcomes than women do; women respond better to treatment with antipsychotic medications.

As mentioned earlier, the efficacy of antipsychotic medications is enhanced by adjunct psychosocial therapy. Because the psychotic manifestations of the illness subside with use of the drugs, clients on medication are generally more cooperative with the psychosocial therapies. However, it takes several weeks for the antipsychotics to effectively treat positive symptoms, which often leads to discontinuation of the medication. Clients and families need to be educated about

the importance of waiting, often for several weeks, to determine if the drug will be effective.

These medications are classified as either *typical* (first-generation, conventional antipsychotics) or *atypical* (the newer, novel antipsychotics). Examples of commonly used antipsychotic agents are presented in Table 24–5. A description of these medications follows. More detailed information is available in Chapter 4, Psychopharmacology.

Indications

Antipsychotic medications are used in the treatment of schizophrenia and other psychotic disorders. Selected agents are used in the treatment of bipolar mania (olanzapine, aripiprazole, chlorpromazine, quetiapine, risperidone, asenapine, ziprasidone, cariprazine).

Action

Typical antipsychotics work by blocking postsynaptic dopamine receptors in the basal ganglia, hypothalamus, limbic system, brainstem, and medulla. They also demonstrate varying affinity for cholinergic, alpha$_1$-adrenergic, and histaminic receptors. Antipsychotic effects may also be related to inhibition of dopamine-mediated transmission of neural impulses at the synapses.

Atypical antipsychotics are weaker dopamine receptor antagonists than conventional antipsychotics but more potent antagonists of the serotonin (5-hydroxytryptamine) type 2A (5HT$_{2A}$) receptors. They also exhibit antagonism for cholinergic, histaminic, and adrenergic receptors. A detailed discussion of contraindications, precautions, side effects, and drug interactions associated with antipsychotic medications is available in Chapter 4.

Side Effects

The effects of these medications are related to blockage of receptors for which they exhibit various degrees of affinity. Blockage of the dopamine receptors is thought to be responsible for controlling positive symptoms of schizophrenia. Dopamine blockage also results in **extrapyramidal symptoms** (EPS) and prolactin elevation (galactorrhea; **gynecomastia**). (A list of medications commonly used to treat EPS is included in Table 24–6). Cholinergic blockade causes anticholinergic side effects (dry mouth, blurred vision, constipation, urinary retention, tachycardia). Blockage of the alpha$_1$-adrenergic receptors produces dizziness, orthostatic hypotension, tremors, and reflex tachycardia. Histamine blockade is associated with weight gain and sedation.

The plan of care should include monitoring for the side effects from antipsychotic medications and

TABLE 24–5 Antipsychotic Agents

CATEGORIES	GENERIC (TRADE NAME)	PREGNANCY CATEGORIES/ HALF-LIFE (hr)	DAILY DOSAGE RANGE (mg)
Typical antipsychotic agents (first generation; conventional)	Chlorpromazine	C/ 24	40–400
	Fluphenazine	C/ HCl: 18 hr Decanoate: 6.8–9.6 days	2.5–10
	Haloperidol (Haldol)	C/ ~18 (oral); ~3 wk (IM decanoate)	1–100
	Loxapine	C/ 8	20–250
	Perphenazine	C/ 9–12	12–64
	Pimozide (Orap)	C/ ~55	1–10
	Prochlorperazine	C/ 3–5 (oral); 6.9 (IV)	15–150
	Thioridazine	C/ 24	150–800
	Thiothixene (Navane)	C/ 34	6–30
	Trifluoperazine	C/ 18	4–40
Atypical antipsychotic agents (second generation; novel)	Aripiprazole (Abilify)	C/ 75–146	10–30
	Asenapine (Saphris)	C/ 24	10–20
	Brexpiprazole (Rexulti)	NA/ 19–91	2–4
	Cariprazine (Vraylar)	NA/ 48–96	1.5–6
	Clozapine (Clozaril)	B/ 8 (single dose); 12 (at steady state)	300–900
	Iloperidone (Fanapt)	C/ 18–33	12–24
	Lurasidone (Latuda)	B/ 18	40–80
	Olanzapine (Zyprexa)	C/ 21–54	5–20
	Paliperidone (Invega)	C/ 23	6–12
	Quetiapine (Seroquel)	C/ ~6	300–400
	Risperidone (Risperdal)	C/ 3–20	4–8
	Ziprasidone (Geodon)	C/ ~7 (oral); 2–5 (IM)	40–160

TABLE 24–6 Antiparkinsonian Agents Used to Treat Extrapyramidal Side Effects of Antipsychotic Drugs

Indication	Used to treat parkinsonism of various causes and drug-induced extrapyramidal reactions.
Action	Restores the natural balance of acetylcholine and dopamine in the CNS. The imbalance is a deficiency in dopamine that results in excessive cholinergic activity.
Contraindications/precautions	Antiparkinsonian agents are contraindicated in individuals with hypersensitivity. Anticholinergics should be avoided by individuals with angle-closure glaucoma; pyloric, duodenal, or bladder neck obstructions; prostatic hypertrophy; or myasthenia gravis. Caution should be used in administering these drugs to clients with hepatic, renal, or cardiac insufficiency; elderly and debilitated clients; those with a tendency toward urinary retention; or those exposed to high environmental temperatures.
Common side effects	Anticholinergic effects (dry mouth, blurred vision, constipation, paralytic ileus, urinary retention, tachycardia, elevated temperature, decreased sweating), nausea/GI upset, sedation, dizziness, orthostatic hypotension, exacerbation of psychoses.

CHEMICAL CLASS	GENERIC (TRADE NAME)	PREGNANCY CATEGORIES/ HALF-LIFE (hr)	DAILY DOSAGE RANGE (mg)
Anticholinergics	Benztropine (Cogentin) Biperiden (Akineton) Trihexyphenidyl	C/ UKN C/ 18.4–24.3 C/ 5.6–10.2	1–8 2–6 1–15
Antihistamines	Diphenhydramine (Benadryl)	C/ 4–15	25–200
Dopaminergic agonists	Amantadine	C/ 10–25	200–300

educating the client/family about safety precautions when taking antipsychotic medication. (A list of side effects and relevant nursing interventions is included in Chapter 4).

Client and Family Education Related to Antipsychotics

The client should:

- Use caution when driving or operating dangerous machinery. Drowsiness and dizziness can occur.
- Not discontinue the drug abruptly after long-term use. To do so might produce withdrawal symptoms, such as nausea, vomiting, dizziness, gastritis, headache, tachycardia, insomnia, and tremulousness.
- Use sunblock lotion and wear protective clothing when spending time outdoors. Skin is more susceptible to sunburn, which can occur in as little as 30 minutes.
- Report weekly (if receiving clozapine therapy) to have blood levels drawn and to obtain a weekly supply of the drug.
- Report the occurrence of any of the following symptoms to the physician immediately: sore throat, fever, malaise, unusual bleeding, easy bruising, persistent nausea and vomiting, severe headache, rapid heart rate, difficulty urinating, muscle twitching, tremors, dark-colored urine, excessive urination, excessive thirst, excessive hunger, weakness, pale stools, yellow skin or eyes, muscular incoordination, or skin rash.

- Rise slowly from a sitting or lying position to prevent a sudden drop in blood pressure.
- Take frequent sips of water, chew sugarless gum, or suck on hard candy if dry mouth is a problem. Good oral care (frequent brushing and flossing) is very important.
- Consult the physician regarding smoking while on antipsychotic therapy. Smoking increases the metabolism of antipsychotics, requiring an adjustment in dosage to achieve a therapeutic effect.
- Dress warmly in cold weather and avoid extended exposure to very high or low temperatures. Body temperature is harder to maintain with this medication.
- Avoid drinking alcohol while on antipsychotic therapy. These drugs potentiate each other's effects.
- Avoid taking other medications (including over-the-counter products) without the physician's approval. Many medications contain substances that interact with antipsychotics in a way that may be harmful.
- Be aware of possible risks of taking antipsychotics during pregnancy. Safe use during pregnancy has not been established. Antipsychotics are thought to readily cross the placental barrier; if so, a fetus could experience adverse effects of the drug. Inform the physician immediately if pregnancy occurs, is suspected, or is planned.
- Be aware of side effects of antipsychotic drugs. Refer to written materials furnished by health-care providers for safe self-administration.

- Continue to take the medication, even if feeling well and as though it is not needed. Symptoms may return if medication is discontinued.
- Carry a card or other identification at all times describing medications being taken.

Smoking Cessation

Smoking cigarettes has long been identified as a particular health risk for clients with schizophrenia, since the prevalence is three times that of the general population; it is estimated that as many as 88 percent of those with schizophrenia and 70 percent of those with bipolar disorder are smokers (Kranjac, 2016). Besides the obvious health risks of chronic lung diseases and cancers, smoking decreases the effectiveness of some psychotropic medications. Varenicline (Chantix), a nicotine agonist used as a smoking deterrent, was once thought to increase symptoms and even suicide risk in those with severe mental illness. However, a recent meta-analysis (Wu et al., 2016) concluded that varenicline is effective for assisting with smoking cessation in this population and that "there was no clear evidence of neuropsychiatric or other adverse events compared with placebo" (p. 1554). In any scenario, assessing the client's motivation to stop smoking and exploring viable treatment options, including psychological interventions, is an important component of treatment.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Frank is 22 years old. He joined the Marines just out of high school at age 18 for a 3-year enlistment. His final year was spent in Afghanistan. When his enlistment was up, he returned to his hometown and married a young woman with whom he had been a high school classmate. Frank has always been quiet, somewhat withdrawn, and had very few friends. He was the only child of a single mom who never married, and he does not know his father. His mother was killed in an automobile accident the spring before he enlisted in the Marines.

During the past year, he has become increasingly isolated and withdrawn. He is without regular employment but finds work as a day laborer when he can. His wife, Suzanne, works as a secretary and is the primary wage earner. Lately, Frank has become very suspicious of Suzanne and sometimes follows her to work. He also drops in on her at work and accuses her of having affairs with some of the men in the office.

Last evening when Suzanne got home from work, Frank was hiding in the closet. She didn't know he was home. When she started to undress, he jumped out of the closet holding a large kitchen knife and threatened to kill her "for being unfaithful." Suzanne managed to flee their home and ran to the neighbor's house and called the police.

Frank told the police that he received a message over the radio from his Marine commanding officer telling him that he couldn't allow his wife to continue to commit adultery, and the only way he could stop it was to kill her. The police took Frank to the emergency department of the VA Hospital, where he was admitted to the psychiatric unit. Suzanne is helping with the admission history.

Suzanne tells the nurse that she has never been unfaithful to Frank and she doesn't know why he believes that she has. Frank tells the nurse that he has been "taking orders from my commanding officer through my car radio ever since I got back from Afghanistan." He survived a helicopter crash in Afghanistan in which all were killed except Frank and one other man. Frank says, "I have to follow my CO's orders. God saved me to annihilate the impure."

Following an evaluation, the psychiatrist diagnoses Frank with schizophrenia. He orders olanzapine 10 mg PO to be given daily and olanzapine 10 mg IM q6h prn for agitation.

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Frank:

1. **Risk for self-directed or other-directed violence** related to unresolved grief over loss of mother; survivor's guilt associated with helicopter crash; command hallucinations; and history of violence.
   a. **Short-term goals:**
      - Frank will seek out staff when anxiety and agitation start to increase.
      - Frank will not harm self or others.
   b. **Long-term goal:** Frank will not harm self or others.
2. **Disturbed sensory perception: Auditory** related to increased anxiety and agitation, withdrawal into self, and stress of sufficient intensity to threaten an already weak ego
   a. **Short-term goals:**
      - Frank will discuss the content of the hallucinations with the nurse.
      - Frank will maintain anxiety at a manageable level.
   b. **Long-term goal:** Frank will be able to define and test reality, reducing or eliminating the occurrence of hallucinations.

PLANNING AND IMPLEMENTATION

RISK FOR SELF-DIRECTED OR OTHER-DIRECTED VIOLENCE

1. Keep the stimuli as low as possible in Frank's environment.
2. Monitor Frank's behavior frequently, but in a manner of carrying out routine activities so as not to create suspiciousness on his part.
3. Watch for the following signs (considered the prodrome to aggressive behavior): increased motor activity, pounding,

CASE STUDY AND SAMPLE CARE PLAN—cont'd

slamming, tense posture, defiant affect, clenched teeth and fists, arguing, demanding, and challenging or threatening staff.

4. If client should become aggressive, maintain a calm attitude. Try talking. Offer medication. Provide physical activities.

5. If these interventions fail, indicate a show of strength with a team of staff members.

6. Utilize restraints only as a last resort and if Frank is clearly at risk of harm to himself or others.

7. Help Frank recognize unresolved grief and fixation in denial or anger stage of grief process.

8. Encourage him to talk about the loss of his mother and fellow Marines in Afghanistan.

9. Encourage him to talk about guilt feelings associated with survival when others died.

10. Make a short-term contract with Frank that he will seek out staff if considering harming himself or others. When this contract expires, make another, and so on.

DISTURBED SENSORY PERCEPTION: AUDITORY

1. Monitor Frank's behavior for signs that he is hearing voices: listening pose, talking and laughing to self, stopping in midsentence.

2. If these behaviors are observed, ask Frank, "Are you hearing the voices again?"

3. Encourage Frank to share the content of the hallucinations. This information is important for early intervention in case the content contains commands to harm himself or others.

4. Say to Frank, "I understand that the voice is real to you, but I do not hear any voices speaking." It is important for him to learn the difference between what is real and what is not real.

5. Try to help Frank recognize that the voices often appear at times when he becomes anxious about something and his agitation increases.

6. Help him to recognize this increasing anxiety, and teach him methods to keep it from escalating.

7. Use distracting activities to bring him back to reality. Involvement with real people and real situations will help to distract him from the hallucination.

8. Teach him to use *voice dismissal.* When he hears the CO's (or others') voice, he should shout, "Go away!" or "Leave me alone!" These commands may help to diminish the sounds and give him a feeling of control over the situation.

EVALUATION

The outcome criteria identified for Frank have been met. When feeling especially anxious or becoming agitated, he seeks out staff for comfort and for assistance in maintaining his anxiety at a manageable level. He establishes short-term contracts with staff not to harm himself. He is experiencing fewer auditory hallucinations and has learned to use voice dismissal to interrupt the behavior. He is beginning to recognize his position in the grief process and is working toward resolution at his own pace.

Summary and Key Points

■ Of all mental illnesses, schizophrenia undoubtedly results in the greatest amount of personal, emotional, and social costs. It presents an enormous threat to life and happiness, yet it remains an enigma to the medical community.

■ For many years, there was little agreement as to a definition of the concept of schizophrenia. The *DSM-5* (APA, 2013) identifies specific criteria for diagnosis of the disorder.

■ The initial symptoms of schizophrenia most often occur in early adulthood. Development of the disorder can be viewed in four phases: (1) premorbid, (2) prodromal, (3) active psychotic (schizophrenia), and (4) residual.

■ The cause of schizophrenia remains unclear. Research continues, and most contemporary psychiatrists view schizophrenia as a brain disorder with little if any emphasis on psychosocial influences.

■ Schizophrenia most likely results from a combination of influences including genetics, biochemical dysfunction, and physiological and environmental factors.

■ A spectrum of schizophrenic and other psychotic disorders has been identified. These include (on a gradient of psychopathology from least to most severe) schizotypal personality disorder, delusional disorder, brief psychotic disorder, substance-induced psychotic disorder, psychotic disorder associated with another medical condition, catatonic disorder associated with another medical condition, schizophreniform disorder, schizoaffective disorder, and schizophrenia.

■ Nursing care of the client with schizophrenia is accomplished using the six steps of the nursing process.

■ Nursing assessment is based on knowledge of symptomatology related to thought content and form, perception, affect, sense of self, volition,

interpersonal functioning and relationship to the external world, and psychomotor behavior.

■ These behaviors are categorized as *positive* (an excess or distortion of normal functions) or *negative* (a diminution or loss of normal functions).

■ Antipsychotic medications remain the mainstay of treatment for psychotic disorders. Atypical antipsychotics have become the first line of therapy and treat both positive and negative symptoms of schizophrenia. They have a more favorable side-effect profile than the conventional (typical) antipsychotics.

■ Individuals with schizophrenia require long-term integrated treatment with pharmacological and other interventions. Some of these include individual psychotherapy, group therapy, behavior therapy, social skills training, milieu therapy, family therapy, and assertive community treatment. For the majority of clients, the most effective treatment appears to be a combination of psychotropic medication and psychosocial therapy.

■ Some clinicians are choosing a course of therapy based on a model of recovery, similar to that which has been used for many years with addiction. The basic premise of a recovery model is empowerment of the consumer. The recovery model is designed to allow consumers primary control over decisions about their own care and to enable persons with mental health problems to live a meaningful life in a community of their choice while striving to achieve their full potential.

■ Families generally require support and education about psychotic illnesses. The focus is on coping with the diagnosis, understanding the illness and its course, teaching about medication, and learning ways to manage symptoms.

■ The most current, evidence-based approach to treatment, RAISE, demonstrates that early intervention at the first episode of psychosis can significantly improve outcomes.

■ There is a risk for suicide (around 10 percent) among patients with schizophrenia, so suicide risk assessment should always be considered an essential evaluation component.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Josh, age 21, has been diagnosed with schizophrenia. He has been socially isolated and hearing voices telling him to kill his parents. He has been admitted to the psychiatric unit from the emergency department. The *initial* nursing intervention for Josh is to:
   a. Give him an injection of Thorazine.
   b. Ensure a safe environment for him and others.
   c. Place him in restraints.
   d. Order him a nutritious diet.

2. The primary goal in working with an actively psychotic, suspicious client would be to:
   a. Promote interaction with others.
   b. Decrease his anxiety and increase trust.
   c. Improve his relationship with his parents.
   d. Encourage participation in therapy activities.

3. The nurse is caring for a client with schizophrenia. Orders from the physician include 100 mg chlorpromazine IM STAT and then 50 mg PO bid; 2 mg benztropine PO bid prn. Why is chlorpromazine ordered?
   a. To reduce extrapyramidal symptoms
   b. To prevent neuroleptic malignant syndrome
   c. To decrease psychotic symptoms
   d. To induce sleep

Review Questions—cont'd
Self-Examination/Learning Exercise

4. The nurse is caring for a client with schizophrenia. Orders from the physician include 100 mg chlorpromazine IM STAT and then 50 mg PO bid; 2 mg benztropine PO bid prn. Because benztropine was ordered on a prn basis, which of the following assessments by the nurse would convey a need for this medication?
   a. The client's level of agitation increases.
   b. The client complains of a sore throat.
   c. The client's skin has a yellowish cast.
   d. The client develops muscle spasms.

5. Brandon, a client on the psychiatric unit, has been diagnosed with schizophrenia. He begins to tell the nurse about how the CIA is looking for him and will kill him if they find him. The most appropriate response by the nurse is:
   a. "That's ridiculous, Brandon. No one is going to hurt you."
   b. "The CIA isn't interested in people like you, Brandon."
   c. "Why do you think the CIA wants to kill you?"
   d. "I know you believe that, Brandon, but it's really hard for me to believe."

6. Brandon, a client on the psychiatric unit, has been diagnosed with schizophrenia. He begins to tell the nurse about how the CIA is looking for him and will kill him if they find him. Brandon's belief is an example of a:
   a. Delusion of persecution.
   b. Delusion of reference.
   c. Delusion of control or influence.
   d. Delusion of grandeur.

7. The nurse is interviewing a client on the psychiatric unit. The client tilts his head to the side, stops talking in midsentence, and listens intently. The nurse recognizes from these signs that the client is likely experiencing:
   a. Somatic delusions.
   b. Catatonic stupor.
   c. Auditory hallucinations.
   d. Pseudoparkinsonism.

8. The nurse is interviewing a client on the psychiatric unit. The client tilts his head to the side, stops talking in midsentence, and listens intently. The nurse recognizes these behaviors as a symptom of the client's illness. The most appropriate nursing intervention for this symptom is to:
   a. Ask the client to describe his physical symptoms.
   b. Ask the client to describe what he is hearing.
   c. Administer a dose of benztropine.
   d. Call the physician for additional orders.

9. When a client suddenly becomes aggressive and violent on the unit, which of the following approaches would be best for the nurse to use *first*?
   a. Provide large motor activities to relieve the client's pent-up tension.
   b. Administer a dose of prn chlorpromazine to keep the client calm.
   c. Call for sufficient help to control the situation safely.
   d. Convey to the client that his behavior is unacceptable and will not be permitted.

10. The primary focus of family therapy for clients with schizophrenia and their families is:
    a. To discuss concrete problem-solving and adaptive behaviors for coping with stress.
    b. To introduce the family to others with the same problem.
    c. To keep the client and family in touch with the health-care system.
    d. To promote family interaction and increase understanding of the illness.

Review Questions—cont'd
Self-Examination/Learning Exercise

11. A client recently admitted to the hospital reports to the nurse, "I don't understand why I was brought here. I was simply hanging out in my apartment and the police said I had to come with them." This is an example of what symptom of schizophrenia?
    a. Delusions of reference
    b. Loose association
    c. Anosognosia
    d. Auditory hallucinations

12. Recent research on the RAISE approach to treatment of schizophrenia incorporates which of the following elements as important to improving outcomes? (Select all that apply.)
    a. Early intervention at the first episode of psychosis
    b. Support for employment and/or educational pursuits
    c. Rapid high-dose loading with antipsychotic medication
    d. Court-ordered sanctions for treatment
    e. Recovery-focused psychotherapy

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Castillo, E.G., Rosati, J., Williams, C., Pessin, N., & Lindy, D.C. (2015). Metabolic syndrome screening and assertive community treatment: A quality improvement study. *Journal of the American Psychiatric Nurses Association, 21*(4), 233-243.

DESCRIPTION OF THE STUDY: As part of a quality improvement study, the authors sought to improve physical health screening for metabolic syndrome in clients with severe mental illness (SMI) who were being treated in an assertive community treatment (ACT) program. An underlying assumption was that physical illnesses were not routinely being tracked and typically were not treated until after a medical event occurred. This was identified as a significant quality-of-care issue, since studies have shown that people with SMI generally have a 25-year shorter life span than the general population. One of the largest contributors (greater than suicide or injury) is metabolic syndrome and cardiometabolic sequelae such as hypertension, diabetes, and dyslipidemia. A large sample of clients (*N* = 199) agreed to participate in the study and were evaluated on five parameters that are diagnostic for metabolic syndrome: waist circumference, blood pressure, fasting blood glucose, triglycerides, and high-density lipoprotein cholesterol. ACT staff also provided additional support services to encourage adherence with laboratory test completion such as reminders, assistance with overcoming transportation barriers, and even accompanying clients to appointments when requested.

RESULTS OF THE STUDY: Although some of the identified barriers to adherence necessitated time-consuming support from staff, 141 clients completed all five parameters of screening. Fifty-three percent of the clients met criteria for metabolic syndrome, and of those who did not meet criteria, only nine participants had *no* risk factors. As a result, the authors identified new preclinical or clinical diagnoses of hypertension for 68 percent of the clients, of diabetes for 15 percent of the clients, and of dyslipidemia for 53 percent of the clients. The authors concluded that the results justify routine screening for metabolic syndrome among those with SMI.

IMPLICATIONS FOR NURSING PRACTICE:

The Institute of Medicine (IOM, 2003) identifies quality improvement as a core competency needed by nurses to improve safe, effective nursing care. This study is an example of health-care professionals identifying a potential quality-of-care issue, studying the issue, and identifying outcomes needed to improve care based on the results of their study. Nurses, as they review current literature and think critically about the practice settings where they work, can take a leadership role in quality improvement studies such as this one. This particular study highlighted the fact that significant health-care risks for the SMI population can be missed unless screening for these risks is done routinely. The complex needs of the SMI client with regard to managing mental illness symptoms has, at times, taken precedence to the exclusion of attention to other health risks. Nurses need to be thoughtful about providing quality, holistic care to clients with SMI because some of these health risks contribute to a significantly shorter life span when they are not addressed.

TEST YOUR CRITICAL THINKING SKILLS

Sara, a 23-year-old single woman, has just been admitted to the psychiatric unit by her parents. They explain that over the past few months she has become increasingly withdrawn. She stays in her room alone but lately has been heard talking and laughing to herself.

Sara left home for the first time at age 18 to attend college. She performed well during her first semester, but when she returned after Christmas, she began to accuse her roommate of stealing her possessions. She started writing to her parents that her roommate wanted to kill her and that her roommate was turning everyone against her. She said she feared for her life. She started missing classes and stayed in her bed most of the time. Sometimes she locked herself in her closet. Her parents took her home, and she was hospitalized and diagnosed with schizophrenia. She has since been maintained on antipsychotic medication while taking a few classes at the local community college.

Sara tells the admitting nurse that she quit taking her medication 4 weeks ago because the pharmacist who fills the prescriptions is plotting to have her killed. She believes he is trying to poison her. She says she got this information from a television message. As Sara speaks, the nurse notices that she sometimes stops in mid-sentence and listens; sometimes she cocks her head to the side and moves her lips as though she is talking.

Answer the following questions related to Sara:

1. From the assessment data, what would be the most immediate nursing concern in working with Sara?
2. What is the nursing diagnosis related to this concern?
3. What interventions must be accomplished before the nurse can be successful in working with Sara?

💬 Communication Exercises

1. Hal, a patient on the psychiatric unit, has a diagnosis of schizophrenia. He lives in a halfway house, where last evening he began yelling that "aliens were on the way to take over our bodies! The message is coming through loud and clear!" The residence supervisor became frightened and called 911. As Hal was being admitted to the psychiatric unit he tells the nurse, "I'm special! I get messages from a higher being! We are in for big trouble!"
   • How would the nurse respond appropriately to this statement by Hal?
2. The nurse notices that Hal is sitting off by himself in a corner of the dayroom. He appears to be talking to himself and tilts his head to the side as if listening to something.
   • How would the nurse intervene with Hal in this situation?

3. Hal says to the nurse, "We must choose to take a ride. All alone we slip and slide. Now it's time to take a bride."
   • How would the nurse respond appropriately to this statement by Hal?

Depressive Disorders

CORE CONCEPTS

Depression

Mood

KEY TERMS

cognitive therapy

dysthymia

melancholia

postpartum depression

premenstrual dysphoric disorder

psychomotor retardation

OBJECTIVES
After reading this chapter, the student will be able to:

1. Recount historical perspectives of depression.
2. Discuss epidemiological statistics related to depression.
3. Describe various types of depressive disorders.
4. Identify predisposing factors in the development of depression.
5. Discuss implications of depression related to developmental stage.
6. Identify symptomatology associated with depression and use this information in client assessment.
7. Formulate nursing diagnoses and goals of care for clients with depression.
8. Identify topics for client and family teaching relevant to depression.
9. Describe appropriate nursing interventions for behaviors associated with depression.
10. Describe relevant criteria for evaluating nursing care of clients with depression.
11. Discuss various modalities relevant to treatment of depression.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Alterations in which of the neurotransmitters are most closely associated with depression?
2. Depression in adolescence is very hard to differentiate from the normal stormy behavior associated with adolescence. What is the best clue for determining a problem with depression in adolescence?
3. Behaviors of depression often change with the diurnal variation in the level of neurotransmitters. Describe the difference in this phenomenon between moderate and severe depression.
4. All antidepressants carry a black-box warning. What is it?

Depression is likely the oldest and still one of the most frequently diagnosed psychiatric illnesses. Symptoms of depression have been described almost as far back as there is evidence of written documentation.

An occasional bout with the "blues," a feeling of sadness or downheartedness, is common among healthy people and considered a normal response to life's everyday disappointments. These episodes are short-lived as the individual adapts to the loss, change, or failure (real or perceived) that has been experienced. Pathological depression occurs when adaptation is ineffective and the symptoms are significant enough to impair functioning.

CORE CONCEPT

Mood

Mood is a pervasive and sustained emotion that may have a profound influence on a person's perception of the world. Examples of mood include depression, joy, elation, anger, and anxiety. Affect is described as the external, observable emotional reaction associated with an experience. A flat affect describes the state of a person who lacks emotional expression and is often seen in severely depressed clients.

This chapter focuses on the different manifestations of depressive illness and implications for nursing intervention. A historical perspective and epidemiological statistics related to depression are presented. Predisposing factors that have been implicated in the etiology of depression provide a framework for studying the dynamics of the disorder. Similarities and differences between depressive disorders and grief are discussed.

Depressive illnesses specific to individuals at various developmental stages are reviewed. An explanation of the symptomatology is presented as background knowledge for assessing the client with depression. Nursing care is described in the context of the six steps of the nursing process. Various medical treatment modalities are explored.

CORE CONCEPT

Depression

An alteration in mood expressed by feelings of sadness, despair, and pessimism. There is a loss of interest in usual activities, and somatic symptoms may be evident. Changes in appetite, sleep patterns, and cognition are common.

Historical Perspective

Many ancient cultures (e.g., Babylonian, Egyptian, Hebrew) have believed in the supernatural or divine origin of mood disorders. The Old Testament states in the Book of Samuel that King Saul's depression was inflicted by an "evil spirit" sent from God to "torment" him.

A clearly nondivine point of view regarding depression was held by the Greek medical community from the fifth century BC through the third century AD. This perspective represented the thinking of Hippocrates, Celsus, and Galen, among others. They strongly rejected the idea of divine origin and considered the brain the seat of all emotional states. Hippocrates believed that **melancholia** was caused by the effect of excess black bile, a heavily toxic substance produced in the spleen or intestine, on the brain. Melancholia is a severe form of depressive disorder in which symptoms are exaggerated and interest or pleasure in virtually all activities is lost.

During the Renaissance, several new theories evolved. Depression was viewed by some as being the result of obstructed air circulation, excessive brooding, or situations beyond the client's control. Depression was reflected in major literary works of the time, including Shakespeare's *King Lear, Macbeth,* and *Hamlet.*

Contemporary thinking has been substantially shaped by the works of Sigmund Freud, Emil Kraepelin, and Adolf Meyer. Having evolved from these early 20th-century models, current thinking about mood disorders generally encompasses the intrapsychic, behavioral, and biological perspectives. These perspectives support the notion of multiple causation in the development of mood disorders.

Epidemiology

Major depressive disorder (MDD) is one of the leading causes of disability in the United States. In addition to the disability posed by the disorder itself, recent research links depression to an increased risk for coronary artery disease (another leading cause of death), especially in women younger than age 65 (Jiang et al., 2016). In 2014, 6.6 percent of individuals ages 18 and older (15.6 million persons) had at least one major depressive episode in the past year (Substance Abuse and Mental Health Services Administration [SAMHSA], 2015). The lifetime prevalence of depression is about 17 percent, which makes it the most prevalent psychiatric disorder (Sadock, Sadock, & Ruiz, 2015). Further, there is evidence that the incidence of depression is increasing among American teens and young adults, particularly adolescent girls.

From 2005 to 2014, the incidence rose from 4.5 to 5.7 percent among teenage boys and from 13.1 to 17.3 percent for teenage girls (Mojtabai, Olfson, & Han, 2016). The reasons for these increases are unclear, but the overall preponderance has led to the consideration of depression by some researchers as "the common cold of psychiatric disorders" and this generation as an "age of melancholia."

Age and Gender

Research indicates that the incidence of depressive disorder is higher in women than it is in men by almost two to one. Sadock and associates (2015) report that this finding is "an almost universal observation, independent of country or culture" (p. 349). The gender difference is less pronounced between ages 44 and 65, but after age 65, women are again more likely than men to be depressed. This occurrence may be related to gender differences in social roles and economic and social opportunities and the shifts that occur with age. The construction of gender stereotypes, or *gender socialization,* promotes typical female characteristics, such as helplessness, passivity, and emotionality, that are associated with depression. In contrast, some studies have suggested that "masculine" characteristics are associated with higher self-esteem and less depression.

Social Class

Some studies have indicated an inverse relationship between social class and report of depressive symptoms. However, there has yet to be a definitive causal structure in the relationship between socioeconomic status and mental illness. A National Center for Health Statistics report identified that for the 45 to 64 age group, depression was five times more prevalent among those below the poverty level (National Center for Health Statistics [NCHS], 2012). One study identified a greater increase in depression with age when compared to more affluent individuals (Green & Benzeval, 2009). Nauert (2010) reports on research that revealed current treatments were less effective for working-class individuals than for middle-class counterparts, regardless of whether they received therapy or medication. This finding may be influential in higher levels of depression among lower socioeconomic class members. Whether these findings are related to lack of access to resources and early treatment, difficulty managing multiple stressors associated with socioeconomic well-being, or a combination of many factors requires further research.

Race and Culture

Studies have shown no consistent relationship between race and affective disorder. One problem encountered in reviewing racial comparisons involves the socioeconomic class of the race being investigated. Sample populations of nonwhite clients are often predominantly lower socioeconomic class populations that are compared with white populations from middle and upper social classes.

Other studies suggest a second problematic factor in the study of racial comparisons. Clinicians tend to underdiagnose mood disorders and overdiagnose schizophrenia in clients who have racial or cultural backgrounds different from their own (Sadock et al., 2015). This misdiagnosis may result from language barriers between clients and physicians who are unfamiliar with cultural aspects of nonwhite clients' language and behavior.

Marital Status

A number of studies have suggested that marriage has a positive effect on psychological well-being compared to those who are single or do not have a close relationship with another person. Other studies have suggested that marital status alone is not a valid indicator of risk for depression (Lapate et al., 2014; LaPierre, 2004). Some of those studies have identified age as an important variable in risk for depression among married and single individuals. Lapate and associates (2014) report that marital stress was associated with increased risk for depression, suggesting that social stress may also be an important variable to consider.

Seasonality

Studies exploring whether seasonality is a cause of depression have yielded varying results. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (APA, 2013) uses the term *seasonal pattern* to describe and specify any depressive disorder that occurs at "characteristic times of the year" (p. 187). The authors note that episodes are most common in fall or winter, but some clients have recurrent summer episodes. Authors of one large study report that prevalence rates of depression with seasonal patterns have varied from 1 percent to 12 percent, but in their study of 5,549 patients from primary care settings, there was no evidence of seasonal patterns for major depressive disorder (Winthorst et al., 2011). In another study, Cobb and associates (2014) found that a small but significant peak in depression symptoms occurred in winter months, but over 20 years of following those clients, the winter seasonal pattern was not stable. Seasonal affective disorder (SAD) continues to be popularly referred to as a separate condition, although the *DSM-5* does not list it as a distinct diagnosis. Reported benefits of light therapy may support a seasonal cause for depression during winter months when there is often less exposure to natural sunlight, but more research is needed to determine a causal relationship.

Types of Depressive Disorders

Major Depressive Disorder

MDD is characterized by depressed mood or loss of interest or pleasure in usual activities, impaired social and occupational functioning that has existed for at least 2 weeks, no history of manic behavior, and symptoms that cannot be attributed to use of substances or a general medical condition. Additionally, the diagnosis of MDD is specified according to whether it is a *single episode* (the individual's first encounter with a major depressive episode) or *recurrent* (the individual has a history of previous major depressive episodes).

The diagnosis will also identify the degree of severity of symptoms (mild, moderate, or severe) and whether there is evidence of psychotic, catatonic, or melancholic features. The presence of anxiety and severity of suicide risk may also be noted. MDD is differentiated from schizoaffective disorder, a condition in which the individual expresses symptoms of a mood disorder as well as symptoms of schizophrenia. Read Josh's story on his experience with depression and an eventual diagnosis of schizoaffective disorder in the "Real People, Real Stories" feature. The *DSM-5* (APA, 2013) diagnostic criteria for major depressive episode are presented in Box 25–1.

Real People, Real Stories: Josh's Experience With Depression and Schizoaffective Disorder

(This individual preferred to remain anonymous, so his name has been changed.)

Consider reflecting on factors that may contribute to Josh's perceptions about his illness and his perceptions about the contributions of health-care providers in his recovery process.

Karyn: Tell me about the time when you first became aware that you had a mood disorder [Josh had told me he had depression. I was unaware when we began the interview that his actual diagnosis was schizoaffective disorder.]

Josh: I was in senior high school and was doing well. I was in advanced placement (AP) courses, and suddenly I got an F in AP English. Nothing like that had ever happened before. I started becoming more withdrawn. I was smoking pot with my friends, and I wonder now if that had an impact. I graduated high school, then attended college for two years until the symptoms really surfaced. I was cut from the soccer team, so there were some disappointments, but I became very withdrawn and depressed. I had suicide ideas and a plan. I had to take a break from school, and I just wasn't doing anything; I was just very withdrawn. Four years later I was diagnosed with schizoaffective disorder.

Karyn: What did you think about that diagnosis?

Josh: I thought it was wrong. I did have some difficulty tracking objects with my eyes, and I still do when I don't get enough sleep. I guess now that I think of it, there was a time in college when I thought my roommates were talking about me, and then I started thinking people in the next room were talking about me. I would read into things a lot. Sometimes I thought I saw something out of the corner of my eye, and sometimes I heard voices.

Karyn: It seems like that would be difficult, maybe even frightening, to have these symptoms and get this diagnosis. What was that like for you?

Josh: Yeah, it was, but I was glad to get a diagnosis because then I knew what I had to deal with. At the same time, though, I thought it was too quickly made and they were too quick to prescribe pills. If I had it to do over, I would have just trusted the doctors, but I rebelled against the drugs several times—sometimes because I was having side effects like tardive dyskinesia; one time because I was convinced the meds were holding me back and even hurting me; and one time because I just gave up, since I didn't have any of the things I wanted, like marriage, a college degree, or a career. Sometimes I thought, "I can just be smarter than this, and I'll get over it." But I was very disorganized and incoherent. Each time I didn't take the pills, I became withdrawn, depressed, and hearing voices, and eventually I just couldn't find anything else to blame it on. I tried to hide the fact that I had stopped taking the pills, but it always became evident eventually. I stay on the medications now because I know I have to.

Karyn: You've come so far since then!

Josh: (smiles) Yeah, it took me eight years to finish my college degree, but now I have a good job in information technology at a large hospital system, and I live on my own. I was engaged, and although it didn't work out, I'm dating again and hopeful about pursuing a committed relationship.

Karyn: What do you think has been most important in supporting your recovery?

Josh: My parents supported me through all of it. They were my only support, and I didn't want other people to know my "stuff." I was able to stay with my parents until I got back on my feet, and that was really important. The last time I stopped taking my meds, I'd have to consult court records to remember everything that happened, but I know there were trespassing charges. I had run-ins with the police. I also had run-ins with my parents, who eventually called in a crisis team, and I was hospitalized against my will. I was in the hospital for around 30 days, and I saw people who were homeless and had no one supporting them, and they were really doing poorly. Knowing I had someplace to live really helped me. Also, I had a job and some successes at work, so that gave me focus. My job is largely mathematical and doesn't require a lot of social skills challenges. That was helpful for me because, while some people may be self-taught with social skills, I've always struggled with that. My job allows me to develop great insights, be quirky, and not have to try to figure people out.

Real People, Real Stories: Josh's Experience With Depression and Schizoaffective Disorder—cont'd

Karyn: What are your thoughts about the impact of the health-care providers with whom you've interacted?

Josh: I work in a hospital, so I have a great appreciation for their hard work. I saw an NP who gave me good advice and was very supportive. She asked some probing questions and confronted me at times, and that was challenging, but she was just doing her job and I was trying to hide from my illness. She told me the medications might end up being less effective if I didn't take them or stay on them early in my illness, so that may have encouraged me to keep taking them.

I had good community health services—a case worker, a psychiatrist, and a behavioral health specialist that I found to be particularly supportive because we talked about spiritual things, and that made it okay to explore other issues.

In the hospital, the nurses mostly worked at the station, and that was probably better for their safety, but still I could talk to them and they made it seem like it was okay that I was there. That was important because I wasn't sure what was happening to me, and they just talked about normal, everyday stuff. They seemed more like warm people than cold or clinical. I go to NAMI [National Alliance on Mental Illness] meetings now because I want to share the message with people who have a mental illness (and with their family members) that the professionals could see things I was unable to see at the time I was symptomatic, so it's important to trust the process. I also want families to know that having ongoing support from family members was a lifeline for me even when we were having run-ins and they were facilitating hospitalization against my will.

BOX 25–1 Diagnostic Criteria for Major Depressive Disorder

A. Five (or more) of the following symptoms have been present during the same 2-week period and represent a change from previous functioning; at least one of the symptoms is either (1) depressed mood or (2) loss of interest or pleasure. *Note:* Do not include symptoms that are clearly due to another medical condition.

1. Depressed mood most of the day, nearly every day, as indicated by either subjective report (e.g., feels sad, empty, or hopeless) or observation made by others (e.g., appears tearful). *Note:* In children and adolescents, can be irritable mood

2. Markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day (as indicated by either subjective account or observation)

3. Significant weight loss when not dieting or weight gain (e.g., a change of more than 5% of body weight in a month), or decrease or increase in appetite nearly every day. *Note:* In children, consider failure to make expected weight gain

4. Insomnia or hypersomnia nearly every day

5. Psychomotor agitation or retardation nearly every day (observable by others, not merely subjective feelings of restlessness or being slowed down)

6. Fatigue or loss of energy nearly every day

7. Feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick)

8. Diminished ability to think or concentrate, or indecisiveness, nearly every day (either by subjective account or as observed by others)

9. Recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide

B. The symptoms cause clinically significant distress or impairment in social, occupation, or other important areas of functioning.

C. The episode is not attributable to the physiological effects of a substance or another medical condition.

Note: Criteria A–C represent a major depressive episode.

Note: Responses to a significant loss (e.g., bereavement, financial ruin, losses from a natural disaster, a serious medical illness or disability) may include the feelings of intense sadness, rumination about the loss, insomnia, poor appetite, and weight loss noted in Criterion A, which may resemble a depressive episode. Although such symptoms may be understandable or considered appropriate to the loss, the presence of a major depressive episode in addition to the normal response to a significant loss should also be carefully considered. This decision inevitably requires the exercise of clinical judgment based on the individual's history and the cultural norms for the expression of distress in the context of loss.

D. The occurrence of the major depressive episode is not better explained by schizoaffective disorder, schizophrenia, schizophreniform disorder, delusional disorder, or other specified and unspecified schizophrenia spectrum and other psychotic disorders.

E. There has never been a manic episode or a hypomanic episode.

Specify:

With anxious distress

With mixed features

With melancholic features

With atypical features

With mood-congruent psychotic features

With mood-incongruent psychotic features

With catatonia

With peripartum onset

With seasonal pattern

Persistent Depressive Disorder (Dysthymia)

Characteristics of **dysthymia** are similar to, if somewhat milder than, those ascribed to MDD. Individuals with this mood disturbance describe their mood as sad or "down in the dumps." There is no evidence of psychotic symptoms. The essential feature is a chronically depressed mood (or possibly an irritable mood in children or adolescents) for most of the day, more days than not, for at least 2 years (1 year for children and adolescents). The diagnosis is identified as *early onset* (occurring before age 21 years) or *late onset* (occurring at age 21 years or older). The *DSM-5* diagnostic criteria for persistent depressive disorder (dysthymia) are presented in Box 25–2.

Premenstrual Dysphoric Disorder

The essential features of **premenstrual dysphoric disorder** (PMDD) include markedly depressed mood, excessive anxiety, mood swings, and decreased interest in activities during the week prior to menses, improving shortly after the onset of menstruation, and becoming minimal or absent in the week postmenses (APA, 2013).

The *DSM-5* diagnostic criteria for PMDD are presented in Box 25–3.

Substance/Medication-Induced Depressive Disorder

The symptoms associated with a substance/medication-induced depressive disorder are considered the direct result of physiological effects of a substance (e.g., a drug of abuse, a medication, or toxin exposure). This disorder causes clinically significant distress or impairment in social, occupational, or other important areas of functioning. The depressed mood is associated with *intoxication* or *withdrawal* from substances such as alcohol, amphetamines, cocaine, hallucinogens, opioids, phencyclidine-like substances, sedatives, hypnotics, or anxiolytics. The symptoms meet the full criteria for a relevant depressive disorder (APA, 2013).

A number of medications have been known to evoke mood symptoms. Classifications include anesthetics, analgesics, anticholinergics, anticonvulsants, antihypertensives, antiparkinsonian agents, antiulcer agents, cardiac medications, oral contraceptives,

---

BOX 25–2 Diagnostic Criteria for Persistent Depressive Disorder (Dysthymia)

A. Depressed mood for most of the day, for more days than not, as indicated by either subjective account or observation by others, for at least 2 years. *Note:* In children and adolescents, mood can be irritable and duration must be at least 1 year.

B. Presence, while depressed, of two (or more) of the following:
1. Poor appetite or overeating
2. Insomnia or hypersomnia
3. Low energy or fatigue
4. Low self-esteem
5. Poor concentration or difficulty making decisions
6. Feelings of hopelessness

C. During the 2-year period (1 year for children or adolescents) of the disturbance, the individual has never been without the symptoms in Criteria A and B for more than 2 months at a time.

D. Criteria for a major depressive disorder may be continuously present for 2 years.

E. There has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder.

F. The disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder.

G. The symptoms are not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition (e.g., hypothyroidism).

H. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Specify if:
With anxious distress
With mixed features
With melancholic features
With atypical features
With mood-congruent psychotic features
With mood-incongruent psychotic features
With peripartum onset

Specify if:
With pure dysthymic syndrome
With persistent major depressive episode
With intermittent major depressive episodes, with current episode
With intermittent major depressive episodes, without current episode

Specify if:
In partial remission
In full remission

Specify if:
Early onset (onset before age 21 years)
Late onset (onset at age 21 years or older)

Specify if:
Mild
Moderate
Severe

BOX 25–3 Diagnostic Criteria for Premenstrual Dysphoric Disorder

A. In the majority of menstrual cycles, at least five symptoms must be present in the final week before the onset of menses, start to *improve* within a few days after the onset of menses, and become *minimal* or absent in the week postmenses.

B. One (or more) of the following symptoms must be present:
   1. Marked affective lability (e.g., mood swings; feeling suddenly sad or tearful or increased sensitivity to rejection)
   2. Marked irritability or anger or increased interpersonal conflicts
   3. Marked depressed mood, feelings of hopelessness, or self-deprecating thoughts
   4. Marked anxiety, tension, feelings of being keyed up or on edge

C. One (or more) of the following symptoms must additionally be present, to reach a total of *five* symptoms when combined with symptoms from Criterion B above.
   1. Decreased interest in usual activities (e.g., work, school, friends, hobbies)
   2. Subjective difficulty in concentration
   3. Lethargy, easy fatigability, or marked lack of energy
   4. Marked change in appetite; overeating; or specific food cravings
   5. Hypersomnia or insomnia

6. A sense of being overwhelmed or out of control
7. Physical symptoms, such as breast tenderness or swelling, joint or muscle pain, a sensation of "bloating," weight gain

Note: The symptoms in Criteria A–C must have been met for most menstrual cycles that occurred in the preceding year.

D. The symptoms are associated with clinically significant distress or interferences with work, school, usual social activities, or relationships with others (e.g., avoidance of social activities, decreased productivity, and efficiency at work, school, or home).

E. The disturbance is not merely an exacerbation of the symptoms of another disorder, such as major depressive disorder, panic disorder, persistent depressive disorder (dysthymia), or a personality disorder (although it may co-occur with any of these disorders).

F. Criteria A should be confirmed by prospective daily ratings during at least two symptomatic cycles. (*Note:* The diagnosis may be made provisionally prior to this confirmation).

G. The symptoms are not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication, or other treatment) or another medical condition (e.g., hyperthyroidism).

---

psychotropic medications, muscle relaxants, steroids, and sulfonamides. Some specific examples are included in the discussion of predisposing factors to depressive disorders.

Depressive Disorder Due to Another Medical Condition

This disorder is characterized by symptoms associated with a major depressive episode that are the direct physiological consequence of another medical condition (APA, 2013). The depression causes clinically significant distress or impairment in social, occupational, or other important areas of functioning. Types of physiological influences are included in the discussion on predisposing factors to depression.

Predisposing Factors

The etiology of depression is unclear. No single theory or hypothesis has been postulated that substantiates a clear-cut explanation for the disease. Evidence continues to mount in support of multiple causations, recognizing the combined effects of genetic, biochemical, and psychosocial influences on an individual's susceptibility to depression. A number of theoretical postulates are presented here.

Biological Theories

Genetics

Affective illness has been the subject of considerable research on the relevance of hereditary factors. A genetic link has been suggested in numerous studies; however, a definitive mode of genetic transmission has yet to be demonstrated.

Twin Studies

Twin studies suggest a strong genetic factor in the etiology of affective illness, including depressive disorders. Heritability is estimated at 40 to 50 percent (Lohoff, 2010). Twin studies looking specifically at the major depressive disorders–recurrent unipolar (MDD-RU) identify the risk for MDD-RU at 37 percent for twins "with a substantial component of unique individual environmental risk but little shared environmental risk" (Lohoff, 2010, p. 539). These findings suggest that while twin studies do identify genetic risk, they do not explain all depressions. Environmental risks not only are an important variable but are uniquely individual.

Family Studies

Most family studies have shown that major depression is more common among first-degree biological relatives of people with the disorder than among the general

population (Black & Andreasen, 2014). The evidence to support an increased risk of depressive disorder in individuals with positive family history is quite compelling. It is unlikely that random environmental factors could cause the concentration of illness that is seen within families.

Adoption Studies

Support for heritability as an etiological influence in depression comes from studies of the adopted offspring of biological parents with depression. Some studies have found a threefold increase in depression among children of biological relatives with affective illness, but other studies have found no difference in the rate of mood disorders (Sadock et al., 2015). Conversely, adoption studies have also been used to examine the effects of being reared by an adoptive parent (particularly the maternal parent) with depression and the risks for depression in their nongenetically similar children. Interestingly, these studies have demonstrated an increased risk of depression (as well as oppositional defiant disorder and conduct disorder) in adopted children that cannot be explained by genetics (Natsuaki et al., 2014). Again, this finding suggests that environmental factors also play a role in the etiology of depressive illnesses.

Biochemical Influences

Biogenic Amines

It has been hypothesized that depressive illness may be related to a deficiency of the neurotransmitters norepinephrine, serotonin, and dopamine at functionally important receptor sites in the brain. Historically, the biogenic amine hypothesis of mood disorders grew out of the observation that reserpine, an antihypertensive that depletes the brain of amines such as norepinephrine, was associated with the development of a depressive syndrome. The catecholamine norepinephrine has been identified as a key component in the mobilization of the body to deal with stressful situations. Neurons that contain serotonin are critically involved in the regulation of many psychobiological functions, such as mood, anxiety, arousal, vigilance, irritability, thinking, cognition, appetite, aggression, sleep–wake cycles, eating, and intestinal motility. Tryptophan, the amino acid precursor of serotonin, has been shown to enhance the efficacy of antidepressant medications and on occasion to be effective as an antidepressant itself. The level of dopamine in the mesolimbic system of the brain is thought to exert a strong influence over human mood and behavior. A diminished supply of these biogenic amines inhibits the transmission of impulses from one neuronal fiber to another, causing a failure of the cells to fire or become charged (see Figure 25–1).

More recently, the biogenic amine hypothesis has been expanded to include another neurotransmitter, acetylcholine. Because cholinergic agents have profound effects on mood, electroencephalograms, sleep, and neuroendocrine function, it has been suggested that the problem in depression and mania may be an imbalance between the biogenic amines and acetylcholine. Cholinergic transmission is thought to be excessive in depression and inadequate in mania (Sadock et al., 2015). The precise role that any neurotransmitters play in the etiology of depression is unknown because these chemicals cannot be measured in the brain. It has been theorized that since selective serotonin reuptake inhibitors (SSRIs) are drugs that elevate serotonin levels, low serotonin levels in the brain must be responsible for depression. However, SSRIs also seem to be beneficial in the treatment of anxiety, leading to the hypothesis that low serotonin levels are responsible for anxiety. Further, too *much* serotonin has also been implicated in anxiety states and in schizophrenia. All of this seemingly contradictory information has led many current researchers to believe that neurotransmitters such as serotonin might be better explained as modulators of intense emotional states rather than associated with any one particular emotion (Sadock et al., 2015). As the body of research grows, increased knowledge regarding the biogenic amines undoubtedly will contribute to a greater capacity for understanding and treating affective illness.

Neuroendocrine Disturbances

Neuroendocrine disturbances may play a role in the pathogenesis or persistence of depressive illness. This notion has arisen in view of the marked disturbances in mood observed with the administration of certain hormones or in the presence of spontaneously occurring endocrine disease.

Hypothalamic-Pituitary-Adrenocortical Axis

In clients who are depressed, the normal system of hormonal inhibition fails, resulting in a hypersecretion of cortisol. This elevated serum cortisol is the basis for the dexamethasone suppression test that is sometimes used to determine if an individual has somatically treatable depression.

Hypothalamic-Pituitary-Thyroid Axis

Thyrotropin-releasing factor (TRF) from the hypothalamus stimulates the release of thyroid-stimulating hormone (TSH) from the anterior pituitary gland. In turn, TSH stimulates the thyroid gland. Diminished TSH response to administered TRF is observed in approximately 25 percent of depressed persons and appears to be associated with increased risk for relapse despite treatment with antidepressants (Sadock et al.,
FIGURE 25–1 Neurobiology of depression.

NEUROTRANSMITTERS

Although other neurotransmitters have also been implicated in the pathophysiology of depression, disturbances in serotonin and norepinephrine have been the most extensively scrutinized.

Cell bodies of origin for the serotonin pathways lie within the raphe nuclei located in the brainstem. Those for norepinephrine originate in the locus ceruleus. Projections for both neurotransmitters extend throughout the forebrain, prefrontal cortex, cerebellum, and limbic system.

AREAS OF THE BRAIN AFFECTED

Areas of the brain affected by depression and the symptoms that they mediate include the following:
• Hippocampus: Memory impairments, feelings of worthlessness, hopelessness, and guilt
• Amygdala: Anhedonia, anxiety, reduced motivation
• Hypothalamus: Increased or decreased sleep and appetite; decreased energy and libido
• Other limbic structures: Emotional alterations
• Frontal cortex: Depressed mood; problems concentrating
• Cerebellum: Psychomotor retardation/agitation

MEDICATIONS AND THEIR EFFECTS ON THE BRAIN

All medications that increase serotonin, norepinephrine, or both can improve the emotional and vegetative symptoms of depression. Medications that produce these effects include those that block the presynaptic reuptake of the neurotransmitters or block receptors at nerve endings (tricyclics; SSRIs; SNRIs) and those that inhibit monoamine oxidase, an enzyme that is involved in the metabolism of the monoamines serotonin, norepinephrine, and dopamine (MAOIs).

Side effects of these medications relate to their specific neurotransmitter receptor–blocking action. Tricyclic (e.g., imipramine, amitriptyline) and tetracyclics (e.g. mirtazapine, maprotiline) block reuptake and/or receptors for serotonin, norepinephrine, acetylcholine, and histamine. SSRIs are selective serotonin reuptake inhibitors. Others, such as bupropion, venlafaxine, and duloxetine, block serotonin and norepinephrine reuptake, and also are weak inhibitors of dopamine.

Blockade of norepinephrine reuptake results in side effects of tremors, cardiac arrhythmias, sexual dysfunction, and hypertension. Blockade of serotonin reuptake results in side effects of gastrointestinal disturbances, increased agitation, and sexual dysfunction. Blockade of dopamine reuptake results in side effects of psychomotor activation. Blockade of acetylcholine reuptake results in dry mouth, blurred vision, constipation, and urinary retention. Blockade of histamine reuptake results in sedation, weight gain, and hypotension.

2015). About 4.6 percent of the U.S. population suffers from hypothyroidism (more women than men), and depression is a common symptom (in addition to a host of other symptoms) (National Institutes of Health [NIH], 2016a). Laboratory testing to evaluate TSH is relevant to distinguish between depressive disorders and thyroid disorders, since in thyroid disorders the symptoms of depression are treated with hormone replacement rather than antidepressants.

Physiological Influences

Depressive symptoms that occur as a consequence of a non-mood disorder or as an adverse effect of certain medications are called *secondary* depression. Secondary depression may be related to medication side effects, neurological disorders, electrolyte or hormonal disturbances, nutritional deficiencies, and other physiological or psychological conditions.

Medication Side Effects

A number of drugs, either alone or in combination with other medications, can produce a depressive syndrome. Most common are those that have a direct effect on the central nervous system, such as anxiolytics, antipsychotics, sedative-hypnotics (including barbiturates and opioids), and anticonvulsant mood stabilizers. Many drugs used to treat general medical conditions have also been associated with inducing depression (Vann, 2015), and several are listed here:

- Antibacterial agents, antifungal agents, and antiviral agents
- Antimalarials (including mefloquine)
- Antihypertensives and statins (including beta blockers and calcium blockers)
- Antineoplastics (including vincristine and zidovudine)
- Dermatologics (including isotretinoin and finasteride)
- Hormones (including contraceptives)
- Nonnucleoside reverse transcriptase inhibitors (HIV medications)
- Respiratory agents (leukotriene inhibitors)
- Steroids
- Smoking cessation agents (varenicline)
- Vigabatrin (anticonvulsant)

Neurological Disorders

An individual who has suffered a cardiovascular accident (CVA) may experience despondency unrelated to the severity of the CVA. These are true mood disorders, and antidepressant drug therapy may be indicated. Brain tumors, particularly in the area of the temporal lobe, often cause symptoms of depression. Agitated depression may be part of the clinical picture associated with Alzheimer's disease, Parkinson's disease, and Huntington's disease. Agitation and restlessness may also represent underlying depression in the individual with multiple sclerosis.

Electrolyte Disturbances

Excessive levels of sodium bicarbonate or calcium can produce symptoms of depression, as can deficits in magnesium and sodium. Potassium is also implicated in the syndrome of depression. Symptoms have been observed with excesses of potassium in the body as well as in instances of potassium depletion.

Hormonal Disturbances

Depression is associated with dysfunction of the adrenal cortex and is commonly observed in both Addison's disease and Cushing's syndrome. Other endocrine conditions that may result in symptoms of depression include hypoparathyroidism, hyperparathyroidism, hypothyroidism, and hyperthyroidism.

An imbalance of the hormones estrogen and progesterone has been implicated in the predisposition to PMDD, although the exact etiology is unknown. The interaction of these hormonal changes has an impact on serotonin levels, which may contribute to the depression associated with this disorder. It is also noted that individuals with PMDD often have underlying depression and anxiety, so it is possible that hormone changes are exacerbating an already existing condition (Thielen, 2015).

Nutritional Deficiencies

Deficiencies in proteins, carbohydrates, vitamin B_1 (thiamine), vitamin B_2 (riboflavin), vitamin B_6 (pyridoxine), B_9 (folate), vitamin B_{12}, iron, zinc, calcium, chromium, iodine, lithium, selenium, potassium, and omega-3 fatty acids have all been associated with symptoms of depression (Sathyanarayana Rao et al., 2008; Schimelpfening, 2012). A recent large study also found that vitamin D deficiency was linked to depressive symptoms (Shin et al., 2016). It is not a surprise that individuals with anorexia nervosa, who have significant nutritional deficiencies, commonly have comorbid depression.

Other Physiological Conditions

Other conditions that have been associated with secondary depression include collagen disorders, such as systemic lupus erythematosus (SLE) and polyarteritis nodosa; cardiovascular disease, such as cardiomyopathy, congestive heart failure, and myocardial infarction; infections, such as encephalitis, hepatitis, mononucleosis, pneumonia, and syphilis; and metabolic disorders, such as diabetes mellitus and porphyria.

Psychosocial Theories

Psychoanalytical Theory

Freud (1957) presented his classic paper "Mourning and Melancholia" in 1917. He defined the distinguishing features of melancholia as:

> a profoundly painful dejection, cessation of interest in the outside world, loss of the capacity to love, inhibition of all activity, and a lowering of the self-regarding feelings to a degree that finds utterances in self-reproaches and self-revilings, and culminates in a delusional expectation of punishment.

He observed that melancholia occurs after the loss of a loved object, either actually by death or emotionally by rejection, or the loss of some other abstraction of value to the individual. Freud indicated that in melancholia, the depressed patient's rage is internally directed because of identification with the lost object (Sadock et al., 2015).

Freud believed that the individual predisposed to melancholia experienced ambivalence in love relationships. He postulated, therefore, that once the loss is incorporated into the self (ego), the hostile part of the ambivalence that had been felt for the lost object is then turned inward against the ego.

Learning Theory

The model of "learned helplessness" arises out of Seligman's (1973) experiments with dogs. The animals were exposed to electrical stimulation from which they could not escape. Later, when they were given the opportunity to avoid the traumatic experience, they reacted with helplessness and made no attempt to escape. A similar state of helplessness exists in humans who have experienced numerous failures (either real or perceived). The individual abandons any further attempt to succeed. Seligman theorized that learned helplessness predisposes individuals to depression by imposing a feeling of lack of control over their life situations. They become depressed because they feel helpless; they have learned that whatever they do is futile. Learned helplessness can be especially damaging very early in life, because the sense of mastery over one's environment is an important foundation for future emotional development.

Object Loss Theory

The theory of object loss suggests that depressive illness occurs as a result of having been abandoned by or otherwise separated from a significant other during the first 6 months of life. Because the mother represents the child's main source of security during this period, she is considered the "object." This absence of attachment, which may be either physical or emotional, leads to feelings of helplessness and despair that contribute to lifelong patterns of depression in response to loss.

The concept of "anaclitic depression" was introduced in 1946 by psychiatrist René Spitz to refer to children who became depressed after being separated from their mothers for an extended period of time during the first year of life. The condition, as described by Spitz, included symptoms such as excessive crying, anorexia, withdrawal, **psychomotor retardation,** stupor, and a generalized impairment in the normal process of growth and development. Some researchers suggest that loss in adult life afflicts people much more severely in the form of depression if the individuals have suffered early childhood loss.

Cognitive Theory

Beck and colleagues (1979) proposed a theory suggesting that the primary disturbance in depression is cognitive rather than affective. The underlying cause of the depression is cognitive distortions that result in negative, defeated attitudes. Beck and colleagues identified three cognitive distortions that they believe serve as the basis for depression:

1. Negative expectations of the environment
2. Negative expectations of the self
3. Negative expectations of the future

These cognitive distortions arise out of a defect in cognitive development, and the individual feels inadequate, worthless, and rejected by others. Outlook for the future is one of pessimism and hopelessness.

Cognitive theorists believe that depression is the product of negative thinking. This is in contrast to the other theorists, who suggest that negative thinking occurs when an individual is depressed. **Cognitive therapy** focuses on helping the individual alter mood by changing the way he or she thinks. The individual is taught to control negative thought distortions that lead to pessimism, lethargy, procrastination, indecisiveness, and low self-esteem (see Chapter 19, Cognitive Therapy).

The Transactional Model

No single theory or hypothesis exists to substantiate a clear-cut explanation for depressive disorder. Evidence continues to mount in support of multiple causation. The transactional model recognizes the combined effects of genetic, biochemical, and psychosocial influences on an individual's susceptibility to depression. The dynamics of depression using the transactional model of stress and adaptation are presented in Figure 25–2.

Developmental Implications

Childhood

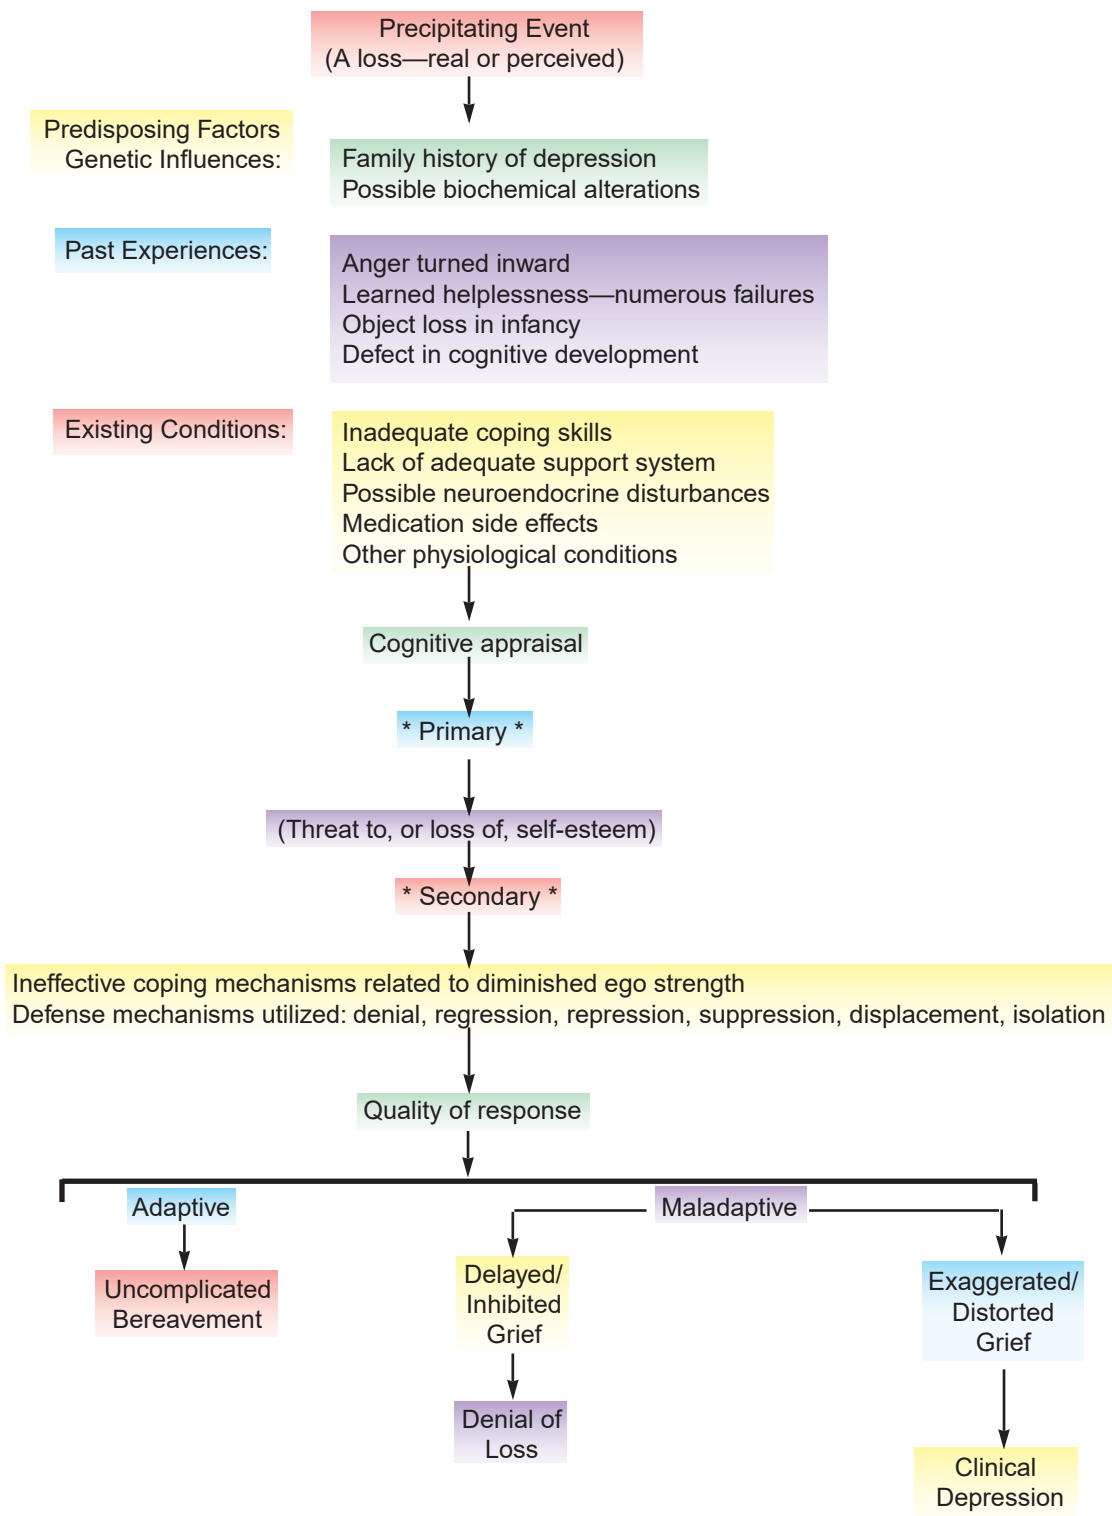
Only in recent years has a consensus developed among investigators identifying major depressive disorder as an entity in children and adolescents that can be identified using criteria similar to those used for adults. It is not uncommon, however, for the symptoms of


FIGURE 25–2 The dynamics of depression using the transactional model of stress and adaptation.

depression to be manifested differently in childhood, and the picture changes with age (Anxiety and Depression Association of America, 2016; Sadock et al., 2015):

■ **Up to age 3:** Signs may include feeding problems, tantrums, lack of playfulness and emotional expressiveness, failure to thrive, or delays in speech and gross motor development.

■ **Ages 3 to 5:** Common symptoms may include accident proneness, phobias, aggressiveness, and excessive self-reproach for minor infractions.

Mood-congruent auditory hallucinations are not uncommon. The incidence of depression among preschool children is estimated to be between 0.3 and 0.9 percent.

■ **Ages 6 to 8:** There may be vague physical complaints and aggressive behavior. Children in this age group may cling to parents and avoid new people and challenges. They may lag behind their classmates in social skills and academic competence.

■ **Ages 9 to 12:** Common symptoms include morbid thoughts, excessive worrying, and poor self-esteem. These children may reason that they are depressed because they have disappointed their parents in some way. There may be lack of interest in playing with friends. The incidence of depression among school-aged children is estimated to be around 2 to 3 percent.

Other symptoms of childhood depression may include hyperactivity, delinquency, school problems, psychosomatic complaints, sleeping and eating disturbances, social isolation, delusional thinking, and suicidal thoughts or actions. The APA (2013) has included a new diagnostic category in the Depressive Disorders chapter of the *DSM-5*. This childhood disorder is called *disruptive mood dysregulation disorder*.

The diagnostic criteria for disruptive mood dysregulation disorder are presented in Box 25–4.

Children may become depressed for various reasons. In many depressed children, there is a genetic predisposition toward the condition, which is then precipitated by a stressful situation. Common precipitating factors include physical or emotional detachment by the primary caregiver, parental separation or divorce, death of a loved one (person or pet), a move, academic failure, or physical illness. In any event, the common denominator is loss.

The focus of therapy with depressed children is to alleviate the child's symptoms and strengthen his or her coping and adaptive skills, with the hope of possibly preventing future psychological problems. Some studies have shown that untreated childhood depression may lead to subsequent problems in adolescence and adult life. Most children are treated on an outpatient basis. Hospitalization of the depressed child usually occurs only if he or she is actively suicidal, when the home environment precludes adherence to a treatment regimen, or if the child needs to be separated from the home because of psychosocial deprivation.

Parental and family therapy are commonly used to help the younger depressed child. Recovery is

BOX 25–4 Diagnostic Criteria for Disruptive Mood Dysregulation Disorder

A. Severe recurrent temper outbursts manifested verbally (e.g., verbal rages) and/or behaviorally (e.g., physical aggression toward people or property) that are grossly out of proportion in intensity or duration to the situation or provocation.

B. The temper outbursts are inconsistent with developmental level.

C. The temper outbursts occur, on average, three or more times per week.

D. The mood between temper outbursts is persistently irritable or angry most of the day, nearly every day, and is observable by others (e.g., parents, teachers, peers).

E. Criteria A–D have been present for 12 or more months. Throughout that time, the individual has not had a period lasting 3 or more consecutive months without all of the symptoms of Criteria A–D.

F. Criteria A and D are present in at least two of three settings (i.e., at home, at school, with peers) and are severe in at least one of these.

G. The diagnosis should not be made for the first time before age 6 or after age 18 years.

H. By history or observation, the age at onset of Criteria A–E is before 10 years.

I. There has never been a distinct period lasting more than 1 day during which the full symptom criteria, except duration,

for a manic or hypomanic episode have been met. *Note:* Developmentally appropriate mood elevation, such as occurs in the context of a highly positive event or its anticipation, should not be considered as a symptom of mania or hypomania.

J. The behaviors do not occur exclusively during an episode of major depressive disorder and are not better explained by another mental disorder (e.g., autism spectrum disorder, posttraumatic stress disorder, separation anxiety disorder, persistent depressive disorder [dysthymia]).

Note: This diagnosis cannot coexist with oppositional defiant disorder, intermittent explosive disorder, or bipolar disorder, though it can coexist with others, including major depressive disorder, attention-deficit/hyperactivity disorder, conduct disorder, and substance use disorders. Individuals whose symptoms meet criteria for both disruptive mood dysregulation disorder and oppositional defiant disorder should only be given the diagnosis of disruptive mood dysregulation disorder. If an individual has ever experienced a manic or hypomanic episode, the diagnosis of disruptive mood dysregulation disorder should not be assigned.

K. The symptoms are not attributable to the physiological effects of a substance or to another medical or neurological condition.

facilitated by emotional support and guidance to family members. Children older than age 8 usually participate in family therapy. In some situations, individual treatment may be appropriate for older children. Medications such as antidepressants can be important in the treatment of children, especially for the more serious and recurrent forms of depression. The SSRIs have been used with success, particularly in combination with psychosocial therapies. However, because there has been some concern that the use of antidepressant medications may cause suicidal behavior in young people, the U.S. Food and Drug Administration (FDA) has applied a black-box warning (described in the next section) to all antidepressant medications. The National Institute of Mental Health (2016) stated:

> In some cases, children, teenagers, and young adults under 25 may experience an increase in suicidal thoughts or behavior when taking antidepressants, especially in the first few weeks after starting or when the dose is changed. This warning from the U.S. Food and Drug Administration (FDA) also says that patients of all ages taking antidepressants should be watched closely, especially during the first few weeks of treatment.

Adolescence

Depression may be even harder to recognize in an adolescent than in a younger child. Feelings of sadness, loneliness, anxiety, and hopelessness associated with depression may be perceived as the normal emotional stresses of growing up. Therefore, many young people whose symptoms are attributed to the "normal adjustments" of adolescence do not get the help they need. Depression is a major cause of suicide among teens, and suicide is the second-leading cause of death in the 15- to 24-year-old age group (NCHS, 2015).

Common symptoms of depression in the adolescent are inappropriately expressed anger, aggressiveness, running away, delinquency, social withdrawal, sexual acting out, substance abuse, restlessness, and apathy. Loss of self-esteem, sleeping and eating disturbances, and psychosomatic complaints are also common.

What, then, differentiates mood disorder from the typical stormy behavior of adolescence? A visible manifestation of *behavioral change that lasts for several weeks* is the best clue for a mood disorder. Examples include the normally outgoing and extroverted adolescent who has become withdrawn and isolates herself, the good student who previously received consistently high marks but is now failing and skipping classes, and the usually self-confident teenager who is now inappropriately irritable and defensive with others.

Adolescents become depressed for all the same reasons discussed under childhood depression. In adolescence, however, depression is a common manifestation of the stress and independence conflicts associated with the normal maturation process. Depression may also be the response to death of a parent, other relative, or friend or to a breakup with a boyfriend or girlfriend. This perception of abandonment by parents or the closest peer relationship is thought to be the most frequent immediate precipitant to adolescent suicide.

Treatment of the depressed adolescent is often conducted on an outpatient basis. Hospitalization may be required in cases of severe depression or threat of imminent suicide, when a family situation is such that treatment cannot be carried out in the home, when the physical condition precludes self-care of biological needs, or when the adolescent has indicated possible harm to self or others in the family.

In addition to supportive psychosocial intervention, antidepressant therapy may be part of the treatment of adolescent mood disorders. However, as mentioned previously, the FDA has issued a public health advisory warning the public about the increased risk of suicidal thoughts and behavior in children and adolescents being treated with antidepressant medications. The black-box warning label on all antidepressant medications describes this risk and emphasizes the need for close monitoring of clients started on these medications. The advisory language does not prohibit the use of antidepressants in children and adolescents. Rather, it warns of the increased risk of suicidal ideation and encourages prescribers to balance this risk with clinical need.

Fluoxetine (Prozac) has been approved by the FDA to treat depression in children aged 8 and older, and escitalopram (Lexapro) was approved in 2009 for treatment of MDD in adolescents aged 12 and older. The other SSRI medications, such as sertraline, citalopram, and paroxetine, and the serotonin-norepinephrine reuptake inhibitor (SNRI) antidepressants duloxetine, venlafaxine, and desvenlafaxine have not been approved for treatment of depression in children or adolescents, although they have been prescribed to children by physicians in "off-label use"—a use other than the FDA-approved use. In June 2003, the FDA recommended that paroxetine not be used in children and adolescents for the treatment of MDD. The FDA analysis of antidepressant medications, as reported by the Mayo Clinic (2016a), identified that 4 percent of those taking antidepressants had an increase in suicidal thoughts and that none of the children in the study actually took his or her own life. Nonetheless, the potential risk is considered significant enough to carefully evaluate risks versus benefits before prescribing antidepressants to children and adolescents.
