Depression is the most common psychiatric disorder of the elderly, who make up 14.5 percent of the general population of the United States (Administration on Aging, 2016). This is not surprising considering the disproportionate value our society places on youth, vigor, and uninterrupted productivity. These societal attitudes continually nurture the feelings of low self-esteem, helplessness, and hopelessness that become more pervasive and intensive with advanced age. Further, the aging individual's adaptive coping strategies may be seriously challenged by major stressors, such as financial problems, physical illness, changes in bodily functioning, and an increasing awareness of approaching death. The problem is often intensified by the numerous losses individuals experience during this period in life, such as spouse, friends, children, home, and independence. A phenomenon called *bereavement overload* occurs when individuals experience so many losses in their lives that they are not able to resolve one grief response before another begins. Bereavement overload predisposes elderly individuals to depressive illness. The elderly population is growing, and it is estimated that by 2030, one in five Americans will be over the age of 65 (CDC, 2013). Evidence-based treatments for depression will continue to be a focal point of care for this population.

Although they make up only about 14.5 percent of the population, the elderly account for a proportionately larger percentage of suicides in the United States. In the 65 to 84 age group, the prevalence of suicide is 16.6 percent; the rate of suicide in those 85 years of age and older jumps to 19.3 percent (American Foundation for Suicide Prevention, 2016). The highest number of these cases is among white men at almost four times the national rate.

Some symptoms of depression in the elderly are similar to those in younger adults. However, depressive syndromes are often confused by other illnesses associated with the aging process. Symptoms of depression are often misdiagnosed as neurocognitive disorder (NCD) when in fact the memory loss, confused thinking, or apathy symptomatic of NCD actually may be the result of depression. This condition is often referred to as *pseudodementia*. The early awakening and reduced appetite typical of depression are common among many older people who are not depressed. Compounding this situation is that many medical conditions, such as endocrinological, neurological, nutritional, and metabolic disorders, often present with classic symptoms of depression. Many medications commonly used by the elderly, such as antihypertensives, corticosteroids, and analgesics, can also produce a depressant effect.

Depression accompanies many illnesses that are common among older people, such as Parkinson's disease, cancer, arthritis, and the early stages of Alzheimer's disease. Treating depression in these situations can reduce unnecessary suffering and help afflicted individuals cope with their medical problems.

The most effective treatment of depression in the elderly individual is thought to be a combination of psychosocial and biological approaches. Antidepressant medications are administered with consideration for age-related physiological changes in absorption, distribution, elimination, and brain receptor sensitivity. Because of these changes, plasma concentrations of these medications can reach very high levels despite moderate oral doses. Anticholinergic side effects associated with tricyclic antidepressants can be problematic for the elderly, and SSRIs have been associated with inducing significant hyponatremia in this population, so careful evaluation and monitoring is essential.

Electroconvulsive therapy (ECT) is an important alternative for treatment of major depression in the elderly, especially considering the problematic side effects of antidepressants in this population. The response to ECT appears to be slower with advancing age, and the therapeutic effects are of limited duration. Research has identified ECT as generally safe for the acute treatment of late-life depression (Van der Wurff et al., 2003). It may be considered the treatment of choice for the elderly individual who is an acute suicidal risk or is unable to tolerate antidepressant medications. Confusion, a side effect of ECT that typically last a few minutes to several hours, is generally more pronounced in the elderly (Mayo Clinic, 2016b).

Other therapeutic approaches include interpersonal, behavioral, cognitive, group, and family psychotherapies. Appropriate treatment of the depressed elderly individual can bring relief from suffering and offer a new lease on life with a feeling of renewed productivity.

Postpartum Depression

The severity of depression in the postpartum period varies from a feeling of the blues, to moderate depression, to severe depression with psychotic features. About 50 percent of these episodes actually begin prior to delivery (APA, 2013), and the onset of symptoms during pregnancy, including the "baby blues," increases risk for major depression in the postpartum period. Major depression with psychotic features occurs in about 1 or 2 out of 1,000 postpartum women.

Symptoms of the baby blues include worry, sadness, and fatigue after having a baby. These symptoms affect about 80 percent of mothers and usually subside on their own within a week or two (NIH, 2016b).

Symptoms of moderate **postpartum depression** have been described as depressed mood varying from day to day, with more bad days than good, worsening toward evening and associated with fatigue, irritability, loss of appetite, sleep disturbances, and loss of libido. In addition, the new mother expresses a great deal of concern about her inability to care for her baby. These symptoms begin somewhat later than those attributable to the baby blues and take from a few weeks to several months to abate.

Postpartum depression with psychotic features is characterized by depressed mood, agitation, indecision, lack of concentration, guilt, and an abnormal attitude toward bodily functions. The symptoms can be severe and incapacitating. There may be lack of interest in or rejection of the baby or a morbid fear that the baby may be harmed, accompanied by delusions and hallucinations. Risks of suicide and infanticide should not be overlooked. There is a 30 to 50 percent likelihood of postpartum psychosis recurring with subsequent pregnancies (APA, 2013).

The etiology of postpartum depression remains unclear. Baby blues may be associated with hormonal changes, tryptophan metabolism, or alterations in membrane transport during the early postpartum period. Besides being exposed to these same somatic changes, the woman who experiences moderate to severe symptoms probably possesses a vulnerability to depression related to heredity, upbringing, early life experiences, personality, or social circumstances. A history of depression appears to be a risk factor for postpartum depression (Sword et al., 2012). The etiology of postpartum depression may very likely be a combination of hormonal, metabolic, and psychosocial influences.

Treatment of postpartum depression varies with the severity of the illness. Psychotic depression may be treated with antidepressant medication along with supportive psychotherapy, group therapy, and possibly family therapy. Moderate depression may be relieved with supportive psychotherapy and continuing assistance with home management until the symptoms subside. Baby blues usually needs no treatment beyond a word of reassurance from the physician or nurse that these feelings are common and will soon pass. Extra support and comfort from significant others also is important.

Application of the Nursing Process

Background Assessment Data

Symptomatology of depression can be viewed on a continuum from transient symptoms to severe depression according to severity of the illness. All individuals become depressed from time to time in response to life's disappointments, and these symptoms tend to be transient. Severe depression, however, is marked by significant distress that interferes with social, occupational, cognitive, and emotional functioning.

The individual who is severely depressed may also demonstrate a loss of contact with reality. This level is associated with a complete lack of pleasure in all activities, and ruminations about suicide are common. MDD is an example of severe depression. A continuum of depression is presented in Figure 25–3.

A number of assessment rating scales are available for measuring severity of depressive symptoms. Some are meant to be clinician administered, whereas others may be self-administered. Examples of self-rating scales include the Zung Self-Rating Depression Scale and the Beck Depression Inventory. One of the most widely used clinician-administered scales is the Hamilton Depression Rating Scale (HDRS). It has been reviewed and revised over the years and exists today in several versions. The original version (see Box 25–5) contains 17 items and is designed to measure mood, guilty feelings, suicidal ideation, sleep disturbances, anxiety levels, and weight loss.

Symptoms of depression can be described as alterations in four spheres of human functioning: (1) affective, (2) behavioral, (3) cognitive, and (4) physiological. Alterations within these spheres differ according to degree of severity of symptomatology.

Transient Depression

Symptoms at this level of the continuum are not necessarily dysfunctional; in fact, they may be considered part of the broad range of typical human emotional

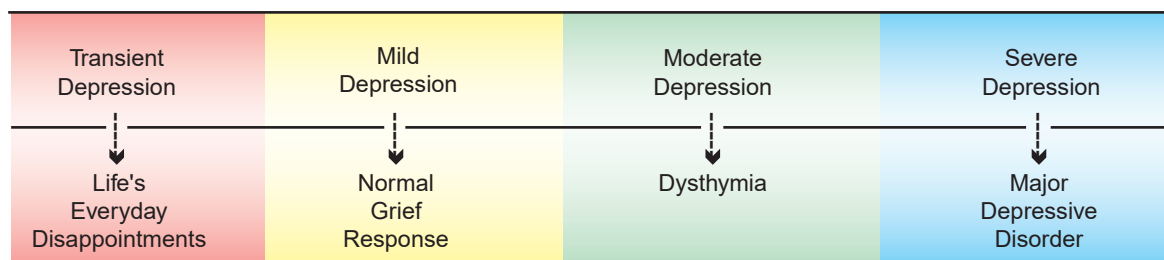
Transient Depression	Mild Depression	Moderate Depression	Severe Depression
↓	↓	↓	↓
Life's Everyday Disappointments	Normal Grief Response	Dysthymia	Major Depressive Disorder


FIGURE 25–3   A continuum of depression.

BOX 25–5 Hamilton Depression Rating Scale (HDRS)

Instructions: For each item, circle the number to select the one "cue" that best characterizes the patient.

1. Depressed Mood (sadness, hopeless, helpless, worthless)

0 = Absent

1 = These feeling states indicated only on questioning

2 = These feeling states spontaneously reported verbally

3 = Communicates feeling states nonverbally, i.e., through facial expression, posture, voice, tendency to weep

4 = Patient reports virtually only these feeling states in spontaneous verbal and nonverbal communication

2. Feelings of Guilt

0 = Absent

1 = Self-reproach; feels he/she has let people down

2 = Ideas of guilt or rumination over past errors or sinful deeds

3 = Present illness is a punishment. Delusions of guilt

4 = Hears accusatory or denunciatory voices and/or experiences threatening visual hallucinations

3. Suicide

0 = Absent

1 = Feels life is not worth living

2 = Wishes he/she were dead or any thoughts of possible death to self

3 = Suicidal ideas or gesture

4 = Attempts at suicide (any serious attempt rates 4)

4. Insomnia: Early in the Night

0 = No difficulty falling asleep

1 = Complains of occasional difficulty falling asleep, i.e., more than 1/2 hour

2 = Complains of nightly difficulty falling asleep

5. Insomnia: Middle of the Night

0 = No difficulty

1 = Complains of being restless and disturbed during the night

2 = Waking during the night—any getting out of bed rates 2 (except for purposes of voiding)

6. Insomnia: Early Hours of the Morning

0 = No difficulty

1 = Waking in early hours of the morning, but goes back to sleep

2 = Unable to fall asleep again if he/she gets out of bed

7. Work and Activities

0 = No difficulty

1 = Thoughts and feelings of incapacity, fatigue, or weakness related to activities, work, or hobbies

2 = Loss of interest in activity, hobbies, or work—either directly reported by patient, or indirectly in listlessness, indecision, and vacillation (feels he/she has to push self to work or activities)

3 = Decrease in actual time spent in activities or decrease in productivity. Rate 3 if patient does not spend at least 3 hours a day in activities (job or hobbies), excluding routine chores

4 = Stopped working because of present illness. Rate 4 if patient engages in no activities except routine chose, or if does not perform routine chores unassisted

8. Psychomotor Retardation (slowness of thought and speech, impaired ability to concentrate, decreased motor activity)

0 = Normal speech and thought

1 = Slight retardation during the interview

2 = Obvious retardation during the interview

3 = Interview difficult

4 = Complete stupor

9. Agitation

0 = None

1 = Fidgetiness

2 = Playing with hands, hair, etc.

3 = Moving about, can't sit still

4 = Hand wringing, nail biting, hair pulling, biting of lips

10. Anxiety (Psychic)

0 = No difficulty

1 = Subjective tension and irritability

2 = Worrying about minor matters

3 = Apprehensive attitude apparent in face or speech

4 = Fears expressed without questioning

11. Anxiety (Somatic): Physiological concomitants of anxiety (e.g., dry mouth, indigestion, diarrhea, cramps, belching, palpitations, headache, tremor, hyperventilation, sighing, urinary frequency, sweating, flushing)

0 = Absent

1 = Mild

2 = Moderate

3 = Severe

4 = Incapacitating

12. Somatic Symptoms (Gastrointestinal)

0 = None

1 = Loss of appetite, but eating without encouragement. Heavy feelings in abdomen

2 = Difficulty eating without urging from others. Requests or requires medication for constipation or gastrointestinal symptoms

13. Somatic Symptoms (General)

0 = None

1 = Heaviness in limbs, back, or head. Backaches, headache, muscle aches. Loss of energy and fatigability

2 = Any clear-cut symptom rates 2

BOX 25–5 Hamilton Depression Rating Scale (HDRS)–cont'd

14. **Genital Symptoms** (e.g., loss of libido, impaired sexual performance, menstrual disturbances)
    0 = Absent
    1 = Mild
    2 = Severe
15. **Hypochondriasis**
    0 = Not present
    1 = Self-absorption (bodily)
    2 = Preoccupation with health
    3 = Frequent complaints, requests for help, etc.
    4 = Hypochondriacal delusions
16. **Loss of Weight** (Rate *either* A *or* B)
    A. **According to subjective patient history:**
       0 = No weight loss
       1 = Probably weight loss associated with present illness
       2 = Definite weight loss associated with present illness

B. **According to objective weekly measurements:**
   0 = Less than 1 lb weight loss in week
   1 = Greater than 1 lb weight loss in week
   2 = Greater than 2 lb weight loss in week
17. **Insight**
   0 = Acknowledges being depressed and ill
   1 = Acknowledges illness but attributes cause to bad food, climate, overwork, virus, need for rest, etc.
   2 = Denies being ill at all

SCORING:
   0–6 = No evidence of depressive illness
   7–17 = Mild depression
   18–24 = Moderate depression
   >24 = Severe depression

TOTAL SCORE_____

responses that accompany everyday disappointments in life. Transient depression subsides quickly, and the individual is able to refocus on other goals and achievements. Alterations include the following:

■ **Affective:** Sadness, dejection, feeling downhearted, having the blues
■ **Behavioral:** Some crying possible
■ **Cognitive:** Some difficulty getting mind off of one's disappointment
■ **Physiological:** Feeling tired and listless

Mild Depression

Symptoms at the mild level of depression are like those associated with uncomplicated grieving. Alterations at the mild level include the following:

■ **Affective:** Denial of feelings, anger, anxiety, guilt, helplessness, hopelessness, sadness, despondency
■ **Behavioral:** Tearfulness, regression, restlessness, agitation, withdrawal
■ **Cognitive:** Preoccupation with the loss, self-blame, ambivalence, blaming others
■ **Physiological:** Anorexia or overeating, insomnia or hypersomnia, headache, backache, chest pain, or other symptoms associated with the loss of a significant other

Moderate Depression

Dysthymia (also called persistent depressive disorder) is an example of moderate depression and represents a more problematic disturbance, which, according to the *DSM-5*, is characterized by symptoms that are

enduring for at least 2 years (APA, 2013). Symptoms associated with this disorder include the following:

■ **Affective:** Feelings of sadness, dejection, helplessness, powerlessness, hopelessness; gloomy and pessimistic outlook; low self-esteem; difficulty experiencing pleasure in activities
■ **Behavioral:** Sluggish physical movements (i.e., psychomotor retardation); slumped posture; slowed speech; limited verbalizations, possibly consisting of ruminations about life's failures or regrets; social isolation with a focus on the self; increased use of substances possible; self-destructive behavior possible; decreased interest in personal hygiene and grooming
■ **Cognitive:** Slowed thinking processes; difficulty concentrating and directing attention; obsessive and repetitive thoughts, generally portraying pessimism and negativism; verbalizations and behavior reflecting suicidal ideation
■ **Physiological:** Anorexia or overeating; insomnia or hypersomnia; sleep disturbances; amenorrhea; decreased libido; headaches; backaches; chest pain; abdominal pain; low energy level; fatigue and listlessness; feeling best early in the morning and continually worse as the day progresses (possibly related to the diurnal variation in the level of neurotransmitters that affect mood and level of activity)

Severe Depression

Severe depression (also called major depressive disorder) is characterized by an intensification of the

symptoms described for moderate depression (see Box 25–2). Symptoms at the severe level of depression include the following:

■ **Affective:** Feelings of total despair, hopelessness, and worthlessness; flat (unchanging) affect, appearing devoid of emotional tone; prevalent feelings of nothingness and emptiness; apathy; loneliness; sadness; inability to feel pleasure.
■ **Behavioral:** Psychomotor retardation so severe that physical movement may literally come to a standstill, or psychomotor behavior manifested by rapid, agitated, purposeless movements; slumped posture; sitting in a curled-up position; walking slowly and rigidly; virtually nonexistent communication (when verbalizations do occur, they may reflect delusional thinking); no personal hygiene and grooming; social isolation is common, with virtually no inclination toward interaction with others
■ **Cognitive:** Prevalent delusional thinking, with delusions of persecution and somatic delusions being most common; confusion, indecisiveness, and an inability to concentrate; hallucinations reflecting misinterpretations of the environment; excessive self-deprecation, self-blame, and thoughts of suicide

NOTE: Because of the low energy level and slow thought processes, the individual may be unable to follow through on suicidal ideas. However, the desire is strong at this level.

■ **Physiological:** A general slowdown of the entire body, reflected in sluggish digestion, constipation, and urinary retention; amenorrhea; impotence; diminished libido; anorexia; weight loss or weight gain associated with appetite changes; changes in sleep patterns, including difficulty falling asleep and awakening very early in the morning; feeling worse early in the morning and somewhat better as the day progresses (as with moderate depression, this may reflect the diurnal variation in the level of neurotransmitters that affect mood and activity)

Diagnosis and Outcome Identification

Using information collected during the assessment, the nurse completes the client database from which the selection of appropriate nursing diagnoses is determined. Table 25–1 presents a list of client behaviors and the NANDA-I nursing diagnoses that correspond to those behaviors, which may be used in planning care for the depressed client.

TABLE 25–1 Assigning Nursing Diagnoses to Behaviors Commonly Associated With Depression

BEHAVIORS	NURSING DIAGNOSES
Depressed mood; feelings of hopelessness and worthlessness; anger turned inward in the self; misinterpretations of reality; suicidal ideation, plan, and available means	Risk for suicide
Depression, preoccupation with thoughts of loss, self-blame, grief avoidance, inappropriate expression of anger, decreased functioning in life roles	Complicated grieving
Expressions of helplessness, uselessness, guilt, and shame; hypersensitivity to slight or criticism; negative, pessimistic outlook; lack of eye contact; self-negating verbalizations	Low self-esteem
Apathy, verbal expressions of having no control, dependence on others to fulfill needs	Powerlessness
Expresses anger toward God, expresses lack of meaning in life, sudden changes in spiritual practices, refuses interactions with significant others or with spiritual leaders	Spiritual distress
Withdrawn, uncommunicative, seeks to be alone, dysfunctional interaction with others, discomfort in social situations	Social isolation/Impaired social interaction
Inappropriate thinking, confusion, difficulty concentrating, impaired problem-solving ability, inaccurate interpretation of environment, memory deficit	Disturbed thought processes*
Weight loss, poor muscle tone, pale conjunctiva and mucous membranes, poor skin turgor, weakness	Imbalanced nutrition: Less than body requirements
Difficulty falling asleep, difficulty staying asleep, lack of energy, difficulty concentrating, verbal reports of not feeling well rested	Insomnia
Uncombed hair, disheveled clothing, offensive body odor	Self-care deficit (hygiene, grooming)

*This diagnosis has been resigned from the NANDA-I list of approved diagnoses. It is used in this instance because it is most compatible with the identified behaviors.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the depressed client.

The client:

- Has experienced no physical harm to self
- Discusses feelings with staff and family members
- Expresses hopefulness
- Sets realistic goals for self
- Is no longer afraid to attempt new activities
- Is able to identify aspects of self-control over life situation
- Expresses personal satisfaction and support from spiritual practices
- Interacts willingly and appropriately with others
- Is able to maintain reality orientation
- Is able to concentrate, reason, solve problems, and make decisions
- Eats a well-balanced diet with snacks, to prevent weight loss and maintain nutritional status
- Sleeps 6 to 8 hours per night and reports feeling well rested
- Bathes, washes and combs hair, and dresses in clean clothing without assistance

Planning and Implementation

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Some institutions use a case management model to coordinate care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing, for more detailed explanation). In case management models, the plan of care may take the form of a critical pathway.

Risk for Suicide

Risk for suicide is defined as "vulnerable to self-inflicted, life-threatening injury" (Herdman & Kamitsuru, 2014, p. 417). For additional information on interventions for this diagnosis see Chapter 17, Suicide Prevention.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

- Client will seek out staff when feeling urge to harm self.
- Client will not harm self.

Long-term goal

- Client will not harm self.

Interventions

- Create a safe environment for the client. Remove all potentially harmful objects from client's access (sharp objects, straps, belts, ties, glass items, alcohol).

Supervise closely during meals and medication administration. Perform room searches as deemed necessary.

> **CLINICAL PEARL**
>
> Ask the client directly, "Have you thought about killing yourself?" or "Have you thought about harming yourself in any way?" "If so, what do you plan to do? Do you have the means to carry out this plan?" "How strong are your intentions to die?" The risk of suicide is greatly increased if the client has developed a plan, has strong intentions, and especially if means exist for the client to execute the plan.

- Assess frequently for the presence and lethality risk of suicidal ideation. The intensity of suicide ideation can change over the course of hours or days, so it is important to assess subjective and objective data to evaluate current risk. Discussion of suicidal feelings with a trusted individual provides some relief to the client.
- Convey an attitude of unconditional acceptance of the client as a worthwhile individual. (See Chapter 17 for more detailed information about relevant assessment and intervention strategies.)
- Encourage the client to actively participate in establishing a safety plan. (See Chapter 17 for guidelines on establishing safety plans). Suicidal clients are often very ambivalent about their feelings. Discussion of strategies for maintaining safety with a trusted individual may provide assistance before the client experiences a crisis situation.

> **CLINICAL PEARL** Be direct. Talk openly and matter-of-factly about suicide. Listen actively and encourage expression of feelings, including anger. Accept the client's feelings in a nonjudgmental manner.

- Maintain close observation of the client. Depending on level of suicide precaution, provide one-to-one contact, constant visual observation, or checks at least every 15 minutes conducted at irregular intervals. Place the client in a room close to the nurse's station; do not assign to a private room. Accompany the client to off-ward activities if attendance is indicated and, if necessary, to the bathroom. Close observation is necessary to ensure that the client does not harm self in any way. Being alert for suicidal and escape attempts facilitates being able to prevent or interrupt harmful behavior.
- Maintain special care in administration of medications. This prevents saving up to overdose or discarding and not taking.
- Make rounds at frequent, *irregular* intervals (especially at night, toward early morning, at change of shift, or other predictably busy times for staff). This prevents staff surveillance from becoming

predictable. Awareness of client's location is important, especially when staff is busy, unavailable, or less observable.

■ Encourage verbalizations of honest feelings. Through exploration and discussion, help the client identify symbols of hope in his or her life.

■ Encourage the client to express angry feelings within appropriate limits. Provide a safe method of hostility release. Help the client identify the true source of anger and work on adaptive coping skills for use outside the treatment setting. Depression and suicidal behaviors may be viewed as anger turned inward on the self. If this anger can be verbalized in a nonthreatening environment, the client may be able to eventually resolve these feelings.

■ Identify community resources that the client may use as a support system and from whom he or she may request help if feeling suicidal once discharged from the hospital. Having a concrete plan for seeking assistance during a crisis may discourage or prevent self-destructive behaviors.

■ Orient the client to reality, as required. Point out sensory misperceptions or misinterpretations of the environment. Take care not to belittle the client's fears or indicate disapproval of verbal expressions.

■ Most importantly, spend time with client. This provides a feeling of safety and security while also conveying the message, "I want to spend time with you because I think you are a worthwhile person."

Complicated Grieving

Complicated grieving is defined as "a disorder that occurs after the death of a significant other [or any other loss of significance to the individual], in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment" (Herdman & Kamitsuru, p. 339). Table 25–2 presents this nursing diagnosis in care plan format.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ Client will express anger about the loss.
■ Client will identify coping strategies and rational thought patterns in response to loss.

Table 25–2 | CARE PLAN FOR THE DEPRESSED CLIENT

NURSING DIAGNOSIS: COMPLICATED GRIEVING

RELATED TO: Real or perceived loss, bereavement overload

EVIDENCED BY: Denial of loss, inappropriate expression of anger, idealization of or obsession with lost object, inability to carry out activities of daily living

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals: • Client expresses anger about the loss. • Client verbalizes behaviors associated with normal grieving. Long-Term Goal: • Client is able to recognize his or her own position in the grief process while progressing at own pace toward resolution.	1. Determine the stage of grief in which client is fixed. Identify behaviors associated with this stage. 2. Develop a trusting relationship with client. Show empathy, concern, and unconditional positive regard. Be honest and keep all promises. 3. Convey an accepting attitude, and enable client to express feelings openly. 4. Encourage client to express anger. Do not become defensive if the initial expression of anger is displaced on the nurse or therapist. Help client explore angry feelings so that they may be directed toward the actual intended person or situation.	1. Accurate baseline assessment data are necessary to effectively plan care for the grieving client. 2. Trust is the basis for a therapeutic relationship. 3. An accepting attitude conveys to client that you believe he or she is a worthwhile person. Trust is enhanced. 4. Verbalization of feelings in a nonthreatening environment may help client come to terms with unresolved issues.

Table 25–2 | CARE PLAN FOR THE DEPRESSED CLIENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	5. Help client to discharge pent-up anger through participation in large motor activities (e.g., brisk walks, jogging, physical exercises, volleyball, punching bag, exercise bike).	5. Physical exercise provides a safe and effective method for discharging pent-up tension.
	6. Teach the normal stages of grief and behaviors associated with each stage. Help client to understand that feelings such as guilt and anger toward the lost concept are appropriate and acceptable during the grief process and should be expressed rather than held inside.	6. Knowledge of acceptability of the feelings associated with normal grieving may help to relieve some of the guilt that these responses generate.
	7. Encourage client to review the relationship with the lost concept. With support and sensitivity, point out the reality of the situation in areas where misrepresentations are expressed.	7. Client must give up an idealized perception and be able to accept both positive and negative aspects about the lost concept before the grief process is complete.
	8. Communicate to client that crying is acceptable. Use of touch may also be therapeutic.	8. Some cultures believe it is important to remain stoic and refrain from crying openly. Individuals from certain cultures are uncomfortable with touch. It is important to be aware of cultural influences before employing these interventions.
	9. Encourage client to reach out for spiritual support during this time in whatever form is desirable to him or her. Assess spiritual needs of client, and assist as necessary in the fulfillment of those needs.	9. Client may find comfort in religious rituals with which he or she is familiar.

Long-term goal

■ Client will be able to recognize his or her own position in the grief process while progressing at own pace toward resolution.

Interventions

■ Determine the stage of grief in which the client is fixed. Identify behaviors associated with this stage. It is important to obtain accurate baseline assessment data to effectively plan care for the grieving client.

■ Develop a trusting relationship with the client. Show empathy, concern, and unconditional positive regard. Be honest and keep all promises. Convey an accepting attitude, and encourage the client to express feelings openly.

■ Encourage the client to express anger. Do not become defensive if the initial expression of anger is displaced on the nurse or therapist. Help the client explore angry feelings so that the feelings may be directed toward the actual intended person or situation.

■ Help the client to discharge pent-up anger through participation in large motor activities (e.g., brisk walks, jogging, physical exercises, volleyball, punching bag, exercise bike). Physical exercise provides a safe and effective method for discharging pent-up tension.

■ Teach the stages of grief and behaviors associated with each stage. Help the client understand that feelings such as guilt and anger toward the lost

concept/entity are appropriate and acceptable during the grief process and should be expressed rather than held inside. Knowledge of acceptability of the feelings associated with grieving may help relieve some of the guilt that these responses generate.

■ Encourage the client to review the relationship with the lost concept/entity. With support and sensitivity, point out the reality of the situation in areas where misrepresentations are expressed. The client must give up an idealized perception and be able to accept both positive and negative aspects about the lost concept/entity before the grief process is complete.

■ Communicate to the client that crying is acceptable. This can be accomplished by verbal reassurance and, in some cases, with caring touch. Use of touch must also consider cultural influences and trauma history before including this as part of the intervention.

■ Assist the client in problem-solving as he or she attempts to determine methods for more adaptive coping with the experienced loss. Provide positive feedback for strategies identified and decisions made.

■ Encourage the client to reach out for spiritual support during this time in whatever form is desirable to him or her. Assess spiritual needs of the client and assist as necessary in the fulfillment of those needs. (See Chapter 6, Cultural and Spiritual Concepts Relevant to Psychiatric-Mental Health Nursing, for more information about spiritual assessment and interventions.)

■ Encourage the client to attend a support group of individuals who are experiencing life situations similar to his or her own. Help the client to locate a group of this type.

Low Self-Esteem/Self-Care Deficit

Low self-esteem is defined as "negative self-evaluating/ feelings about self or self-capabilities [either long-standing or in response to a current situation]" (Herdman & Kamitsuru, pp. 271–274). *Self-care deficit* is defined as "impaired ability to perform or complete [activities of daily living (ADLs)] for self" (Herdman & Kamitsuru, 2014, pp. 242–245).

Client Goals

Short-term goals

■ Client will verbalize attributes he or she likes about self.

■ Client will participate in activities of daily living (ADLs) with assistance from health-care provider.

Long-term goals

■ By time of discharge from treatment, the client will exhibit increased feelings of self-worth as evidenced by verbal expression of positive aspects of self, past accomplishments, and future prospects.

■ By time of discharge from treatment, the client will exhibit increased feelings of self-worth by setting realistic goals and trying to reach them, thereby demonstrating a decrease in fear of failure.

■ By time of discharge from treatment, the client will satisfactorily accomplish ADLs independently.

Interventions

■ Be accepting of the client, and spend time with him or her even though pessimism and negativism may seem objectionable. Focus on strengths and accomplishments and minimize failures.

■ Promote attendance in therapy groups that offer the client simple methods of accomplishment. Encourage the client to be as independent as possible.

■ Encourage the client to recognize areas of change and provide assistance toward this effort.

■ Teach assertiveness techniques: the ability to recognize the differences among passive, assertive, and aggressive behaviors and the importance of respecting the human rights of others while protecting one's own basic human rights. Self-esteem is enhanced by the ability to interact with others in an assertive manner.

■ Teach effective communication techniques, such as the use of "I" messages.

■ Emphasize ways to avoid making judgmental statements.

■ Encourage independence in the performance of ADLs, but intervene when client is unable to perform.

CLINICAL PEARL

Offer recognition and positive reinforcement for independent accomplishments. (Example: "Mrs. J., I see you have put on a clean dress and combed your hair.")

■ Show the client how to perform activities with which he or she is having difficulty. When a client is depressed, he or she may require simple, concrete demonstrations of activities that would be performed without difficulty under normal conditions.

■ Keep strict records of food and fluid intake. Offer nutritious snacks and fluids between meals. The client may be unable to tolerate large amounts of food at mealtimes and may therefore require additional nourishment at other times during the day to receive adequate nutrition.

■ Before bedtime, provide nursing measures that promote sleep, such as back rub; warm bath; warm, nonstimulating drinks; soft music; and relaxation exercises.

Powerlessness

Powerlessness is defined as "the lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect an outcome" (Herdman & Kamitsuru, 2014, p. 343).

Client Goals

Short-term goal

■ Client will participate in decision-making regarding own care within 5 days.

Long-term goal

■ Client will be able to effectively problem-solve ways to take control of his or her life situation by time of discharge from treatment, thereby decreasing feelings of powerlessness.

Interventions

■ Encourage the client to take as much responsibility as possible for his or her own self-care practices. In the most acute stage of severe depression, clients may have extreme difficulty making decisions. At this point, it may be more helpful to use *active communication* to help the client accomplish even basic ADLs. For example, "It's time to eat lunch," rather than, "Would you like to eat lunch now?" Ongoing assessment is important so that the client can be encouraged to make choices as soon as possible. Providing the client with choices whenever possible will increase feelings of control. For example,

  ■ Include the client in setting the goals of care he or she wishes to achieve.
  ■ Allow the client to establish own schedule for self-care activities.
  ■ Provide the client with privacy as need is determined.
  ■ Provide positive feedback for decisions made. Respect the client's right to make those decisions independently, and refrain from attempting to influence him or her toward those that may seem more logical.

■ Help the client set realistic goals. Unrealistic goals set the client up for failure and reinforce feelings of powerlessness.

■ Help the client identify areas of his or her life situation that can be controlled. The client's emotional condition interferes with his or her ability to solve problems. Assistance is required to perceive the benefits and consequences of available alternatives accurately.

■ Discuss with the client areas of life that are not within his or her ability to control. Encourage verbalization of feelings related to this inability in an effort to deal with unresolved issues and accept what cannot be changed.

Concept Care Mapping

The concept map care plan is an approach to planning and organizing nursing care (see Chapter 9) that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with depression is presented in Figure 25–4.

Client and Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client and family education relevant to depression is presented in Box 25–6.

Evaluation of Care for the Depressed Client

In the final step of the nursing process, a reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the depressed client may be facilitated by gathering information using the following types of questions:

■ Has self-harm to the individual been avoided?
■ Have suicidal ideations subsided?
■ Does the individual know where to seek assistance outside the hospital when suicidal thoughts occur?
■ Has the client discussed the recent loss with staff and family members?
■ Is he or she able to verbalize feelings and behaviors associated with each stage of the grieving process and recognize own position in the process?
■ Has obsession with and idealization of the lost object subsided?
■ Is anger toward the lost object expressed appropriately?
■ Does the client set realistic goals for self?
■ Is he or she able to verbalize positive aspects about self, past accomplishments, and future prospects, including a desire to live?
■ Can the client identify areas of life situation over which he or she has control?
■ Is the client able to participate in usual religious practices and feel satisfaction and support from them?
■ Is the client seeking out interaction with others in an appropriate manner?
■ Does the client maintain reality orientation with no evidence of delusional thinking?
■ Is he or she able to concentrate and make decisions concerning own self-care?
■ Is the client selecting and consuming foods sufficiently high in nutrients and calories to maintain weight and nutritional status?
■ Does the client sleep without difficulty and wake feeling rested?

Clinical Vignette: Judith, age 56, has been despondent since her husband of 30 years left her 3 months ago to live with a 26-year-old secretary from his office. She has lost weight and rarely goes out of her house. Today the divorce was finalized. When Judith's daughter, Cathy, went to her mother's house, she found Judith going through her medication saying she was going to "take enough to put me to sleep for good." Cathy convinced her mother to go to the hospital, and Judith was admitted to the psychiatric unit with a diagnosis of Major Depressive Disorder. Judith tells the nurse, "I'm so angry at my husband, I could just kill him! How could he do this to me? I guess it's my fault. I'm not as pretty as his girlfriend." Then she says, "What's the use of going on? No one would want me now. I'm old, and I don't have anything to live for." The nurse develops the following concept map care plan for Judith.

Signs and Symptoms
- Depressed mood
- Feelings of worthlessness and hopelessness
- Anger turned inward on self

Signs and Symptoms
- Fixed in anger stage of grief
- Social isolation
- Obsession with loss
- Loss of weight

Signs and Symptoms
- Self-negating comments
- Expressions of worthlessness
- Negative, pessimistic outlook

Signs and Symptoms
- Feelings of no control over life situation
- Cannot perceive improvement in life situation

Nursing Diagnosis
Risk for suicide

Nursing Diagnosis
Complicated grieving

Nursing Diagnosis
Low self-esteem

Nursing Diagnosis
Powerlessness

Nursing Actions
- Inquire about suicidal thoughts, plan, means.
- Make environment safe.
- Collaborate with patient to develop a safety plan
- Observe closely.
- Make frequent rounds at irregular intervals.
- Encourage open, honest expression of feelings.

Nursing Actions
- Assess stage of grief process.
- Develop trust.
- Explore feelings of anger.
- Teach normal behaviors associated with grief.
- Promote honest review of relationship that has been lost.

Nursing Actions
- Spend time with client and develop trust.
- Focus on strengths; minimize failures.
- Encourage group attendance.
- Assist with behaviors requiring change.
- Teach assertiveness and effective communication.

Nursing Actions
- Encourage participation in goal setting and decision making regarding own care.
- Ensure that goals are realistic.
- Encourage expression of feelings about areas not within client's ability to control.

Medical Rx:
Sertraline 100 mg
PO qd

Outcomes
- Has not harmed self
- Denies suicidal ideations
- Collaborates to establish a plan for ongoing safety

Outcomes
- Is able to discuss feelings about loss
- Recognizes own position in grief process
- Obsession with loss has subsided

Outcomes
- Sets realistic goals for self
- Verbalizes positive aspects about self, past accomplishments, and future prospects

Outcomes
- Participates in decision-making regarding life situation
- Accepts areas of life situation not within her control

FIGURE 25–4 Concept map care plan for a client with depression.

- Does the client show pride in appearance by attending to personal hygiene and grooming?
- Have somatic complaints subsided?

Quality and Safety Education for Nurses (QSEN)

Health Professions Education: A Bridge to Quality (Institute of Medicine, 2003) challenged faculties of medicine, nursing, and other health professions to ensure that their graduates have achieved a core set of competencies in order to meet the needs of the 21st-century health-care system. These competencies include *providing patient-centered care, working in interdisciplinary teams, maintaining safety, employing evidence-based practice, applying quality improvement,* and *utilizing informatics.* A QSEN teaching strategy is included in Box 25–7. This type of activity is

intended to arm the instructor and student with guidelines for attaining the knowledge, skills, and attitudes necessary for achievement of quality and safety competencies in nursing.

Treatment Modalities for Depression

Individual Psychotherapy

Research has documented both the importance of close and satisfactory attachments in the prevention of depression and the role of disrupted attachments in the development of depression. With this concept in mind, interpersonal psychotherapy focuses on the client's current interpersonal relations. Interpersonal psychotherapy with the depressed person proceeds through three phases and interventions.

Phase I

During the first phase, the client is assessed to determine the extent of the illness. Complete information is given to the individual regarding the nature of depression, symptom pattern, frequency, clinical course, and alternative treatments. If the level of depression is severe, interpersonal psychotherapy has been shown

---

BOX 25–6 Topics for Client and Family Education Related to Depression

NATURE OF THE ILLNESS
1. Stages of grief and symptoms associated with each stage
2. What is depression?
3. Why do people get depressed?
4. What are the symptoms of depression?

MANAGEMENT OF THE ILLNESS
1. Medication management
   a. Nuisance side effects
   b. Side effects to report to physician
   c. Importance of taking regularly
   d. Length of time to take effect
   e. Diet (related to MAO Inhibitors)
2. Assertiveness techniques
3. Stress-management techniques
4. Ways to increase self-esteem
5. Electroconvulsive therapy

SUPPORT SERVICES
1. Suicide hotline
2. Support groups
3. Legal and/or financial assistance

BOX 25–7 QSEN TEACHING STRATEGY

Assignment: Staff Workarounds
Placing a Client on Suicide Precautions

Competency Domains: Evidence-Based Practice; Patient-Centered Care; Quality Improvement; Safety; Teamwork and Collaboration

Learning Objectives: Student will:
• Demonstrate skills in identifying gaps between practice on the unit and what has been identified as best practice.
• Demonstrate skills at finding professional practice standards and research literature related to placing a client on suicide precautions.
• Demonstrate skills in accounting for patient preferences within the boundaries of safe and therapeutic practice.
• Demonstrate attitudes and behaviors that show that they value teamwork and want to contribute to maintaining standards of safe and effective care.

Strategy Overview: This assignment is meant to familiarize the student with standardized nursing policies, procedures, standards of care, and other evidence-based nursing practice guidelines and to encourage students to observe actual nursing practice on the units to note compliance with, deviations from, or "workarounds" for those policies, procedures, standards, and guidelines by registered nurses (RNs) when implementing nursing procedures. The following aspects of the assignment can guide students in preparation for clinical conference discussion, in writing a paper, or in putting together a poster presentation.
1. Identify a need to place a client on suicide precautions.
2. Find the current written nursing policy or procedure in place for your institution or unit, and answer these questions:
   a. How easy or difficult was it to find the policy/procedure?
   b. Did the RNs know where to find the written policy/procedure?
   c. How was the policy/procedure originally disseminated to the staff?
   d. Is the policy/procedure evidence based?
      (Review the current practice standards from professional organizations and/or oversight and accreditation groups [e.g., The Joint Commission, CDC] and/or the research literature.)

BOX 25–7 QSEN TEACHING STRATEGY—cont'd

3. Observe RNs on the unit putting a client on suicide precautions and describe:
   a. What steps the RN took.
   b. In what ways the RN deviated from the written policy/procedure.
   c. What prompted the RN to make the deviations she or he made.
   d. As many details as you can recollect.
4. Discuss why RNs may or may not follow the institution's written policies and procedures. Reflect on the opportunities and challenges of evidence-based practice and the implementation into actual bedside nursing practice.
5. Discuss what the proper response should be when you, as an RN, discover unsafe practice that deviates from standards, policies, or procedures.

Adapted from teaching strategy submitted by Lisa Day, Assistant Clinical Professor, UCSF, School of Nursing, San Francisco, CA. © 2009 QSEN; http://qsen.org. With permission.

more effective if conducted in combination with antidepressant medication. The client is encouraged to continue working and participating in regular activities during therapy. A mutually agreeable therapeutic contract is negotiated.

Phase II

Treatment at this phase focuses on helping the client resolve complicated grief reactions. This may include resolving the ambivalence with a lost relationship and assistance with establishing new relationships. Other areas of treatment focus may include interpersonal disputes between the client and a significant other, difficult role transitions at various developmental life cycles, and correction of interpersonal deficits that may interfere with the client's ability to initiate or sustain interpersonal relationships.

Phase III

During the final phase of interpersonal psychotherapy, the therapeutic alliance is terminated. With emphasis on reassurance, clarification of emotional states, improvement of interpersonal communication, testing of perceptions, and performance in interpersonal settings, interpersonal psychotherapy has been successful in helping depressed persons recover enhanced social functioning.

Group Therapy

Group therapy forms an important dimension of multimodal treatment for the depressed client. Once an acute phase of the illness has passed, groups can provide an atmosphere in which individuals may discuss issues in their lives that cause, maintain, or arise from having a serious affective disorder. The element of peer support provides a feeling of security, as troublesome or embarrassing issues are discussed and resolved. Some groups have other specific purposes, such as helping to monitor medication-related issues or serving as an avenue for promoting education related to the affective disorder and its treatment. Therapy groups help members gain a sense of perspective on their condition and encourage them to link up with others who have common problems. A sense of hope is conveyed when the individual is able to see that he or she is not alone or unique in experiencing affective illness.

Self-help groups offer another avenue of support for the depressed client. These groups are usually peer led and are not meant to substitute for or compete with professional therapy. Rather, they offer supplementary support that frequently enhances compliance with the medical regimen. Examples of self-help groups are the Depression and Bipolar Support Alliance (DBSA), Depressives Anonymous, Recovery International, and GriefShare (grief recovery support groups). Although self-help groups are not psychotherapy groups, they do provide important adjunctive support experiences, which often have therapeutic benefit for participants.

Family Therapy

The ultimate objectives in working with families of clients with mood disorders are to resolve the symptoms and initiate or restore adaptive family functioning. Similar to group therapy, the most effective approach appears to be a combination of psychotherapeutic and pharmacotherapeutic treatments. Sadock and associates (2015) stated:

> Family therapy is indicated if the disorder jeopardizes the patient's marriage or family functioning or if the mood disorder is promoted or maintained by the family situation. Family therapy examines the role of the mood-disordered member in the overall psychological well-being of the whole family; it also examines the role of the entire family in the maintenance of the patient's symptoms. (p. 373)

Cognitive Therapy

In cognitive therapy, the individual is taught to control thought distortions that are a factor in the development and maintenance of mood disorders. In the

cognitive model, depression is characterized by a triad of negative distortions related to expectations of the environment, self, and future. The environment and activities within it are viewed as unsatisfying, the self is unrealistically devalued, and the future is perceived as hopeless.

The general goals in cognitive therapy are to obtain symptom relief as quickly as possible, assist the client in identifying dysfunctional patterns of thinking and behaving, and guide the client to evidence and logic that effectively tests the validity of the dysfunctional thinking (see Chapter 19, Cognitive Therapy). Therapy focuses on changing "automatic thoughts" that occur spontaneously and contribute to the distorted affect. Following are examples of automatic thoughts that may be common cognitive distortions in depression:

- **Personalizing:** "I'm the only one who failed."
- **All or nothing:** "I'm a complete failure."
- **Mind reading:** "He thinks I'm foolish."
- **Discounting positives:** "The other questions were so easy. Any dummy could have gotten them right."

The client is asked to describe evidence that both supports and disputes the automatic thought. The logic underlying the inferences is then reviewed with the client. Another technique involves evaluating what would most likely happen if the client's automatic thoughts were true. Implications of the consequences are then discussed.

Clients should not become discouraged if one technique seems not to be working. No single technique works with all clients. He or she should be reassured that any of a number of techniques may be used, and both therapist and client may explore these possibilities.

Cognitive therapy has offered encouraging results in the treatment of depression. In fact, the results of several studies with depressed clients show that in some cases cognitive therapy may be equally as or even more effective than antidepressant medication (Amick et al., 2015; Page & Hooke, 2012; Siddique et al., 2012).

Electroconvulsive Therapy

ECT is the induction of a grand mal (generalized) seizure through the application of electrical current to the brain. ECT is effective with clients who are acutely suicidal and in the treatment of severe depression, particularly in those clients who are also experiencing psychotic symptoms and those with psychomotor retardation and neurovegetative changes, such as disturbances in sleep, appetite, and energy. It is often considered for treatment only after a trial of therapy with antidepressant medication has proved ineffective (see Chapter 20, Electroconvulsive Therapy, for a detailed discussion of ECT).

Transcranial Magnetic Stimulation

Transcranial magnetic stimulation (TMS) is a procedure that is used to treat depression by stimulating nerve cells in the brain. TMS involves the use of very short pulses of magnetic energy to stimulate nerve cells at localized areas in the cerebral cortex, similar to the electrical activity observed with ECT. However, unlike with ECT, the electrical waves generated by TMS do not result in generalized seizure activity (George, Taylor, & Short, 2013). The waves are passed through a coil placed on the scalp to areas of the brain involved in mood regulation. It is noninvasive and considered generally safe. A typical course of treatment is 40-minute sessions, three to five times a week for 4 to 6 weeks (Raposelli, 2015). Some clinicians believe that TMS holds a great deal of promise in the treatment of depression, whereas others remain skeptical. In a study at King's College in London, researchers compared the efficacy of TMS with ECT in the treatment of severe depression (Eranti et al., 2007). They concluded that ECT is substantially more effective for the short-term treatment of depression and indicated the need for further intense clinical evaluation of TMS. In one study (Connolly et al., 2012), identified that 24.7 percent of patients receiving TMS were in remission at 6 weeks. Effectiveness ratings for ECT have varied from 17 to 70 percent. Although the effectiveness ratings may seem small or highly variable, both treatments provide an option for clients who are otherwise treatment-resistant. Magnezi and associates (2016) compared ECT to TMS and found that although ECT was more effective than TMS and additionally relieved anxiety symptoms, ECT had a much higher incidence (60%) of adverse effects, mostly related to memory loss. From the client's perspective, TMS was still deemed preferable to ECT (if it was covered by insurance), which may be related to the stigma associated with ECT.

George and associates (2013) stated:

> Since FDA approval, TMS has been generally safe and well tolerated with a low incidence of treatment discontinuation, and the therapeutic effects once obtained appear at least as durable as other antidepressant treatments. TMS also shows promise in several other psychiatric disorders, particularly treating acute and chronic pain. (p. 17)

More recently, researchers compared TMS to pharmacotherapy and found both effective but identified TMS as more cost effective (Raposelli, 2015). Currently, not all insurance companies cover this treatment, so from the client's standpoint, it may be a more expensive alternative. Raposelli reports that up to 40 percent of clients with MDD do not respond to pharmacotherapy, so again, alternatives such as ECT and TMS may offer hope of recovery for treatment-resistant conditions.

Vagal Nerve Stimulation and Deep Brain Stimulation

When studied in the treatment of epilepsy, vagal nerve stimulation (VNS) was found to improve the client's mood. This treatment involves implanting an electronic device in the skin to stimulate the vagus nerve. The mechanism of action is not known, but preliminary studies have shown that many clients with chronic recurrent depression improved when treated with VNS (Sadock et al., 2015). Trials are ongoing to determine its effectiveness.

Another new approach is deep brain stimulation (DBS), a form of psychosurgery. In this procedure, as in VNS, an electrode is implanted with the intent of stimulating brain function. Unlike VNS, however, DBS involves a deep implant that requires craniotomy. DBS has been well studied to determine its safety and effectiveness for other conditions, and controlled trials are ongoing. Currently, DBS is reserved for clients with severe, incapacitating depression or obsessive-compulsive disorder who have not responded to any more conservative treatments (Sadock et al., 2015).

Light Therapy

The prevalence of depression with a seasonal pattern is reported to be up to 10 percent but varies on the basis of geographic location (Kurlansik & Ibay, 2013). The *DSM*-5 identifies this disorder as Major Depressive Disorder, Recurrent, With Seasonal Pattern. It has commonly been known as seasonal affective disorder (SAD).

Theories suggest that SAD is related to the presence of the hormone melatonin (Cotterell, 2010), which is produced by the pineal gland. Melatonin plays a role in the regulation of biological rhythms for sleep and activation. It is produced during the cycle of darkness and shuts off in the light of day. During the months of longer darkness hours, there is increased production of melatonin, which seems to trigger the symptoms of SAD in susceptible people. Other research has pointed to seasonal serotonin transporter fluctuations associated with variation in exposure to daylight (McMahon et al., 2016).

Light therapy, or exposure to light, has been shown an effective treatment for SAD. The light therapy is administered by a 10,000-lux light box, which contains white fluorescent light tubes covered with a plastic screen that blocks ultraviolet rays. The individual sits in front of the box with eyes open (although one should not look directly into the light). Therapy usually begins with 10- to 15-minute sessions and gradually progresses to 30 to 45 minutes. The mechanism of action is believed to be related to retinal stimulation, which triggers a reduction of melatonin and an increase in serotonin in the brain (Rodriguez, 2015). A recent study demonstrated benefits of bright light therapy in nonseasonal affective disorders as well (Lam et al., 2015). Some people notice improvement rapidly, within a few days, whereas others may take several weeks to feel better. Side effects appear to be dosage related and include headache, eyestrain, nausea, irritability, photophobia (eye sensitivity to light), or insomnia agitation, but these are usually mild and short-lived (Kurlansik & Ibay, 2013). Light therapy and antidepressants have shown comparable efficacy in studies of SAD treatment. One study compared the efficacy of light therapy for SAD to daily treatment with 20 mg of fluoxetine (Lam et al., 2015). The authors concluded, "Light treatment showed earlier response onset and lower rate of some adverse events relative to fluoxetine, but there were no other significant differences in outcome between light therapy and antidepressant medication" (p. 805). Although improvement is often noted within 2 weeks, most clients relapse in the short term. Treatment should therefore be continued until an expected time of spontaneous remission, such as the change in season to spring or summer (Kurlansik & Ibay, 2013).

Psychopharmacology

Antidepressant medication is generally considered first-line treatment for severe clinical depression and is used in the treatment of other depressive disorders. These include tricyclic, tetracyclic, monoamine oxidase inhibitors (MAOIs), SSRIs, SNRIs, and SSRI/SNRI combination drugs. Examples of commonly used antidepressant medications are presented in Table 25–3. A detailed description of these medications can be found in Chapter 4, Psychopharmacology. In addition to the side effects and safety issues addressed in Chapter 4, it is important to highlight that antidepressant medication can be lethal in overdose, so depressed, suicidal patients must be observed closely and suicide risk assessed frequently in the use of this treatment modality.

CLINICAL PEARL All antidepressants carry an FDA black-box warning for increased risk of suicidality in children and adolescents.

CLINICAL PEARL As antidepressant drugs take effect and mood begins to lift, the individual may have increased energy with which to implement a suicide plan. Suicide potential often increases as level of depression decreases. The nurse should be particularly alert to sudden lifts in mood.

TABLE 25–3 Medications Used in the Treatment of Depression

CHEMICAL CLASS	GENERIC (TRADE) NAME*	PREGNANCY CATEGORIES/ HALF-LIFE (hr)	DAILY ADULT DOSAGE RANGE (mg)†	THERAPEUTIC PLASMA RANGES
Tricyclics	Amitriptyline	D/ 31–46	50–300	110–250 (including metabolite)
	Amoxapine	C/ 8	50–300	200–500
	Clomipramine (Anafranil)	C/ 19–37	25–250	80–100
	Desipramine (Norpramin)	C/ 12–24	25–300	125–300
	Doxepin	C/ 8–24	25–300	100–200 (including metabolite)
	Imipramine (Tofranil)	D/ 11–25	30–300	200–350 (including metabolite)
	Nortriptyline (Aventyl; Pamelor)	D/ 18–44	30–100	50–150
	Protriptyline (Vivactil)	C/ 67–89	15–60	100–200
	Trimipramine (Surmontil)	C/ 7–30	50–300	180 (including metabolite)
Selective Serotonin Reuptake Inhibitors (SSRIs)	Citalopram (Celexa)	C/ ~35	20–40	Not well established
	Escitalopram (Lexapro)	C/ 27–32	10–20	Not well established
	Fluoxetine (Prozac; Sarafem)	C/ 1–16 days (including metabolite)	20–80	Not well established
	Fluvoxamine (Luvox)	C/ 13.6–15.6	50–300	Not well established
	Paroxetine (Paxil)	D/ 21 (CR: 15–20)	10–50 (CR: 12.5–75)	Not well established
	Sertraline (Zoloft)	C/ 26–104 (including metabolite)	25–200	Not well established
	Vilazodone (Viibryd) (also acts as a partial serotonergic agonist)	C/ 25	40	Not well established
	Vortioxetine (Trintellix)	C/ 66	5–20	Not well established
Monoamine Oxidase Inhibitors	Isocarboxazid (Marplan)	C/ Not established	20–60	Not well established
	Phenelzine (Nardil)	C/ 2–3	45–90	Not well established
	Tranylcypromine (Parnate)	C/ 2.4–2.8	30–60	Not well established
	Selegiline Transdermal System (Emsam)	C/ 18–25 (including metabolites)	6/24-hr– 12/24-hr patch	Not well established
Atypical Antidepressants	Bupropion (Wellbutrin, Zyban)		200–450	Not well established
	Forfivo XL		450	
	Maprotiline	B/ 21–25	25–225	200–300 (including metabolite)
	Mirtazapine (Remeron)	C/ 20–40	15–45	Not well established
	Nefazodone‡ (Serzone)	C/ 2–4	200–600	Not well established
	Trazodone	C/ 4–9	150–600	800–1,600
Serotonin-Norepinephrine Reuptake Inhibitors (SNRIs)	Desvenlafaxine (Pristiq)	C/ 11	50–400	Not well established
	Duloxetine (Cymbalta)	C/ 8–17	40–60	Not well established
	Venlafaxine (Effexor)	C/ 5–11 (including metabolite)	75–375	Not well established

TABLE 25–3 **Medications Used in the Treatment of Depression–cont'd**				
CHEMICAL CLASS	**GENERIC (TRADE) NAME***	**PREGNANCY CATEGORIES/ HALF-LIFE (hr)**	**DAILY ADULT DOSAGE RANGE (mg)†**	**THERAPEUTIC PLASMA RANGES**
Psychotherapeutic Combinations	Olanzapine and fluoxetine (Symbyax)	C/ (see individual drugs)	6/25–12/50	Not well established
	Chlordiazepoxide and fluoxetine (Limbitrol)	D/ (see individual drugs)	20/50– 40/100	Not well established
	Perphenazine and amitriptyline (Etrafon)	C–D/ (see individual drugs)	6/30–16/200	Not well established

*Drugs without trade names are available in generic form only.
†Dosage requires slow titration; onset of therapeutic response may be 1 to 4 weeks.
‡Bristol-Myers Squibb voluntarily removed its brand of nefazodone (Serzone) from the market in 2004. The generic equivalent is currently available through various other manufacturers.

Client and Family Education Related to Antidepressants

The client should:

- Continue to take the medication even though symptoms have not subsided. The therapeutic effect may not be seen for as long as 4 weeks. If after this length of time no improvement is noted, the physician may prescribe a different medication.
- Use caution when driving or operating dangerous machinery. Drowsiness and dizziness can occur. If these side effects become persistent or interfere with ADLs, the client should report them to the physician. Dosage adjustment may be necessary.
- Not discontinue use of the drug abruptly. To do so might produce withdrawal symptoms, such as nausea, vertigo, insomnia, headache, malaise, nightmares, and return of symptoms for which the medication was prescribed.
- Use sunblock lotion and wear protective clothing when spending time outdoors. The skin may be sensitive to sunburn.
- Report occurrence of any of the following symptoms to the physician immediately: sore throat, fever, malaise, yellowish skin, unusual bleeding, easy bruising, persistent nausea/vomiting, severe headache, rapid heart rate, difficulty urinating, anorexia/weight loss, seizure activity, stiff or sore neck, and chest pain.
- Rise slowly from a sitting or lying position to prevent a sudden drop in blood pressure.
- Take frequent sips of water, chew sugarless gum, or suck on hard candy if dry mouth is a problem. Good oral care (frequent brushing and flossing) is very important.
- Not consume the following foods or medications while taking MAOIs: aged cheese, wine (especially Chianti), beer, chocolate, colas, coffee, tea, sour cream, smoked and processed meats, beef or chicken liver, canned figs, soy sauce, overripe and fermented foods, pickled herring, raisins, caviar, yogurt, yeast products, broad beans, cold remedies, diet pills. To do so could cause a life-threatening hypertensive crisis.
- Avoid smoking while receiving tricyclic therapy. Smoking increases the metabolism of tricyclics, requiring an adjustment in dosage to achieve the therapeutic effect.
- Avoid drinking alcohol while taking antidepressant therapy. These drugs potentiate the effects of each other.
- Avoid use of other medications (including over-the-counter medications) without physician's approval while receiving antidepressant therapy. Many medications contain substances that could precipitate a life-threatening hypertensive crisis in combination with antidepressant medication.
- Notify physician immediately if inappropriate or prolonged penile erections occur while taking trazodone. If the erection persists longer than 1 hour, seek emergency department treatment. This condition is rare but has occurred in some men who have taken trazodone. If measures are not instituted immediately, impotence can result.
- Not "double up" on medication if a dose of bupropion (Wellbutrin) is missed unless advised to do so by the physician. Taking bupropion in divided doses will decrease the risk of seizures and other adverse effects.
- Follow the correct procedure for applying the selegiline transdermal patch:
  - Apply to dry, intact skin on upper torso, upper thigh, or outer surface of upper arm.
  - Apply approximately same time each day to new spot on skin after removing and discarding old patch.
  - Wash hands thoroughly after applying the patch.

- Avoid exposing application site to direct heat (e.g., heating pads, electric blankets, heat lamps, hot tub, or prolonged direct sunlight).
- If patch falls off, apply new patch to a new site and resume previous schedule.
- Be aware of possible risks of taking antidepressants during pregnancy. Safe use during pregnancy and lactation has not been fully established. These drugs are believed to readily cross the placental barrier; if so, the fetus could experience adverse effects of the drug. Inform the physician immediately if pregnancy occurs, is suspected, or is planned.
- Be aware of the side effects of antidepressants. Refer to written materials furnished by health-care providers for safe self-administration.
- Carry a card or other identification at all times describing the medications being taken.

Pharmacogenomics

Recent genetic studies have demonstrated that variations in genes can predict whether a person will respond to SSRIs (Lee, 2015). This is important because, as Lee notes, between 30 and 50 percent of people do not respond to the first antidepressant they have been prescribed. It is no wonder that patients and family members often express frustration as medicines and doses are changed in an effort to find the right antidepressant and dose that will be effective for the individual. Genotyping has also demonstrated benefits in identifying which individuals may be more prone to certain side effects. One study cited by Lee demonstrated that Asian populations with a specific genotype were at increased risk for sexual dysfunction side effects associated with SSRIs. This could be useful information because sexual dysfunction is a primary reason that many people choose to stop taking these medications. Currently, this area of study is in its infancy, and further study is needed to identify benefits of routine testing, cost effectiveness, and their ability to provide timely results so that therapy can be initiated promptly.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Sam is a 45-year-old white male admitted to the psychiatric unit of a general medical center by his family physician, Dr. Jones, who reported that Sam had become increasingly despondent over the past month. His wife reported that he had made statements such as, "Life is not worth living," and "I think I could just take all those pills Dr. Jones prescribed at one time; then it would all be over." Sam says he loves his wife and children and does not want to hurt them but feels they no longer need him. He states, "They would probably be better off without me." His wife appears to be very concerned about his condition, although in his despondency, he seems oblivious to her feelings. His mother (a widow) lives in a neighboring state, and he sees her infrequently. His father was an alcoholic and physically abused Sam and his siblings. He admits that he is somewhat bitter toward his mother for allowing him and his siblings to "suffer from the physical and emotional brutality of their father." His siblings and their families live in distant states, and he sees them rarely, during holiday gatherings.

Sam earned a college degree while working full time at night to pay his way. He is employed in the administration department of a large corporation. Over the past 12 years, Sam has watched while a number of his peers were promoted to management positions. Sam has been considered for several of these positions but has never been selected. Last month, a management position became available for which Sam felt he was qualified. He applied for this position, believing he had a good chance of being promoted. However, his wife reports that when the announcement was made that the position had been given to a younger man who had been with the company only 5 years, Sam initially expressed anger and then seemed to accept the decision. But over the past few weeks, he has become increasingly withdrawn. He speaks to very few people at the office and is falling behind in his work. At home, he eats very little, talks to family members only when they ask a direct question, withdraws to his bedroom very early in the evening, and does not come out until time to leave for work the next morning. Today, he refused to get out of bed or to go to work, and he told his wife he has nothing to live for. His wife convinced him to talk to their family doctor, who admitted him to the hospital after hearing Sam acknowledge that he desires to end his life. The referring psychiatrist diagnosed Sam with Major Depressive Disorder.

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Sam:

1. **Risk for suicide** related to depressed mood and expressions of having nothing to live for.
   a. **Short-Term Goals:**
      - Sam will discuss suicide ideation and intentions with staff.
      - Sam will collaborate with the nurse to identify a plan for maintaining safety.

  b. **Long-Term Goal:**
  - ■ Sam will not harm himself during his hospitalization.
2. **Complicated grieving** related to unresolved losses (job promotion and unsatisfactory parent-child relationships) evidenced by expressed anger over loss of a job opportunity and desire to end his life.
  a. **Short-Term Goal:**
  - ■ Sam will discuss anger toward boss and parents within 1 week.
  b. **Long-Term Goal:**
  - ■ Sam will verbalize his position in the grief process and begin movement in the progression toward resolution by time of discharge from treatment.

PLANNING AND IMPLEMENTATION

RISK FOR SUICIDE

The following nursing interventions have been identified for Sam's care:

1. Develop a trusting relationship with Sam that facilitates open, nonjudgmental discussion of suicide ideation and related thoughts and feelings.
2. Ask Sam directly, "Have you thought about killing yourself? If so, what do you plan to do? Do you have the means to carry out this plan?"
3. Create a safe environment. Remove all potentially harmful objects from immediate access (sharp objects, straps, belts, ties, glass items).
4. Assess suicide risk each shift and identify any changes in level of hopelessness. Encourage verbalizations of honest feelings. Through exploration and discussion, help Sam to identify symbols of hope in his life (participating in activities he finds satisfying outside of his job).
5. Allow Sam to express angry feelings within appropriate limits. Encourage use of the exercise room and other activities for releasing energy appropriately. Help him identify the true source of his anger, and work on adaptive coping skills for use outside the hospital (e.g., jogging, exercise club available to employees of his company).
6. Identify community resources that he may use as a support system and from whom he may request help if feeling suicidal (e.g., suicidal or crisis hotline; psychiatrist or social worker at community mental health center; hospital HELP line).
7. Introduce Sam to support and education groups for adult children of alcoholics (ACoA).
8. Spend time with Sam. This will help him to feel safe and secure while conveying the message that he is a worthwhile person.

COMPLICATED GRIEVING

The following nursing interventions have been identified for Sam:

1. Discuss with Sam the stages in the grief process and encourage him to explore his feelings so that he may come to realize the connection between grief and his anger.
2. Develop a trusting relationship with Sam. Show empathy and caring. Be honest and keep all promises.
3. Convey an accepting attitude—one in which Sam is not afraid to express his feelings openly.
4. Allow him to verbalize feelings of anger. The initial expression of anger may be displaced on to the health-care provider. Do not become defensive if this should occur. Have Sam write letters *(not to be mailed)* to his boss and to his parents stating his true feelings toward them. Discuss these feelings with him, then destroy the letters.
5. Assist Sam to discharge pent-up anger through participation in large motor activities (brisk walks, jogging, physical exercises, volleyball, punching bag, exercise bike, or other equipment).
6. Help Sam to understand that feelings such as guilt and anger toward his boss and parents are appropriate and acceptable during the grieving process. Help him also to understand that he must work through these feelings and move past this stage in order to eventually feel better. Knowledge of acceptability of the feelings associated with normal grieving may help to relieve some of the guilt that these responses generate. Knowing why he is experiencing these feelings may also help to resolve them.
7. Encourage Sam to review the relationship with his parents. Educate Sam about common roles and behaviors of members in an alcoholic family. Encourage Sam to identify his roles and behaviors within his family of origin. Assist Sam in problem-solving as he attempts to determine methods for more adaptive coping. Suggest alternatives to automatic negative thinking (e.g., thought-stopping techniques). Provide positive feedback for strategies identified and decisions made.
8. Encourage Sam to reach out for spiritual support during this time in whatever form is desirable to him. Assess spiritual needs (see Chapter 6, Cultural and Spiritual Concepts Relevant to Psychiatric-Mental Health Nursing), and assist as necessary in the fulfillment of those needs. Sam may find comfort in religious rituals with which he is familiar.

EVALUATION

The outcome criteria identified for Sam have been met. He sought out staff when feelings of suicide surfaced and has identified a safety plan for which he reports willingness to engage. He has not harmed himself in any way. He verbalizes no further thought of suicide and expresses hope for the future. He is able to verbalize names of resources outside the hospital from whom he may request help if thoughts of suicide return. Sam is able to verbalize normal stages of the grief process and behaviors associated with each stage. He is able to identify his own position in the grief process and express honest feelings related to the loss of his job promotion and satisfactory parent-child relationships. He expresses willingness to continue exploring behaviors and coping mechanisms through a local ACoA meeting.

Summary and Key Points

■ Depression is one of the oldest recognized psychiatric illnesses that is still prevalent today. It is so common, in fact, that it has been referred to as the "common cold of psychiatric disorders."

■ The cause of depressive disorders is not entirely known. A number of factors, including genetics, biochemical influences, and psychosocial experiences likely enter into the development of the disorder.

■ Secondary depression occurs in response to other physiological disorders.

■ Symptoms of depression occur along a continuum according to the degree of severity from transient to severe.

■ The disorder occurs in all developmental levels, including childhood, adolescence, senescence, and during the puerperium.

■ Treatment of depression includes individual therapy, group and family therapy, cognitive therapy, electroconvulsive therapy, light therapy, transcranial magnetic stimulation, and psychopharmacology.

■ Nursing care of the depressed client is provided using the six steps of the nursing process.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Margaret, age 68, is a widow of 6 months. Since her husband died, her sister reports that Margaret has become socially withdrawn, has lost weight, and does little more each day than visit the cemetery where her husband is buried. She told her sister today that she "doesn't have anything more to live for." She has been hospitalized with major depressive disorder. The *priority* nursing diagnosis for Margaret would be:
    a. Imbalanced nutrition: less than body requirements.
    b. Complicated grieving.
    c. Risk for suicide.
    d. Social isolation.

2. The physician orders sertraline (Zoloft) 50 mg PO bid for Margaret, a 68-year-old woman with major depressive disorder. After 3 days of taking the medication, Margaret says to the nurse, "I don't think this medicine is doing any good. I don't feel a bit better." What is the most appropriate response by the nurse?
    a. "Cheer up, Margaret. You have so much to be happy about."
    b. "Sometimes it takes a few weeks for the medicine to bring about an improvement in symptoms."
    c. "I'll report that to the physician, Margaret. Maybe he will order something different."
    d. "Try not to dwell on your symptoms, Margaret. Why don't you join the others down in the dayroom?"

3. The goal of cognitive therapy with depressed clients is to:
    a. Identify and change dysfunctional patterns of thinking.
    b. Resolve the symptoms and initiate or restore adaptive family functioning.
    c. Alter the neurotransmitters that are creating the depressed mood.
    d. Provide feedback from peers who are having similar experiences.

4. Education for the client who is taking MAOIs should include which of the following?
    a. Fluid and sodium replacement when appropriate, frequent drug blood levels, signs and symptoms of toxicity
    b. Lifetime of continuous use, possible tardive dyskinesia, advantages of an injection every 2 to 4 weeks
    c. Short-term use, possible tolerance to beneficial effects, careful tapering of the drug at end of treatment
    d. Tyramine-restricted diet, prohibitive concurrent use of over-the-counter medications without physician notification

Review Questions—cont'd
Self-Examination/Learning Exercise

5. A client expresses interest in alternative treatments for depression with seasonal variations and asks the nurse about light therapy. Which of the following are evidence-based teaching points that the nurse may share with the client? (Select all that apply.)
   a. Light therapy has demonstrated effectiveness that is comparable to antidepressants.
   b. Light therapy should be used regularly until the season changes.
   c. Light therapy should be used only when ECT has proven to be ineffective.
   d. Side effects such as headache, nausea, or agitation, when they occur, are usually mild and transient.
   e. Light therapy causes sedation, so the best time to use it is before bedtime.

6. A client has just been admitted to the psychiatric unit with a diagnosis of major depressive disorder. Which of the following behavioral manifestations might the nurse expect to assess? (Select all that apply.)
   a. Slumped posture
   b. Delusional thinking
   c. Feelings of despair
   d. Feels best early in the morning and worse as the day progresses
   e. Anorexia

7. A client with depression asks the nurse, "Why would they be checking my thyroid function when I clearly have depression and I'm not overweight?" Which of these is an accurate response?
   a. An underactive thyroid gland can manifest as depression.
   b. Depression has been proven to be a hormonal illness.
   c. Thyroid hormone replacement is a first-line treatment for most clients with depression.
   d. All of the above.

8. A client whose husband died 6 months ago is diagnosed with major depressive disorder. She says to the nurse, "I start feeling angry that Harold died and left me all alone; he should have stopped smoking years ago! But then I start feeling guilty for feeling that way." What is an appropriate response by the nurse?
   a. "Yes, he should have stopped smoking. Then he probably wouldn't have gotten lung cancer."
   b. "I can understand how you must feel."
   c. "Those feelings are a normal part of the grief response."
   d. "Just think about the good times that you had while he was alive."

9. An acutely depressed client isolates herself in her room and just sits and stares into space. Which of these is the best example of an active communication approach with this client?
   a. "Do you like exercise?"
   b. "Come with me. I will go with you to group therapy."
   c. "Would you like to go to group therapy, stay in bed, or come out to the day lounge for some activities?"
   d. "Why do you stay in your room all the time?"

10. Sally is admitted to the hospital with major depressive disorder and repeatedly makes negative statements about herself. Which of the following interventions are identified as those that will promote positive self-esteem in the patient? (Select all that apply.)
    a. Teach assertive communication skills.
    b. Make observations to Sally when she completes a goal or task.
    c. Instruct Sally that you will not talk with her unless she stops talking negatively about herself.
    d. Offer to spend time with Sally using a nonjudgmental, accepting approach.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Pessagno, R.A., & Hunker, D. (2012). Using short-term group psychotherapy as an evidence-based intervention for first-time mothers at risk for postpartum depression. *Perspectives in Psychiatric Care, 49*(3), 202-209. doi:10.1111/j.1744-6163.2012.00350.x

DESCRIPTION OF THE STUDY: The purpose of this study was to determine if an 8-week, short-term psychotherapy group decreased the risk of developing postpartum depression (PPD) among first-time mothers at risk for PPD. The sample consisted of 16 women between the ages of 20 and 38 (mean 28.5 yr). All were Caucasian, and the majority were Catholic. Thirteen were married, two were partnered, and one participant was single. Two psychotherapy groups with eight women in each group met once a week for 8 weeks beginning one month after discharge from the hospital. Each session lasted 90 minutes, and both groups were led by the same advanced practice psychiatric nurse practitioner. All participants completed the Edinburgh Postnatal Depression Scale (EPDS) within 3 days of giving birth, and all scored 11 or higher, which was targeted as a high risk for PPD score by the participant hospital (a community hospital in New Jersey). The psychotherapy groups followed an unstructured format, with an interpersonal-focused theoretical model. The authors stated, "This focus was structured to provide optimal opportunity in developing skills relative to their new maternal roles as new mothers, coping with depression and stress, honing communication skills with their husbands and partners, and sharing their individual, weekly experiences."

The EPDS was administered to all participants at the end of the 8 sessions.

RESULTS OF THE STUDY: The mean preintervention score on the EPDS for group 1 was 16.13, and for group 2, the mean score was 15.5, placing participants from both groups at high risk for PPD. Following the intervention, the mean score for group 1 participants was 6.38 and for group 2 was 6.63. The EPDS was administered at 6 months postintervention to determine the long-term effects. At that time, both groups demonstrated a significant decrease in scores on the EPDS, indicating a continued effect of the group intervention for participants. The authors stated, "This is suggestive that group psychotherapy can have long-term effects to reduce risk for PPD for first-time mothers."

IMPLICATIONS FOR NURSING PRACTICE: The results of this study indicate that, particularly in those states that mandate screening for PPD, implementing nonpharmacologic interventions such as short-term group psychotherapy provides a choice for women who decide against the use of medication. The authors stated, "In today's mental health services market, significant focus is placed on the importance of medication management skills of the psychiatric APN, yet the intervention in this project supports the need for continued education and training of advanced practice psychiatric nursing as psychotherapists with group psychotherapy skills."

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Schomerus, G., Matschinger, H., & Angermeyer, M.C. (2014). Causal beliefs of the public and social acceptance of persons with mental illness: A comparative analysis of schizophrenia, depression, and alcohol dependence. *Psychological Medicine 44*(2), 303-314. doi:10.1017/S003321971300072X

DESCRIPTION OF THE STUDY: The aim of the study was to identify whether biological explanations for mental illness (including schizophrenia, depression, and alcohol dependence) improved people's perceptions about and tolerance of people with these conditions. This study was conducted in Germany with a large sample ($N = 3,642$). The researchers used path models to compare different variables such as beliefs that these illnesses are caused by biogenetic factors, current stress, and/or childhood adversity. Then, on the basis of those beliefs, the researchers identified the participants' attitudes and social acceptance of patients with a mental illness.

RESULTS OF THE STUDY: Biogenetic beliefs as a cause for mental illness were associated with lower acceptance

of people with schizophrenia and depression but higher acceptance of individuals with alcohol dependence. Lower social acceptance was related to the perceptions of differentness and dangerous that were believed to be "etched in stone" if the illness is genetic in origin (an oversimplification of the influence of genetic factors). Current stress as a cause for mental illness was associated with higher acceptance of people with schizophrenia, while belief in childhood adversity as a cause was associated with lower acceptance of people with depression.

IMPLICATIONS FOR NURSING PRACTICE: Stigmatization (a devaluing attitude about peoples' ability to function in society because of an illness or disability) has been identified as a major barrier to recovery for people with mental illnesses. This study provides evidence that we need to be thoughtful as we educate patients and families. In reality, and based on current evidence, mental illnesses are probably caused by many factors, including genetic vulnerability, current stress, and past trauma. Often, mental illnesses are explained strictly as biogenetic diseases of the brain, and this explanation

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE–cont'd

sometimes is misrepresented as completely known when, in fact, much of our current knowledge about causality in mental illness is theoretical. The researchers conclude that we may not be helping our clients or combating stigma when we try to oversimplify causality explanations.

When interpreting findings from a study such as this one, it is important to consider what variables might influence the findings. For example, might cultural beliefs about mental illness and biogenetics in Germany differ from those in other parts of the world? These questions become the foundation for additional research. Interestingly, the researchers cite a study by Hansell and associates in 2011* that reviewed Web sites in the United States and found that

information provided by universities and government agencies more often provided a balanced view of potential causative factors where nongovernment agencies and pharmaceutical Web sites tended to overemphasize biological causes. Nurses need to be cautious about the reliability of their sources for information to maintain the public trust in the information that is shared. The bottom line is that, as nurses, we need to ensure that we are providing balanced information, based on current evidence, when we provide patient education. This is critical to providing accurate information to clients and families and, as the study suggests, may help in the battle against stigmatization of people with mental illness.

TEST YOUR CRITICAL THINKING SKILLS

Carol is a 17-year-old high school senior. She will graduate in 1 month and has plans to attend the state university a few hours from her home. Carol has always made good grades in school, has participated in many activities, and is a pep squad cheerleader. She had been dating the star quarterback, Alan, since last summer, and they had spoken a number of times about going to the senior prom together. About a month before the prom, Alan broke up with Carol and began dating Salima, whom he subsequently took to the prom. Since that time, Carol has become despondent. She does not go out with her friends, she dropped out of the pep squad, her grades have fallen, and she has lost 10 pounds. She attends classes most of the time, but evenings and weekends she spends in her room alone listening to her music, crying, and sleeping. Her parents have become very concerned and contacted the family physician, who has had Carol admitted to the psychiatric unit of the local hospital. The admitting psychiatrist has made the diagnosis of Major Depressive Disorder. Carol tells the nurse, "Sometimes I drive around and try to find Alan and Salima. I don't know why he broke up with me. I hate myself! I just want to die!"

Answer the following questions related to Carol:

1. What is the primary nursing diagnosis that is identified for Carol?
2. To determine the seriousness of this problem, what are important nursing assessments that must be made?
3. What medication might the physician order for Carol?
4. What concern has the FDA identified that is associated with this medication?

Communication Exercises

1. Carrie, age 75, is a patient on the psychiatric unit with a diagnosis of Major Depressive Disorder. She says to the nurse, "I never knew my life would end up like this. I've lost my husband, all my friends, and my home."
   - How would the nurse respond appropriately to this statement by Carrie?
2. "I have spent my whole life taking care of others. Now someone else has to take care of me. I feel so useless."
   - How would the nurse respond appropriately to this statement by Carrie?
3. "I don't know why anyone would want to bother taking care of me. I really have nothing left to live for."
   - How would the nurse respond appropriately to this statement by Carrie?

Bipolar and Related Disorders 26

CORE CONCEPTS
Mania

KEY TERMS

bipolar disorder
cyclothymic disorder

delirious mania
flight of ideas

hypomania

OBJECTIVES
After reading this chapter, the student will be able to:

1. Recount historical perspectives of bipolar disorder.
2. Discuss epidemiological statistics related to bipolar disorder.
3. Describe various types of bipolar disorders.
4. Identify predisposing factors in the development of bipolar disorder.
5. Discuss implications of bipolar disorder related to developmental stage.
6. Identify symptomatology associated with bipolar disorder and use this information in client assessment.
7. Formulate nursing diagnoses and goals of care for clients experiencing a manic episode.
8. Identify topics for client and family teaching relevant to bipolar disorder.
9. Describe appropriate nursing interventions for clients experiencing a manic episode.
10. Describe relevant criteria for evaluating nursing care of clients experiencing a manic episode.
11. Discuss various modalities relevant to treatment of bipolar disorder.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What is the most common medication that has been known to trigger manic episodes?
2. What is the speech pattern of a person experiencing a manic episode?
3. What is the difference between cyclothymic disorder and bipolar disorder?
4. Why should a person on lithium therapy have blood levels drawn regularly?

Mood was defined in Chapter 25, Depressive Disorders, as a pervasive and sustained emotion that may have a profound influence on a person's perception of the world. Examples of mood include depression, joy, elation, anger, and anxiety. *Affect* is described as the external, observable emotional reaction associated with an experience.

The previous chapter focused on the consequences of complicated grieving as it is manifested by depressive disorders. This chapter addresses mood

533

disorders as they are manifested by cycles of mania and depression—called **bipolar disorder.** A historical perspective and epidemiological statistics related to bipolar disorder are presented. Predisposing factors that have been implicated in the etiology of bipolar disorder provide a framework for studying the dynamics of the disorder.

The implications of bipolar disorder relevant to children and adolescents are discussed. An explanation of the symptomatology is presented as background knowledge for assessing the client with bipolar disorder. Nursing care is described in the context of the six steps of the nursing process. Various medical treatment modalities are explored.

CORE CONCEPT

Mania

An alteration in mood that may be expressed by feelings of elation, inflated self-esteem, grandiosity, hyperactivity, agitation, racing thoughts, and accelerated speech. Mania can occur as part of the psychiatric disorder bipolar disorder, as part of some other medical conditions, or in response to some substances.

Historical Perspective

Documentation of the symptoms associated with bipolar disorder dates back to about the second century in ancient Greece. Aretaeus of Cappadocia, a Greek physician, is credited with associating these extremes of mood as part of the same illness. He described patients who could at times laugh and play all night and day but at other times appeared "torpid, dull, and sorrowful" (Burton, 2012). His view that these mood swings were part of the same illness did not gain acceptance until much later.

In early writings, mania was categorized with all forms of "severe madness." In 1025, the Persian physician Avicenna wrote *The Canon of Medicine* in which he described mania as "bestial madness characterized by rapid onset and remission, with agitation and irritability."

The modern concept of manic-depressive illness began to emerge in the 19th century. In 1854, Jules Baillarger presented information to the French Imperial Academy of Medicine in which he used the term *dual-form insanity* to describe the illness. In the same year, Jean-Pierre Falret described the same disorder, one with alternating periods of depression and manic excitation, with the term *circular insanity* (Burton, 2012). Falret also noted that this disorder appeared to have genetic underpinnings, a belief that is adhered to today (Krans & Cherney, 2016).

Contemporary thinking about bipolar disorder has been shaped by the works of Emil Kraepelin, who first coined the term *manic-depressive* in 1913. He added that this disorder was characterized by acute episodes followed by relatively symptom-free periods. In 1980, the American Psychiatric Association adopted the term *bipolar disorder* as the diagnostic category for manic-depressive illness in the third edition of the *Diagnostic and Statistical Manual of Mental Disorders.* This term identified a period of mood elevation and excitation as a defining characteristic of the disorder that distinguishes it from other mood or psychotic disorders. In addition, it replaced the term *mania* because descriptions of people as "maniacs" were considered stigmatizing (Krans & Cherney, 2016).

Epidemiology

Bipolar disorder affects approximately 5.7 million American adults, or about 2.6 percent of the U.S. population aged 18 and older in a given year. Of these cases, 82.9 percent are considered severe (National Institute of Mental Health [NIMH], 2015). In terms of gender, the incidence of bipolar disorder is roughly equal, with a ratio of women to men of about 1.2 to 1. The average age of onset for bipolar disorder is 25 years, and following the first manic episode, the disorder tends to be recurrent. Unlike depressive disorders, bipolar disorder appears to occur more frequently among the higher socioeconomic classes (Sadock, Sadock, & Ruiz, 2015). Bipolar disorder is the sixth-leading cause of disability in the middle-age group, but for those who respond to lithium treatment (about 33% of those treated with lithium), bipolar disorder is completely treatable, with no further episodes. Unfortunately, many individuals go for years without an accurate diagnosis or treatment, and for some the consequences can be devastating.

Types of Bipolar Disorders

A bipolar disorder is characterized by mood swings from profound depression to extreme euphoria (mania), with intervening periods of normalcy. Delusions or hallucinations may or may not be part of the clinical picture, and onset of symptoms may reflect a seasonal pattern.

During a manic episode, the mood is elevated, expansive, or irritable. The disturbance is sufficiently severe to cause marked impairment in occupational functioning or in usual social activities or relationships with others, or to require hospitalization to prevent harm to self or others. Motor activity is excessive and frenzied. Psychotic features may be present. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (APA, 2013) diagnostic criteria for a manic episode are presented in Box 26–1.

BOX 26–1 **Diagnostic Criteria for Manic Episode**

A. A distinct period of abnormally and persistently elevated, expansive, or irritable mood, and abnormally and persistently increased goal-directed activity or energy, lasting at least 1 week and present most of the day, nearly every day (or any duration if hospitalization is necessary).

B. During the period of mood disturbance and increased energy or activity, three (or more) of the following symptoms (four if the mood is only irritable) are present to a significant degree, and represent a noticeable change from usual behavior:
1. Inflated self-esteem or grandiosity.
2. Decreased need for sleep (e.g., feels rested after only 3 hours of sleep).
3. More talkative than usual or pressure to keep talking.
4. Flight of ideas or subjective experience that thoughts are racing.
5. Distractibility (i.e., attention too easily drawn to unimportant or irrelevant external stimuli), as reported or observed.
6. Increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation (i.e., purposeless non-goal-directed activity).
7. Excessive involvement in activities that have a high potential for painful consequences (e.g., engaging in unrestrained buying sprees, sexual indiscretions, or foolish business investments).

C. The mood disturbance is sufficiently severe to cause marked impairment in social or occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features.

D. The episode is not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication, or other treatment) or to another medical condition. *Note:* A full manic episode that emerges during antidepressant treatment (e.g., medication, electroconvulsive therapy) but persists at a fully syndromal level beyond the physiological effect of that treatment is sufficient evidence for a manic episode and, therefore, a bipolar I diagnosis.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

A somewhat milder degree of this clinical symptom picture is called **hypomania.** Hypomania is not severe enough to cause marked impairment in social or occupational functioning or to require hospitalization, and it does not include psychotic features. The *DSM-5* diagnostic criteria for a hypomanic episode are presented in Box 26–2.

The diagnostic picture for depression associated with bipolar disorder is similar to that described for major depressive disorder, with one major distinction: the client must have a history of one or more manic episodes. When the presentation includes symptoms associated with both depression and mania, the diagnosis is further specified as *with mixed features.*

Bipolar I Disorder

Bipolar I disorder is the diagnosis given to an individual who is experiencing a manic episode or has a history of one or more manic episodes. The client may also have experienced episodes of depression. This diagnosis is further specified by the current or most recent behavioral episode experienced. For example, the specifier might be *single manic episode* (to describe individuals having a first episode of mania) or *current* (or most recent) *episode manic, hypomanic, mixed,* or *depressed* (to describe individuals who have had recurrent mood episodes). Psychotic or catatonic features may also be noted.

Bipolar II Disorder

The bipolar II disorder diagnostic category is characterized by recurrent bouts of major depression with

episodic occurrence of hypomania. The individual who is assigned this diagnosis may present with symptoms (or history) of depression or hypomania. The client has never experienced a full manic episode, and the symptoms are "not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization" (APA, 2013, p. 133). The diagnosis may specify whether the current or most recent episode is hypomanic, depressed, or with mixed features. If the current syndrome is a major depressive episode, psychotic or catatonic features may be noted.

Cyclothymic Disorder

The essential feature of **cyclothymic disorder** is a chronic mood disturbance of at least 2 years' duration, involving numerous periods of elevated mood that do not meet the criteria for a hypomanic episode and numerous periods of depressed mood of insufficient severity or duration to meet the criteria for major depressive episode. The individual is never without the symptoms for more than 2 months. The *DSM-5* criteria for cyclothymic disorder are presented in Box 26–3.

Substance/Medication-Induced Bipolar Disorder

The disturbance of mood associated with this disorder is considered to be the direct result of physiological effects of a substance (e.g., ingestion of or withdrawal from a drug of abuse or a medication). The mood disturbance may involve elevated, expansive, or irritable mood with inflated self-esteem, decreased need for

---

BOX 26–2 Diagnostic Criteria for Hypomanic Episode

A. A distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased activity or energy, lasting at least 4 consecutive days and present most of the day, nearly every day.

B. During the period of mood disturbance and increased energy and activity, three (or more) of the following symptoms (four if the mood is only irritable) have persisted, represent a noticeable change from usual behavior, and have been present to a significant degree:

  1. Inflated self-esteem or grandiosity.

  2. Decreased need for sleep (e.g., feels rested after only 3 hours of sleep).

  3. More talkative than usual or pressure to keep talking.

  4. Flight of ideas or subjective experience that thoughts are racing.

  5. Distractibility (i.e., attention too easily drawn to unimportant or irrelevant external stimuli), as reported or observed.

  6. Increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation.

  7. Excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g., engaging in unrestrained buying sprees, sexual indiscretions, or foolish business investments).

C. The episode is associated with an unequivocal change in functioning that is uncharacteristic of the individual when not symptomatic.

D. The disturbance in mood and the change in functioning are observable by others.

E. The episode is not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization. If there are psychotic features, the episode is, by definition, manic.

F. The episode is not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication, or other treatment).

  NOTE: A full hypomanic episode that emerges during antidepressant treatment (medication, electroconvulsive therapy) but persists at a fully syndromal level beyond the physiological effect of that treatment is sufficient evidence for a hypomanic episode diagnosis. However, caution is indicated so that one or two symptoms (particularly increased irritability, edginess or agitation following antidepressant use) are not taken as sufficient for diagnosis of a hypomanic episode, nor necessarily indicative of a bipolar diathesis.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

BOX 26–3 Diagnostic Criteria for Cyclothymic Disorder

A. For at least 2 years (at least 1 year in children and adolescents) there have been numerous periods with hypomanic symptoms that do not meet criteria for hypomanic episode and numerous periods with depressive symptoms that do not meet the criteria for a major depressive episode.

B. During the above 2-year period (1 year in children and adolescents), the hypomanic and depressive periods have been present for at least half the time and the individual has not been without the symptoms for more than 2 months at a time.

C. Criteria for a major depressive, manic, or hypomanic episode have never been met.

D. The symptoms in Criterion A are not better explained by schizoaffective disorder, schizophrenia, schizophreniform disorder, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder.

E. The symptoms are not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition (e.g., hyperthyroidism).

F. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Specify if:

With anxious distress

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

---

sleep, and distractibility. The disorder causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Mood disturbances are associated with *intoxication* from substances such as alcohol, amphetamines, cocaine, hallucinogens, inhalants, opioids, phencyclidine, sedatives, hypnotics, and anxiolytics. Symptoms can also occur during *withdrawal* from substances such as alcohol, amphetamines, cocaine, sedatives, hypnotics, and anxiolytics.

A number of medications have been known to evoke mood symptoms. Classifications include anesthetics,

analgesics, anticholinergics, anticonvulsants, antihypertensives, antiparkinsonian agents, antiulcer agents, cardiac medications, oral contraceptives, psychotropic medications, muscle relaxants, steroids, and sulfonamides. Some specific examples are included in the discussion of predisposing factors associated with bipolar disorders.

Bipolar Disorder Due to Another Medical Condition

This disorder is characterized by an abnormally and persistently elevated, expansive, or irritable mood and excessive activity or energy judged to be the direct physiological consequence of another medical condition (APA, 2013). The mood disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning. Types of physiological influences are included in the discussion of predisposing factors associated with bipolar disorders.

Predisposing Factors

The exact etiology of bipolar disorder has yet to be determined. Scientific evidence supports a chemical imbalance in the brain, although the cause of the imbalance remains unclear. Theories that consider a combination of hereditary factors and environmental triggers (stressful life events) appear to hold the most credibility.

Biological Theories

Genetics

Research suggests that bipolar disorder strongly reflects an underlying genetic vulnerability. Evidence from family, twin, and adoption studies exists to support this observation. A large study that looked at genetic variations associated with five major mental illnesses found that schizophrenia and bipolar disorders had about 15 percent of genetic variations in common (NIMH, 2013).

Twin Studies

Twin studies have indicated a concordance rate for bipolar disorder among monozygotic twins at 60 to 80 percent, compared to 10 to 20 percent in dizygotic twins. Because monozygotic twins have identical genes and dizygotic twins share only approximately half their genes, this is strong evidence that genes play a major role in the etiology. However, since identical twins do not always both develop the illness, other factors must also be involved. It is likely that many different genes as well as environmental factors are involved, although researchers do not yet know how these factors interact to cause bipolar disorder (NIMH, 2012).

Family Studies

In general, family studies have shown that if one parent has a mood disorder, the risk that a child will have a mood disorder is between 10 and 25 percent (Sadock et al., 2015). Sadock and associates report that "a family history of bipolar disorder conveys a greater risk for mood disorders in general and, specifically, a much greater risk for bipolar disorder" (p. 352). If both parents have the disorder, the risk is two to three times greater. This has also been the case in studies of children born to parents with bipolar disorder who were adopted at birth and reared by adoptive parents without evidence of the disorder.

Other Genetic Studies

Soreff and McInnes (2012) state:

> Studies from the first series of genome-wide association studies have given combined support for two particular genes, *ANK3* (ankyrin G) and *CACNA1C* (alpha 1C subunit of the L-type voltage-gated calcium channel) in a sample of 4,387 cases and 6,209 controls.

The *ANK3* protein, located on the first part of the axon, is involved in making the determination of whether a neuron will fire. Studies have shown that lithium carbonate, the most common medication used to prevent manic episodes, reduces expression of *ANK3* (Leussis et al., 2013). The *CACNA1C* protein regulates the influx and outflow of calcium from the cells and is the site of action of the calcium channel blockers sometimes used in the treatment of bipolar disorder.

Recent research looking specifically at factors associated with lithium's effectiveness identified "a number of candidate genes related to neurotransmitters, intracellular signaling, neuroprotection, circadian rhythms, and other pathogenic mechanisms of bipolar disorder [that] were found to be associated with lithium's prophylactic response" (Rybakowski, 2014, p. 353). Evidence from another recent study identified that common gene sets demonstrated altered expression in patients with schizophrenia, bipolar disorder, and depression (Darby, Yolken, & Sabunciyan, 2016). Specifically, ribosomal genes were overexpressed, and those involved with neuronal connections such as gamma-aminobutyric acid (GABA) signaling were underexpressed. The researchers suggest that this finding may lead the way to RNA processing and protein synthesis as targets for therapeutic intervention. Ongoing genetic research will continue to shed light on the genetic influences in the development of bipolar disorder and the genetic factors that influence treatment response.

Biochemical Influences

Biogenic Amines

Early studies have associated symptoms of mania with a functional excess of norepinephrine and dopamine.

The neurotransmitter serotonin is believed to remain low in both depression and mania, but the exact mechanisms and biochemical influences are complex and not yet completely understood. For example, even though low serotonin is thought to play a role in both depression and manic states, selective serotonin reuptake inhibitors (SSRIs) sometimes trigger manic episodes and rapid cycling of mood swings in clients with bipolar disorders. Likely, multiple factors influence serotonin's role in this illness. Acetylcholine is another neurotransmitter believed to be related to symptoms in bipolar disorder. Medications that have an effect on cholinergic transmission, particularly cholinergic agonists, can reduce symptoms in mania (Sadock et al., 2015). Excessive levels of glutamate, an excitatory neurotransmitter, have been associated with bipolar disorder. Many of the mood stabilizers used to treat bipolar disorder inhibit the actions of glutamate. The primary support for neurotransmitter hypotheses is the effects that neuroleptic drugs have on the levels of these biogenic amines and the resulting reduction in symptoms of the disorder.

Although several neurotransmitters have been implicated in influencing symptoms, the cause of bipolar disorder remains unknown.

Physiological Influences

Neuroanatomical Factors

Neuroanatomical changes have been correlated with dysfunction in the prefrontal cortex, basal ganglia, temporal and frontal lobes of the forebrain, and parts of the limbic system including the amygdala, thalamus, and striatum. The different symptoms in bipolar disorder may be correlated to those specific areas of dysfunction (Semeniken & Dudás, 2012). Sadock and associates (2015) report that widely replicated positive emission tomography (PET) demonstrates decreased anterior brain function on the left side in depression and greater right-side reductions in brain activity in mania. Although causality of bipolar disorder cannot yet be defined as solely a neuroanatomical disorder, it is clear that mood disorders, including bipolar disorder, involve pathology in the brain.

Medication Side Effects

Certain medications used to treat somatic illnesses have been known to trigger a manic response. The most common of these are the steroids frequently used to treat chronic illnesses such as multiple sclerosis and systemic lupus erythematosus. Some clients whose first episode of mania occurred during steroid therapy have reported spontaneous recurrence of manic symptoms years later. Amphetamines, antidepressants, and high doses of anticonvulsants and narcotics also have the potential for initiating a manic episode.

Psychosocial Theories

Interest in psychosocial theories has declined in recent years with the focus of research on genetic and biochemical predisposing factors. Consequently, conditions such as schizophrenia and bipolar disorder are more often viewed as diseases of the brain with biological etiologies. However, several studies have confirmed a link between childhood trauma (emotional, physical, and sexual abuse) and the development of bipolar disorder (Aas et al., 2016; Etain et al., 2013; Janiri et al., 2015; Watson et al., 2013). Aas and associates (2016) identify that childhood trauma interacts with genes along several different pathways, which influences not only an increased risk for bipolar disorder but also earlier onset, more severe symptoms, substance use, and suicide risk. As research continues, the interaction of genetics and psychosocial stressors becomes more apparent. More research is needed to translate these connections into practical applications for treatment or prevention.

The Transactional Model of Stress and Adaptation

Bipolar disorder clearly results from an interaction between genetic, biological, and psychosocial determinants. The transactional model takes into consideration these etiological influences as well as those associated with past experiences, existing conditions, and the individual's perception of the event. Figure 26–1 depicts the dynamics of bipolar mania using the transactional model of stress and adaptation.

Developmental Implications

Childhood and Adolescence

The lifetime prevalence of adolescent bipolar disorders is estimated to be about 1 percent. In younger children, the incidence is very rare, but children and adolescents are often difficult to diagnose (Sadock et al., 2015). In the past decade, diagnosis of bipolar I disorder in youth has rapidly increased, which prompted researchers to look more closely at factors contributing to this trend. A connection is thought to exist between attention-deficit/hyperactivity disorder (ADHD) and the development of bipolar disorder in youth, but research has not supported this theory (Hassan et al., 2011; Sadock et al., 2015).

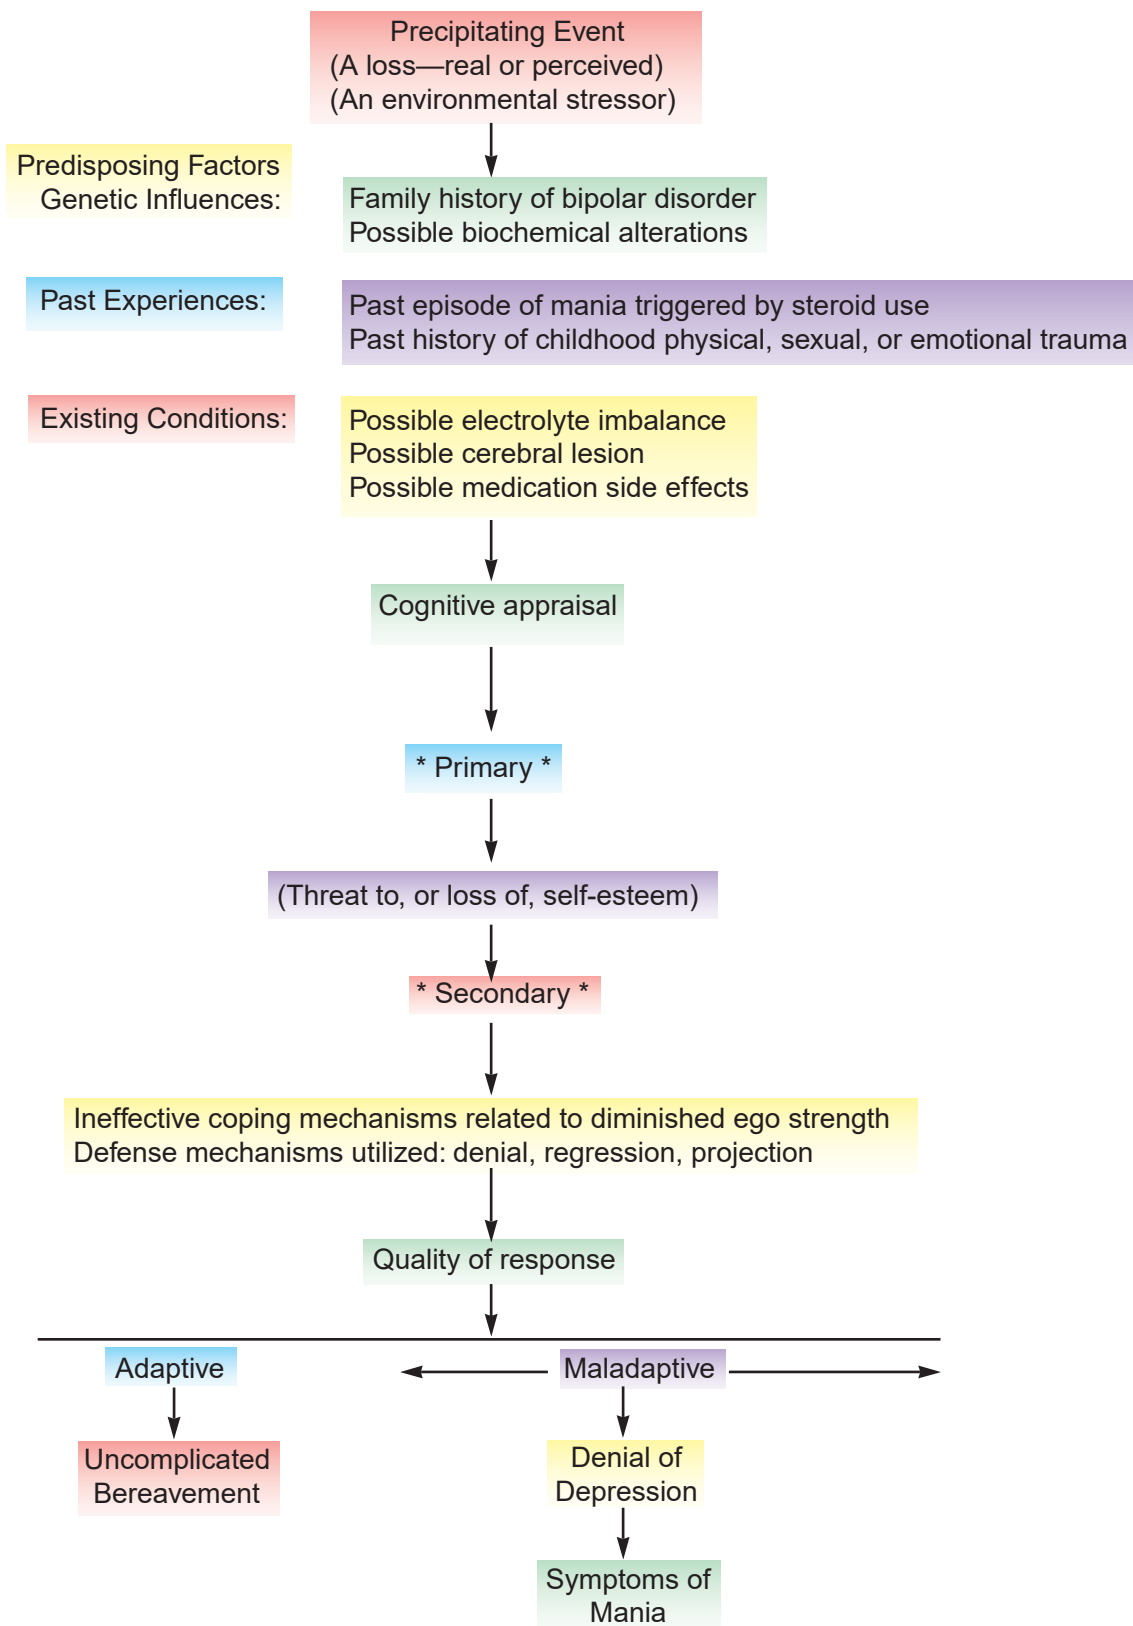
Studies also found that youth given this diagnosis more often manifested with a host of atypical symptoms, including nondiscrete mood episodes, chronic irritability, and temper tantrums. The *DSM-5* incorporated a new diagnosis, *disruptive mood dysregulation disorder,* that more aptly describes this symptom profile. Since then, a longitudinal study of children with


FIGURE 26–1 The dynamics of bipolar mania using the transactional model of stress and adaptation.

nonepisodic irritability found that while these children had higher risk for anxiety and depression, they were not typically at higher risk for developing bipolar disorder (Sadock et al., 2015). In addition, Sadock and associates report that when true mania associated with bipolar disorder does occur in adolescents, it is frequently accompanied by flight of ideas, grandiose or persecutory delusions, and hallucinations. Since family studies show a familial risk for bipolar disorder, whenever a child is exhibiting mood-related symptoms (including depression) and there is a family history of bipolar disorder, the possibility for developing bipolar disorder should be carefully evaluated.

Treatment Strategies

Psychopharmacology

Monotherapy with the traditional mood stabilizers (e.g., lithium, divalproex, carbamazepine) or atypical antipsychotics (e.g., olanzapine, quetiapine, risperidone, aripiprazole) has historically been the first-line treatment. In the event of inadequate response to initial monotherapy, an alternative monotherapeutic agent is suggested. Augmentation with a second medication is indicated when monotherapy fails.

In a more recent analysis to examine the preponderance of research data, Hazell and Jairam (2012) reported "evidence favoring the use of second-generation antipsychotics (SGAs), limited evidence favoring the use of combinations of SGA with a mood stabilizer, and no evidence supporting the use of mood stabilizer monotherapy" (p. 264). They suggest that the first-line treatment for mania in children and adolescents is SGA, with combination therapies offering no clear advantage.

ADHD has been identified as the most common comorbid condition in children and adolescents with bipolar disorder. Because stimulants can exacerbate mania, it is suggested that medication for ADHD be initiated only after bipolar symptoms have been controlled with a mood-stabilizing agent (Jain & Jain, 2014). Nonstimulant medications indicated for ADHD (e.g., atomoxetine, bupropion, the tricyclic antidepressants) may also induce switches to mania or hypomania.

Bipolar disorder in children and adolescents appears to be a chronic condition with a high risk of relapse. Maintenance therapy incorporates the same medications used to treat acute symptoms, although few research studies exist that deal with long-term maintenance of bipolar disorder in children. The American Academy of Child and Adolescent Psychiatry (AACAP) instructs parents to consider bipolar disorder a chronic illness much like diabetes and epilepsy (2010). As such, many people will require long-term or lifelong medication treatment. The AACAP encourages parents, even when their child appears to be in remission, to discuss with the child's doctor the benefits and risks of stopping medication.

Family Interventions

Although pharmacological treatment is acknowledged as the primary method of stabilizing acute symptoms, a combination of medications with psychosocial interventions has been recognized as playing an important role in preventing relapses and improving adjustment. Treatment adherence must be emphasized as an essential component of relapse prevention.

Family dynamics and attitudes can play a crucial role in the outcome of a client's recovery. Interventions with family members must include education that promotes understanding that at least part of the client's negative behaviors, as opposed to being willful and deliberate, are attributable to an illness that must be managed.

Studies show that psychoeducational family-focused therapy (FFT) is an effective method of reducing relapses and increasing medication adherence in clients with bipolar disorder (Miklowitz et al., 2013). In addition, Miklowitz and associates found that clients involved in FFT who demonstrated high risk for developing bipolar disorder (those with depressive symptoms and a first-degree relative with bipolar disorder) recovered more quickly than those who were provided only educational sessions. FFT includes sessions that deal with psychoeducation about bipolar disorder (i.e., symptoms, early recognition, etiology, treatment, self-management), communication training, and problem-solving skills training. Teaching the client and family about early warning signs and how to respond provides the client with a needed support system and the family with needed tools to provide that support.

Application of the Nursing Process to Bipolar Disorder (Mania)

Background Assessment Data

Symptoms of manic states can be described according to three stages: hypomania, acute mania, and **delirious mania.** Symptoms of mood, cognition and perception, and activity and behavior are presented for each stage.

Stage I: Hypomania

At this stage, the disturbance is not sufficiently severe to cause marked impairment in social or occupational functioning or to require hospitalization (APA, 2013).

Mood

The mood of a hypomanic person is cheerful and expansive. An underlying irritability surfaces rapidly when the person's wishes and desires go unfulfilled,

however. The nature of the hypomanic person is volatile and fluctuating (see Box 26–2).

Cognition and Perception

Perceptions of the self are exalted—the individual has ideas of great worth and ability. Thinking is flighty, with a rapid flow of ideas. Perception of the environment is heightened, but the individual is so easily distracted by irrelevant stimuli that goal-directed activities are difficult.

Activity and Behavior

Hypomanic individuals exhibit increased motor activity. They are perceived as being extroverted and sociable and thus attract numerous acquaintances. However, they lack the depth of personality and warmth to formulate close friendships. They talk and laugh a great deal, usually very loudly and often inappropriately. Increased libido is common. Some individuals experience anorexia and weight loss. The exalted self-perception leads some hypomanic individuals to engage in inappropriate behaviors, such as phoning the President of the United States or running up debt on a credit card without having the resources to pay.

Stage II: Acute Mania

Symptoms of acute mania may progress in intensification from those experienced in hypomania, or they may be manifested directly. Most individuals experience marked impairment in functioning and require hospitalization (see Box 26–1).

Mood

Acute mania is characterized by euphoria and elation. The person appears to be on a continuous "high." However, the mood is always subject to frequent variation, easily changing to irritability and anger or even to sadness and crying.

Cognition and Perception

Cognition and perception become fragmented and often psychotic in acute mania. Accelerated thinking proceeds to racing thoughts; overconnection of ideas; and rapid, abrupt movement from one thought to another **(flight of ideas)** and may be manifested by a continuous flow of accelerated, pressured speech (loquaciousness) to the point that conversing with this individual may be extremely difficult. When flight of ideas is severe, speech may be disorganized and incoherent. Distractibility becomes all-pervasive. Attention can be diverted by even the smallest of stimuli. Hallucinations and delusions (usually paranoid and grandiose) are common.

Activity and Behavior

Psychomotor activity is excessive. Sexual interest is increased. There is poor impulse control and low frustration tolerance. The individual who is normally discreet may become socially and sexually uninhibited. Excessive spending is common. In acute mania, the individual typically has little insight into his or her behavior and communication. This lack of insight manifests at times as unreliable reporting of events and denial of problems when confronted by friends or family, which may be interpreted as lying. Energy seems inexhaustible, and the need for sleep is diminished. An individual experiencing acute mania may go for many days without sleep and still not feel tired. Hygiene and grooming may be neglected. Dress may be disorganized, flamboyant, or bizarre, and the use of excessive makeup or jewelry is common.

Stage III: Delirious Mania

Delirious mania is a grave form of the disorder characterized by severe clouding of consciousness and an intensification of the symptoms associated with acute mania. This condition has become relatively rare since the availability of antipsychotic medication.

Mood

The mood of the delirious person is very labile. He or she may exhibit feelings of despair, quickly converting to unrestrained merriment and ecstasy or becoming irritable or totally indifferent to the environment. Panic-level anxiety may be evident.

Cognition and Perception

Cognition and perception are characterized by a clouding of consciousness, with accompanying confusion, disorientation, and sometimes stupor. Other common manifestations include religiosity, delusions of grandeur or persecution, and auditory or visual hallucinations. The individual is extremely distractible and incoherent.

Activity and Behavior

Psychomotor activity is frenzied and characterized by agitated, purposeless movements. The safety of these individuals is at stake unless this activity is curtailed. Exhaustion, injury to self or others, and eventually death could occur without intervention.

Diagnosis and Outcome Identification

Using information collected during the assessment, the nurse completes the client database, from which the selection of appropriate nursing diagnoses is determined. Table 26–1 presents a list of client behaviors and the NANDA International nursing diagnoses that correspond to those behaviors, which may be used in planning care for the client experiencing a manic episode.

Outcome Criteria

The following criteria may be used for measuring outcomes in the care of the client experiencing a manic episode.

TABLE 26–1 Assigning Nursing Diagnoses to Behaviors Commonly Exhibited by Individuals Experiencing a Manic Episode	
BEHAVIORS	**NURSING DIAGNOSES**
Extreme hyperactivity; increased agitation and lack of control over purposeless and potentially injurious movements	Risk for injury
Manic excitement, delusional thinking, hallucinations, impulsivity	Risk for violence: Self-directed or other-directed
Loss of weight, amenorrhea, refusal or inability to sit still long enough to eat	Imbalanced nutrition: Less than body requirements
Delusions of grandeur and persecution; inaccurate interpretation of the environment	Disturbed thought processes*
Auditory and visual hallucinations; disorientation	Disturbed sensory-perception*
Inability to develop satisfying relationships, manipulation of others for own desires, use of unsuccessful social interaction behaviors	Impaired social interaction
Difficulty falling asleep, sleeping only short periods	Insomnia

*These diagnoses have been resigned from the NANDA-I list of approved diagnoses. They are used in this instance because they are most compatible with the identified behaviors.

The client:

- Exhibits no evidence of physical injury
- Has not harmed self or others
- Is no longer exhibiting signs of physical agitation
- Eats a well-balanced diet with snacks to prevent weight loss and maintain nutritional status
- Verbalizes an accurate interpretation of the environment
- Verbalizes that hallucinatory activity has ceased and demonstrates no outward behavior indicating hallucinations
- Accepts responsibility for own behaviors
- Does not manipulate others for gratification of own needs
- Interacts appropriately with others
- Is able to fall asleep within 30 minutes of retiring
- Is able to sleep 6 to 8 hours per night without medication

Planning and Implementation

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each. Some institutions use a case management model to coordinate care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing, for a more detailed explanation). In case management models, the plan of care may take the form of a critical pathway.

Risk for Violence: Self-Directed or Other-Directed

Risk for self- or other-directed violence is defined as "vulnerable to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to [self or to others]" (Herdman & Kamitsuru, 2014, pp. 410–411).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

- Within [a specified time], client will recognize signs of increasing anxiety and agitation and report to staff (or other care provider) for assistance with intervention.
- Client will not harm self or others.

Long-term goal

- Client will not harm self or others.

Interventions

- Maintain a low level of stimuli in the client's environment (low lighting, few people, simple decor, low noise level). Anxiety level rises in a stimulating environment. A suspicious, agitated client may perceive individuals as threatening.
- Assess for concurrent substance use issues. There is a high incidence of comorbid substance use disorders in clients with bipolar disorder. Substance use issues can increase the client's risk for harm to self or others. In addition, the use of mood-altering chemicals beyond what is prescribed can make the evaluation of pharmacotherapy more difficult. (See Chapter 23, Substance-Related and Addictive Disorders, for more information on substance use disorders and relevant nursing interventions.)

- Observe the client's behavior frequently. Do this while carrying out routine activities so as to avoid creating suspiciousness in the individual. Close observation is necessary so that intervention can occur if required to ensure client (and others') safety.
- Remove all dangerous objects from the client's environment so the client may not use them to harm self or others in an agitated, confused state.
- Intervene at the first sign of increased anxiety, agitation, or verbal or behavioral aggression. Offer empathetic response to client's feelings: "You seem anxious (or frustrated, or angry) about this situation. How can I help?" Validation of the client's feelings conveys a caring attitude and offering assistance reinforces trust. Since the client may be highly distractible, providing a distraction can aid in diffusing anxiety and agitation as well.
- It is important to maintain a calm attitude toward the client. As the client's anxiety increases, offer some alternatives: participating in a physical activity (e.g., punching bag, physical exercise), talking about the situation, taking antianxiety medication. Offering alternatives to the client gives him or her a feeling of some control over the situation.
- Have sufficient staff available to indicate a show of strength to the client if it becomes necessary. This shows the client evidence of control over the situation and provides some physical security for staff.
- If the client is not calmed by "talking down" or by medication, use of mechanical restraints may be necessary.

> **CLINICAL PEARL** The avenue of the "least restrictive alternative" must be selected when planning interventions for a violent client. Restraints should be used only as a last resort, after all other interventions have been unsuccessful and the client is clearly at risk of harm to self or others.

- If restraint is deemed necessary, ensure that sufficient staff is available to assist. Follow protocol established by the institution.
- As agitation decreases, assess the client's readiness for restraint removal or reduction. Remove one restraint at a time while assessing the client's response. This minimizes the risk of injury to client and staff.

Impaired Social Interaction

Impaired social interaction is defined as "insufficient or excessive quantity or ineffective quality of social exchange" (Herdman & Kamitsuru, 2014, p. 301). Table 26–2 presents this nursing diagnosis in care plan format.

Table 26–2 | CARE PLAN FOR THE CLIENT EXPERIENCING A MANIC EPISODE

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Delusional thought processes (grandeur and/or persecution); underdeveloped ego and low self-esteem

EVIDENCED BY: Inability to develop satisfying relationships and manipulation of others for own desires

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client verbalizes which of his or her interaction behaviors are appropriate and which are inappropriate within 1 week. Long-Term Goal: • Client demonstrates use of appropriate interaction skills as evidenced by lack of, or marked decrease in, manipulation of others to fulfill own desires.	1. Recognize the purpose manipulative behaviors serve for client: to reduce feelings of insecurity by increasing feelings of power and control. 2. Set limits on manipulative behaviors. Explain to client what is expected and what the consequences are if limits are violated. Terms of the limitations must be agreed on by all staff who will be working with client. 3. Do not argue, bargain, or try to reason with client. Merely state the limits and expectations. Confront client as soon as possible when interactions with others	1. Understanding the motivation behind the manipulation may facilitate acceptance of the individual and his or her behavior. 2. Client is unable to establish own limits, so this must be done for him or her. Unless administration of consequences for violation of limits is consistent, manipulative behavior will not be eliminated. 3. Because the client may be vulnerable to impulsive, reckless, or pleasure seeking behavior without considering consequences, he or she should receive immediate feedback when behavior is unacceptable. Consistency in enforcing

Continued

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	are manipulative or exploitative. Follow through with established consequences for unacceptable behavior.	the consequences is essential if positive outcomes are to be achieved. Inconsistency creates confusion and encourages testing of limits.
	4. Provide positive reinforcement for nonmanipulative behaviors. Explore feelings and help client seek more appropriate ways of dealing with them.	4. Positive reinforcement enhances self-esteem and promotes repetition of desirable behaviors.
	5. Help client recognize that he or she must accept the consequences of own behaviors and refrain from attributing them to others.	5. Client must accept responsibility for own behaviors before adaptive change can occur.
	6. Help client identify positive aspects about self, recognize accomplishments, and feel good about them.	6. As self-esteem is increased, client will feel less need to manipulate others for own gratification.

Table title: **Table 26–2 | CARE PLAN FOR THE CLIENT EXPERIENCING A MANIC EPISODE–cont'd**

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will verbalize which of his or her interaction behaviors are appropriate and which are inappropriate within 1 week.

Long-term goal

■ Client will demonstrate use of appropriate interaction skills as evidenced by lack of, or marked decrease in, manipulation of others to fulfill own desires.

Interventions

■ Recognize the purpose these behaviors serve for the client: to reduce feelings of insecurity by increasing feelings of power and control. Understanding the motivation behind the manipulation may help to facilitate acceptance of the individual and his or her behavior.

■ Set limits on manipulative behaviors. Explain to the client what is expected and what the consequences are if the limits are violated. Terms of the limitations must be agreed on by all staff who will be working with the client. The client is unable to establish own limits, so this must be done for him or her. Unless administration of consequences for violation of limits is consistent, manipulative behavior will not be eliminated. Comorbid borderline personality disorder has been identified as a risk in patients with bipolar disorder. (See Chapter 32, Personality Disorders, for more information on borderline personality disorder features and nursing interventions.)

■ Do not argue, bargain, or try to reason with the client. Merely state the limits and expectations. Individuals with mania can be very charming in their efforts to fulfill their own desires. Confront the client as soon as possible when interactions with others are manipulative or exploitative. Follow through with established consequences for unacceptable behavior. Because of the strong id influence on the client's behavior, he or she should receive immediate feedback when behavior is unacceptable. Consistency in enforcing the consequences is essential if positive outcomes are to be achieved. Inconsistency creates confusion and encourages testing of limits.

■ Provide positive reinforcement for nonmanipulative behaviors. Explore feelings and help the client seek more appropriate ways of dealing with them.

■ Help the client recognize that he or she must accept the consequences of behaviors and refrain from attributing them to others. The client must accept responsibility for own behaviors before adaptive change can occur.

■ Help the client identify positive aspects about self, recognize accomplishments, and feel good about them. As self-esteem increases, the client will feel less need to manipulate others for own gratification.

Imbalanced Nutrition: Less Than Body Requirements/Insomnia

Imbalanced nutrition: Less than body requirements is defined as "intake of nutrients insufficient to meet metabolic needs" (Herdman & Kamitsuru, 2014, p. 161). *Insomnia* is defined as "a disruption in amount and quality of sleep that impairs functioning" (p. 209).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

- Client will consume sufficient finger foods and between-meal snacks to meet recommended daily allowances of nutrients.
- Within 3 days, with the aid of a sleeping medication, client will sleep 4 to 6 hours without awakening.

Long-term goals

- Client will exhibit no signs or symptoms of malnutrition.
- By time of discharge from treatment, client will be able to acquire 6 to 8 hours of uninterrupted sleep without medication.

Interventions

- In collaboration with the dietitian, determine the number of calories required to provide adequate nutrition for maintenance or realistic (according to body structure and height) weight gain. Determine client's likes and dislikes, and provide favorite foods if possible. The client is more likely to eat foods that he or she particularly enjoys.
- Provide the client with high-protein, high-calorie, nutritious finger foods and drinks that can be consumed "on the run." Because of the hyperactive state, the client has difficulty sitting still long enough to eat a meal. He or she is more likely to consume food and drinks that can be carried around and eaten with little effort. Have juice and snacks available on the unit at all times. Regular nutritious intake is required to compensate for increased caloric requirements of hyperactivity.
- Maintain an accurate record of intake, output, and calorie count. Weigh the client daily. Administer vitamin and mineral supplements as ordered by the physician. Monitor laboratory values, and report significant changes to the physician. It is important to carefully monitor data that provide an objective assessment of the client's nutritional status.
- Assess the client's activity level. He or she may ignore or be unaware of feelings of fatigue. Observe for signs such as increasing restlessness; fine tremors; slurred speech; and puffy, dark circles under eyes. The client could collapse from exhaustion if hyperactivity is uninterrupted and rest is not achieved.
- Monitor sleep patterns. Provide a structured schedule of activities that includes established times for naps or rest. Accurate baseline data are important in planning care to help the client with this problem. A structured schedule, including time for short naps, will help the hyperactive client achieve much-needed rest.
- Client should avoid intake of caffeinated drinks, such as tea, coffee, and colas. Caffeine is a central nervous system (CNS) stimulant and may interfere with the client's achievement of rest and sleep.
- Before bedtime, provide nursing measures that promote sleep, such as back rub; warm bath; warm, nonstimulating drinks; soft music; and relaxation exercises.
- Administer sedative medications as ordered to help client achieve sleep until normal sleep pattern is restored.

Concept Care Mapping

The concept map care plan (see Chapter 9) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client experiencing a manic episode is presented in Figure 26–2.

Client and Family Education

The role of client-teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client and family education relevant to bipolar disorder is presented in Box 26–4.

Evaluation of Care for the Client Experiencing a Manic Episode

In the final step of the nursing process, a reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client experiencing a manic episode may be facilitated by gathering information using the following types of questions.

- Has the individual avoided personal injury?
- Has violence to client or others been prevented?
- Has agitation subsided?
- Have nutritional status and weight been stabilized? Is the client able to select foods to maintain adequate nutrition?
- Have delusions and hallucinations ceased? Is the client able to interpret the environment correctly?

Clinical Vignette: Sam and Janet had been engaged for a year. Three months ago, Sam called Janet and told her he didn't want to get married, and he was leaving to take a job in Japan. Janet became hysterical, then depressed, and then seemed to be accepting the situation. She got a new hairstyle, bought lots of new clothes, and started going to lots of parties with her roommate, Nancy. She started losing weight, exercising excessively, and sleeping very little. She became quite promiscuous. She stopped menstruating and said to Nancy, "I wonder if I'm pregnant!" Tonight she and Nancy went to a bar. Janet started buying drinks "for the house." She became quite loud and disruptive, climbing on the bar and announcing to the crowd that she had received a "message" that she would be the winner of tonight's multimillion-dollar lottery. When the bar owner eventually asked her to leave, she became violent, striking out at him and destroying bar property. He called 911, and Janet was taken to the emergency department of the hospital. She has been admitted to the psychiatric unit with Bipolar I Disorder, Manic Episode. She is agitated and restless. The nurse develops the following concept map care plan for Janet.

Signs and Symptoms
- Increased agitation
- Extreme hyperactivity

Signs and Symptoms
- Manic excitement
- Delusional thinking
- Hallucinations

Signs and Symptoms
- Weight loss
- Amenorrhea

Nursing Diagnosis

Risk for injury

Nursing Diagnosis

Risk for self- or other-directed violence

Nursing Diagnosis

Imbalanced nutrition: less than body requirements

Nursing Actions
- Reduce stimuli.
- Assign private room.
- Remove hazardous objects from area.
- Stay with client when she is agitated.
- Provide physical activities.
- Administer tranquilizers as ordered.

Nursing Actions
- Observe client q 15 min.
- Remove sharps, belts, and other dangerous objects from environment.
- Maintain calm attitude.
- Have sufficient staff for show of strength if necessary.
- Administer tranquilizers as ordered.
- Apply mechanical restraints if necessary.

Nursing Actions
- Provide high-protein, high-calorie finger foods.
- Have juice and snacks on unit.
- Measure I&O, calorie count, daily weights.
- Provide favorite foods.
- Supplement with vitamins and minerals.
- Sit with client during meals.

Medical Rx: Olanzapine 15 mg PO daily

Outcomes
- No evidence of physical injury
- No longer experiencing physical agitation

Outcomes
- Client has not harmed self or others
- No evidence of delusions or hallucinations

Outcomes
- Eats a well-balanced diet
- Nutritional status restored
- Weight has stabilized

FIGURE 26–2 Concept map care plan for a client with bipolar mania.

■ Is the client able to make decisions about own self-care? Has hygiene and grooming improved?

■ Is behavior socially acceptable? Is client able to interact with others in a satisfactory manner? Has the client stopped manipulating others to fulfill own desires?

■ Is the client able to sleep 6 to 8 hours per night and awaken feeling rested?

■ Does the client understand the importance of maintenance medication therapy? Does he or she understand that symptoms may return if medication is discontinued?

BOX 26–4 Topics for Client and Family Education Related to Bipolar Disorder

NATURE OF THE ILLNESS
1. Causes of bipolar disorder
2. Cyclic nature of the illness
3. Symptoms of depression
4. Symptoms of mania

MANAGEMENT OF THE ILLNESS
1. Medication management
   a. Lithium
   b. Others
      1) Carbamazepine
      2) Valproic acid
      3) Clonazepam
      4) Verapamil
      5) Lamotrigine
      6) Gabapentin
      7) Topiramate
      8) Oxcarbazepine
      9) Olanzapine
      10) Risperidone
      11) Chlorpromazine
      12) Aripiprazole
      13) Quetiapine
      14) Ziprasidone
      15) Asenapine
   c. Side effects
   d. Symptoms of lithium toxicity
   e. Importance of regular blood tests
   f. Adverse effects
   g. Importance of not stopping medication, even when feeling well
2. Assertive techniques
3. Anger management

SUPPORT SERVICES
1. Crisis hotline
2. Support groups
3. Individual psychotherapy
4. Legal and/or financial assistance

■ Can the client taking lithium verbalize early signs of lithium toxicity? Does he or she understand the necessity for monthly blood level checks?

Treatment Modalities for Bipolar Disorder (Mania)

Individual Psychotherapy

In a review of the evidence on psychotherapy for clients with bipolar disorder, Swartz and Swanson (2014) conclude that bipolar-specific psychotherapies in conjunction with medication treatment have better outcomes than medication alone. Evidence supports the benefits of psychoeducation, cognitive-behavioral therapy (CBT), FFT, interpersonal and social rhythm therapy (IPSRT), and integrated care management (Strakowski, 2016).

IPSRT is a type of therapy specifically designed for bipolar patients. Developed by Frank (2005), IPSRT focuses on helping clients regulate social rhythms or daily activities such as the sleep–wake cycle and exercise routines that may otherwise disrupt underlying biological rhythms and contribute to mood disturbances. In combination with this strategy, IPSRT also engages principles of interpersonal therapy to help clients address relationship problems.

Group Therapy

Once an acute phase of the illness has passed, groups can provide an atmosphere in which individuals may discuss issues in their lives that cause, maintain, or arise from having a serious affective disorder. Both group psychoeducation and group CBT have demonstrated benefits for this population (Swartz & Swanson, 2014). The element of peer support may provide a feeling of security, as troublesome or embarrassing issues are discussed and resolved. Some groups have other specific purposes, such as helping to monitor medication-related issues or serving as an avenue for promoting education related to the affective disorder and its treatment.

Support groups help members gain a sense of perspective on their condition and tangibly encourage them to connect with others who have common problems. A sense of hope is conveyed when the individual is able to see that he or she is not alone or unique in experiencing affective illness.

Self-help groups offer another avenue of support for the individual with bipolar disorder. These groups are usually peer led and are not meant to substitute for or compete with professional therapy. They offer supplementary support that frequently enhances compliance with the medical regimen. Examples of self-help groups are the Depression and Bipolar Support Alliance (DBSA) and the Child and Adolescent Bipolar Foundation, which put individuals in touch with their local support groups. Although self-help groups are not psychotherapy groups, they do provide important adjunctive support experiences that often have therapeutic benefit for participants.

Family Therapy

The ultimate objectives in working with families of clients with mood disorders are to resolve the symptoms and initiate or restore adaptive family functioning. Some studies with bipolar disorder have shown that behavioral family treatment combined with medication substantially reduces relapse rate compared with medication therapy alone.

Sadock and associates (2015) state:

> Family therapy is indicated if the disorder jeopardizes the patient's marriage or family functioning or if the mood disorder is promoted or maintained by the family situation. Family therapy examines the role of the mood-disordered member in the overall psychological well-being of the whole family; it also examines the role of the entire family in the maintenance of the patient's symptoms. (p. 373)

Family functioning and marital relationships are often disrupted in clients with bipolar disorder, especially when symptoms are contributing to disloyalty in the marriage and to financial problems related to the client's excessive spending behaviors. Whether intervention occurs in the form of family education, support, formal therapy, or a combination of these approaches, it is clear that families need to be involved in treatment whenever possible.

Cognitive Therapy

In cognitive therapy, the individual is taught to control thought distortions that are considered a factor in the development and maintenance of mood disorders. In the cognitive model, depression is characterized by a triad of negative distortions related to expectations of the environment, self, and future. The environment and activities within it are viewed as unsatisfying, the self is unrealistically devalued, and the future is perceived as hopeless. In the same model, mania is characterized by exaggeratedly positive cognitions and perceptions. The individual perceives the self as highly valued and powerful. Life is experienced with overstated self-assurance, and the future is viewed with unrealistic optimism.

The general goals in cognitive therapy are to obtain symptom relief as quickly as possible, assist the client in identifying dysfunctional patterns of thinking and behaving, and guide the client to evidence and logic that effectively tests the validity of the dysfunctional thinking (see Chapter 19, Cognitive Therapy). Therapy focuses on changing "automatic thoughts" that occur spontaneously and contribute to the distorted affect. Examples of automatic thoughts in bipolar mania include the following:

- **Personalizing:** "I'm the only reason my husband is a successful businessman."
- **All or nothing:** "Everything I do is great."
- **Mind reading:** "She thinks I'm wonderful."
- **Discounting negatives:** "None of those mistakes are really important."

The client is asked to describe evidence that both supports and disputes the automatic thought. The logic underlying the inferences is then reviewed with the client. Another technique involves evaluating what would most likely happen if the client's automatic thoughts were true. Implications of the consequences are then discussed.

Clients should not become discouraged if one technique does not seem to be working. No single technique works with all clients. He or she should be reassured that any of a number of techniques may be used, and both therapist and client may explore these possibilities.

The Recovery Model

Research provides support for recovery as an obtainable objective for individuals with bipolar disorder. Conceptual models of recovery from mental illness are presented in Chapter 21, The Recovery Model. The recovery model has been used primarily in caring for individuals with serious mental illness, such as schizophrenia and bipolar disorder. However, concepts of the model can be used with all individuals experiencing emotional conditions that require assistance and who have a desire to take control and manage their lives more independently.

In bipolar disorder, recovery is a continuous process. The individual identifies goals based on personal values or what he or she defines as giving meaning and purpose to life. The clinician and client work together to develop a treatment plan that is in alignment with the goals set forth by the client. In the recovery process, the individual may still be experiencing symptoms. Weiden (2010) states:

> Patients do not have to be in remission, nor does remission automatically have to be a desired (or likely) goal when embarking on a recovery-oriented treatment plan. As long as the patient (and family) understands that a process recovery treatment plan is not to be confused with a promise of "cure" or even "remission," then one does not overpromise.

In the process of recovery, the client and clinician work on strategies to help the individual with bipolar disorder take control of and manage his or her illness. Some of these strategies include the following (Carolla, 2013; National Alliance on Mental Illness [NAMI], 2008):

- Exhibiting self-awareness
- Becoming an expert on the disorder
- Taking medications regularly
- Recognizing earliest symptoms
- Identifying and reducing sources of stress
- Knowing when to seek help
- Developing a personal support system
- Managing lifestyle factors such as sleep time and exercise
- Developing a plan for emergencies

During the process of recovery, individuals actively work on the strategies they have identified to keep themselves well. The clinician serves as a support person to help the individual take the necessary steps to achieve the goals he or she has previously set forth.

Although there is no cure for bipolar disorder, there are effective treatments and interventions. Recovery is possible when the client is empowered and actively engaged in a multifaceted illness management approach.

Electroconvulsive Therapy

Episodes of acute mania are occasionally treated with electroconvulsive therapy (ECT), particularly when the client does not tolerate or fails to respond to lithium or other drug treatment or when life is threatened by dangerous behavior or exhaustion. See Chapter 20, Electroconvulsive Therapy, for a detailed discussion of ECT.

Psychopharmacology With Mood-Stabilizing Agents

For many years, the drug of choice for treatment and management of bipolar mania was lithium carbonate. However, in recent years a number of investigators and clinicians in practice have achieved satisfactory results with other medications, including anticonvulsant drugs that have a mood-stabilizing effect, either alone or in combination with lithium. (See Chapter 4, Psychopharmacology, for a detailed discussion of indications, actions, contraindications, and other safety issues related to mood-stabilizing agents.)

Both lithium and mood stabilizers demonstrate effectiveness in managing bipolar depression. Three products are currently approved by the U.S. Food and Drug Administration (FDA) for that purpose: the combination of olanzapine and fluoxetine, quetiapine, and lurasidone (Strakowski, 2016). Antidepressants have shown little evidence of effectiveness in treating bipolar depression as an adjunct to mood stabilizers. Additionally, Strakowski identifies that antidepressants carry as high as a 40 percent risk of potentially triggering a switch from depression to mania in individuals with bipolar disorder.

Clients who respond to lithium can be virtually symptom free over the long term. About 33 percent of people treated with lithium respond positively (Rybakowski, 2014), so having other pharmacological treatments available is important in the treatment of this illness. Since bipolar disorder is a chronic, episodic illness, most people will remain on medication throughout their lives. See Table 26–3 for a list of commonly used medications in the treatment of bipolar disorder. Lithium, like other medications, has side effects. Most notably, its therapeutic range (0.6–1.2 mEq/L) can have toxic side effects and is potentially fatal when exceeded.

Client and Family Education for Lithium
The client should:

■ Take medication on a regular basis, even when feeling well. Discontinuation can result in return of symptoms.
■ Not drive or operate dangerous machinery until lithium levels are stabilized. Drowsiness and dizziness can occur.
■ Not skimp on dietary sodium intake. He or she should eat a variety of healthy foods and avoid "junk" foods. The client should drink six to eight large glasses of water each day and avoid excessive use of beverages containing caffeine (coffee, tea, colas), which promote increased urine output.
■ Notify the physician if vomiting or diarrhea occurs. These symptoms can result in sodium loss and an increased risk of lithium toxicity.
■ Carry a card or other identification noting that he or she is taking lithium.
■ Be aware of appropriate diet should weight gain become a problem. Include adequate sodium and other nutrients while decreasing number of calories.
■ Be aware of risks of becoming pregnant while receiving lithium therapy. Use information furnished by health-care providers regarding methods of contraception. Notify the physician as soon as possible if pregnancy is suspected or planned.
■ Be aware of side effects and symptoms associated with toxicity. Notify the physician if any of the following symptoms occur: persistent nausea and vomiting, severe diarrhea, ataxia, blurred vision, tinnitus, excessive urine output, increasing tremors, or mental confusion.
■ Refer to written materials furnished by health-care providers while receiving self-administered maintenance therapy. Keep appointments for outpatient follow-up; have serum lithium level checked every 1 to 2 months or as advised by physician.

Client and Family Education for Anticonvulsant Mood Stabilizers
The client should:

■ Refrain from discontinuing the drug abruptly. Physician will administer orders for tapering the drug when therapy is to be discontinued.
■ Report the following symptoms to the physician immediately: skin rash, unusual bleeding, spontaneous bruising, sore throat, fever, malaise, dark urine, and yellow skin or eyes.
■ Not drive or operate dangerous machinery until reaction to the medication has been established.

TABLE 26–3 Mood Stabilizing Agents

CLASSIFICATION: GENERIC (TRADE)	PREGNANCY CATEGORY/ HALF-LIFE/ INDICATIONS	MECHANISM OF ACTION	CONTRAINDICATIONS/ PRECAUTIONS	DAILY ADULT DOSAGE RANGE/ THERAPEUTIC PLASMA RANGE
ANTIMANIC Lithium carbonate (Eskalith, Lithobid)	D/ 24 hr/ Prevention and treatment of manic episodes of bipolar disorder *Unlabeled uses:* ■ Neutropenia ■ Cluster headaches (prophylaxis) ■ Alcohol dependence ■ Bulimia ■ Postpartum affective psychosis ■ Corticosteroid-induced psychosis	Not fully understood but may modulate the effects of various neurotransmitters (e.g., norepinephrine, serotonin, dopamine, glutamate, and GABA) that are thought to play a role in the symptomatology of bipolar disorder (may take 1–3 weeks for symptoms to subside)	Hypersensitivity Cardiac or renal disease, dehydration, sodium depletion, brain damage, pregnancy and lactation Caution with thyroid disorders, diabetes, urinary retention, history of seizures, and the elderly	Acute mania: 1,800–2,400 mg Maintenance: 900–1,200 mg/ Acute mania: 1.0–1.5 mEq/L Maintenance: 0.6–1.2 mEq/L
ANTICONVULSANTS Carbamazepine (Tegretol)	D/ 25–65 hr (initial); 12–17 hr (repeated doses)/ ■ Epilepsy ■ Trigeminal neuralgia *Unlabeled uses:* ■ Bipolar disorder ■ Resistant schizophrenia ■ Management of alcohol withdrawal ■ Restless legs syndrome ■ Postherpetic neuralgia	Action in the treatment of bipolar disorder is unclear	Hypersensitivity With MAOIs, lactation Caution with elderly; liver, renal, cardiac disease; pregnancy	200–1,600 mg/ 4–12 mcg/mL
Clonazepam (Klonopin)	C/ 18–60 hr/ ■ Petit mal, akinetic, and myoclonic seizures ■ Panic disorder *Unlabeled uses:* ■ Acute manic episodes ■ Uncontrolled leg movements during sleep ■ Neuralgias	Action in the treatment of bipolar disorder is unclear	Hypersensitivity, glaucoma, liver disease, lactation Caution in elderly; liver, renal disease; pregnancy	0.5–20 mg/ 0.02–0.08 mcg/mL
Valproic acid (Depakene; Depakote)	D/ 5–20 hr/ ■ Epilepsy ■ Manic episodes ■ Migraine prophylaxis ■ Adjunct therapy in schizophrenia	Action in the treatment of bipolar disorder is unclear	Hypersensitivity, liver disease Caution in elderly; renal, cardiac diseases; pregnancy and lactation	5 mg/kg–60 mg/kg/ 50–150 mcg/mL
Lamotrigine (Lamictal)	C/ ~33 hr/ ■ Epilepsy *Unlabeled use:* ■ Bipolar disorder	Action in the treatment of bipolar disorder is unclear	Hypersensitivity Caution in renal and hepatic insufficiency, pregnancy, lactation, and children <16 years old	100–200 mg/ Not established

Drug	Uses	Action	Contraindications/Precautions	Dose (Adult/Child)
Gabapentin (Neurontin)	C/ 5–7 hr/ ■ Epilepsy ■ Postherpetic neuralgia *Unlabeled uses:* ■ Bipolar disorder ■ Migraine prophylaxis ■ Neuropathic pain ■ Tremors associated with multiple sclerosis	Action in the treatment of bipolar disorder is unclear	Hypersensitivity and children <3 years Caution in renal insufficiency, pregnancy, lactation, children, and the elderly	900–1,800 mg/ Not established
Topiramate (Topamax)	C/ 21 hr/ ■ Epilepsy ■ Migraine prophylaxis *Unlabeled uses:* ■ Bipolar disorder ■ Cluster headaches ■ Bulimia ■ Binge eating disorder ■ Weight loss in obesity	Action in the treatment of bipolar disorder is unclear	Hypersensitivity Caution in renal and hepatic impairment, pregnancy, lactation, children, and the elderly	50–400 mg/ Not established
Oxcarbazepine (Trileptal)	C/ 2–9 hr/ ■ Epilepsy *Unlabeled uses:* ■ Bipolar disorder ■ Diabetic neuropathy ■ Neuralgia	Action in the treatment of bipolar disorder is unclear	Hypersensitivity Caution in renal and hepatic impairment, pregnancy, lactation, children, and the elderly	600–2,400 mg/ Not established
ANTIPSYCHOTICS ALL ANTIPSYCHOTICS:				
Olanzapine (Zyprexa)	C/ 21–54 hr/ ■ Schizophrenia ■ Acute manic episodes ■ Management of bipolar disorder ■ Agitation associated with schizophrenia or mania *Unlabeled uses:* ■ Obsessive-compulsive disorder	Efficacy in schizophrenia is achieved through a combination of dopamine and serotonin type 2 (5HT₂) antagonism. Mechanism of action in the treatment of mania is unknown. Action may be mediated via effects on dopamine and serotonin (5HT2a) receptor antagonism	Hypersensitivity, children, lactation Caution with hepatic or cardiovascular disease, history of seizures, coma or other CNS depression, prostatic hypertrophy, narrow-angle glaucoma, diabetes or risk factors for diabetes, pregnancy, elderly and debilitated patients, history of suicide attempts	10–20 mg/ Not established
Olanzapine and fluoxetine (Symbyax)	C/ (see individual drugs)/ ■ Treatment of depressive episodes associated with bipolar disorder			6/25–12/50 mg/ Not established
Aripiprazole (Abilify)	C/ 50–80 hr/ ■ Bipolar mania ■ Schizophrenia			10–30 mg/ Not established

TABLE 26–3 Mood Stabilizing Agents—cont'd

CLASSIFICATION: GENERIC (TRADE)	PREGNANCY CATEGORY/ HALF-LIFE/ INDICATIONS	MECHANISM OF ACTION	CONTRAINDICATIONS/ PRECAUTIONS	DAILY ADULT DOSAGE RANGE/ THERAPEUTIC PLASMA RANGE
Lurasidone (Latuda)	B/ 18 hr/ ■ Depressive episodes in bipolar I disorder ■ Schizophrenia			20–120 mg/ Not established
Chlorpromazine	C/ 24 hr/ ■ Bipolar mania ■ Schizophrenia ■ Emesis, hiccoughs ■ Acute intermittent porphyria ■ Preoperative apprehension *Unlabeled uses:* ■ Migraine headaches			75–400 mg/ Not established
Quetiapine (Seroquel)	C/ 6 hr/ ■ Schizophrenia ■ Acute manic episodes			100–800 mg/ Not established
Risperidone (Risperdal)	C/ 3–20 hr/ ■ Bipolar mania ■ Schizophrenia *Unlabeled uses:* ■ Severe behavioral problems in children ■ Behavioral problems associated with autism ■ Obsessive-compulsive disorder			1–6 mg/ Not established
Ziprasidone (Geodon)	C/ 7 hr (oral)/ ■ Bipolar mania ■ Schizophrenia ■ Acute agitation in schizophrenia			40–160 mg/ Not established
Asenapine (Saphris)	C/ 24 hr/ ■ Schizophrenia ■ Bipolar mania			10–20 mg/ Not established

■ Avoid consuming alcoholic beverages and non-prescription medications without approval from physician.

■ Carry a card at all times identifying the name of medications being taken.

> **CLINICAL PEARL** The FDA requires that all antiepileptic (anticonvulsant) drugs carry a warning label indicating that use of the drugs increases risk for suicidal thoughts and behaviors. Patients being treated with these medications should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, or any unusual changes in mood or behavior.

Client and Family Education for Calcium Channel Blocker

The client should:

■ Take medication with meals if gastrointestinal upset occurs.

■ Use caution when driving or when operating dangerous machinery. Dizziness, drowsiness, and blurred vision can occur.

■ Refrain from discontinuing the drug abruptly. To do so may precipitate cardiovascular problems. Physician will administer orders for tapering the drug when therapy is to be discontinued.

■ Report occurrence of any of the following symptoms to physician immediately: irregular heartbeat, shortness of breath, swelling of the hands and feet, pronounced dizziness, chest pain, profound mood swings, severe and persistent headache.

■ Rise slowly from a sitting or lying position to prevent a sudden drop in blood pressure.

■ Avoid taking other medications (including over-the-counter medications) without physician's approval.

■ Carry a card at all times describing medications being taken.

Client and Family Education for Antipsychotics

The client should:

■ Use caution when driving or operating dangerous machinery. Drowsiness and dizziness can occur.

■ Refrain from discontinuing the drug abruptly after long-term use. To do so might produce withdrawal symptoms, such as nausea, vomiting, dizziness, gastritis, headache, tachycardia, insomnia, and tremulousness. Physician will administer orders for tapering the drug when therapy is to be discontinued.

■ Use sunblock lotion and wear protective clothing when spending time outdoors. Skin is more susceptible to sunburn, which can occur in as little as 30 minutes.

■ Report the occurrence of any of the following symptoms to the physician immediately: sore throat, fever, malaise, unusual bleeding, easy bruising, persistent nausea and vomiting, severe headache, rapid heart rate, difficulty urinating, muscle twitching, tremors, dark-colored urine, excessive urination, excessive thirst, excessive hunger, weakness, pale stools, yellow skin or eyes, muscular incoordination, or skin rash.

■ Rise slowly from a sitting or lying position to prevent a sudden drop in blood pressure.

■ Take frequent sips of water, chew sugarless gum, or suck on hard candy, if dry mouth is a problem. Good oral care (frequent brushing, flossing) is very important.

■ Consult the physician regarding smoking while on antipsychotic therapy. Smoking increases the metabolism of these drugs, requiring an adjustment in dosage to achieve a therapeutic effect.

■ Dress warmly in cold weather, and avoid extended exposure to very high or low temperatures. Body temperature is harder to maintain with this medication.

■ Avoid drinking alcohol while on antipsychotic therapy. These drugs potentiate each other's effects.

■ Avoid taking other medications (including over-the-counter products) without the physician's approval. Many medications contain substances that interact with antipsychotic medications in a way that may be harmful.

■ Be aware of possible risks of taking antipsychotics during pregnancy. Safe use during pregnancy has not been established. Antipsychotics are thought to readily cross the placental barrier; if so, a fetus could experience adverse effects of the drug. Inform the physician immediately if pregnancy occurs, is suspected, or is planned.

■ Be aware of side effects of antipsychotic medications. Refer to written materials furnished by health-care providers for safe self-administration.

■ Continue to take the medication even if feeling well. Symptoms may return if medication is discontinued.

■ Carry a card or other identification at all times describing medications being taken.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Candace, age 32, recently moved to New York City from Omaha, Nebraska, where she had been working as a television reporter. She felt that Omaha had become "too boring" and wanted to experience the big city life. Candace has a history of bipolar I disorder and has been maintained on lithium since she was 23 years old. Since she arrived in New York City, she has run out of her medication and has not found a doctor to have her prescription renewed. She has been staying in an inexpensive apartment and living on savings. She has been seeking employment in her chosen line of work, but it has been 2 months now, and she has been unable to find a job. She is becoming anxious as her savings have depleted. She has lost weight and has trouble sleeping.

Today, after two failed interviews, Candace went to a bar and began drinking. She ordered several rounds of drinks for everyone in the bar and told the bartender to "put it on my tab." The bartender called the police when Candace refused to pay her tab and became loud and belligerent. He said she began shouting that she knew the mayor, and he was going to help her find a job, and if they didn't leave her alone, she would tell the mayor how they were treating her. She took out her cell phone and said she was calling the mayor. When others in the room began laughing at her, she began cursing and saying that they "would be sorry one day that they laughed at her." When the police arrived, Candace was resistant and had to be physically restrained. The police took Candace to the emergency department of the community hospital, where she was admitted with a diagnosis of Bipolar I Disorder, current episode manic. The psychiatrist ordered olanzapine 10 mg IM STAT, olanzapine 10 mg PO qd, lithium carbonate 600 mg PO bid, and vitamin supplement daily. He ordered lithium level to be drawn prior to first dose of lithium.

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the admitting nurse develops the following nursing diagnoses for Candace:

1. **Risk for self- or other-directed violence** related to manic hyperactivity, delusional thinking, impulsivity
   a. Short-Term Goal:
      - Agitation and hyperactivity will be maintained at manageable level with the administration of tranquilizing medication.
   b. **Long-Term Goal:**
      - Candace will not harm self or others during hospitalization.
2. **Imbalanced nutrition: Less than body requirements** related to lack of appetite and excessive physical agitation, evidenced by loss of weight.
   a. **Short-Term Goal:**
      - Candace will consume sufficient finger foods and between-meal snacks to meet recommended daily allowances of nutrients.
   b. **Long-Term Goal:**
      - Candace will begin to regain weight and exhibit no signs or symptoms of malnutrition.

PLANNING AND IMPLEMENTATION

RISK FOR SELF- OR OTHER-DIRECTED VIOLENCE

The following nursing interventions have been identified for Candace:

1. Place Candace in a private room near the nurse's station. Observe her behavior frequently.
2. Remove all dangerous objects from her environment.
3. Plan some physical activities for Candace (e.g., treadmill, punching bag) and regular rest periods during the day.
4. Administer tranquilizing medication as ordered by physician.
5. Monitor lithium levels three times during first week of therapy. Monitor for signs and symptoms of toxicity (e.g., ataxia, blurred vision, severe diarrhea, persistent nausea and vomiting, tinnitus).
6. Ensure that sufficient staff is available to intervene should Candace become agitated and aggressive.

IMBALANCED NUTRITION: LESS THAN BODY REQUIREMENTS

The following nursing interventions have been identified for Candace:

1. Consult dietitian to determine appropriate diet for Candace to restore nutrition and gain weight. Ensure that her diet includes foods that she particularly likes.
2. Ensure that Candace has access to finger foods and between-meal snacks if she cannot or will not sit still to eat off a meal tray.
3. Maintain an accurate record of intake, output, and calorie count.
4. Obtain daily weights.
5. Administer vitamin supplement, as ordered by physician.
6. Sit with Candace during mealtime.

EVALUATION

The outcome criteria identified for Candace have been met. She has not harmed herself or others in any way. She is able to verbalize names of resources outside the hospital from whom she may request help if needed. With help from the social worker, she has applied for unemployment assistance and will begin receiving help within 2 weeks. She has gained 3 pounds in the hospital and verbalizes understanding of the importance of maintaining good nutrition. She is taking her medication regularly, and has a follow-up appointment with the psychiatric nurse practitioner, who will see Candace biweekly and ensure that she is compliant with medication and laboratory requirements. Candace verbalizes understanding of the importance of taking her medication on a continuous basis. She has a hopeful but realistic attitude about finding work in New York City and states that she will give herself a deadline after which she plans to return to her home in Omaha where she will be near family and friends.

Summary and Key Points

■ Bipolar disorder is manifested by mood swings from profound depression to extreme elation and euphoria.

■ Genetic influences have been strongly implicated in the development of bipolar disorder. Various physiological factors, such as biochemical and electrolyte alterations, as well as cerebral structural changes, have been implicated. Side effects of certain medications may also induce symptoms of mania. No single theory can explain the etiology of bipolar disorder, and it is likely that the illness is caused by a combination of factors.

■ Symptoms of mania may be observed on a continuum of three phases, each identified by the degree of severity: phase I, hypomania; phase II, acute mania; and phase III, delirious mania.

■ The symptoms of bipolar disorder may occur in children and adolescents as well as in adults.

■ Treatment of bipolar disorder includes individual therapy, group and family therapy, cognitive therapy, ECT, and psychopharmacology. For the majority of clients, the most effective treatment appears to be a combination of psychotropic medication and psychosocial therapy.

■ Some clinicians choose a course of therapy based on a model of recovery similar to that used for many years to treat addiction. The basic premise of a recovery model is empowerment of the consumer; it is designed to allow consumers primary control over decisions about their own care and to enable a person with a mental health problem to live a meaningful life in a community of choice while striving to achieve his or her full potential.

■ For many years, the pharmacological treatment of choice for bipolar mania was lithium carbonate. A number of other medications are now being used with satisfactory results, including anticonvulsants and antipsychotics.

■ There is a narrow margin between the therapeutic and toxic levels of lithium. Serum lithium levels must be monitored regularly while on maintenance therapy.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Margaret, a 68-year-old widow, is brought to the emergency department by her sister-in-law. Margaret has a history of bipolar disorder and has been maintained on medication for many years. Her sister-in-law reports that Margaret quit taking her medication a few months ago, thinking she no longer needed it. Margaret is agitated, pacing, demanding, and speaking very loudly. Her sister-in-law reports that Margaret eats very little, is losing weight, and almost never sleeps. "I'm afraid she's going to just collapse!" Margaret is admitted to the psychiatric unit. What is the *priority* nursing diagnosis for Margaret?
   a. Imbalanced nutrition: Less than body requirements related to not eating
   b. Risk for injury related to hyperactivity
   c. Disturbed sleep pattern related to agitation
   d. Ineffective coping related to denial of depression

2. Margaret, age 68, is diagnosed with bipolar I disorder, current episode manic. She is extremely hyperactive and has lost weight. One way to promote adequate nutritional intake for Margaret is to:
   a. Sit with her during meals to ensure that she eats everything on her tray.
   b. Have her sister-in-law bring all her food from home because she knows Margaret's likes and dislikes.
   c. Provide high-calorie, nutritious finger foods and snacks that Margaret can eat "on the run."
   d. Tell Margaret that she will be on room restriction until she starts gaining weight.

3. The physician orders lithium carbonate 600 mg tid for a newly diagnosed client with bipolar I disorder. There is a narrow margin between the therapeutic and toxic levels of lithium. Therapeutic range for *acute* mania is:
   a. 1.0 to 1.5 mEq/L.
   b. 10 to 15 mEq/L.
   c. 0.5 to 1.0 mEq/L.
   d. 5 to 10 mEq/L.

Continued

Review Questions—cont'd
Self-Examination/Learning Exercise

4. Although historically lithium has been the medication of choice for mania, several others have been used with good results. Which of the following are used in the treatment of bipolar disorder? (Select all that apply.)
   a. Olanzapine (Zyprexa)
   b. Oxycodone (OxyContin)
   c. Carbamazepine (Tegretol)
   d. Gabapentin (Neurontin)
   e. Tranylcypromine (Parnate)

5. Margaret, a 68-year-old widow experiencing a manic episode, is admitted to the psychiatric unit after being brought to the emergency department by her sister-in-law. Margaret yells, "My sister-in-law is just jealous of me! She's trying to make it look like I'm insane!" This behavior is an example of:
   a. A delusion of grandeur.
   b. A delusion of persecution.
   c. A delusion of reference.
   d. A delusion of control or influence.

6. What is the most common comorbid condition in children with bipolar disorder?
   a. Schizophrenia
   b. Substance disorders
   c. Oppositional defiant disorder
   d. Attention-deficit/hyperactivity disorder

7. A nurse is educating a client about his lithium therapy and explaining signs and symptoms of lithium toxicity. Which of the following would she instruct the client to be on the alert for?
   a. Fever, sore throat, malaise
   b. Tinnitus, severe diarrhea, ataxia
   c. Occipital headache, palpitations, chest pain
   d. Skin rash, marked rise in blood pressure, bradycardia

8. A client experiencing a manic episode enters the milieu area dressed in a provocative and physically revealing outfit. Which of the following is the most appropriate intervention by the nurse?
   a. Tell the client she cannot wear this outfit while she is in the hospital.
   b. Do nothing, and allow her to learn from the responses of her peers.
   c. Quietly walk with her back to her room and help her change into something more appropriate.
   d. Explain to her that if she wears this outfit, she must remain in her room.

9. The nurse is prioritizing nursing diagnoses in the plan of care for a client experiencing a manic episode. Number the diagnoses in order of the appropriate priority.
   ____ Disturbed sleep pattern evidenced by sleeping only 4 to 5 hours per night
   ____ Risk for injury related to manic hyperactivity
   ____ Impaired social interaction evidenced by manipulation of others
   ____ Imbalanced nutrition: Less than body requirements evidenced by loss of weight and poor skin turgor

10. A child with bipolar disorder also has attention-deficit/hyperactivity disorder (ADHD). How would these comorbid conditions most likely be treated?
   a. No medication would be given for either condition.
   b. Medication would be given for both conditions simultaneously.
   c. The bipolar condition would be stabilized before ADHD medication would be given.
   d. The ADHD would be treated before consideration of the bipolar disorder.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

DESCRIPTION OF THE STUDY: This study sought evidence for efficacy of group psychoeducation versus peer support for patients with bipolar disorder in remission. The participants ($N = 304$) were randomly assigned to one of the two intervention strategies, and efficacy was measured by time from randomization to the next bipolar episode.

RESULTS OF THE STUDY: The researchers found that there was no significant difference in effectiveness between the two interventions. However, in the subset of participants with fewer than eight previous bipolar episodes, psychoeducation did improve outcomes.

IMPLICATIONS FOR NURSING PRACTICE: Both peer support and group psychoeducation demonstrated good outcomes, but as the researchers note, findings suggest that early intervention with group psychoeducation may have important benefits for clients with bipolar disorder. Nurses play an important role both in providing psychoeducation and referring clients for group treatment. Assessing the client's history of bipolar episodes and providing psychoeducation early in the illness process may improve outcomes. Nurses can also play an active role in conducting and participating in similar research to identify which interventions demonstrate the best evidence of positive outcomes. This forms the foundation for evidence-based practice.

TEST YOUR CRITICAL THINKING SKILLS

Alice, age 29, had been working in the typing pool of a large corporation for 6 years. Her immediate supervisor recently retired, and Alice was promoted to supervisor, in charge of 20 people in the department. Alice was flattered by the promotion but anxious about the additional responsibility of the position. Shortly after the promotion, she overheard two of her former coworkers saying, "Why in the world did they choose her? She's not the best one for the job. I know *I* certainly won't be able to respect her as a boss!" Hearing these comments added to Alice's anxiety and self-doubt.

Shortly after Alice began her new duties, her friends and coworkers noticed a change. She had a great deal of energy and worked long hours on her job. She began to speak very loudly and rapidly. Her roommate noticed that Alice slept very little yet seldom appeared tired. Every night she would go out to bars and dances. Sometimes she brought men she had just met home to the apartment, something she had never done before. She bought lots of clothes and makeup and had her hair restyled in a more youthful look. She failed to pay her share of the rent and bills but came home with a brand new convertible. She lost her temper and screamed at her roommate, "Mind your own business!" when asked to pay her share.

She became irritable at work, and several of her subordinates reported her behavior to the corporate manager. When the manager confronted Alice about her behavior, she lost control, shouting, cursing, and striking out at anyone and anything that happened to be within her reach. The security officers restrained her and took her to the emergency department of the hospital, where she was admitted to the psychiatric unit. She had no previous history of psychiatric illness.

The psychiatrist assigned a diagnosis of Bipolar I Disorder and wrote orders for olanzapine (Zyprexa) 10 mg IM STAT, olanzapine 15 mg PO daily, and lithium carbonate 600 mg tid.

Answer the following questions related to Alice:
1. What are the most important considerations for the nurse who is taking care of Alice?
2. Why was Alice given the diagnosis of Bipolar I Disorder?
3. The doctor should order a lithium level drawn after 4 to 6 days. For what symptoms should the nurse be on alert?
4. Why did the physician order olanzapine in addition to the lithium carbonate?

Communication Exercise

1. Bob, a newly admitted client diagnosed with bipolar disorder, states to the nurse, "I was looking at the sky, blue is the color of my eyes, too. I went to Florida on a plane."
   • How might the nurse respond to this client's statement?
2. John, who is in a manic phase of bipolar disorder, is jumping from chair to chair in the patient lounge during visiting hours, loudly proclaiming to the visitors that he is a famous gymnast. He begins doing somersaults, nearly tripping a visitor.
   • How might the nurse respond to the client at this point?

systematic desensitization

OBJECTIVES

After reading this chapter, the student will be able to:

1. Differentiate among stress, anxiety, and fear.
2. Discuss historical aspects and epidemiological statistics related to anxiety, obsessive-compulsive, and related disorders.
3. Differentiate between normal anxiety and psychoneurotic anxiety.
4. Describe types of anxiety, obsessive-compulsive, and related disorders, and identify symptomatology associated with each. Use this information in client assessment.
5. Identify predisposing factors in the development of anxiety, obsessive-compulsive, and related disorders.
6. Formulate nursing diagnoses and outcome criteria for clients with anxiety, obsessive-compulsive, and related disorders.
7. Describe appropriate nursing interventions for behaviors associated with anxiety, obsessive-compulsive, and related disorders.
8. Identify topics for client and family teaching relevant to anxiety, obsessive-compulsive, and related disorders.
9. Evaluate nursing care of clients with anxiety, obsessive-compulsive, and related disorders.
10. Discuss various modalities relevant to treatment of anxiety, obsessive-compulsive, and related disorders.

HOMEWORK ASSIGNMENT

Please read the chapter and answer the following questions:

1. What are the symptoms of a person with agoraphobia?
2. What neurotransmitter has been implicated in the development of obsessive-compulsive disorder?
3. What are some predisposing factors that have been associated with hair-pulling disorder?
4. What is the primary nursing intervention for a person in panic anxiety?

Singer, actor, and producer Barbra Streisand relates her experience of dealing with an anxiety disorder following a performance in which she forgot the lyrics to a song:

> I couldn't come out of it . . . it was shocking to me to forget the words. So I didn't have any sense of humor about it. Some performers do really well when they forget the words. They forget the words all the time but they somehow have humor about it. I remember I didn't have a sense of humor about it. I was quite shocked. I didn't sing and charge people for 27 years because of that night. . . . I was like "God, I don't know. What if I forget the words again?" (ABC News, 2005)

Barbra Streisand, who was diagnosed with social anxiety disorder, has a story similar to that of many others who experience anxiety disorders. The interference with occupational, social, and other areas of functioning can be profound. Streisand has sought therapy and medication and has since returned to performing on stage. Her story highlights not only the impact that anxiety disorders can have on one's functioning but also that treatment can be successful and improve one's quality of life.

CORE CONCEPT

Anxiety
A feeling of discomfort, apprehension, or dread related to anticipation of danger, the source of which is often nonspecific or unknown. Anxiety is considered a disorder (or pathological) when fears and anxieties are excessive (in a cultural context) and there are associated behavioral disturbances such as interference with social and occupational functioning (American Psychiatric Association [APA], 2013).

Individuals face anxiety on a daily basis. Anxiety, which provides the motivation for achievement, is a necessary force for survival. The term *anxiety* is often used interchangeably with the word *stress;* however, they are not the same. Stress, or more properly, a *stressor,* is an external pressure that is brought to bear on the individual. Anxiety is the subjective emotional response to that stressor. (See Chapter 2, Mental Health and Mental Illness: Historical and Theoretical Concepts, for an overview of anxiety as a psychological response to stress.)

Anxiety may be distinguished from *fear* in that anxiety is an emotional process, whereas fear is a cognitive one. Fear involves the intellectual appraisal of a threatening stimulus; anxiety involves the emotional response to that appraisal.

This chapter focuses on disorders that are characterized by exaggerated and often disabling anxiety

reactions. Historical aspects and epidemiological statistics are presented. Predisposing factors that have been implicated in the etiology of the disorders provide a framework for studying the dynamics of phobias, obsessive-compulsive disorders, generalized anxiety disorder, panic disorder, and other anxiety disorders. Various theories of causation are presented, although it is most likely that a combination of factors contribute to the etiology of these disorders. The neurobiology of anxiety disorders is presented in Figure 27–1.

An explanation of the symptomatology is presented as background knowledge for assessing the client with an anxiety or obsessive-compulsive disorder. Nursing care is described in the context of the nursing process. Various treatment modalities are explored.

Historical Aspects

Individuals have experienced anxiety throughout the ages. Yet anxiety, like fear, was not clearly defined or isolated as a separate entity by psychiatrists or psychologists until the 19th and 20th centuries. In fact, what we now know as anxiety was once solely identified by its physiological symptoms, focusing largely on the cardiovascular system. Clinicians used a myriad of diagnostic terms in attempting to identify these symptoms. For example, cardiac neurosis, DaCosta's syndrome, irritable heart, nervous tachycardia, neurocirculatory asthenia, soldier's heart, vasomotor neurosis, and vasoregulatory asthenia are just a few of the names under which anxiety has been concealed over the years (Sadock, Sadock, & Ruiz, 2015).

Freud first introduced the term *anxiety neurosis* in 1895. Freud wrote, "I call this syndrome 'anxiety neurosis' because all its components can be grouped round the chief symptom of anxiety" (Freud, 1959). This notion attempted to negate the previous concept of the problem as strictly physical, although it was some time before physicians of internal medicine were ready to accept psychological implications for the symptoms. In fact, it was not until the years during World War II that the psychological dimensions of various functional heart conditions were recognized.

For many years, anxiety disorders were viewed as purely psychological or purely biological in nature. Researchers now focus on the interrelatedness of mind and body, and anxiety disorders provide an excellent example of this complex relationship. It is likely that various factors, including genetic, developmental, environmental, and psychological, play a role in the etiology of anxiety disorders.

Epidemiological Statistics

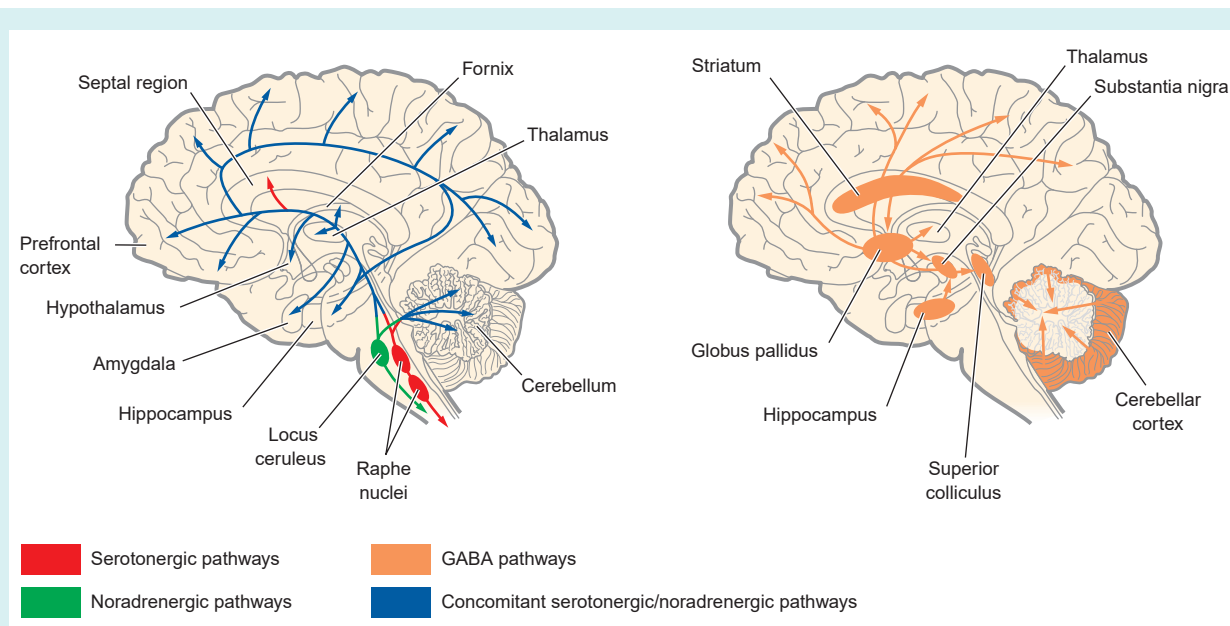
Anxiety disorders are the most common of all psychiatric illnesses and result in considerable functional


FIGURE 27–1   Neurobiology of anxiety disorders.

NEUROTRANSMITTERS

Although other neurotransmitters have also been implicated in the pathophysiology of anxiety disorders, disturbances in serotonin, norepinephrine, and gamma-aminobutyric acid (GABA) appear to be most significant.

Cell bodies of origin for the serotonin pathways lie within the raphe nuclei located in the brainstem. Serotonin is thought to be decreased in anxiety disorders (based on the efficacy of SSRIs in the treatment of anxiety disorders), but some studies suggest that serotonin may have a modulating effect in response to intense emotions in general. Cell bodies for norepinephrine originate in the locus ceruleus. Norepinephrine is thought to be increased in anxiety disorders. GABA is the major inhibitory neurotransmitter in the brain, involved in the reduction and slowing of cellular activity. It is synthesized from glutamic acid, with vitamin B_6 as a cofactor. It is found in almost every region of the brain. GABA is thought to be decreased in anxiety disorders (allowing for increased cellular excitability).

AREAS OF THE BRAIN AFFECTED

Areas of the brain affected by anxiety disorders and the symptoms that they mediate include the following:
• Amygdala: Fear; particularly important in panic and phobic disorders
• Hippocampus: Associated with memory related to fear responses
• Locus ceruleus: Arousal
• Brainstem: Respiratory activation; heart rate
• Hypothalamus: Activation of stress response
• Frontal cortex: Cognitive interpretations
• Thalamus: Integration of sensory stimuli
• Basal ganglia: Tremor

Anxiolytic Agents	Action	Side Effects
Benzodiazepines	Increases the affinity of the GABA$_A$ receptor for GABA	Sedation, dizziness, weakness, ataxia, decreased motor performance, dependence, withdrawal
SSRIs SNRIs	SSRIs: Block reuptake of serotonin into the presynaptic nerve terminal, increasing synaptic concentration of serotonin	SSRIs: Nausea, diarrhea, headache, insomnia, somnolence, sexual dysfunction
	SNRIs: Inhibit reuptake of neuronal serotonin and norepinephrine; mild reuptake of dopamine	SNRIs: Headache, dry mouth, nausea, somnolence, dizziness, insomnia, asthenia, constipation, diarrhea
Noradrenergic Agents (e.g., propranolol, clonidine)	Propranolol: Blocks beta adrenergic receptor activity	Propranolol: Bradycardia, hypotension, weakness, fatigue, impotence, gastrointestinal upset, bronchospasm
	Clonidine: Stimulates alpha-adrenergic receptors	Clonidine: Dry mouth, sedation, fatigue, hypotension
Barbiturates	CNS depression. Also produces effects in the hepatic and cardiovascular systems	Somnolence, agitation, confusion, ataxia, dizziness, bradycardia, hypotension, constipation
Buspirone	Partial agonist of 5-HT$_{1A}$ receptor	Dizziness, drowsiness, dry mouth, headache, nervousness, nausea, insomnia

impairment and distress (Anxiety and Depression Association of America [ADAA], 2016). Statistics vary widely, but most agree that anxiety disorders are more common in women than in men by at least two to one. Prevalence rates (ADAA, 2016) for anxiety disorders within the general population are identified as follows:

Specific phobias	8.7 percent
Social anxiety disorder	6.8 percent
Posttraumatic stress disorder	3.5 percent
Generalized anxiety disorder	3.1 percent
Panic disorder	2.7 percent
Obsessive-compulsive disorder	1 percent

The prevalence for any anxiety disorder is estimated at 18.1 percent for adults and 25.2 percent for children aged 13 to 18 years of age (National Institute of Mental Health [NIMH], 2015). Common comorbidities include another anxiety disorder, depression, and substance abuse. Vulnerability to comorbidities include parental psychiatric history, childhood trauma, and negative life events (Hofmeijer-Sevink et al., 2012), but regardless of the contributing factors, comorbidities are associated with poorer outcomes, higher healthcare utilization, and greater impairment in functioning. Studies of familial patterns suggest that a familial predisposition to anxiety disorders probably exists.

How Much Is Too Much?

Anxiety is usually considered a normal reaction to a realistic danger or threat to biological integrity or self-concept. Normal anxiety dissipates when the danger or threat is no longer present.

It is difficult to draw a precise line between normal and abnormal anxiety. Normality is determined by societal standards; what is considered normal in Chicago, Illinois, may not be so in Cairo, Egypt. There may even be regional differences within a country or cultural differences within a region. So what criteria can be used to determine if an individual's anxious response is normal? Anxiety can be considered abnormal or pathological if

1. It is out of proportion to the situation that is creating it.

EXAMPLE

Mrs. K. witnessed a serious automobile accident 4 weeks ago when she was out driving in her car, and since that time, she refuses to drive even to the grocery store a few miles from her house. When he is available, her husband must take her wherever she needs to go.

2. The anxiety interferes with social, occupational, or other important areas of functioning.

EXAMPLE

Because of the anxiety associated with driving her car, Mrs. K. has been forced to quit her job in a downtown bank for lack of transportation.

It is clear that when anxiety becomes excessive and persistent, humans respond in a variety of ways that are likely a complex interaction of genetic vulnerability, biochemical influences, and environmental factors. Various manifestations of pathological anxiety are discussed in the following section.

Application of the Nursing Process–Assessment

CORE CONCEPT

Panic

A sudden, overwhelming feeling of terror or impending doom. This most severe form of emotional anxiety is usually accompanied by behavioral, cognitive, and physiological signs and symptoms considered extremely intense and frightening.

Panic Disorder

Background Assessment Data

Panic disorder is characterized by recurrent *panic attacks,* the onset of which is unpredictable and manifested by intense apprehension, fear, or terror, often associated with feelings of impending doom (clients often fear they are dying) and accompanied by intense physical discomfort. The physical sensations can be so intense that the individual believes he or she is having a heart attack or other critical illness. The symptoms come on suddenly and unexpectedly; that is, they do not occur immediately before or on exposure to a situation that usually causes anxiety (as in specific phobia). They are not triggered by situations in which the person is the focus of others' attention (as in social anxiety disorder). The role of organic factors in the etiology has been ruled out.

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-*5) (APA, 2013) states that at least four of the following symptoms must be present to identify the presence of a panic attack.

- Palpitations, pounding heart, or accelerated heart rate
- Sweating
- Trembling or shaking
- Sensations of shortness of breath or smothering
- Feelings of choking
- Chest pain or discomfort
- Nausea or abdominal distress
- Feeling dizzy, unsteady, lightheaded, or faint
- Chills or heat sensations

- Paresthesias (numbness or tingling sensations)
- Derealization (feelings of unreality) or depersonalization (feelings of being detached from oneself)
- Fear of losing control or going crazy
- Fear of dying

The attacks usually last minutes or, more rarely, hours. The individual often experiences varying degrees of nervousness and apprehension between attacks. Symptoms of depression are common.

The average age of onset of panic disorder is the late 20s. Frequency and severity of the panic attacks vary widely. Some individuals may have attacks of moderate severity weekly; others may have less severe or limited-symptom attacks several times a week. Still others may experience panic attacks separated by weeks or months. The disorder may last for a few weeks or months or for a number of years. Sometimes the individual experiences periods of remission and exacerbation. Limited-symptom attacks ("fearful spells" that do not meet criteria for panic attacks) may be a risk factor for later panic attacks and panic disorder. Genetic vulnerability, tendency toward negative emotions, history of childhood physical and sexual abuse, and smoking have also been identified as risk factors (APA, 2013).

Generalized Anxiety Disorder

Background Assessment Data

Generalized anxiety disorder (GAD) is characterized by persistent, unrealistic, and excessive anxiety and worry that have occurred more days than not for at least 6 months and cannot be attributed to specific organic factors, such as caffeine intoxication or hyperthyroidism. The anxiety and worry are associated with muscle tension, restlessness, or feeling keyed up or on edge (APA, 2013). These symptoms are like those often associated with anxiety in the general population, but unlike the typical experience of anxiety, the symptoms in generalized anxiety disorder are intense enough to cause clinically significant impairment in social, occupational, or other important areas of functioning. The individual often avoids activities or events that may result in negative outcomes or spends considerable time and effort preparing for such activities. Anxiety and worry often result in procrastination in behavior or decision-making, and the individual repeatedly seeks reassurance from others.

The disorder may begin in childhood or adolescence, but onset is not uncommon after age 20. Depressive symptoms are common, and numerous somatic complaints may also be a part of the clinical picture. GAD tends to be chronic, with frequent stress-related exacerbations and fluctuations in the course of the illness.

Theories of Etiology Related to Panic and Generalized Anxiety Disorders

Psychodynamic Theory

The psychodynamic view focuses on the inability of the ego to intervene when conflict occurs between the id and the superego, producing anxiety. For various reasons (unsatisfactory parent-child relationship; conditional love or provisional gratification), ego development is delayed. When developmental defects in ego functions compromise the capacity to modulate anxiety, the individual resorts to unconscious mechanisms to resolve the conflict. Use of defense mechanisms rather than coping and management skills results in maladaptive responses to anxiety.

Cognitive Theory

The main thesis of the cognitive view is that faulty, distorted, or counterproductive thinking patterns accompany or precede maladaptive behaviors and emotional disorders (Sadock et al., 2015). A disturbance in this central mechanism of cognition results in a consequent disturbance in feeling and behavior. Because of distorted thinking, anxiety is maintained by erroneous or dysfunctional appraisal of a situation. There is a loss of ability to reason regarding the problem, whether it is physical or interpersonal. The individual feels vulnerable in a given situation, and the distorted thinking results in an irrational appraisal, fostering a negative outcome.

Biological Aspects

Research investigations into the psychobiological correlation of panic and generalized anxiety disorders have implicated a number of possibilities.

Genetics Genetic studies have identified variations on specific genes that may be associated with anxiety disorders (including panic disorder and obsessive-compulsive disorder), and some studies suggest that genetic variations may affect the sensitivity of emotional processing centers in the brain (Ressler & Smoller, 2016). Twin studies identify a 30 to 40 percent risk of heritability. But as Ressler and Smoller point out, genetic findings are indicative of risk rather than determinants of illness, and many current genetic studies are ironically teaching us more about the impact of environmental factors in interaction with genes rather than genetic influences alone.

Neuroanatomical Structural brain imaging studies in clients with panic disorder have implicated pathological involvement in the temporal lobes, particularly the hippocampus and the amygdala (Sadock et al., 2015). Dysfunctions in the limbic system (often referred to as "the emotional brain") and the frontal cerebral cortex have also been noted in clients with anxiety disorders.

Biochemical Abnormal elevations of blood lactate have been noted in clients with panic disorder. Likewise, infusion of sodium lactate into clients with anxiety produced symptoms of panic disorder. Studies have suggested that people with panic disorders may be more sensitive to hypercapnia (which increases lactate levels), and carbon dioxide (CO_2) challenge tests have supported this sensitivity (Amaral et al., 2013). Additionally, studies of various medications and treatments such as cognitive-behavioral therapy have demonstrated decreased sensitivity to CO_2 inhalation after treatment, suggesting a relationship between lactate levels and anxiety reduction.

Neurochemical Stronger evidence exists for the involvement of the neurotransmitter norepinephrine in the etiology of panic disorder. Norepinephrine is known to mediate arousal and causes hyperarousal and anxiety. This fact has been demonstrated by a notable increase in anxiety following the administration of drugs that increase the synaptic availability of norepinephrine, such as yohimbine. The neurotransmitters serotonin and gamma aminobutyric acid (GABA) are thought to be decreased in anxiety disorders. These hypotheses are related to the efficacy of benzodiazepines, which enhance the activity of GABA, and the efficacy of selective serotonin reuptake inhibitors (SSRIs), which enhance the activity of serotonin. Similarly, deep-breathing exercises have been shown to elevate thalamic GABA levels through stimulation of vagal nerve pathways with a subsequent reduction in heart rate and improvement in emotional regulation and stress responses (Gerbard & Brown, 2016). Studies of serotonin's function in anxiety disorders have had mixed results (Sadock et al., 2015).

CORE CONCEPT
Phobia

A persistent, intensely felt, and irrational fear of a specific object, activity, or situation that results in a compelling desire to avoid the feared stimulus (Venes, 2014). Responses typically include intense anxiety or panic attacks.

Phobias

Two of the more common phobia disorders include **agoraphobia** and social anxiety disorder (social phobia). Agoraphobia has a 12-month prevalence rate of 0.8 percent, and approximately 40 percent of those cases are considered severe (NIMH, 2015). Social anxiety disorder has a 12-month prevalence rate of 7 percent (APA, 2013).

Agoraphobia
Background Assessment Data

The literal Greek translation of the word *agoraphobia* is "fear of the marketplace." This term defines the fear that some clients have of being in open shops and markets, although it may be more related to fears of being vulnerable and in a less secure environment (Black & Andreasen, 2014). The individual experiences fear of being in places or situations from which escape might be difficult or in which help might not be available in the event that panic symptoms should occur. It is possible that the individual may have experienced the symptom(s) in the past and is preoccupied with fears of their recurrence. The *DSM-5* diagnostic criteria for agoraphobia are presented in Box 27–1.

Onset of symptoms most commonly occurs in the 20s and 30s and persists for many years. It is diagnosed more commonly in women than in men. Impairment can be severe. In extreme cases, the individual is unable to leave his or her home without being accompanied by a friend or relative. If this is not possible, the person may become totally confined to his or her home.

Social Anxiety Disorder (Social Phobia)
Background Assessment Data

Social anxiety disorder is an excessive fear of situations in which a person might do something embarrassing or be evaluated negatively by others. The individual has extreme concerns about being exposed to possible scrutiny by others and fears social or performance situations in which embarrassment may occur (APA, 2013). In some instances, the fear may be quite defined, such as the fear of speaking or eating in a public place, fear of using a public restroom, or fear of writing in the presence of others. In other cases, the social phobia may involve general social situations, such as saying things or answering questions in a manner that would provoke laughter on the part of others. Exposure to the phobic situation usually results in feelings of panic anxiety, with sweating, tachycardia, and dyspnea.

Onset of symptoms of this disorder often begins in late childhood or early adolescence and runs a chronic, sometimes lifelong, course. It appears to be more common in women than in men (Puri & Treasaden, 2011). Impairment interferes with social or occupational functioning and causes marked distress. The *DSM-5* diagnostic criteria for social anxiety disorder are presented in Box 27–2.

Specific Phobia
Background Assessment Data

Specific phobia is identified by fear of specific objects or situations that could conceivably cause harm (e.g., snakes, heights), but the person's reaction to them is excessive, unreasonable, and inappropriate.

BOX 27–1 Diagnostic Criteria for Agoraphobia

A. Marked fear or anxiety about two (or more) of the following five situations:
   1. Using public transportation (e.g., automobiles, buses, trains, ships, planes)
   2. Being in open spaces (e.g., parking lots, marketplaces, bridges)
   3. Being in enclosed places (e.g., shops, theaters, cinemas)
   4. Standing in line or being in a crowd
   5. Being outside of the home alone
B. The individual fears these situations because of thoughts that escape might be difficult or help might not be available in the event of panic-like symptoms or other incapacitating or embarrassing symptoms (e.g., fear of falling in the elderly, fear of incontinence).
C. The agoraphobic situations almost always provoke fear or anxiety.
D. The agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety.
E. The fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context.
F. The fear, anxiety, or avoidance is persistent, typically lasting 6 months or more.
G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.
H. If another medical condition (e.g., inflammatory bowel disease, Parkinson's disease) is present, the fear, anxiety, or avoidance is clearly excessive.
I. The fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder—for example, the symptoms are not confined to specific phobia, situational type; do not involve only social situations (as in social anxiety disorder); and are not related exclusively to obsessions (as in obsessive-compulsive disorder), perceived defects or flaws in physical appearance (as in body dysmorphic disorder), reminders of traumatic events (as in posttraumatic stress disorder), or fear of separation (as in separation anxiety disorder).

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

BOX 27–2 Diagnostic Criteria for Social Anxiety Disorder (Social Phobia)

A. Marked fear or anxiety about one or more social situations in which the individual is exposed to possible scrutiny by others. Examples include social interactions (e.g., having a conversation, meeting unfamiliar people), being observed (e.g., eating or drinking), and performing in front of others (e.g., giving a speech). *Note:* In children, the anxiety must occur in peer settings and not just during interactions with adults.
B. The individual fears that he or she will act in a way or show anxiety symptoms that will be negatively evaluated (i.e., will be humiliating or embarrassing; will lead to rejection or offend others).
C. The social situations almost always provoke fear or anxiety. *Note*: In children, the fear or anxiety may be expressed by crying, tantrums, freezing, clinging, shrinking, or failing to speak in social situations.
D. The social situations are avoided or endured with intense fear or anxiety.
E. The fear or anxiety is out of proportion to the actual threat posed by the social situation and to the sociocultural context.
F. The fear, anxiety, or avoidance is persistent, typically lasting 6 months or more.
G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupation, or other important areas of functioning.
H. The fear, anxiety, or avoidance is not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.
I. The fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder, such as panic disorder, body dysmorphic disorder, or autism spectrum disorder.
J. If another medical condition (e.g., Parkinson's disease, obesity, disfigurement from burns or injury) is present, the fear, anxiety, or avoidance is clearly unrelated or is excessive.

Specify if:
Performance only: If the fear is restricted to speaking or performing in public

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

Specific phobias are often identified when other anxiety disorders have become a focus of clinical attention. Treatment is generally aimed at the primary diagnosis because it usually produces the greatest distress and interferes with functioning more so than does a specific phobia. A diagnosis of specific phobia is made only when the irrational fear restricts the individual's activities and interferes with his or her daily living.

The phobic person may be no more (or less) anxious than anyone else until exposed to the phobic

object or situation. Exposure to the phobic stimulus produces overwhelming symptoms of panic, including palpitations, sweating, dizziness, and difficulty breathing. In fact, these symptoms may occur in response to the individual's merely *thinking* about the phobic stimulus. Invariably, the person recognizes that his or her fear is excessive or unreasonable but is powerless to change, even though the individual may occasionally endure the phobic stimulus when experiencing intense anxiety.

Phobias may begin at almost any age. Those that begin in childhood often disappear without treatment, but those that begin or persist into adulthood usually require assistance with therapy. The disorder is diagnosed more often in women than in men.

Even though the disorder is relatively common among the general population, people seldom seek treatment unless the phobia interferes with ability to function. Obviously, the individual who has a fear of snakes but who lives on the 23rd floor of an urban, high-rise apartment building is not likely to be bothered by the phobia unless he or she decides to move to an area where snakes are prevalent. On the other hand, a fear of elevators may very well interfere with this individual's daily functioning.

Specific phobias are classified according to the phobic stimulus. A list of some of the identified phobias appears in Table 27–1. This list is by no means all-inclusive. People can become phobic about almost any object or situation, and anyone with a little knowledge of Greek or Latin can produce a phobia classification, thereby making possibilities for the list almost infinite.

Theories of Etiology Related to Phobias

The cause of phobias is unknown. However, various theories exist that may offer insight into the etiology.

Psychoanalytic Theory

Freud's classic theory associated phobias with a symbolic displacement of anxiety rooted in castration anxiety. Modern-day psychoanalysts accept this concept of phobic development but believe that castration anxiety is not the sole source of phobias. They believe that other unconscious fears may also be expressed in a symbolic manner as phobias. For example, a female child who was sexually abused by an adult male family friend when he was taking her for a ride in his boat grew up with an intense, irrational fear of all water vessels. Psychoanalytic theory postulates that fear of the man was repressed and displaced onto boats. Boats became an unconscious symbol for the feared person, but one that the young girl viewed as safer because her fear of boats prevented her from having to confront the real fear.

TABLE 27–1 **Classifications of Specific Phobias**	
CLASSIFICATION	FEAR
Acrophobia	Height
Ailurophobia	Cats
Algophobia	Pain
Anthophobia	Flowers
Anthropophobia	People
Aquaphobia	Water
Arachnophobia	Spiders
Astraphobia	Lightning
Belonephobia	Needles
Brontophobia	Thunder
Claustrophobia	Closed spaces
Cynophobia	Dogs
Dementophobia	Insanity
Equinophobia	Horses
Gamophobia	Marriage
Herpetophobia	Lizards, reptiles
Homophobia	Homosexuality
Murophobia	Mice
Mysophobia	Dirt, germs, contamination
Numerophobia	Numbers
Nyctophobia	Darkness
Ochophobia	Riding in a car
Ophidiophobia	Snakes
Pyrophobia	Fire
Scoleciphobia	Worms
Siderodromophobia	Railroads or train travel
Taphophobia	Being buried alive
Thanatophobia	Death
Trichophobia	Hair
Triskaidekaphobia	The number 13
Xenophobia	Strangers
Zoophobia	Animals

Learning Theory

Classic conditioning in the case of phobias may be explained as follows: a stressful stimulus produces an "unconditioned" response of fear. When the stressful stimulus is repeatedly paired with a harmless object, eventually the harmless object alone produces a "conditioned" response: fear. The fear becomes a phobia when the individual consciously avoids the harmless object to escape fear.

Some learning theorists hold that fears are conditioned responses and thus are learned by imposing rewards for certain behaviors. In the instance of phobias, when the individual avoids the phobic object, he or she escapes fear, which is indeed a powerful reward.

Phobias also may be acquired by direct learning or imitation (modeling; e.g., a mother who exhibits fear toward an object will provide a model for the child, who may also develop a phobia of the same object).

Cognitive Theory

Cognitive theorists espouse that anxiety is the product of faulty cognitions or anxiety-inducing self-instructions. Two types of faulty thinking have been investigated: negative self-statements and irrational beliefs. Cognitive theorists believe that some individuals engage in negative and irrational thinking that produces anxiety reactions. The individual begins to seek out avoidance behaviors to prevent the anxiety reactions, and phobias result.

Somewhat related to the cognitive theory is the involvement of locus of control. Johnson and Sarason (1978) suggested that individuals with internal locus of control and those with external locus of control might respond differently to life change. These researchers proposed that locus of control orientation may be an important variable in the development of phobias. Individuals with an external control orientation experiencing anxiety attacks in a stressful period are likely to mislabel the anxiety and attribute it to external sources (e.g., crowded areas) or to a disease (e.g., heart attack). They may perceive the experienced anxiety as outside of their control. Figure 27–2 depicts a graphic model of the relationship between locus of control and the development of phobias.

Biological Aspects

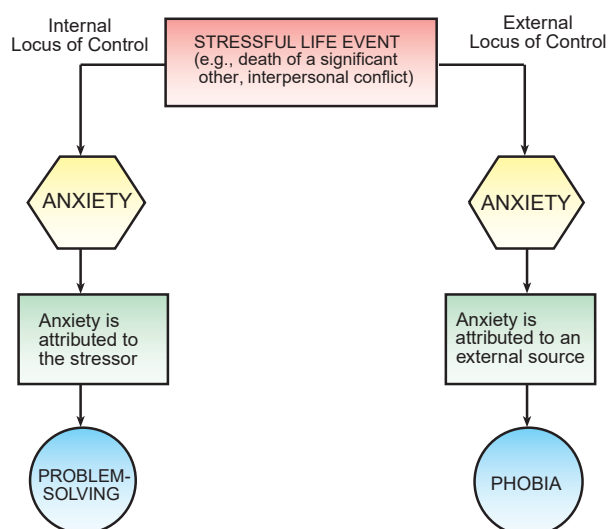
Neuroanatomical Specific areas in the prefrontal cortex and the amygdala play a role in storing and recalling information about threatening or potentially deadly events. Similar future events can trigger those memories, after which the amygdala triggers release of fight-or-flight hormones and the individual experiences heightened stress and fear as though the original threat was happening again (Nordqvist, 2016). Other researchers (Dias & Ressler, 2014) have found


FIGURE 27–2 Locus of control as a variable in the etiology of phobias.

that parental traumatic exposure creates gene "memories" that are passed down to subsequent generations via parental gametes which are then expressed as phobias in their offspring.

Temperament Children experience fears as a part of normal development. Most infants are afraid of loud noises. Common fears of toddlers and preschoolers include strangers, animals, darkness, and fears of being separated from parents or attachment figures. During the school-age years, there is fear of death and anxiety about school achievement. Fears of social rejection and sexual anxieties are common among adolescents.

Innate fears represent a part of the overall characteristics or tendencies one is born with that influence how he or she responds to specific situations. Innate fears usually do not reach phobic intensity but may have the capacity for such development if reinforced by events in later life. For example, a 4-year-old girl is afraid of dogs. By age 5, however, she has overcome her fear and plays with her own dog and the neighbors' dogs without fear. Then, when she is 19, she is bitten by a stray dog and develops a phobia of dogs.

Life Experiences

Certain early experiences may set the stage for phobic reactions later in life. Some researchers believe that phobias, particularly specific phobias, are symbolic of original anxiety-producing objects or situations that have been repressed. For example,

■ A child who is punished by being locked in a closet develops a phobia of elevators or other closed places.
■ A child who falls down a flight of stairs develops a phobia of high places.
■ A young woman who survived a plane crash during childhood in which both her parents were killed has a phobia of airplanes.

Anxiety Disorder Due to Another Medical Condition and Substance/Medication-Induced Anxiety Disorder
Background Assessment Data

The symptoms associated with these disorders are the direct physiological consequence of another medical condition, substance intoxication or withdrawal, or exposure to a medication. A number of medical conditions have been associated with the development of anxiety symptoms. Some of these include cardiac conditions, such as myocardial infarction, congestive heart failure, and mitral valve prolapse; endocrine conditions, such as hypoglycemia, hypo- or hyperthyroidism, and pheochromocytoma; respiratory conditions, such as chronic obstructive pulmonary disease and hyperventilation; and neurological conditions, such as complex partial seizures, neoplasms, and encephalitis.

Nursing care of clients with this disorder must take into consideration the underlying cause of the anxiety. Holistic nursing care is essential to ensure that the client's physiological and psychosocial needs are met. Nursing actions appropriate for the specific medical condition must be considered.

The diagnosis of substance-induced anxiety disorder is made only if the anxiety symptoms are in excess of those usually associated with the intoxication or withdrawal syndrome and warrant independent clinical attention. Evidence of intoxication or withdrawal must be available from history, physical examination, or laboratory findings to substantiate the diagnosis. Substance-induced anxiety disorder may be associated with use of the following substances: alcohol, amphetamines, cocaine, hallucinogen, sedatives, hypnotics, anxiolytics, caffeine, cannabis, or other substances (APA, 2013). Nursing care of the client with substance-induced anxiety disorder must take into consideration the nature of the substance and the context in which the symptoms occur; that is, intoxication or withdrawal.

CORE CONCEPT
Obsessions
Intrusive thoughts that are recurrent and stressful. Although they are recognized by the individual as irrational they continue to be repetitive and cannot be ignored.

CORE CONCEPT
Compulsions
Repetitive ritualistic behaviors or mental acts an individual feels driven to perform which are intended to reduce the anxiety associated with obsessive thoughts (APA, 2013).

Obsessive-Compulsive Disorder
Background Assessment Data

The manifestations of **obsessive-compulsive disorder** (OCD) include the presence of obsessions, compulsions, or both, the severity of which is significant enough to cause distress or impairment in social, occupational, or other important areas of functioning (APA, 2013). The individual recognizes that the behavior is excessive or unreasonable, but because of the feeling of relief from discomfort that it promotes, is compelled to continue the act. Common compulsions include hand washing, ordering, checking, praying, counting, and repeating words silently (APA, 2013).

The disorder is equally common among men and women. It may begin in childhood but more often begins in adolescence or early adulthood. The course is usually chronic and may be complicated by depression or substance abuse. OCD is identified more frequently in single people than in married people, but this finding probably reflects the difficulty that individuals with this disorder have with maintaining interpersonal relationships (Sadock et al., 2015). The *DSM-5* diagnostic criteria for OCD are presented in Box 27–3.

Body Dysmorphic Disorder
Background Assessment Data

Body dysmorphic disorder is characterized by the exaggerated belief that the body is deformed or defective in some specific way. The most common complaints involve imagined or slight flaws of the face or head, such as wrinkles or scars, the shape of the nose, excessive facial hair, and facial asymmetry (Puri & Treasaden, 2011). Other complaints may have to do with some aspect of the ears, eyes, mouth, lips, or teeth. Some clients may present with complaints involving other parts of the body, and in some instances a true defect is present. The significance of the defect is unrealistically exaggerated, however, and the person's concern is grossly excessive. These beliefs are differentiated from delusions in that individuals with body dysmorphic disorder are aware that their beliefs are exaggerated. In some cases, though, people with body dysmorphic disorder also develop psychotic disorders.

People with body dysmorphic disorder often have other comorbid mental disorders. One study found that 90 percent of people with body dysmorphic disorder had major depressive disorder, about 70 percent had an anxiety disorder (often OCD), and 30 percent had experienced a psychotic disorder (Sadock et al., 2015). Social and occupational impairment may occur because of the excessive anxiety experienced by the individual in relation to the imagined defect. The person's medical history may reflect numerous visits

BOX 27–3 Diagnostic Criteria for Obsessive-Compulsive Disorder

A. Presence of obsessions, compulsions, or both:

Obsessions are defined by (1) and (2)

1. Recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress.
2. The individual attempts to ignore or suppress such thoughts, urges, or images, or to neutralize them with some other thought or action (i.e., by performing a compulsion).

Compulsions are defined by (1) and (2):

1. Repetitive behaviors (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the person feels driven to perform in response to an obsession or according to rules that must be applied rigidly.
2. The behaviors or mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviors or mental acts either are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive. *Note:* Young children may not be able to articulate the aims of these behaviors or mental acts.

B. The obsessions or compulsions are time-consuming (e.g., take more than 1 hour a day) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

C. The obsessive-compulsive symptoms are not attributable to the direct physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

D. The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder; preoccupation with appearance, as in body dysmorphic disorder; difficulty discarding or parting with possessions, as in hoarding disorder; hair pulling, as in trichotillomania [hair-pulling disorder]; skin picking, as in excoriation [skin-picking] disorder; stereotypies, as in stereotypic movement disorder; ritualized eating behavior, as in eating disorders; preoccupation with substances or gambling, as in substance-related and addictive disorders; preoccupation with having an illness, as in illness anxiety disorder; sexual urges or fantasies, as in paraphilic disorders; impulses, as in disruptive, impulse-control, and conduct disorders; guilty ruminations, as in major depressive disorder; thought insertion or delusional preoccupations, as in schizophrenia spectrum and other psychotic disorders; or repetitive patterns of behavior, as in autism spectrum disorder).

to plastic surgeons and dermatologists in an unrelenting drive to correct the imagined defect. He or she may undergo unnecessary surgical procedures toward this effort.

The *DSM-5* diagnostic criteria for body dysmorphic disorder are presented in Box 27–4.

Trichotillomania (Hair-Pulling Disorder)

Background Assessment Data

The *DSM*-5 defines this disorder as the recurrent pulling out of one's hair that results in hair loss (APA, 2013). The impulse is preceded by an increasing sense of tension and results in a sense of release or gratification from pulling out the hair. The most common sites for hair pulling are the scalp, eyebrows, and eyelashes, but it may occur in any area of the body on which hair grows. The areas of hair loss are often found on the opposite side of the body from the dominant hand. Pain is seldom reported to accompany the hair pulling, although tingling and pruritus in the area are not uncommon.

Comorbid psychiatric disorders are common with hair-pulling disorder. The most frequent comorbidities include major depressive disorder, GAD, OCD, other impulse control disorders, and substance use disorder (Kaplan, 2012).

The disorder usually begins in childhood and is seven times more prevalent in children (between the ages of 4 and 17) than adults (Yasgur, 2015). It may be accompanied by nail biting, head banging, scratching, biting, or other acts of self-mutilation. This phenomenon occurs more often in women than in men. Studies indicate that it affects about 4 percent of the population (Yasgur, 2015).

Hoarding Disorder

Background Assessment Data

The *DSM*-5 defines the essential feature of **hoarding disorder** as "persistent difficulties discarding or parting with possessions, regardless of their actual value" (APA, 2013, p. 248). Additionally, the diagnosis may be specified as *with excessive acquisition*, which identifies

---

BOX 27–4 Diagnostic Criteria for Body Dysmorphic Disorder

A. Preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear slight to others.

B. At some point during the course of the disorder, the individual has performed repetitive behaviors (e.g., mirror checking, excessive grooming, skin picking, reassurance seeking) or mental acts (e.g., comparing his or her appearance with that of others) in response to the appearance concerns.

C. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

D. The appearance preoccupation is not better explained by concerns with body fat or weight in an individual whose symptoms meet diagnostic criteria for an eating disorder.

---

the excessive need for continual acquiring of items (either by buying them or by other means). In previous editions of the *DSM*, hoarding was considered a symptom of OCD. However, in the *DSM-5,* it has been reclassified as a diagnosable disorder.

Individuals with hoarding disorder collect items until virtually all surfaces within the home are covered. There may be only narrow pathways winding through stacks of clutter. Some individuals also hoard food and animals, keeping dozens or hundreds of pets, often in unsanitary conditions (Mayo Clinic, 2014a).

Hoarding disorder affects an estimated 700,000 to 1.4 million Americans, but few receive adequate treatment (Symonds & Janney, 2013). More men than women are diagnosed with the disorder, and it is almost three times more prevalent in older adults (aged 55–94) than in younger adults (aged 34–44) (APA, 2013). The symptoms, regardless of when they begin, appear to become more severe with each decade of life. Associated symptoms include perfectionism, indecisiveness, anxiety, depression, distractibility, and difficulty planning and organizing tasks (APA, 2013; Symonds & Janney, 2013). In addition to OCD, hoarding is associated with high comorbidity for dependent, avoidant, schizotypal, and paranoid personality disorders (Sadock et al., 2015). Research has shown that hoarding disorder runs in families and there may be a genetic vulnerability.

Treatment of hoarding disorder has been met with mixed results. It is often difficult to convince individuals with the disorder that they are actually ill. Change is slow, and the relapse rate is high; when possessions or animals are taken away, they are often quickly replaced to provide emotional comfort (Mayo Clinic, 2014a). Psychoeducation about the disorder is almost always the initial intervention, and treatment is most commonly a combination of cognitive-behavioral therapy and psychopharmacology with SSRIs. Families and friends may misinterpret hoarding behavior as laziness or uncleanliness. Psychoeducation that includes the client's identified support system assists the client in a recovery plan. Some experts have identified unresolved grief issues as associated with hoarding behavior, which may provide another avenue for psychological intervention.

Theories of Etiology in Obsessive-Compulsive and Related Disorders

Psychoanalytic Theory

Psychoanalytic theorists propose that individuals with OCD have underdeveloped egos (for any of a variety of reasons: unsatisfactory parent-child relationship, conditional love, or provisional gratification). The psychoanalytical concept views clients with OCD as having regressed to earlier developmental stages of the infantile superego—the harsh, exacting, punitive characteristics that now reappear as part of the psychopathology. Regression and use of defense mechanisms (isolation, undoing, displacement, reaction formation) produces the clinical symptoms of obsessions and compulsions (Sadock et al., 2015).

Learning Theory

Learning theorists explain obsessive-compulsive behavior as a conditioned response to a traumatic event. The traumatic event produces anxiety and discomfort, and the individual learns to prevent the anxiety and discomfort by avoiding the situation with which they are associated. This type of learning is called *passive avoidance* (staying away from the source). When passive avoidance is not possible, the individual learns to engage in behaviors that provide relief from the anxiety and discomfort associated with the traumatic situation. This type of learning is called *active avoidance* and describes the behavior pattern of the individual with OCD (Sadock et al., 2015).

According to this classic conditioning interpretation, a traumatic event should mark the beginning of

the obsessive-compulsive behaviors. However, in a significant number of cases, the onset of the behavior is gradual, and the clients relate the onset of their problems to life stress in general rather than to one or more traumatic events.

Psychosocial Influences

The onset of trichotillomania can be related to stressful situations in more than a quarter of cases. Additional factors that have been implicated include disturbances in mother-child relationship, fear of abandonment, and recent object loss. Trichotillomania has at times been connected to childhood trauma, but Woods (as cited by Kaplan, 2012) indicates that only 5 percent of patients have comorbid trichotillomania and post-traumatic stress disorder (PTSD).

Biological Aspects

Genetics Trichotillomania demonstrates a 38 percent heritability in monozygotic twins and no concordance in dizygotic twins. Researchers identify that multiple genes are likely involved in biological vulnerability (Kaplan, 2012). Structural abnormalities in various areas of the brain and alterations in the serotonin and endogenous opioid systems have also been noted.

Genetics also may play a role in the development of hoarding disorder. Family and twin studies indicate that approximately 50 percent of individuals who hoard report having a relative who also hoards (APA, 2013).

Neuroanatomy Recent findings suggest that neurobiological disturbances may play a role in the pathogenesis and maintenance of OCD. Abnormalities in various regions of the brain have been implicated in the neurobiology of OCD. Neuroimaging and neurocognitive assessment have identified an impairment in motor inhibition responses (the ability to stop an action once initiated) in patients with OCD and trichotillomania (Kaplan, 2012). In individuals with hoarding disorder, neuroimaging studies have indicated less activity in the cingulate cortex, the area of the brain that connects the emotional part of the brain with the parts that control higher-level thinking (Saxena, 2013). Yasgur (2015) reports that "animal models and brain imaging studies of patients with trichotillomania suggest abnormalities in neural regions involved in cognition (frontal cortex), affect regulation (amygdala-hippocampal formation), and habit learning (putamen). One study suggests that TTM may be associated with altered reward processing within the central nervous system."

Physiology Electrophysiological studies, sleep electroencephalogram studies, and neuroendocrine studies have suggested that there are commonalities between depressive disorders and OCD (Sadock et al., 2015). Neuroendocrine commonalities were suggested in studies in which about one-third of OCD clients show nonsuppression on the dexamethasone-suppression test and decreased growth hormone secretion with clonidine infusions.

Biochemical Factors A number of studies have implicated the neurotransmitter serotonin as influential in the etiology of obsessive-compulsive behaviors. Drugs that have been used successfully in alleviating the symptoms of OCD are clomipramine and the SSRIs, all of which are believed to block the neuronal reuptake of serotonin, thereby potentiating serotoninergic activity in the central nervous system (see Figure 27–1). The serotonergic system may also be a factor in the etiology of body dysmorphic disorder. This can be reflected in a high incidence of comorbidity with major mood disorder and anxiety disorder and the positive responsiveness of the condition to the serotonin-specific drugs.

Transactional Model of Stress and Adaptation

Anxiety, obsessive-compulsive, and related disorders are most likely caused by multiple factors. In Figure 27–3, a graphic depiction of this theory of multiple causation is presented in the transactional model of stress and adaptation.

Assessment Scales

A number of assessment rating scales are available for measuring severity of anxiety symptoms. Some are meant to be clinician administered, whereas others may be self-administered. Examples of self-rating scales include the Beck Anxiety Inventory and the Zung Self-Rated Anxiety Scale. One of the most widely used clinician-administered scales is the Hamilton Anxiety Rating Scale (HAM-A), which is used in both clinical and research settings. The scale consists of 14 items and measures both psychic and somatic anxiety symptoms (psychological distress and physical complaints associated with anxiety). A copy of the HAM-A is presented in Box 27–5.

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Table 27–2 presents a list of client behaviors and the NANDA International (NANDA-I) nursing diagnoses that correspond to those behaviors, which may be used in planning care for clients with anxiety, obsessive-compulsive, and related disorders.

Outcome Criteria

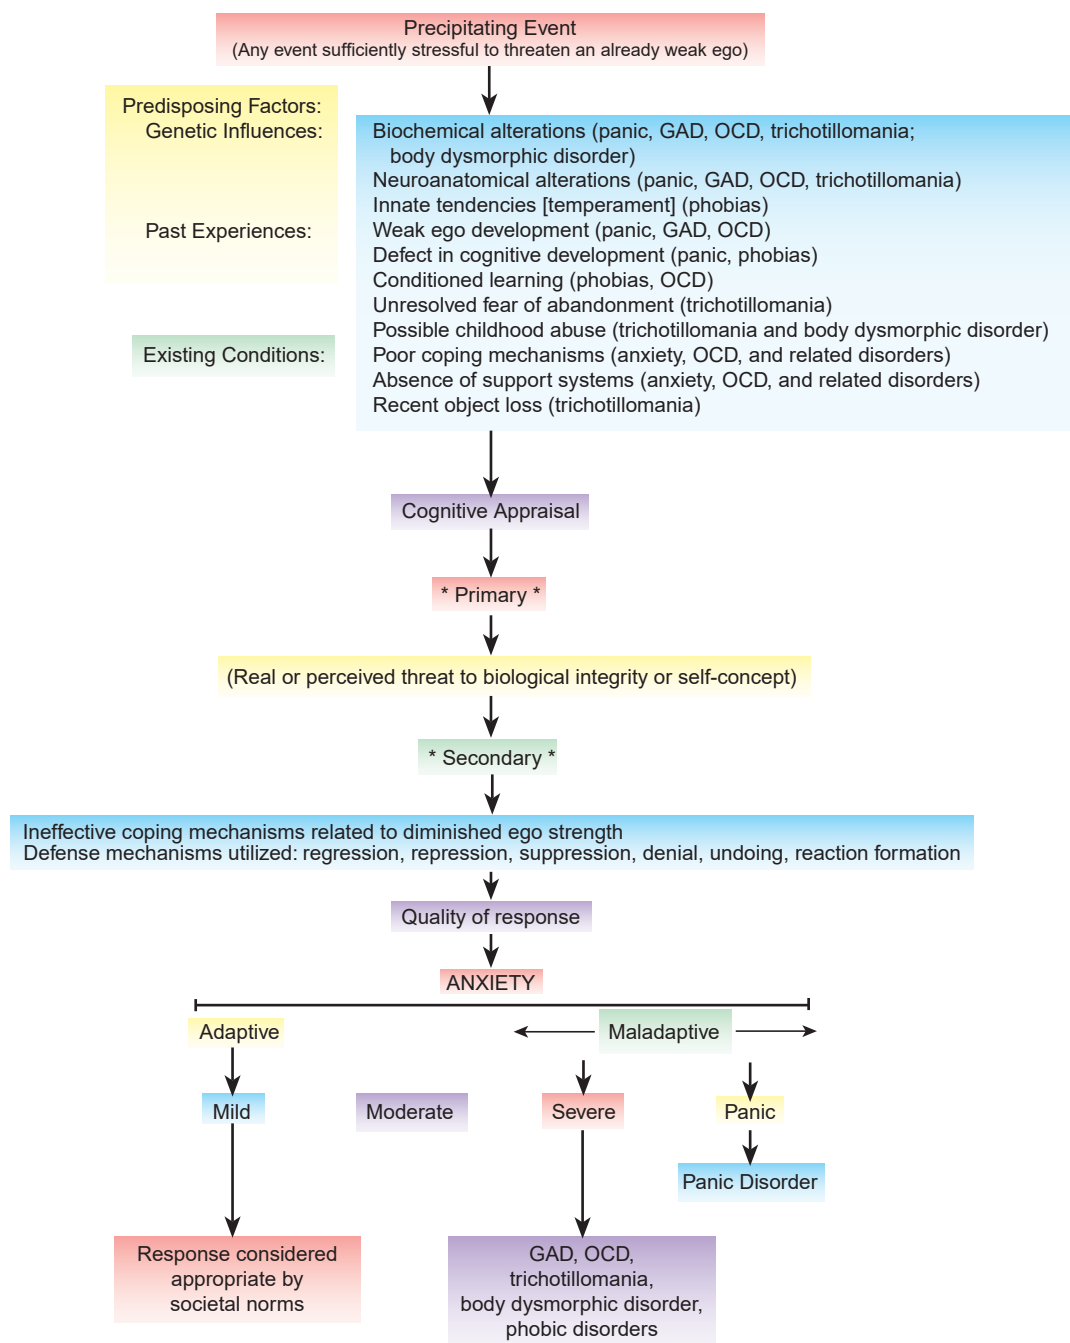
The following criteria may be used for measurement of outcomes in the care of the client with anxiety disorders.


FIGURE 27–3 The dynamics of anxiety, obsessive-compulsive, and related disorders using the transactional model of stress and adaptation.

The client:

■ Is able to recognize signs of escalating anxiety and intervene before reaching panic level *(panic and generalized anxiety disorders)*

■ Is able to maintain anxiety at manageable level and make independent decisions about life situations *(panic and generalized anxiety disorders)*

■ Functions adaptively in the presence of the phobic object or situation without experiencing panic anxiety *(phobic disorder)*

■ Verbalizes a future plan of action for responding in the presence of the phobic object or situation without developing panic anxiety *(phobic disorder)*

■ Is able to maintain anxiety at a manageable level without resorting to the use of ritualistic behavior *(OCD)*

■ Demonstrates more adaptive coping strategies for dealing with anxiety than ritualistic behaviors *(OCD)*

■ Verbalizes a realistic perception of his or her appearance and expresses feelings that reflect a positive body image *(body dysmorphic disorder)*

BOX 27–5 Hamilton Anxiety Rating Scale (HAM-A)

Below are descriptions of symptoms commonly associated with anxiety. Assign the client the rating between 0 and 4 (for each of the 14 items) that best describes the extent to which he/she has these symptoms.

| 0 = Not present | 1 = Mild | 2 = Moderate | 3 = Severe | 4 = Very severe |

Rating

1. **Anxious mood**

   _____
   Worries, anticipation of the worst, fearful anticipation, irritability

2. **Tension**

   _____
   Feelings of tension, fatigability, startle response, moved to tears easily, trembling, feelings of restlessness, inability to relax

3. **Fears**

   _____
   Of dark, of strangers, of being left alone, of animals, of traffic, of crowds

4. **Insomnia**

   _____
   Difficulty in falling asleep, broken sleep, unsatisfying sleep and fatigue on waking, dreams, nightmares, night terrors

5. **Intellectual**

   _____
   Difficulty in concentration, poor memory

6. **Depressed mood**

   _____
   Loss of interest, lack of pleasure in hobbies, depression, early waking, diurnal swing

7. **Somatic (muscular)**

   _____
   Pains and aches, twitching, stiffness, myoclonic jerks, grinding of teeth, unsteady voice, increased muscular tone

Rating

8. **Somatic (sensory)**

   _____
   Tinnitus, blurred vision, hot/cold flushes, feelings of weakness, tingling sensation

9. **Cardiovascular symptoms**

   _____
   Tachycardia, palpitations, pain in chest, throbbing of vessels, feeling faint

10. **Respiratory symptoms**

    _____
    Pressure or constriction in chest, choking feelings, sighing, dyspnea

11. **Gastrointestinal symptoms**

    _____
    Difficulty swallowing, flatulence, abdominal pain and fullness, burning sensations, nausea/vomiting, borborygmi, diarrhea, constipation, weight loss

12. **Genitourinary symptoms**

    _____
    Urinary frequency, urinary urgency, amenorrhea, menorrhagia, loss of libido, premature ejaculation, impotence

13. **Autonomic symptoms**

    _____
    Dry mouth, flushing, pallor, tendency to sweat, giddiness, tension headache,

14. **Behavior at interview**

    _____
    Fidgeting, restlessness or pacing, tremor of hands, furrowed brow, strained face, sighing or rapid respiration, facial pallor, swallowing, clearing throat

Client's Total Score _____

SCORING:

14–17 = Mild anxiety

18–24 = Moderate anxiety

25–30 = Severe anxiety

TABLE 27–2 Assigning Nursing Diagnoses to Behaviors Commonly Associated With Anxiety, Obsessive-Compulsive, and Related Disorders

BEHAVIORS	NURSING DIAGNOSES
Palpitations, trembling, sweating, chest pain, shortness of breath, fear of going crazy, fear of dying (panic disorder); excessive worry, difficulty concentrating, sleep disturbance (generalized anxiety disorder)	Anxiety (severe/panic)
Verbal expressions of having no control over life situation; nonparticipation in decision-making related to own care or life situation; expressions of doubt regarding role performance (panic and generalized anxiety disorders)	Powerlessness

TABLE 27–2 **Assigning Nursing Diagnoses to Behaviors Commonly Associated With Anxiety, Obsessive-Compulsive, and Related Disorders–cont'd**	
BEHAVIORS	**NURSING DIAGNOSES**
Behavior directed toward avoidance of a feared object or situation *(phobic disorder)*	Fear
Stays at home alone, afraid to venture out alone *(agoraphobia)*	Social isolation
Ritualistic behavior; obsessive thoughts, inability to meet basic needs; severe level of anxiety *(OCD)*	Ineffective coping
Inability to fulfill usual patterns of responsibility because of need to perform rituals *(OCD)*	Ineffective role performance
Preoccupation with imagined defect; verbalizations that are out of proportion to any actual physical abnormality that may exist; numerous visits to plastic surgeons or dermatologists seeking relief *(body dysmorphic disorder)*	Disturbed body image
Repetitive and impulsive pulling out of one's hair *(trichotillomania)*	Ineffective impulse control

■ Verbalizes and demonstrates more adaptive strategies for coping with stressful situations *(trichotillomania)*

Planning and Implementation

Care Plan for the Client With Anxiety, OCD, and Related Disorders

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Some institutions use a case management model to coordinate care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing, for more detailed explanation). In case management models, the plan of care may take the form of a critical pathway.

Anxiety (Panic)

Anxiety is defined as a "vague uneasy feeling of discomfort or dread accompanied by an autonomic response (the source often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. It is an alerting signal that warns of impending danger and enables the individual to take measures to deal with threat" (Herdman & Kamitsuru, 2014, p. 323). Table 27–3 presents this nursing diagnosis in care plan format.

Table 27–3	CARE PLAN FOR THE CLIENT WITH ANXIETY, OBSESSIVE-COMPULSIVE, AND RELATED DISORDERS		
NURSING DIAGNOSIS: PANIC ANXIETY		
RELATED TO: Real or perceived threat to biological integrity or self-concept		
EVIDENCED BY: Any or all of the physical symptoms identified by the DSM-5		
OUTCOME CRITERIA	**NURSING INTERVENTIONS**	**RATIONALE**
Short-Term Goal: • The client verbalizes ways to intervene in escalating anxiety within 1 week.	1. Stay with client and offer reassurance of safety and security. Do not leave client in panic anxiety alone.	1. Client may fear for his or her life. Presence of a trusted individual provides a feeling of security and assurance of personal safety.
Long-Term Goal: • By time of discharge from treatment, the client is able to recognize symptoms of onset of	2. Maintain a calm, nonthreatening, matter-of-fact approach.	2. Anxiety is contagious and may be transferred from staff to client or vice versa. Client develops a feeling of security in the presence of a calm staff person.

Table 27–3 | CARE PLAN FOR THE CLIENT WITH ANXIETY, OBSESSIVE-COMPULSIVE, AND RELATED DISORDERS–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
anxiety and intervene before reaching panic level.	3. Use simple words and brief messages, spoken calmly and clearly, to explain hospital experiences.	3. In an intensely anxious situation, client is unable to comprehend anything but the most elemental communication.
	4. Hyperventilation may occur during periods of extreme anxiety. Hyperventilation causes the amount of carbon dioxide in the blood to decrease, possibly resulting in lightheadedness, rapid heart rate, shortness of breath, numbness or tingling in the hands or feet, and syncope. If hyperventilation occurs, assist client to breathe into a small paper bag held over the mouth and nose. Six to 12 natural breaths should be taken, alternating with short periods of diaphragmatic breathing.	4. Hyperventilation may result in injury to client, and client safety is a nursing priority. The technique here should not be used with clients who have coronary or respiratory disorders, such as coronary artery disease, asthma, or chronic obstructive pulmonary disease.
	5. Keep immediate surroundings low in stimuli (dim lighting, few people, simple decor).	5. A stimulating environment may increase level of anxiety.
	6. Administer tranquilizing medication, as ordered by physician. Assess for effectiveness and for side effects.	6. Antianxiety medication provides relief from the immobilizing effects of anxiety.
	7. When level of anxiety has been reduced, explore possible reasons for occurrence.	7. Recognition of precipitating factor(s) is the first step in teaching client to interrupt escalation of anxiety.
	8. Teach signs and symptoms of escalating anxiety, and ways to interrupt its progression (relaxation techniques, such as deep-breathing exercises and meditation, or physical exercise, such as brisk walks and jogging).	8. Relaxation techniques result in a physiological response opposite that of the anxiety response. Physical activities discharge excess energy in a healthful manner.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ The client will verbalize ways to intervene in escalating anxiety within 1 week.

Long-term goal

■ By time of discharge from treatment, the client will be able to recognize symptoms of onset of anxiety and intervene before reaching panic stage.

Interventions

■ Do not leave a client who is experiencing panic anxiety alone. Stay with him or her and offer reassurance of safety and security. At this level of anxiety, clients often express a fear of dying or of "going crazy." They need the presence of and assurance of their safety from a trusted individual.

■ Maintain a calm, nonthreatening, matter-of-fact approach. Anxiety is contagious and can be transferred from staff to client or vice versa. The presence of a calm person provides a feeling of security to an anxious client.

■ Use simple words and brief messages, spoken calmly and clearly, to explain hospital experiences to the client. In an intensely anxious situation, the client is unable to comprehend anything but the most elementary communication.

■ Hyperventilation may occur during periods of extreme anxiety. Hyperventilation causes the amount of CO_2 in the blood to decrease, possibly resulting in lightheadedness, rapid heart rate, shortness of breath, numbness or tingling in the hands or feet, and syncope. If hyperventilation occurs, assist the client to breathe into a small paper bag held over the mouth and nose. Six to 12 natural breaths should be taken, alternating with short periods of diaphragmatic breathing. This technique should not be used with clients who have coronary or respiratory disorders, such as coronary artery disease, asthma, or chronic obstructive pulmonary disease.

■ Keep the immediate surroundings low in stimuli (dim lighting, few people, simple decor). A stimulating environment may increase the level of anxiety.

■ Administer antianxiety medications as ordered by the physician. Assess the medication for effectiveness and for adverse side effects.

■ When the level of anxiety has been reduced, explore with the client possible reasons for its occurrence. If the client is going to learn to interrupt escalating anxiety, he or she must first learn to recognize the factors that precipitate its onset.

■ Teach the client the signs and symptoms of escalating anxiety. Discuss ways to interrupt its progression, such as relaxation techniques, deep-breathing exercises, physical exercises, brisk walks, jogging, and meditation. The client will determine which method is most appropriate for him or her. Relaxation techniques result in a physiological response opposite that of the anxiety response, and physical activities discharge excess energy in a healthful manner.

Fear

Fear is defined as the "response to perceived threat that is consciously recognized as a danger" (Herdman & Kamitsuru, 2014, p. 336).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will discuss the phobic object or situation with the health-care provider within (time specified).

Long-term goal

■ By time of discharge from treatment, client will be able to function in the presence of the phobic object or situation without experiencing panic anxiety.

Interventions

■ Explore the client's perception of threat to physical integrity or threat to self-concept. Reassure the client of his or her safety and security. It is important to understand the client's perception of the phobic object or situation in order to assist with the desensitization process.

■ Discuss the reality of the situation with the client in order to recognize aspects that can be changed and those that cannot. The client must accept the reality of the situation (aspects that cannot change) before the work of reducing the fear can progress. For example, a man who has a fear of flying and whose employment position requires long-distance air travel must accept that he needs to conquer the fear of flying if he is going to stay in this particular job.

■ Include the client in making decisions related to the selection of alternative coping strategies. For example, the client may choose to either avoid the phobic stimulus or attempt to eliminate the fear associated with it. Encouraging the client to make choices promotes feelings of empowerment and serves to increase feelings of self-worth.

■ If the client elects to work on elimination of the fear, the techniques of systematic desensitization or implosion therapy may be employed. (See the explanation of these techniques under "Treatment Modalities" at the end of this chapter.) Systematic desensitization is a plan of behavior modification designed to expose the individual gradually to the situation or object (either in reality or through fantasizing) until the fear is no longer experienced. With implosion therapy the individual is "flooded" with stimuli related to the phobic situation or object (rather than in gradual steps) until anxiety associated with the object or situation is no longer experienced. Fear is decreased as the physical and psychological sensations diminish in response to repeated exposure to the phobic stimulus under nonthreatening conditions.

■ Encourage the client to explore underlying feelings that may be contributing to irrational fears and to face them rather than suppress them. Exploring underlying feelings may help the client confront unresolved conflicts and develop more adaptive coping abilities.

Ineffective Coping

Ineffective coping is defined as the "inability to form a valid appraisal of the stressors, inadequate choices of practiced responses, and/or inability to use available resources" (Herdman & Kamitsuru, 2014, p. 326).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Within 1 week, the client will decrease participation in ritualistic behavior by half.

Long-term goal

■ By the time of discharge from treatment, the client will demonstrate the ability to cope effectively without resorting to obsessive-compulsive behaviors or increased dependency.

Interventions

■ Work with the client to determine the types of situations that increase anxiety and result in ritualistic behaviors. If the client is going to learn to interrupt escalating anxiety, he or she must first learn to recognize the factors that precipitate its onset.

■ Initially meet the client's dependency needs as required. To suddenly and completely eliminate all avenues for dependency would create intense anxiety on the part of the client. Encourage independence and give positive reinforcement for independent behaviors. Positive reinforcement enhances self-esteem and may encourage repetition of the desired behaviors.

■ In the beginning of treatment, allow plenty of time for rituals. Do not be judgmental or verbalize disapproval of the behavior. To deny the client this activity may precipitate panic level of anxiety. Also, low levels of anxiety provide a better foundation for exploring thoughts, feelings, and associated behaviors, and mild anxiety is most beneficial for teaching and learning.

■ Support the client's efforts to explore the meaning and purpose of the behavior. He or she is most likely unaware of the relationship between emotional problems and compulsive behaviors. Knowledge and recognition of this fact is important before change can occur.

■ Provide a structured schedule of activities for the client, including adequate time for the completion of rituals. The anxious individual needs a great deal of structure in his or her life. Assistance is needed with decision-making, and structure provides a sense of security and comfort to deal with activities of daily living.

■ Gradually begin to limit the amount of time allotted for ritualistic behavior as the client becomes more involved in other activities. Anxiety is minimized when the client is able to replace ritualistic behaviors with more adaptive ones. Give positive reinforcement for nonritualistic behaviors.

■ Help the client learn ways to interrupt obsessive thoughts and ritualistic behavior with techniques such as thought-stopping (see Chapter 19, Cognitive Therapy) and relaxation techniques, including physical exercise or other constructive activity with which the client feels comfortable. Knowledge and practice of coping techniques that are more adaptive will help the client change and let go of maladaptive responses to anxiety.

Disturbed Body Image

Disturbed body image is defined as the "confusion in mental picture of one's physical self" (Herdman & Kamitsuru, 2014, p. 275).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will verbalize understanding that changes in bodily structure or function are exaggerated out of proportion to the change that actually exists. (Time frame for this goal must be determined according to individual client's situation.)

Long-term goal

■ Client will verbalize perception of own body that is realistic to actual structure or function by time of discharge from treatment.

Interventions

■ Assess the client's perception of his or her body image. Keep in mind that this image is real to the client even though he or she may recognize it as an exaggeration. Assessment information is necessary in developing an accurate plan of care. Denial of the client's feelings impedes the development of a trusting, therapeutic relationship.

■ Help the client to see that his or her body image is distorted or out of proportion in relation to the significance of an actual physical anomaly. Recognition that a misperception exists is necessary before the client can accept reality and reduce the significance of the imagined defect.

■ Encourage verbalization of fears and anxieties associated with identified stressful life situations. Discuss alternative adaptive coping strategies. Verbalization of feelings with a trusted individual may help the client come to terms with unresolved issues. Knowledge of alternative coping strategies may help the client respond to stress more adaptively in the future.

■ Involve the client in activities that reinforce a positive sense of self not based on appearance. When the client is able to develop self-satisfaction based on accomplishments and unconditional acceptance,

significance of the imagined defect or minor physical anomaly will diminish.

■ Make referrals to support groups of individuals with similar histories (e.g., Adult Children of Alcoholics [ACOA], Victims of Incest, Survivors of Suicide [SOS], Adults Abused as Children).

Ineffective Impulse Control

Ineffective impulse control is defined as "a pattern of performing rapid, unplanned reactions to internal or external stimuli without regard for the negative consequences of these reactions to the impulsive individual or to others" (Herdman & Kamitsuru, 2014, p. 256).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will verbalize adaptive ways to cope with stress by means other than pulling out own hair (time dimension to be individually determined).

Long-term goal

■ Client will be able to demonstrate adaptive coping strategies in response to stress and a discontinuation of pulling out own hair (time dimension to be individually determined).

Interventions

■ Support the client in his or her effort to stop hair pulling. Help the client understand that it is possible to discontinue the behavior. The client realizes that the behavior is maladaptive but feels helpless to stop. Support from the nurse builds trust.

■ Ensure that a nonjudgmental attitude is conveyed and criticism of the behavior is avoided. An attitude of acceptance promotes feelings of dignity and self-worth.

■ Assist the client with **habit reversal training** (HRT), which has been shown to be an effective tool in treatment of hair-pulling disorder. HRT involves three components:

   ■ **Awareness training:** Help the client become aware of times when the hair pulling most often occurs (e.g., the client learns to recognize urges, thoughts, or sensations that precede the behavior; the therapist points out to the client each time the behavior occurs). Awareness helps the client identify situations in which the behavior occurs or is most likely to occur and gives the client a feeling of increased self-control.

   ■ **Competing response training:** In this step, the client learns to substitute another response to the urge to pull his or her hair. For example, when a client experiences a hair-pulling urge, suggest that the individual ball up his or her hands into fists, tightening arm muscles, and "locking" his or her arms so as to make hair pulling impossible at that moment. Substituting an incompatible behavior may help to extinguish the undesirable behavior.

   ■ **Social support:** Encourage family members to participate in the therapy process and offer positive feedback for attempts at habit reversal. Positive feedback enhances self-esteem and increases the client's desire to continue with the therapy. It also provides cues for family members to use in their attempts to help the client in treatment.

■ Once the client has become aware of hair-pulling times, suggest that the client hold something (a ball, paperweight, or other item) in his or her hand at times when hair pulling is anticipated. Occupying the hands can help to prevent behaviors from occurring without the client's awareness.

■ Practice stress management techniques: deep breathing, meditation, stretching, physical exercise, listening to soft music. Hair pulling is thought to occur at times of increased anxiety.

■ Offer support and encouragement when setbacks occur. Help the client to understand the importance of not quitting when it seems that change is not happening as quickly as he or she would like. Although some people see a decrease in the behavior within a few days, most take several months to notice the greatest change.

Concept Care Mapping

The concept map care plan (see Chapter 9) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for the client with an anxiety disorder is presented in Figure 27–4.

Client and Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client and family education relevant to anxiety disorders is presented in Box 27–6.

Evaluation

In the final step of the nursing process, a reassessment is conducted in order to determine if the nursing actions have been successful in achieving the objectives

Clinical Vignette: During her senior year in college, Candice, now age 24, began having panic attacks. All during her college years, she had experienced high anxiety and spent time with a counselor because of severe test anxiety. The college physician prescribed buspirone 15 mg/day, which was helpful and eased some of her symptoms. She married shortly after graduation and works as a Web site designer from her computer at home. She must visit clients in their offices several times a week. Lately, she has started having panic attacks when it is time to make her client visits. She tells the psychiatric nurse practitioner at the mental health clinic, "Just thinking about leaving my house causes me to panic. I have chest pains, I have trouble breathing. I get dizzy, and I feel like I'm going to pass out! My clients are getting upset with me for not keeping my appointments. I don't know what to do!" The nurse develops the following concept map care plan for Candice.

Signs and Symptoms

- Is afraid to leave her home to make client visits

Signs and Symptoms

- Palpitations
- Sweating
- Dyspnea
- Chest pain
- Dizziness
- Paresthesia

Nursing Diagnosis

Fear

Nursing Diagnosis

Panic anxiety

Nursing Actions

- Reassure client of safety.
- Encourage client to verbalize fears.
- Discuss reality of the situation.
- Help client select alternative coping strategies.
- Help client face underlying feelings that may be contributing to irrational fears.

Nursing Actions

- Offer reassurance of safety.
- Remain calm.
- Use simple explanations.
- Ensure low-stimulus environment.
- Provide tranquilizers as ordered.
- Encourage verbalization of current situation.
- Teach ways to interrupt escalating anxiety.

Medical Rx: Alprazolam 0.5 mg tid

Outcomes

- Client discusses phobia without excessive anxiety
- Client is able to leave her home and accomplish role expectations while keeping anxiety at a manageable level

Outcomes

- Client recognizes signs and symptoms of escalating anxiety and intervenes to prevent panic
- Client uses adaptive activities (exercise, relaxation) to maintain anxiety at manageable level

FIGURE 27–4 Concept map care plan for a client with agoraphobia.

of care. Evaluation of the nursing actions for the client with an anxiety, OCD, or related disorder may be facilitated by gathering information utilizing the following types of questions:

- Can the client recognize signs and symptoms of escalating anxiety?

- Can the client use learned skills to interrupt the escalating anxiety before it reaches the panic level?
- Can the client demonstrate the activities (e.g., relaxation techniques, physical exercise) most appropriate for him or her that can be used to maintain anxiety at a manageable level?

BOX 27–6 Topics for Client and Family Education Related to Anxiety, Obsessive-Compulsive, and Related Disorders

NATURE OF THE ILLNESS
1. What is anxiety?
2. To what might it be related?
3. What is OCD?
4. What is body dysmorphic disorder?
5. What is trichotillomania?
6. Symptoms of anxiety disorders.

MANAGEMENT OF THE ILLNESS
1. Medication management:
   - Possible adverse effects
   - Length of time to take effect
   - What to expect from the medication
   a. For panic disorder and generalized anxiety disorder
      (1) Benzodiazepines
      (2) Buspirone (BuSpar)
      (3) Tricyclics
      (4) SSRIs
      (5) SNRIs
      (6) Propranolol
      (7) Clonidine
   b. For phobic disorders
      (1) Benzodiazepines
      (2) Tricyclics
      (3) Propranolol
      (4) SSRIs
   c. For OCD
      (1) SSRIs
      (2) Clomipramine
   d. For body dysmorphic disorder
      (1) Clomipramine
      (2) Fluoxetine
   e. For hair-pulling disorder (trichotillomania)
      (1) Chlorpromazine
      (2) Amitriptyline
      (3) Lithium carbonate
      (4) SSRIs/pimozide
      (5) Olanzapine
2. Stress management
   a. Teach ways to interrupt escalating anxiety
      (1) Relaxation techniques
         (a) Progressive muscle relaxation
         (b) Imagery
         (c) Music
         (d) Meditation
         (e) Yoga
         (f) Physical exercise

SUPPORT SERVICES
1. Crisis hotline
2. Support groups
3. Individual psychotherapy

- Can the client maintain anxiety at a manageable level without medication?
- Can the client verbalize a long-term plan for preventing panic anxiety in the face of a stressful situation?
- Can the client discuss the phobic object or situation without becoming anxious?
- Can the client function in the presence of the phobic object or situation without experiencing panic anxiety?
- Can the OCD client refrain from performing rituals when anxiety level rises?
- Can the OCD client demonstrate substitute behaviors to maintain anxiety at a manageable level?
- Does the OCD client recognize the relationship between escalating anxiety and the dependence on ritualistic behaviors for relief?
- Can the client with trichotillomania refrain from hair pulling?
- Can the client with trichotillomania successfully substitute a more adaptive behavior when urges to pull hair occur?
- Does the client with body dysmorphic disorder verbalize a realistic perception and satisfactory acceptance of personal appearance?

Treatment Modalities

Individual Psychotherapy

Most clients experience a marked lessening of anxiety when given the opportunity to discuss their difficulties with a concerned and sympathetic therapist. Supportive psychotherapy is designed to help clients identify their personal strengths and explore adaptive coping mechanisms. Insight-oriented psychotherapy, which is rooted in Freudian psychology is designed to help clients identify, explore, and resolve internal psychological conflicts that are contributing to anxiety.

The psychotherapist also can use logical and rational explanations to increase the client's understanding about various situations that create anxiety in his or her life. Psychoeducational information may also be presented in individual psychotherapy.

Cognitive Therapy

The cognitive model relates to how individuals respond in stressful situations to their subjective cognitive appraisal of the event. Anxiety is experienced when the cognitive appraisal is one of danger with which the individual perceives that he or she is unable to cope. Impaired cognition can contribute to anxiety and related disorders when the individual's appraisals are chronically negative. Automatic negative appraisals provoke self-doubts, negative evaluations, and negative

predictions. Anxiety is maintained by this dysfunctional appraisal of a situation.

Cognitive therapy strives to assist the individual to reduce anxiety responses by altering cognitive distortions. Anxiety is described as being the result of exaggerated, *automatic* thinking.

Cognitive therapy for anxiety is brief and time-limited, usually lasting from 5 to 20 sessions. Brief therapy discourages the client's dependency on the therapist, which is prevalent in anxiety disorders, and encourages the client's self-sufficiency.

A sound therapeutic relationship is a necessary condition for effective cognitive therapy. For the therapeutic process to occur, the client must be able to talk openly about fears and feelings. A major part of treatment consists of encouraging the client to face frightening situations to be able to view them realistically, and talking about them is one way of achieving this goal. Treatment is a collaborative effort between client and therapist.

Rather than offering suggestions and explanations, the therapist uses questions to encourage the client to correct his or her anxiety-producing thoughts. The client is encouraged to become aware of the thoughts, examine them for cognitive distortions, substitute more balanced thoughts, and eventually develop new patterns of thinking.

Cognitive therapy is very structured and orderly, which is important for the client with an anxiety or related disorder who is often confused and lacks self-assurance. The focus is on solving current problems. Together, the client and therapist work to identify and correct maladaptive thoughts and behaviors that maintain a problem and block its solution.

Cognitive therapy is based on education. The premise is that one develops anxiety because he or she has learned inappropriate ways of thinking about and responding to life experiences. The belief is that, with practice, individuals can learn more effective ways of responding to these experiences through cognitive reframing. Homework assignments, a central feature of cognitive therapy, provide an experimental, problem-solving approach to overcoming long-held anxieties. Through fulfillment of these personal "experiments," the effectiveness of specific strategies and techniques is determined.

Behavior Therapy

Behavior modification has been used to treat trichotillomania. Various techniques have been tried, including covert desensitization and HRT. These may include a system of positive and negative reinforcements in an effort to modify the hair-pulling behaviors. With HRT, in an attempt to extinguish the unwanted behavior, the individual learns to become more aware of the hair pulling, identify times of occurrence, and substitute a more adaptive coping strategy. (See interventions listed under the nursing diagnosis "Ineffective Impulse Control.")

Other forms of behavior therapy include **systematic desensitization** and **implosion therapy,** or **flooding.** They are commonly used to treat clients with phobic disorders and modify the stereotyped behavior of clients with OCD. They have also been shown to be effective in a variety of other anxiety-producing situations.

Systematic Desensitization

In systematic desensitization, the client is gradually exposed to the phobic stimulus in either a real or imagined situation. The concept was introduced by Joseph Wolpe in 1958 and is based on behavioral conditioning principles. Emphasis is placed on reciprocal inhibition or counterconditioning.

Reciprocal inhibition is described as the restriction of anxiety prior to the effort of reducing avoidance behavior. The rationale behind this concept is that because relaxation is antagonistic to anxiety, individuals cannot be anxious and relaxed at the same time.

Systematic desensitization with reciprocal inhibition involves two main elements:

1. Training in relaxation techniques
2. Progressive exposure to a hierarchy of fear stimuli while in the relaxed state

The individual is instructed in the art of relaxation using techniques most effective for him or her (e.g., progressive relaxation, mental imagery, tense and relax, meditation). When the individual has mastered the relaxation technique, exposure to the phobic stimulus is initiated. He or she is asked to present a hierarchal arrangement of situations pertaining to the phobic stimulus in order from most disturbing to least disturbing. While in a state of maximum relaxation, the client may be asked to imagine the phobic stimulus. Initial exposure is focused on a concept of the phobic stimulus that produces the least amount of fear or anxiety. In subsequent sessions, the individual is gradually exposed to stimuli that are more fearful. Sessions may be executed in fantasy, in real-life (in vivo) situations, or sometimes in a combination of both. Following is a case study describing systematic desensitization.

Implosion Therapy (Flooding)

Implosion therapy, or flooding, is a therapeutic process in which the client must imagine, for a prolonged period of time, situations or participate in real-life situations that he or she finds extremely frightening. Relaxation training is not a part of this technique. Plenty of time must be allowed for these sessions because brief periods may be ineffective or even harmful.

CASE STUDY: SYSTEMATIC DESENSITIZATION

Carlos was afraid to ride on elevators. He had been known to climb 24 flights of stairs in an office building to avoid riding the elevator. Carlos's own insurance office had plans for moving the company to a high-rise building soon, with offices on the 32nd floor. Carlos sought assistance from a therapist for help to treat this fear. He was taught to achieve a sense of calmness and well-being by using a combination of mental imagery and progressive relaxation techniques. In the relaxed state, Carlos was initially instructed to imagine the entry level of his office building, with a clear image of the bank of elevators. In subsequent sessions, and always in the relaxed state, Carlos progressed to images of walking onto an elevator, having the elevator door close after he had entered, riding the elevator to the 32nd floor, and emerging from the elevator once the doors were opened. The progression included being accompanied in the activities by the therapist and eventually accomplishing them alone.

Therapy for Carlos also included in vivo sessions in which he was exposed to the phobic stimulus in real-life situations (always after achieving a state of relaxation). This technique, combining imagined and in vivo procedures, proved successful for Carlos, and his employment in the high-rise complex was no longer in jeopardy because of his fear of elevators.

A session is terminated when the client responds with considerably less anxiety than at the beginning of the session.

In implosion therapy, the therapist "floods" the client with information concerning situations that trigger anxiety in him or her. The therapist describes anxiety-provoking situations in vivid detail and is guided by the client's response; the more anxiety provoked, the more expedient is the therapeutic endeavor. The same theme is continued as long as it arouses anxiety. The therapy is continued until a topic no longer elicits inappropriate anxiety on the part of the client. Sadock and associates (2015) state:

> Many patients refuse flooding because of the psychological discomfort involved. It is also contraindicated when intense anxiety would be hazardous to a patient (e.g., those with heart disease or fragile psychological adaptation). The technique works best with specific phobias. (p. 879)

Psychopharmacology
Antianxiety Agents

Antianxiety drugs are also called *anxiolytics* and historically were referred to as *minor tranquilizers*. Antianxiety agents are used in the treatment of anxiety disorders, anxiety symptoms, acute alcohol withdrawal, skeletal muscle spasms, convulsive disorders, status epilepticus, and preoperative sedation. Their use and efficacy for periods greater than 4 months have not been evaluated. Benzodiazepines have been the traditional medication treatment for acute anxiety states and are an important adjunct in treatment because a reduction in anxiety is essential for learning and adaptation. Because these medications are addictive, they are used typically as a short-term intervention. Buspirone and other SSRIs have demonstrated efficacy in treating anxiety disorders as well and are not addictive. (See Chapter 4, Psychopharmacology, for a detailed description of contraindications, precautions, and other safety issues related to this class of drugs.)

Examples of commonly used antianxiety agents are presented in Table 27–4.

Medications for Specific Disorders
For Panic and Generalized Anxiety Disorders

Anxiolytics The benzodiazepines have been used with success in the acute treatment of generalized anxiety disorder. They can be prescribed on an as-needed basis when the client is feeling particularly anxious. Alprazolam, lorazepam, and clonazepam have been particularly effective in the treatment of panic disorder. The major risks with benzodiazepine therapy are physical dependence and tolerance, which may encourage abuse. Because withdrawal symptoms can be life threatening, clients must be warned against abrupt discontinuation of the drug and should be tapered off the medication at the end of therapy. Because of this addiction potential, the benzodiazepines have been surpassed as first-line choice of treatment by the SSRIs, the serotonin and norepinephrine reuptake inhibitors (SNRIs), and buspirone.

The antianxiety agent buspirone is effective in about 60 to 80 percent of clients with generalized anxiety disorder (Sadock et al., 2015). One disadvantage of buspirone is its 10- to 14-day delay in alleviating symptoms. However, the benefit of lack of physical dependence and tolerance with buspirone may make it the drug of choice in the treatment of generalized anxiety disorder.

Antidepressants Several antidepressants are effective as major antianxiety agents. The tricyclics clomipramine and imipramine have been used with success in clients experiencing panic disorder. However, since the advent of SSRIs, the tricyclics are less widely used because of their tendency to produce severe side effects at the high doses required to relieve symptoms of panic disorder.

TABLE 27–4 **Antianxiety Agents**					
CHEMICAL CLASS	GENERIC (TRADE) NAME	CONTROLLED CATEGORIES	PREGNANCY CATEGORIES/ HALF-LIFE (hr)	DAILY ADULT DOSAGE RANGE (mg)	COMMON SIDE EFFECTS OF ANTIANXIETY AGENTS
Antihistamines	Hydroxyzine (Vistaril)		C/ 3	100–400	■ Drowsiness, confusion, lethargy.
Benzodiazepines	Alprazolam (Xanax, Niravam)	CIV	D/ 6.3–26.9	0.75–4	■ Tolerance; physical and psychological dependence (does not apply to buspirone). Client should be tapered off long-term use.
	Chlordiazepoxide (Librium)	CIV	D/ 5–30	15–100	
	Clonazepam (Klonopin)	CIV	D/ 18–50	1.5–20	■ Potentiates the effects of other CNS depressants. Client should not take alcohol or other CNS depressants with the medication.
	Clorazepate (Tranxene)	CIV	D/ 40–50	15–60	
	Diazepam (Valium, Diastat)	CIV	D/ 20–80	4–40	
	Lorazepam (Ativan)	CIV	D/ 10–20	2–6	
	Oxazepam (Serax)	CIV	D/ 5–20	30–120	■ May aggravate symptoms of depression.
	Midazolam (Versed)*	CIV	D/ 2–6 Adults	5 mg	■ Orthostatic hypotension. Client should rise slowly from lying or sitting position.
Carbamate derivative	Meprobamate (Miltown, Equanil)	CIV	D/ 6–17	400–1,600	■ Paradoxical excitement. If symptoms opposite of desired effect occur, notify physician immediately.
Azaspirodecanedione	Buspirone		B/ 14	15–60	■ Dry mouth. ■ Nausea and vomiting. May be taken with food or milk. ■ Blood dyscrasias. Symptoms of sore throat, fever, malaise, easy bruising, or unusual bleeding should be reported to the physician immediately. ■ Delayed onset (with buspirone). Lag time of 10–14 days for anxiety symptoms to diminish with buspirone. Buspirone is not recommended for prn administration.

*Primarily used for preoperative sedation, antianxiety, and conscious sedation.
NOTE: Antidepressants (which are also used in the treatment of anxiety disorders) are listed in Chapter 25, Depressive Disorders.

The SSRIs have been effective in the treatment of panic disorder. Paroxetine, fluoxetine, and sertraline have been approved by the U.S. Food and Drug Administration (FDA) for this purpose. Venlafaxine, an SNRI, is also FDA approved for treatment of panic disorder. Clients with panic disorder appear to be sensitive to treatment with antidepressants, so doses are lower initially and titrated slowly.

SSRIs and SNRIs are first-line treatments for generalized anxiety disorder (Mayo Clinic, 2014b). The FDA has approved paroxetine (Paxil), escitalopram (Lexapro), duloxetine (Cymbalta), and extended-release venlafaxine (Effexor XR) in the treatment of generalized anxiety disorder. Atypical antidepressants such as nefazodone (Serzone) and mirtazapine (Remeron), while not FDA-approved for anxiety disorder treatment, have also been identified as beneficial (Bhatt, 2016).

Antihypertensive Agents Several studies have called attention to the effectiveness of beta blockers (e.g., propranolol) and alpha$_2$-receptor agonists (e.g., clonidine) in the amelioration of anxiety symptoms (Bhatt, 2016). Propranolol has potent effects on the somatic manifestations of anxiety (e.g., palpitations, tremors), with less dramatic effects on the psychic component of anxiety. It appears to be most effective in the treatment of acute situational anxiety (e.g., performance anxiety; test anxiety), but it is not the first-line drug of choice in the treatment of panic disorder and generalized anxiety disorder. Propranolol also demonstrated effectiveness in reducing hyperarousal states for up to 1 week after patients with PTSD had a flashback (Bhatt, 2016).

Clonidine is effective in blocking the acute anxiety effects in conditions such as opioid and nicotine withdrawal. However, it has had limited usefulness in the long-term treatment of panic and generalized anxiety disorders, particularly because of the development of tolerance to its antianxiety effects.

Anticonvulsants Pregabalin (Lyrica), which is a GABA derivative, may have benefits in treating anxiety disorders, but it is a schedule V controlled substance and therefore may pose a risk for dependence or drug diversion (Bhatt, 2016).

For Phobic Disorders

Anxiolytics The benzodiazepines have been successful in the treatment of social anxiety disorder (social phobia). Controlled studies have shown the efficacy of alprazolam and clonazepam in reducing symptoms of social anxiety. Both are well tolerated and have a rapid onset of action. However, because of their potential for abuse and dependence, they are not considered first-line choice of treatment.

Antidepressants The tricyclic imipramine and the monoamine oxidase inhibitor (MAOI) phenelzine have been effective in diminishing symptoms of agoraphobia and social anxiety disorder. In recent years, the SSRIs have become the first-line treatment of choice for social anxiety disorder, and paroxetine and sertraline have been approved for this purpose. Additional clinical trials have indicated efficacy with other antidepressants, including nefazodone, venlafaxine, and bupropion. Specific phobias generally are not treated with medication unless panic attacks accompany the phobia.

Antihypertensive Agents The beta blockers propranolol and atenolol have been tried with success in clients experiencing anticipatory performance anxiety or "stage fright." This type of phobic response produces symptoms such as sweaty palms, racing pulse, trembling hands, dry mouth, labored breathing, nausea, and memory loss. The beta blockers appear to be quite effective in reducing these symptoms in some individuals.

For Obsessive-Compulsive Disorder

Antidepressants The SSRIs fluoxetine (Prozac), paroxetine (Paxil), sertraline (Zoloft), and fluvoxamine (Luvox) have been approved by the FDA for the treatment of OCD. Doses in excess of what is effective for treating depression may be required for OCD. Common side effects include sleep disturbances, headache, and restlessness. These effects are often transient and are less troublesome than those of the tricyclics.

The tricyclic antidepressant clomipramine (Anafranil) was the first drug approved by the FDA in the treatment of OCD. Clomipramine is more selective for serotonin reuptake than any of the other tricyclics. Its efficacy in the treatment of OCD is well established, although the adverse effects, such as those associated with all the tricyclics, may make it less desirable than the SSRIs.

For Body Dysmorphic Disorder

Antidepressants The most positive results of pharmacological therapy with body dysmorphic disorder have been with clomipramine (Anafranil) and fluoxetine (Prozac). These medications have been shown to reduce symptoms in more than 50 percent of clients with the disorder (Sadock et al., 2015).

For Trichotillomania (Hair-Pulling Disorder)

No medications have demonstrated consistent benefits for clients with trichotillomania, but SSRIs have yielded moderate results for some clients with this condition (Elston & Ellis, 2016).

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Stephanie is a 34-year-old mother of a 7-year-old girl named April. Stephanie's husband, Chris, brought her to the emergency department when she began complaining of chest pain and shortness of breath. Diagnostic testing ruled out cardiac problems, and Stephanie was referred for psychiatric evaluation. Chris was present at the admission interview. He explained to the nurse that Stephanie has become increasingly "nervous and high-strung" over the past few years. Four years ago, April, then 3 years old, was attending nursery school 2 days a week. April came down with a very severe case of influenza that developed into pneumonia. She was hospitalized, and her prognosis was questionable for a short while, although she eventually made a complete recovery. Since that time, however, Stephanie has been extremely anxious about her family's health. She is fastidious about housekeeping and scrubs her floors three times a week. She launders the bedclothes daily and uses bleach on all the countertops and door handles several times a day. She washes the woodwork twice a week. She washes her hands incessantly, and they are red and noticeably chapped. Chris explained that Stephanie becomes very upset if she is not able to perform all of her cleaning chores according to her self-assigned schedule. This afternoon, April came home from school with a note from the teacher saying that a child in April's class had been diagnosed with a case of meningitis. Chris told the nurse, "Stephanie just lost it. She got all upset and started crying and had trouble breathing. Then she got those pains in her chest. That's when I brought her to the hospital." Stephanie is admitted to the psychiatric unit with a diagnosis of Obsessive-Compulsive Disorder. The physician orders alprazolam 0.5 mg tid and paroxetine 20 mg every morning.

The night nurse finds her up at 2 a.m. scrubbing the shower with a hand towel. She refuses to sleep in the bed, stating that it must certainly be contaminated. When the day nurse makes morning rounds, she finds Stephanie in the bathroom washing her hands.

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Stephanie:

1. **Panic anxiety** related to perceived threat to biological integrity evidenced by chest pain and shortness of breath.
   a. **Short-Term Goal:** Client will be able to relax with effects of medication.
   b. **Long-Term Goal:** Client will be able to maintain anxiety at manageable level.
2. **Ineffective coping** related to panic anxiety and weak ego strength evidenced by compulsive cleaning and washing hands.
   a. **Short-Term Goal:** Client will reduce amount of time performing rituals within 3 days.
   b. **Long-Term Goal:** Client will demonstrate ability to cope effectively without resorting to ritualistic behavior.

PLANNING AND IMPLEMENTATION

PANIC ANXIETY

The following nursing interventions have been identified for Stephanie:

1. Stay with Stephanie and reassure her that she is safe and that she is not going to die.
2. Maintain a calm, nonthreatening manner.
3. Speak very clearly and calmly, and use simple words and messages.
4. Keep the lights low, the noise level down as much as possible, and as few people in her environment as is necessary.
5. Administer the alprazolam and paroxetine as ordered by the physician. Monitor for effectiveness and side effects.
6. After several days, when the anxiety has subsided, discuss with Stephane the causes that precipitated this attack.
7. Teach her the signs that indicate her anxiety level is rising.
8. Teach strategies that she may employ to interrupt the escalation of the anxiety. She may choose which is best for her: relaxation exercises, physical exercise, meditation.

INEFFECTIVE COPING

The following nursing interventions have been identified for Stephanie:

1. Initially, allow Stephanie all the time she needs to wash her hands, straighten up her room, change her own sheets, and so on. To deny her these rituals would result in panic anxiety.
2. Initiate discussions with Stephanie about her behavior. She ultimately must come to understand that these rituals are her way of keeping her anxiety under control.
3. Within a couple of days, begin to limit the amount of time Stephanie may spend on her rituals. Assign her to groups and activities that take up her time and distract her from her obsessions.
4. Explore with Stephanie the types of situations that cause her anxiety to rise. Help her to correlate these times of increased anxiety to initiation of the ritualistic behavior.
5. Help her with problem-solving and with making decisions about more adaptive ways to respond to situations that cause her anxiety to rise.
6. Explore her fears surrounding the health of her daughter. Help her to recognize which fears are legitimate and which are irrational.
7. Discuss possible activities in which she may participate that may distract from obsessions about contamination. Make suggestions, and encourage her to follow through. Examples may include enrollment in classes at the local community college, volunteer work at the local hospital, or part-time employment.
8. Explain to her that she will likely be discharged from the hospital with a prescription for paroxetine. Teach her about the medication, how it should be taken, possible side effects, and what to report to the physician.
9. Suggest that she may benefit from attendance in an anxiety disorder support group. If she is interested, help locate one that would be convenient and appropriate for her.

Continued

CASE STUDY AND SAMPLE CARE PLAN—cont'd

EVALUATION

The outcome criteria for Stephanie have been met. She has remained calm during her hospital stay with the use of the medication. The use of ritualistic behavior in the hospital setting diminished rapidly. She has discussed situations that she knows cause her anxiety to rise. She has learned relaxation exercises and practices them daily. She plans to start jogging and has the phone number for an anxiety support group that she plans to call. She says that she hopes the support group will help her maintain rationality about her daughter's health. She knows about paroxetine and plans to take it every morning.

Summary and Key Points

- Anxiety is a necessary force for survival and has been experienced by humanity throughout the ages.
- Anxiety was first described as a physiological disorder and identified by its physical symptoms, particularly the cardiac symptoms. The psychological implications for the symptoms were not recognized until the early 1900s.
- Anxiety is considered a normal reaction to a realistic danger or threat to biological integrity or self-concept.
- Normality of the anxiety experienced in response to a stressor is defined by societal and cultural standards.
- Anxiety disorders are more common in women than in men by at least two to one.
- Studies of familial patterns suggest that a familial predisposition to anxiety disorders probably exists.
- The *DSM-5* identifies several broad categories of anxiety and related disorders. They include panic and generalized anxiety disorders, phobic disorders, and OCD and related disorders, such as body dysmorphic disorder and trichotillomania. Anxiety disorders may also be the result of other medical conditions and intoxication or withdrawal from substances.
- Panic disorder is characterized by recurrent panic attacks, the onset of which are unpredictable and manifested by intense apprehension, fear, and physical discomfort.
- Generalized anxiety disorder is characterized by chronic, unrealistic, and excessive anxiety and worry.
- Social anxiety disorder is an excessive fear of situations in which a person might do something embarrassing or be evaluated negatively by others.
- Specific phobia is a marked, persistent, and excessive or unreasonable fear when in the presence of or when anticipating an encounter with a specific object or situation.
- Agoraphobia is a fear of being in places or situations from which escape might be difficult or in which help might not be available in the event that the person becomes anxious.
- OCD involves recurrent obsessions or compulsions that are severe enough to interfere with social and occupational functioning.
- Body dysmorphic disorder is an exaggerated belief that the body is deformed or defective in some specific way.
- Trichotillomania (also known as hair-pulling disorder) is a disorder of impulse characterized by the recurrent pulling out of one's own hair that results in noticeable hair loss.
- Hoarding disorder is defined by the persistent difficulty in discarding or parting with possessions, regardless of their actual value.
- A number of elements, including psychosocial factors, biological influences, and learning experiences, most likely contribute to the development of these disorders.
- Treatment of anxiety and related disorders includes individual psychotherapy, cognitive therapy, behavior therapy (including implosion therapy, systematic desensitization, and HRT), and psychopharmacology.
- Nurses can help clients with anxiety and related disorders gain insight and increase self-awareness in relation to their illness.
- Intervention focuses on assisting clients to learn techniques with which they may interrupt the escalation of anxiety before it reaches unmanageable proportions and to replace maladaptive behavior patterns with new, more adaptive, coping skills.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Ms. T. has been diagnosed with agoraphobia. Which behavior would be most characteristic of this disorder?
   a. Ms. T. experiences panic anxiety when she encounters snakes.
   b. Ms. T. refuses to fly in an airplane.
   c. Ms. T. will not eat in a public place.
   d. Ms. T. stays in her home for fear of being in a place from which she cannot escape.

2. Which of the following is the most appropriate therapy for a client with agoraphobia?
   a. 10 mg Valium qid
   b. Group therapy with other agoraphobics
   c. Facing the fear in gradual step progression
   d. Hypnosis

3. With implosion therapy, a client with phobic anxiety would be:
   a. Taught relaxation exercises.
   b. Subjected to graded intensities of the fear.
   c. Instructed to stop the therapeutic session as soon as anxiety is experienced.
   d. Presented with massive exposure to a variety of stimuli associated with the phobic object or situation.

4. A client with OCD spends many hours each day washing her hands. The most likely reason she washes her hands so much is that it:
   a. Relieves her anxiety.
   b. Reduces the probability of infection.
   c. Gives her a feeling of control over her life.
   d. Increases her self-concept.

5. The *initial* care plan for a client with OCD who washes her hands obsessively would include which of the following nursing interventions?
   a. Keep the client's bathroom locked so she cannot wash her hands all the time.
   b. Structure the client's schedule so that she has plenty of time for washing her hands.
   c. Place the client in isolation until she promises to stop washing her hands so much.
   d. Explain the client's behavior to her, since she is probably unaware that it is maladaptive.

6. A client with OCD says to the nurse, "I've been here 4 days now, and I'm feeling better. I feel comfortable on this unit, and I'm not ill-at-ease with the staff or other patients anymore." In light of this change, which nursing intervention is most appropriate?
   a. Give attention to the ritualistic behaviors each time they occur, and point out their inappropriateness.
   b. Ignore the ritualistic behaviors, and they will be eliminated for lack of reinforcement.
   c. Set limits on the amount of time the client may engage in the ritualistic behavior.
   d. Continue to allow the client all the time she wants to carry out the ritualistic behavior.

7. Annie has trichotillomania. She is receiving treatment at the mental health clinic with habit-reversal therapy. Which of the following elements would be included in this therapy? (Select all that apply.)
   a. Awareness training
   b. Competing response training
   c. Social support
   d. Hypnotherapy
   e. Aversive therapy

Review Questions—cont'd
Self-Examination/Learning Exercise

8. Joselyn is a new patient at the mental health clinic. She has been diagnosed with body dysmorphic disorder. Which of the following medications is the psychiatric nurse practitioner most likely to prescribe for Joselyn?
   a. Alprazolam (Xanax)
   b. Diazepam (Valium)
   c. Fluoxetine (Prozac)
   d. Olanzapine (Zyprexa)

9. A client who is experiencing a panic attack has just arrived at the emergency department. Which is the *priority* nursing intervention for this client?
   a. Stay with the client and reassure of safety.
   b. Administer a dose of diazepam.
   c. Leave the client alone in a quiet room so that she can calm down.
   d. Encourage the client to talk about what triggered the attack.

10. Jareth has a diagnosis of generalized anxiety disorder. His physician has prescribed buspirone 15 mg daily. Jareth says to the nurse, "Why do I have to take this every day? My friend's doctor ordered Xanax for him, and he only takes it when he is feeling anxious." Which of the following would be an appropriate response by the nurse?
    a. "Xanax is not effective for generalized anxiety disorder."
    b. "Buspirone must be taken daily in order to be effective."
    c. "I will ask the doctor if he will change your dose of buspirone to prn so that you don't have to take it every day."
    d. "Your friend really should be taking the Xanax every day."

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Uebelacker, L.A., Weisberg, R., Millman, M., Yen, S., & Keller, M. (2013). Prospective study of risk factors for suicidal behavior in individuals with anxiety disorders. *Psychological Medicine, 43,* 1465-1474. doi:10.1017/50033291712002504

DESCRIPTION OF THE STUDY: Recognizing that there is an increased risk of suicide among people with anxiety disorders, the researchers initiated a prospective study of 676 individuals with a diagnosed anxiety disorder to identify associated factors that might predict an increased incidence of suicide attempts in this population. They studied the sample population for 12 years in an attempt to identify whether specific types of anxiety disorders, comorbid psychiatric disorders, physical health, or social/occupational functioning were associated with future risk of suicide attempts in people with anxiety disorders.

RESULTS OF THE STUDY: As the researchers hypothesized, comorbid posttraumatic stress disorder, major depressive disorder (MDD), intermittent depressive disorder (IDD), epilepsy, pain, and poor social/occupational functioning all predicted a shorter time to a suicide attempt. MDD and IDD were independent predictors of time to a suicide attempt even when they controlled for a past history of suicide attempts. No specific type of anxiety disorder predicted a shorter time to suicide attempts. The researchers conclude that the most powerful predictors of future suicide attempts in this sample of people with anxiety disorders was previous history of suicide attempts and comorbid mood disorders.

IMPLICATIONS FOR NURSING PRACTICE: Suicide is a major health problem in the United States, and the increase in incidence has prompted researchers to explore variables that are most associated with suicide risk. The findings in this study highlight the importance of assessing for symptoms of depression and suicidal ideation in individuals with anxiety disorders. (See Chapter 17, Suicide Prevention, for a more thorough discussion of current assessment tools and interventions associated with risks for suicide.) Current research on the topic of suicide is rapidly expanding the evidence base related to this health concern, so nurses in any practice setting need to remain informed of the latest research to improve safety and quality care for this population.

TEST YOUR CRITICAL THINKING SKILLS

Sarah, age 25, was taken to the emergency department by her friends. They were at a dinner party when Sarah suddenly clasped her chest and started having difficulty breathing. She complained of nausea and was perspiring profusely. She had calmed down some by the time they reached the hospital. She denied any pain, and electrocardiogram and laboratory results were unremarkable.

Sarah told the admitting nurse that she had a history of these "attacks." She began having them in her sophomore year of college. She knew her parents had expectations that she should follow in their footsteps and become an attorney. They also expected her to earn grades that would promote acceptance by a top Ivy League university. Sarah experienced her first attack when she made a B in English during her third semester of college. Since that time, she has experienced these symptoms sporadically, often in conjunction with her perception of the need to excel. She graduated with top honors from Harvard.

Last week, Sarah was promoted within her law firm. She was assigned her first solo case of representing a couple whose baby had died at birth and who were suing the physician for malpractice. She has experienced these panic symptoms daily for the past week, stating, "I feel like I'm going crazy!"

Sarah is transferred to the psychiatric unit. The psychiatrist diagnoses panic disorder.

Answer the following questions related to Sarah:

1. What would be the priority nursing diagnosis for Sarah?
2. What is the priority nursing intervention with Sarah?
3. What medical treatment might you expect the physician to prescribe?

Communication Exercises

1. John, who was just admitted to the psychiatric unit with panic disorder, approaches the nurse with complaints of numbness in his fingers and shortness of breath.
   • What would be some appropriate responses by the nurse?
2. After attending a group that discussed irrational thinking patterns, John asks the nurse, "How does this cognitive behavior therapy work?"
   • What would be some appropriate responses to John's question?

🎬 MOVIE CONNECTIONS

As Good As It Gets (OCD) • *The Aviator* (OCD) • *What About Bob?* (phobias) • *Copycat* (agoraphobia) • *Analyze This* (panic disorder) • *Vertigo* (specific phobia)

Trauma- and Stressor-Related Disorders

28

CORE CONCEPTS

Stress
Trauma

KEY TERMS

acute stress disorder   adjustment disorder   posttraumatic stress disorder

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss historical aspects and epidemiological statistics related to trauma- and stressor-related disorders.
2. Describe various types of trauma- and stressor-related disorders and identify symptomatology associated with each; use this information in client assessment.
3. Identify predisposing factors in the development of trauma- and stressor-related disorders.

4. Formulate nursing diagnoses and goals of care for clients with trauma- and stressor-related disorders.
5. Describe appropriate nursing interventions for behaviors associated with trauma- and stressor-related disorders.
6. Evaluate the nursing care of clients with trauma- and stressor-related disorders.
7. Discuss various modalities relevant to treatment of trauma- and stressor-related disorders.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What two variables are considered to be the best predictors of posttraumatic stress disorder (PTSD) according to the psychosocial theory?
2. What is associated with the onset of an adjustment disorder?

3. What are the elements that determine one's response (and subsequent adjustment) to a stressful situation?
4. What agents are considered first-line psychopharmacological treatment for PTSD?

In 2011, a massive earthquake and tsunami claimed the lives of thousands and destroyed communities in eastern Japan. Yuri Sato, a public health nurse charged with helping survivors, shares her courageous experience (Frances, 2015):

> As public health nurses, our immediate task was to treat the injured and sick; collect and dispense medicines; and respond to the desperate conditions of the townspeople. We launched and managed an aid station and

a welfare evacuation site for those in need of urgent nursing care; established countermeasures against infectious disorders; and arranged for emergency food supplies and sanitation. . . .With the entire town disaster-stricken, I was overcome with a sense of doubt and anxiety. Questions continually spun around in my mind: "What is mental health care when all of us have suffered so greatly?" But with everyone in mourning, we were single-mindedly focused on not losing any more lives to suicide or accident. . . . People continued

to be unable to accept the deaths of family members, relatives and friends—and the fact that so many were still missing. I often heard "I should have died," "Why did I survive?" or "I want my time to come soon." I also felt this way, but had too much work to do to linger on my own losses and feelings about them.

Traumas such as these test the very fiber of our human spirit and emotional well-being. Anyone hearing Ms. Sato's recollections would agree that the events were (and are) painfully traumatic. For some, the stress associated with trauma continues to cause enduring, significant distress and interference with their ability to function. This leads to conditions called trauma and stressor-related disorders.

The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* (American Psychiatric Association [APA], 2000) classified **posttraumatic stress disorder** (PTSD) and **acute stress disorder** with anxiety disorders. **Adjustment disorder** carried its own classification and was identified as "a psychological response to an identifiable stressor or stressors" (APA, 2000, p. 679). In the *DSM-5* (APA, 2013), these disorders have been combined into a single chapter, Trauma- and Stressor-Related Disorders. This reclassification "reflects increased recognition of trauma as a precipitant, emphasizing common etiology over common phenomenology" (Friedman et al., 2011, p. 737).

This chapter focuses on disorders that occur following exposure to an identifiable stressor or an extreme traumatic event. Epidemiological statistics are presented, and predisposing factors associated with the etiology of these disorders are discussed. An explanation of the symptomatology is presented as background knowledge for assessing clients with trauma- and stressor-related disorders. Nursing care is described in the context of the nursing process. Various treatment modalities are explored.

Historical and Epidemiological Data

The concept of a posttrauma response has been referred to as *shell shock, battle fatigue, accident neurosis,* and *posttraumatic neurosis.* Reports of symptoms and syndromes with PTSD-like features have existed in writing throughout the centuries. In the early part of the 20th century, traumatic neurosis was viewed as the ego's inability to master the degree of disorganization brought about by a traumatic experience. Very little was written about posttraumatic neurosis between 1950 and 1970. This absence was followed in the 1970s and 1980s with expansive research and writing on the subject. Many of the papers written during this time were about Vietnam veterans. Clearly, the renewed interest in PTSD was linked to the psychological casualties of the Vietnam War.

The diagnostic category of PTSD did not appear until the third edition of the *DSM* in 1980, after a need

was indicated by increasing numbers of problems with Vietnam veterans and victims of multiple disasters. The *DSM-IV-TR* (2000) described the trauma that precedes PTSD as an event that is outside the range of usual human experience, such as rape, war, physical attack, torture, or natural or manmade disaster.

About 60 percent of men and 50 percent of women are exposed to a traumatic event in their lifetimes (Department of Veterans Affairs, 2016). Women are more likely to experience sexual assault and childhood sexual abuse, whereas men are more likely to experience accidents, physical assaults, combat, or proximity to death or injury. Although the prevalence of trauma exposure is high, less than 10 percent of trauma victims develop PTSD. The disorder appears to be more common in women than in men.

Historically, as previously stated, individuals who experienced stress reactions that followed exposure to an extreme traumatic event were given the diagnosis of PTSD. Accordingly, stress reactions from "normal" daily events (e.g., divorce, failure, rejection) were characterized as adjustment disorders (Friedman, 1996).

A number of studies have indicated that adjustment disorders are probably quite common. Sadock, Sadock, and Ruiz, (2015) report:

> Adjustment disorders are one of the most common psychiatric diagnoses for disorders of patients hospitalized for medical and surgical problems. In one study, 5 percent of people admitted to a hospital over a 3-year period were classified as having an adjustment disorder. Up to 50 percent of people with specific medical problems or stressors have been diagnosed with adjustment disorders. (p. 446)

Adjustment disorders are more common in women, unmarried persons, and adolescents (Black & Andreasen, 2014). It can occur at any age, from childhood to senescence.

Application of the Nursing Process— Trauma-Related Disorders

CORE CONCEPT

Trauma

An extremely distressing experience that causes severe emotional shock and may have long-lasting psychological effects.

Posttraumatic Stress Disorder and Acute Stress Disorder

Background Assessment Data

Puri and Treasaden (2011) describe PTSD as "a reaction to an extreme trauma, which is likely to cause pervasive distress to almost anyone, such as natural or

man-made disasters, combat, serious accidents, witnessing the violent death of others, being the victim of torture, terrorism, rape, or other crimes" (p. 197). These symptoms are not related to common experiences such as uncomplicated bereavement, marital conflict, or chronic illness but are associated with events that would be markedly distressing to almost anyone. The individual may experience the trauma alone or in the presence of others.

Characteristic symptoms include reexperiencing the traumatic event, a sustained high level of anxiety or arousal, or a general numbing of responsiveness. Intrusive recollections or nightmares of the event are common. Some individuals may be unable to remember certain aspects of the trauma.

Symptoms of depression are common with this disorder and may be severe enough to warrant a diagnosis of a depressive disorder in addition to PTSD. In the case of a life-threatening trauma shared with others, survivors often describe painful guilt feelings about

surviving when others lost their lives. They may also express trauma and guilt feelings about the things they had to do to survive. Substance abuse, anger and aggressive behavior, and relationship problems are common. The full symptom picture must be present for more than 1 month and cause significant interference with social, occupational, and other areas of functioning. The disorder can occur at any age. Symptoms may begin within the first 3 months after the trauma, or there may be a delay of several months or even years. The *DSM-5* diagnostic criteria for PTSD are presented in Box 28–1.

The *DSM-5* describes a disorder similar to PTSD called *acute stress disorder (ASD)*. There are similarities between the two disorders in terms of precipitating traumatic events and symptomatology, but in ASD the symptoms are time-limited, lasting up to 1 month following the trauma. By definition, if the symptoms last longer than 1 month, the diagnosis would be PTSD. The *DSM-5* diagnostic criteria for ASD are presented in Box 28–2.

BOX 28–1 Diagnostic Criteria for Posttraumatic Stress Disorder

Note: The following criteria apply to adults, adolescents, and children older than 6 years.

A. Exposure to actual or threatened death, serious injury, or sexual violence, in one (or more) of the following ways:
1. Directly experiencing the traumatic event(s).
2. Witnessing, in person, the event(s) as it occurred to others.
3. Learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental.
4. Experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g., first responders collecting human remains; police officers repeatedly exposed to details of child abuse). *Note:* Criterion A4 does not apply to exposure through electronic media, television, movies, or pictures, unless this exposure is work-related.

B. Presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:
1. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s) *Note*: In children older than 6 years, repetitive play may occur in which themes or aspects of the traumatic event(s) are expressed.
2. Recurrent distressing dreams in which the content and/or affect of the dream is related to the traumatic event(s). *Note*: In children, there may be frightening dreams without recognizable content.
3. Dissociative reactions (e.g., flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the most extreme expression being a complete loss of

awareness of present surroundings.) *Note*: In children, trauma-specific reenactment may occur in play.
4. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).
5. Marked physiological reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

C. Persistent avoidance of stimuli associated with the traumatic event(s) beginning after the traumatic event(s) occurred, as evidenced by one or both of the following:
1. Avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).
2. Avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).

D. Negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two or more of the following:
1. Inability to remember an important aspect of the traumatic event(s) (typically due to dissociative amnesia and not to other factors such as head injury, alcohol, or drugs).
2. Persistent and exaggerated negative beliefs or expectations about oneself, others, or the world (e.g., "I am bad," "No one can be trusted," "The world is completely dangerous," "My whole nervous system is permanently ruined").
3. Persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others.

BOX 28–1 Diagnostic Criteria for Posttraumatic Stress Disorder–cont'd

4. Persistent negative emotional state (e.g., fear, horror, anger, guilt, or shame).
5. Markedly diminished interest or participation in significant activities.
6. Feelings of detachment or estrangement from others.
7. Persistent inability to experience positive emotions (e.g., inability to experience happiness, satisfaction, or loving feelings).

E. Marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two or more of the following:
   1. Irritable behavior and angry outbursts (with little or no provocation) typically expressed as verbal or physical aggression toward people or objects.
   2. Reckless or self-destructive behavior.
   3. Hypervigilance.
   4. Exaggerated startle response.

5. Problems with concentration.
6. Sleep disturbance (e.g., difficulty falling or staying asleep or restless sleep).

F. Duration of the disturbance (Criteria B, C, D, and E) is more than 1 month.

G. The disturbance causes clinically significant distress or impairment in social, occupation, or other important areas of functioning.

H. The disturbance is not attributable to the physiological effects of a substance (e.g., medication, alcohol) or another medical condition.

Specify whether:

With dissociative symptoms (depersonalization or derealization)

With delayed expression (full diagnostic criteria not met until at least 6 months after the event)

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

BOX 28–2 Diagnostic Criteria for Acute Stress Disorder

A. Exposure to actual or threatened death, serious injury, or sexual violation, in one (or more) of the following ways:
   1. Directly experiencing the traumatic event(s).
   2. Witnessing, in person, the event(s) as it occurred to others.
   3. Learning that the event(s) occurred to a close family member or close friend. *Note:* In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental.
   4. Experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g., first responders collecting human remains, police officers repeatedly exposed to details of child abuse). *Note*: This does not apply to exposure through electronic media, television, movies, or pictures, unless this exposure is work related.

B. Presence of nine (or more) of the following symptoms from any of the five categories of intrusion, negative mood, dissociation, avoidance, and arousal, beginning or worsening after the traumatic event(s) occurred:

INTRUSION SYMPTOMS
   1. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s). *Note*: In children, repetitive play may occur in which themes or aspects of the traumatic event(s) are expressed.
   2. Recurrent distressing dreams in which the content and/or affect of the dream are related to the event(s). *Note*: In children, there may be frightening dreams without recognizable content.
   3. Dissociative reactions (e.g., flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum,

with the most extreme expression being a complete loss of awareness of present surroundings.) *Note*: In children, trauma-specific reenactment may occur in play.
   4. Intense or prolonged psychological distress or marked physiological reactions in response to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

NEGATIVE MOOD
   5. Persistent inability to experience positive emotions (e.g., inability to experience happiness, satisfaction, or loving feelings).

DISSOCIATIVE SYMPTOMS
   6. An altered sense of the reality of one's surroundings or oneself (e.g., seeing oneself from another's perspective, being in a daze, time slowing).
   7. Inability to remember an important aspect of the traumatic event(s) (typically due to dissociative amnesia and not to other factors such as head injury, alcohol, or drugs).

AVOIDANCE SYMPTOMS
   8. Efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).
   9. Efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).

AROUSAL SYMPTOMS
   10. Sleep disturbance (e.g., difficulty falling or staying asleep, or restless sleep).

Predisposing Factors to Trauma-Related Disorders

Psychosocial Theory

The widely accepted psychosocial model seeks to explain why certain persons exposed to massive trauma develop trauma-related disorders and others do not. Variables include characteristics that relate to (1) the traumatic experience, (2) the individual, and (3) the recovery environment.

The Traumatic Experience

Specific characteristics of the trauma have been identified as crucial in the determination of an individual's long-term response to stress:

- Severity and duration of the stressor
- Extent of anticipatory preparation for the event
- Exposure to death
- Numbers affected by life threat
- Amount of control over recurrence
- Location where the trauma was experienced (e.g., familiar surroundings, at home, in a foreign country)

The Individual

Variables that are considered important in determining an individual's response to trauma include the following:

- Degree of ego-strength
- Effectiveness of coping resources
- Presence of preexisting psychopathology
- Outcomes of previous experiences with stress and trauma
- Behavioral tendencies (temperament)
- Current psychosocial developmental stage
- Demographic factors (e.g., age, socioeconomic status, education)

The Recovery Environment

The quality of the environment in which the individual attempts to work through the traumatic experience is correlated with the outcome. Environmental variables include the following:

- Availability of social supports
- The cohesiveness and protectiveness of family and friends
- The attitudes of society regarding the experience
- Cultural and subcultural influences

In research with Vietnam veterans, the best predictors of PTSD were the severity of the stressor and the degree of psychosocial isolation in the recovery environment.

Learning Theory

Learning theorists view negative reinforcement as behavior that leads to a reduction in an aversive experience, thereby reinforcing and resulting in repetition of the behavior. Avoidance behaviors and psychic numbing in response to a trauma are mediated by negative reinforcement (behaviors that decrease the emotional pain of the trauma). Behavioral disturbances, such as anger, aggression, and drug and alcohol abuse, are the behavioral patterns that are reinforced by their capacity to reduce objectionable feelings.

Cognitive Theory

These models take into consideration the cognitive appraisal of an event and focus on assumptions that an individual makes about the world. Epstein (1991) outlines three fundamental beliefs that most people construct within a personal theory of reality:

1. The world is benevolent and a source of joy.
2. The world is meaningful and controllable.
3. The self is worthy (e.g., lovable, good, and competent).

As life situations occur, some disequilibrium is expected until accommodation for the changed circumstance has been made and it becomes assimilated into one's personal theory of reality. An individual is vulnerable to trauma-related disorders when the fundamental

beliefs are invalidated by a trauma that cannot be comprehended and a sense of helplessness and hopelessness prevail. One's appraisal of the environment can be drastically altered.

Biological Aspects

Exposure to trauma has been associated with hyperarousal of the sympathetic nervous system, excessive amygdala activity, and decreased hippocampus volume, all of which are neurobiological reactions to heightened stress. Dysfunctions in the hypothalamic-pituitary-adrenal (HPA) axis, either from chronic stress or exposure to an extreme stressor, have been linked to many psychiatric illnesses including PTSD, depression, Alzheimer's disease, and substance abuse and to medical conditions such as inflammatory disorders and cardiovascular disease (Valentino & Van Bockstaele, 2015). In addition, neuroendocrine abnormalities, including serotonin, glutamate, thyroid, and endogenous opioids (among others), have been associated with stress responses and PTSD. Valentino and Van Bockstaele (2015) identify that the activation of endogenous opioids both reduces stress and mimics the stress response depending on which opioid receptors are activated. Studies have shown that opioids administered shortly after exposure to a trauma reduced the incidence of PTSD, suggesting a protective effect. Chronic activation, however, may sensitize neurons in a way that increases vulnerability to stress-induced relapse. Lanius (2013) discusses the effects of repeated activation of opioid receptors, including the effect of increasing one's addiction potential to other drugs or even to the learned experience of relief when traumatic stress is reexperienced. He identifies that opiate antagonists such as naltrexone have demonstrated effectiveness in treatment.

Other biological systems have also been implicated in the symptomatology of PTSD. Norepinephrine, dopamine, and benzodiazepine receptors are other neurotransmitters believed to be dysregulated in individuals with PTSD. Whether these factors are suggestive of vulnerability to PTSD or whether these changes result from the brain's efforts to process trauma remains unclear. As with other disorders, it is likely that a complex dynamic of biological, social, and psychological factors is involved.

Trauma-Informed Care

Experts highlight the importance of trauma-informed care as essential to improving the quality of care for clients both in and outside of behavioral health care settings (Hopper, Bassuk, & Olivet, 2010; Substance Abuse and Mental Health Services Administration [SAMHSA], 2015). The National Center for Trauma-Informed Care (SAMHSA, 2015) calls national attention to this critical approach. Trauma-informed care generally describes a philosophical approach that values awareness and understanding of trauma when assessing, planning, and implementing care. SAMHSA advances the following principles in defining this approach. Trauma-informed care

- *Realizes* the widespread impact of trauma and various paths for recovery.
- *Recognizes* the signs and symptoms of trauma in clients, families, staff, and all those involved with the system.
- *Responds* by fully integrating knowledge about trauma in policies, procedures, and practices.
- Seeks to actively resist *retraumatization.*

Hopper and associates (2010) discuss applying this approach with the homeless population (a significant problem for people with severe mental illness). The authors describe the many traumatic experiences that culminate in homelessness and the often co-occurring illnesses such as depression, substance abuse, and severe mental illness. To ignore the significance of trauma or to provide uninformed care leaves this population vulnerable to revictimization and "further complicates their service needs" (p. 81). Childhood trauma, including physical, emotional, and sexual abuse, is also often identified as significant in the development of behavioral problems, eating disorders, some personality disorders, depression, and substance abuse. Health-care providers, if they do not fully understand the impact of previous trauma on the client's current health concerns, may unwittingly retraumatize clients. Even interventions such as seclusion and restraint, which are designed to protect the client's safety when they are at imminent risk of harm to themselves or others, may be retraumatizing to a client with a history of trauma.

Inherent in this definition is the importance of health-care providers being aware of the impact of trauma on themselves, as it may impact their effectiveness in providing care to clients.

Interventions that are considered trauma-informed highlight the importance of respect for the client, collaboration and connection, providing information about the connections between trauma and other health concerns, instilling hope, and empowering the trauma survivor to guide and direct his or her recovery plan (the essence of patient-centered care).

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the

disorder. Following are some common nursing diagnoses for clients with trauma-related disorders:

■ Posttrauma syndrome related to distressing events outside the range of usual human experience, evidenced by flashbacks, intrusive recollections, nightmares, psychological numbness related to the event, dissociation, or amnesia
■ Complicated grieving related to loss of self as perceived before the trauma or other actual or perceived losses incurred during or after the event, evidenced by irritability and explosiveness, self-destructiveness, substance abuse, verbalization of survival guilt, or guilt about behavior required for survival

The following criteria may be used for measurement of outcomes in the care of the client with a trauma-related disorder.

The client:

■ Can acknowledge the traumatic event and the impact it has had on his or her life
■ Is experiencing fewer flashbacks, intrusive recollections, and nightmares than he or she was on admission (or at the beginning of therapy)
■ Can demonstrate adaptive coping strategies (e.g., relaxation techniques, mental imagery, music, art)

■ Can concentrate and has made realistic goals for the future
■ Includes significant others in the recovery process and willingly accepts their support
■ Verbalizes no ideas or intent of self-harm
■ Has worked through feelings of survivor's guilt
■ Gets enough sleep to avoid risk of injury
■ Verbalizes community resources from which he or she may seek assistance in times of stress
■ Attends support group of individuals who have recovered or are recovering from similar traumatic experiences
■ Verbalizes desire to put the trauma in the past and progress with his or her life

Planning and Implementation

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Posttrauma Syndrome

Posttrauma syndrome is defined as "a sustained maladaptive response to a traumatic, overwhelming event" (Herdman & Kamitsuru, 2014, p. 315). Table 28–1 presents this nursing diagnosis in care plan format.

Table 28–1 | CARE PLAN FOR THE CLIENT WITH A TRAUMA-RELATED DISORDER

NURSING DIAGNOSIS: POSTTRAUMA SYNDROME

RELATED TO: Distressing event considered to be outside the range of usual human experience

EVIDENCED BY: Flashbacks, intrusive recollections, nightmares, psychological numbness related to the event, dissociation, or amnesia

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE

Short-Term Goals:
• Client will begin a healthy grief resolution, initiating the process of psychological healing (within time frame specific to individual).
• Client will demonstrate ability to deal with emotional reactions in an individually appropriate manner.
 	
Long-Term Goal:
• Client will integrate the traumatic experience into his or her persona, renew significant relationships, and establish meaningful goals for the future.
	1. a. Assign the same staff as often as possible.
	  b. Use a nonthreatening, matter-of-fact, but friendly approach.
	  c. Respect client's wishes regarding interaction with individuals of opposite sex at this time (especially important if the trauma was rape).
	  d. Be consistent; keep all promises; convey acceptance; spend time with client.
	
	2. Stay with client during periods of flashbacks and nightmares. Offer reassurance of safety and security and that these symptoms are not uncommon following a trauma
		1. A posttrauma client may be suspicious of others in his or her environment. All of these interventions serve to facilitate a trusting relationship.
		
		2. Presence of a trusted individual may calm fears for personal safety and reassure client that he or she is not "going crazy."

Table 28–1 | CARE PLAN FOR THE CLIENT WITH A TRAUMA-RELATED DISORDER–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	of the magnitude he or she has experienced.	
	3. Obtain accurate history from significant others about the trauma and client's specific response.	3. Various types of traumas elicit different responses in clients (e.g., human-engendered traumas often generate a greater degree of humiliation and guilt in victims than trauma associated with natural disasters).
	4. Encourage client to talk about the trauma at his or her own pace. Provide a nonthreatening, private environment, and include a significant other if client wishes. Acknowledge and validate client's feelings as they are expressed.	4. This debriefing process is the first step in the progression toward resolution.
	5. Discuss coping strategies used in response to the trauma, as well as those used during stressful situations in the past. Determine those that have been most helpful, and discuss alternative strategies for the future. Include available support systems, including religious and cultural influences. Identify maladaptive coping strategies (e.g., substance use, psychosomatic responses) and practice more adaptive coping strategies for possible future posttrauma responses.	5. Resolution of the posttrauma response is largely dependent on the effectiveness of the coping strategies employed.
	6. Assist client to try to comprehend the trauma if possible. Discuss feelings of vulnerability and the individual's "place" in the world following the trauma.	6. Posttrauma response is largely a function of the shattering of basic beliefs the victim holds about self and world. Assimilation of the event into one's persona requires that some degree of meaning associated with the event be incorporated into the basic beliefs, which will affect how the individual eventually comes to reappraise self and world (Epstein, 1991).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ The client will begin a healthy grief resolution, initiating the process of psychological healing (within time frame specific to individual).

■ The client will demonstrate ability to deal with emotional reactions in an individually appropriate manner.

Long-term goal

■ The client will integrate the traumatic experience into his or her persona, renew significant relationships, and establish meaningful goals for the future.

Interventions

■ A posttrauma client may be suspicious of others in his or her environment. Establishing a trusting relationship with this individual is essential before care can be given. To promote trust, assign the same staff as often as possible. Use a nonthreatening, matter-of-fact but friendly approach. Ask for permission before using touch as an intervention. Respect the client's wishes regarding interaction with individuals of opposite gender at this time (especially important if the trauma was rape). Be consistent and keep all promises, and convey an attitude of unconditional acceptance.

■ Stay with the client during periods of flashbacks and nightmares. Offer reassurance of safety and security and that these symptoms are not uncommon following a trauma of the magnitude he or she has experienced. The presence of a trusted individual may help to calm fears for personal safety and reassure the anxious client that he or she is not "going crazy."

■ Obtain an accurate history from significant others about the trauma and the client's specific response. Various types of traumas elicit different responses in clients. For example, human-engendered traumas often generate a greater degree of humiliation and guilt in victims than does trauma associated with natural disasters.

■ Encourage the client to talk about the trauma *at his or her own pace*. Provide a nonthreatening, private environment, and include a significant other if the client wishes. Acknowledge and validate the client's feelings as they are expressed. This debriefing process is the first step in the progression toward resolution.

■ Discuss coping strategies used in response to the trauma, as well as those used during stressful situations in the past. Determine those that have been most helpful and discuss alternative strategies for the future. Clients who have suffered multiple or sustained traumas may find longer-term PTSD-focused therapy to be beneficial. Include available support systems, including religious and cultural influences. Identify maladaptive coping strategies, such as substance use or psychosomatic responses, and practice more adaptive coping strategies for possible future posttrauma responses. Resolution of the posttrauma response is largely dependent on the effectiveness of the coping strategies employed.

■ Assist the individual to comprehend the trauma if possible. Discuss feelings of vulnerability and the individual's "place" in the world following the trauma. Posttrauma response is largely a function of the shattering of basic beliefs the survivor holds about self and world. Assimilation of the event into one's persona requires that some degree of meaning associated with the event be incorporated into the basic beliefs, which will affect how the individual eventually comes to reappraise self and world (Epstein, 1991).

Complicated Grieving

Complicated grieving is defined as "a disorder that occurs after the death of a significant other [or any other loss of significance to the individual], in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment" (Herdman & Kamitsuru, 2014, p. 339).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will verbalize feelings (guilt, anger, self-blame, hopelessness) associated with the trauma.

Long-term goal

■ Client will demonstrate progress in dealing with stages of grief and will verbalize a sense of optimism and hope for the future.

Interventions

■ Acknowledge feelings of guilt or self-blame the client may express. Guilt at having survived a trauma in which others died is common. The client needs to discuss these feelings and recognize that he or she is not responsible for what happened but must take responsibility for his or own recovery.

■ Assess stage of grief in which the client is fixed. Discuss normalcy of feelings and behaviors related to stages of grief. Knowledge of grief stage is necessary for accurate intervention. Guilt may be generated if client believes it is unacceptable to have these feelings. Knowing they are normal can provide a sense of relief.

■ Assess impact of the trauma on the client's ability to resume regular activities of daily living. Consider employment, marital relationship, and sleep patterns. Following a trauma, individuals are at high risk for physical injury because of disruption in ability to concentrate and problem-solve and lack of sufficient sleep. Isolation and avoidance behaviors may interfere with interpersonal relatedness.

■ Assess for self-destructive ideas and behavior. The trauma may result in feelings of hopelessness and worthlessness, leading to high risk for suicide.

■ Assess for maladaptive coping strategies such as substance abuse. These behaviors interfere with and delay the recovery process.

■ Identify available community resources from which the individual may seek assistance if problems with complicated grieving persist. Support groups for victims of various types of trauma exist within most communities. The presence of support systems in the recovery environment has been identified as a major predictor in the successful recovery from trauma.

Concept Care Mapping

The concept map care plan (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with a trauma-related disorder is presented in Figure 28–1.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client with a trauma-related disorder may be facilitated by gathering information using the following types of questions:

■ Can the client discuss the traumatic event without experiencing panic anxiety?

■ Does the client voluntarily discuss the traumatic event?

■ Can the client discuss changes that have occurred in his or her life because of the traumatic event?

■ Does the client have flashbacks?

■ Can the client sleep without medication?

■ Does the client have nightmares?

■ Has the client learned new, adaptive coping strategies for assistance with recovery?

■ Can the client demonstrate successful use of these new coping strategies in times of stress?

■ Can the client verbalize stages of grief and the normal behaviors associated with each?

■ Can the client recognize his or her own position in the grieving process?

■ Is guilt being alleviated?

■ Has the client maintained or regained satisfactory relationships with significant others?

■ Can the client look to the future with optimism?

■ Does the client attend a regular support group for victims of similar traumatic experiences?

■ Does the client have a plan of action for dealing with symptoms if they recur?

Application of the Nursing Process–Stressor-Related Disorders

Adjustment Disorders—Background Assessment Data

> **CORE CONCEPT**
> **Stress**
> Perceptions, emotions, anxieties, interpersonal, social, or economic events that are considered threatening to one's physical health, personal safety or well-being (Venes, 2014).

An adjustment disorder is characterized by a maladaptive reaction to an identifiable stressor or stressors that results in the development of clinically significant emotional or behavioral symptoms (APA, 2013). The response occurs within 3 months after onset of the stressor and persists for no longer than 6 months after the stressor or its consequences have ended.

The individual shows impairment in social and occupational functioning or exhibits symptoms that are in excess of an expected reaction to the stressor. The symptoms are expected to remit soon after the stressor is relieved or, if the stressor persists, when a new level of adaptation is achieved.

The stressor itself can be almost anything, but an individual's response to a particular stressor cannot be predicted. If an individual is highly predisposed or vulnerable to maladaptive response, a severe form of the disorder may follow what most people would consider only a mild or moderate stressor. Conversely, a less vulnerable individual may develop only a mild form of the disorder in response to what others might consider a severe stressor.

A number of clinical presentations are associated with adjustment disorders. The following categories, identified by the *DSM*-5 (APA, 2013), are distinguished by the predominant features of the maladaptive response.

Clinical Vignette: Charles is a 29-year-old veteran of two deployments to Afghanistan. He was honorably discharged from the army 2 years ago and has resumed his position as an assembler with a large automobile manufacturing company. His wife reports that he has begun having nightmares, seems angry and bitter, and feels guilty that he survived while many of his friends did not. Recently, while working in their backyard, he threw himself on the ground at the sound of a helicopter flying overhead. Lately, at work, he has become very agitated and irritable at the sounds of loud noises in the factory, a behavior that is interfering with his productivity. Charles has been diagnosed with Posttraumatic Stress Disorder. The mental health nurse develops the following concept map care plan for Charles.

Signs and Symptoms
- Flashbacks
- Intrusive recollections
- Nightmares
- Psychological numbness/ amnesia

Signs and Symptoms
- Irritability
- Explosiveness
- Agitation
- Survivor's guilt

Nursing Diagnosis

Post-trauma syndrome

Nursing Diagnosis

Complicated grieving

Nursing Actions
- Accept client; establish trust.
- Stay with client during flashbacks.
- Encourage verbalization about the trauma when client is ready.
- Discuss coping strategies.
- Assist client to try to comprehend the trauma and how it will be assimilated into his persona.

Nursing Actions
- Acknowledge feelings of guilt or self-blame.
- Assess client's stage in grief process.
- Assess impact of trauma on ability to resume ADLs.
- Assess for self-destructive ideas or behavior.
- Assess for maladaptive coping (e.g., substance abuse).

Medical Rx: Paroxetine 20 mg q AM

Outcomes
- Client discusses trauma without experiencing panic
- Client has fewer flashbacks/nightmares
- Client can sleep without medication
- Client demonstrates use of adaptive coping strategies

Outcomes
- Client recognizes own position in grief process
- Client expresses relief from feelings of guilt
- Client maintains satisfactory relationships
- Client looks to the future with optimism

FIGURE 28–1   Concept map care plan for a client with posttraumatic stress disorder.

Adjustment Disorder With Depressed Mood

This category is the most commonly diagnosed adjustment disorder. The clinical presentation is one of predominant mood disturbance, although less pronounced than that of major depressive disorder. The symptoms, such as depressed mood, tearfulness, and feelings of hopelessness, exceed what is an expected or normative response to an identified stressor.

Adjustment Disorder With Anxiety

This category denotes a maladaptive response to a stressor in which the predominant manifestation is anxiety.

For example, the symptoms may reveal nervousness, worry, and jitteriness. The clinician must differentiate this diagnosis from those of anxiety disorders.

Adjustment Disorder With Mixed Anxiety and Depressed Mood

The predominant features of this category include disturbances in mood (depression, feelings of hopelessness and sadness) and manifestations of anxiety (nervousness, worry, jitteriness) that are more intense than what would be expected or considered a normative response to an identified stressor.

Adjustment Disorder With Disturbance of Conduct

This category is characterized by conduct in which there is violation of the rights of others or of major age-appropriate societal norms and rules. Examples include truancy, vandalism, reckless driving, fighting, and defaulting on legal responsibilities. Differential diagnosis must be made from conduct disorder or antisocial personality disorder, both longer standing and pervasive responses to a variety of situations.

Adjustment Disorder With Mixed Disturbance of Emotions and Conduct

The predominant features of this category include emotional disturbances (e.g., anxiety or depression) as well as disturbances of conduct in which there is violation of the rights of others or of major age-appropriate societal norms and rules (e.g., truancy, vandalism, fighting).

Adjustment Disorder Unspecified

This subtype is used when the maladaptive reaction is not consistent with any of the other categories. The individual may have physical complaints, withdraw from relationships, or exhibit impaired work or academic performance, but without significant disturbance in emotions or conduct.

Predisposing Factors to Adjustment Disorders

Biological Theory

Chronic disorders, such as neurocognitive or intellectual developmental disorders, are thought to impair an individual's ability to adapt to stress, causing increased vulnerability to adjustment disorder. Genetic factors also may influence individual risks for maladaptive response to stress (Sadock et al., 2015).

Psychosocial Theories

Some proponents of psychoanalytic theory view adjustment disorder as a maladaptive response to stress caused by early childhood trauma, increased dependency, and retarded ego development. Freud (1964) theorized that traumatic childhood experiences created points of fixation to which the individual would be likely to regress during times of stress. Other psychoanalysts put considerable weight on birth characteristics that contribute to the manner in which individuals respond to stress. In many instances, adjustment disorder is precipitated by a specific meaningful stressor connecting with a point of vulnerability in an individual of otherwise adequate ego strength.

Some studies relate a predisposition to adjustment disorder to factors such as developmental stage, timing of the stressor, and available support systems. When a stressor occurs and the individual does not have the developmental maturity, available support systems, or adequate coping strategies to adapt, normal functioning is disrupted, resulting in psychological or somatic symptoms. The disorder also may be related to a dysfunctional grieving process. The individual may remain in the denial or anger stage, with inadequate defense mechanisms to complete the grieving process.

Transactional Model of Stress and Adaptation

Why are some individuals able to confront stressful situations adaptively and even gain strength from the experience, while others not only fail to cope adaptively but may even encounter psychopathological dysfunction? The transactional model of stress and adaptation takes into consideration the interaction between the individual and the environment.

The type of stressor that one experiences may influence one's adaptation. Sudden shock stressors occur without warning, and continuous stressors are those an individual is exposed to over an extended period. Although many studies have focused on individuals' responses to sudden shock stressors, continuous stressors were more commonly cited as precipitants to maladaptive functioning.

Both situational and interpersonal factors most likely contribute to an individual's stress response. Situational factors include personal and general economic conditions; occupational and recreational opportunities; and the availability of social supports such as family, friends, neighbors, and cultural or religious support groups.

Interpersonal factors such as constitutional vulnerability have also been implicated in the predisposition to adjustment disorder. Some studies have indicated that a child with a difficult temperament (defined as one who cries loudly and often; adapts to changes slowly; and has irregular patterns of hunger, sleep, and elimination) is at greater risk of developing a behavior disorder. Other intrapersonal factors that might influence one's ability to adjust to a painful life change include social skills, coping strategies, the presence of psychiatric illness, degree of flexibility, and level of intelligence.

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Nursing diagnoses that may be used for the client with an adjustment disorder include the following:

- Complicated grieving related to real or perceived loss of any concept of value to the individual, evidenced by interference with life functioning, developmental regression, or somatic complaints
- Risk-prone health behavior related to change in health status requiring modification in lifestyle (e.g., chronic illness, physical disability), evidenced by inability to problem-solve or set realistic goals for the future (appropriate diagnosis for the person with adjustment disorder if the precipitating stressor was a change in health status)
- Anxiety (moderate to severe) related to situational and/or maturational crisis evidenced by restlessness, increased helplessness, and diminished productivity

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with an adjustment disorder.

The client:

- Verbalizes acceptable behaviors associated with each stage of the grief process
- Demonstrates a reinvestment in the environment
- Accomplishes activities of daily living independently
- Demonstrates ability for adequate occupational and social functioning
- Verbalizes awareness of change in health status and the effect it will have on lifestyle
- Solves problems and sets realistic goals for the future
- Demonstrates ability to cope effectively with change in lifestyle

Planning and Implementation

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Complicated Grieving

Complicated grieving is defined as "a disorder that occurs after the death of a significant other [or any other loss of significance to the individual], in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment" (Herdman & Kamitsuru, 2014, p. 339).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

- By end of 1 week, client will express anger toward lost entity.

Long-term goal

- The client will be able to verbalize behaviors associated with the normal stages of grief and identify own position in grief process, while progressing at own pace toward resolution.

Interventions

- Determine the stage of grief in which client is fixed. Identify behaviors associated with this stage. Accurate baseline assessment data are necessary to plan effective care for the grieving client.
- Develop a trusting relationship with the client. Show empathy and caring. Be honest and keep all promises. Trust is the basis for a therapeutic relationship.
- Convey an accepting attitude so the client is not afraid to express feelings openly. An accepting attitude conveys that you believe he or she is a worthwhile person. Trust is enhanced.
- Allow the client to express anger. Do not become defensive if the initial expression of anger is displaced on the nurse or therapist. Help the client explore angry feelings so that they may be directed toward the intended object or person. Verbalization of feelings in a nonthreatening environment may help the client come to terms with unresolved issues.
- Assist the client to discharge pent-up anger through participation in large motor activities (e.g., brisk walks, jogging, physical exercises, volleyball, punching bag, exercise bike). Physical exercise provides a safe and effective method for discharging pent-up tension.
- Explain to the client the normal stages of grief and the behaviors associated with each stage. Help the client to understand that feelings such as guilt and anger toward the lost entity/concept are natural and acceptable during the grief process. Knowledge of the acceptability of the feelings associated with normal grieving may help to relieve some of the guilt that these responses generate.
- Encourage the client to review his or her perception of the loss or change. With support and sensitivity, point out the reality of the situation in areas where misrepresentations are expressed. The client must give up an idealized perception and be able to accept both positive and negative aspects about the painful life change before the grief process is complete.

- Communicate to the client that crying is acceptable. The use of touch is therapeutic and appropriate with most clients. Knowledge of cultural influences specific to the client is important before employing this technique. Touch is considered inappropriate in some cultures.
- Help the client solve problems as he or she attempts to determine methods for more adaptive coping with the stressor. Provide positive feedback for strategies identified and decisions made. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.
- Encourage the client to reach out for spiritual support during this time in whatever form is desirable. Assess client's spiritual needs and assist as necessary in the fulfillment of those needs. For some individuals, spiritual support can enhance successful adaptation to painful life experiences.

Risk-Prone Health Behavior

Risk-prone health behavior is defined as "impaired ability to modify lifestyle/behaviors in a manner that improves health status" (Herdman & Kamitsuru, 2014, p. 145).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

- The client and primary nurse will discuss the kinds of lifestyle changes that will occur because of the change in health status.
- With the help of the primary nurse, the client will formulate a plan of action for incorporating those changes into his or her lifestyle.
- The client will demonstrate movement toward independence, considering the change in health status.

Long-term goal

- The client will demonstrate competence to function independently to his or her optimal ability, considering the change in health status, by the time of discharge from treatment.

Interventions

- Encourage the client to talk about his or her lifestyle prior to the change in health status. Discuss coping mechanisms that were used at stressful times in the past. It is important to identify the client's strengths so that they may be used to facilitate adaptation to the change or loss that has occurred.
- Encourage the client to discuss the change or loss and particularly to express anger associated with it. Anger is a normal stage in the grieving process and, if not released in an appropriate manner, may be

turned inward on the self, leading to pathological depression.
- Encourage the client to express fears associated with lifestyle alterations imposed by the chronic illness, physical disability, or other change in health status. Change often creates a feeling of disequilibrium, and the individual may respond with fears that are irrational or unfounded. The client may benefit from feedback that corrects misperceptions about how life will be with the change in health status.
- Provide assistance with activities of daily living as required, but encourage independence to the limit that the client's ability allows. Give positive feedback for activities accomplished independently. Independent accomplishments and positive feedback enhance self-esteem and encourage repetition of desired behaviors. Successes also provide hope that adaptive functioning is possible and decrease feelings of powerlessness.
- Help the client with decision-making regarding incorporation of the change or loss into his or her lifestyle. Identify problems the change or loss is likely to create. Discuss alternative solutions, weighing potential benefits and consequences of each alternative. Support the client's decision in the selection of an alternative. The great amount of anxiety that usually accompanies a major lifestyle change often interferes with an individual's ability to solve problems and to make appropriate decisions. The client may need assistance with this process to progress toward successful adaptation.
- Use role-play to practice stressful situations that might occur in relation to the health status change. Role-playing decreases anxiety and provides a feeling of security by developing a plan of action for responding in an appropriate manner when a stressful situation occurs.
- Ensure that the client and family are fully knowledgeable regarding the physiology of the change in health status and understand the necessity of such knowledge for optimal wellness. Encourage them to ask questions, and provide printed material with additional explanation. Knowing what to expect regarding the change or loss decreases anxiety and enhances the capacity for wellness.
- Ensure that the client can identify resources within the community from which he or she may seek assistance in adapting to the change in health status. Examples include self-help or support groups and public health nurse, counselor, or social worker. Encourage the client to keep follow-up appointments with his or her physician and to call the physician's office prior to the follow-up date if problems or concerns arise. Support services provide

a feeling of security that one is not alone and a means to prevent decompensation when stress becomes intolerable.

Concept Care Mapping

Individuals with adjustment disorders may have several physical and mental health issues that impact effective intervention. The concept map care plan (see Chapter 9) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with an adjustment disorder is presented in Figure 28–2.

Clinical Vignette: Hanna, age 16, has just been diagnosed with celiac disease and has been placed on a gluten-free diet. Deviation from this diet results in severe abdominal cramping and diarrhea. Hanna is devastated, has refused to follow the diet, and is losing considerable weight. Her mother is concerned and brings Hanna to the community mental health center for counseling. Hanna tells the nurse, "I'm not going to eat that stuff. All the kids will think I'm a freak! We go for hamburgers every day at noon. I can't even go for pizza! It's not fair!" The nurse develops the following concept map care plan for Hanna.

Signs and Symptoms
- Verbalizes feelings of anger
- Persistent emotional stress
- Depression

Signs and Symptoms
- Demonstrates nonacceptance of health status change
- Failure to take action to prevent health problems

Nursing Diagnosis
Complicated grieving

Nursing Diagnosis
Risk-prone health behavior

Nursing Actions
- Assess client's stage of grief.
- Allow client to express anger.
- Encourage large motor activities.
- Explain stages of grief.
- Help client correct misperceptions about the loss.
- Assist client with problem-solving.
- Assess client's spiritual needs.

Nursing Actions
- Discuss lifestyle before health status change.
- Encourage expression of anger and fears associated with change in health status.
- Help client with decision-making.
- Use role-play to practice potential stressful situations.
- Provide information to client and family about health change.

Medical Rx: Fluoxetine 20 mg q AM

Outcomes
- Verbalizes acceptable behaviors associated with stages of grief
- Demonstrates adequate academic and social functioning
- No longer exhibiting exaggerated emotions related to complicated grieving

Outcomes
- Verbalizes and accepts the effects that the change in health status will have on lifestyle
- Solves problems and sets realistic goals for the future
- Copes effectively with change in lifestyle

FIGURE 28–2 Concept map care plan for a client with an adjustment disorder.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client with an adjustment disorder may be facilitated by gathering information using the following types of questions:

■ Does the client verbalize understanding of the grief process and his or her position in the process?
■ Does the client recognize his or her adaptive and maladaptive behaviors associated with the grief response?
■ Does the client demonstrate evidence of progression along the grief response?
■ Can the client accomplish activities of daily living independently?
■ Does the client demonstrate the ability to perform occupational and social activities adequately?
■ Does the client discuss the change in health status and modification of lifestyle it will affect?
■ Does the client demonstrate acceptance of the modification?
■ Can the client participate in decision-making and problem-solving for his or her future?
■ Does the client set realistic goals for the future?
■ Does the client demonstrate new adaptive coping strategies for dealing with the change in lifestyle?
■ Can the client verbalize available resources to whom he or she may go for support or assistance should it be necessary?

Treatment Modalities

Trauma-Related Disorders

Cognitive Therapy

Cognitive therapy for PTSD and ASD strives to help the individual recognize and modify trauma-related thoughts and beliefs. The individual learns to modify the relationships between thoughts and feelings and to identify and challenge inaccurate or extreme automatic negative thoughts. The goal is to replace these negative thoughts with more accurate and less distressing thoughts and to cope more effectively with feelings such as anger, guilt, and fear. The individual is assisted to modify the appraisal of self and the world as it has been affected by the trauma and to regain hope and optimism about safety, trust, power and control, esteem, and intimacy.

Prolonged Exposure Therapy

Prolonged exposure therapy (PE) is a type of behavioral therapy similar to implosion therapy or flooding. It can be conducted in an imagined or real (in vivo) situation. In the imagined situation, the individual is exposed to repeated and prolonged mental recounting of the traumatic experience. In vivo exposure involves systematic confrontation, within safe limits, of trauma-related situations that are feared and avoided. This intense emotional processing of the traumatic event serves to neutralize the memories so that they no longer result in anxious arousal or escape and avoidance behaviors. PE has four main parts: (1) education about the treatment, (2) breathing retraining for relaxation, (3) imagined exposure through repeated discussion about the trauma with a therapist, and (4) exposure to real-world situations related to the trauma.

Group and Family Therapy

Group therapy has been strongly advocated for clients with PTSD and has proved especially effective with military veterans (Sadock et al., 2015). The importance of being able to share their experiences with empathetic fellow veterans, to talk about problems in social adaptation, and to discuss options for managing aggression toward others has been emphasized. Some PTSD groups are informal and leaderless, such as self-help or support groups, and some are led by experienced group therapists who may have had some first-hand experience with trauma. Some groups involve family members, recognizing that they may also be severely affected by symptoms of PTSD. For example, family members of military veterans sometimes develop PTSD symptoms as a result of exposure to their loved one's PTSD (see Chapter 38, Military Families, for further discussion of this topic).

Eye Movement Desensitization and Reprocessing

Eye movement desensitization and reprocessing (EMDR) is a type of psychotherapy that was developed in 1989 by psychologist Francine Shapiro. It "has evolved from a simple technique into an integrative psychotherapy approach with a theoretical model that emphasizes the brain's information processing system and memories of disturbing experiences as the basis of pathology" (Shapiro, 2007, p. 3). EMDR has been shown to be an effective therapy for PTSD and other trauma-related disorders. It has been used with other disorders, including depression, adjustment disorder, phobias, addictions, generalized anxiety disorder, and panic disorder. However, at present, EMDR has been empirically validated only for trauma-related disorders such as PTSD and ASD (Aetna Healthcare, 2013). EMDR is contraindicated in clients who have neurological impairments (e.g., seizure disorders), clients who are suicidal or experiencing psychosis, those with severe dissociative disorders or unstable substance abuse, and those with detached retina or glaucoma (Center for Integrative Medicine, 2013).

The exact biological mechanisms by which EMDR achieves its therapeutic effects are unknown. Some

studies have indicated that eye movements cause a decrease in imagery vividness and distress and an increase in memory access. The process involves rapid eye movements while processing painful emotions. The EMDR International Association (2016) stresses that "processing" does not mean "talking about it" but rather "setting up a learning state that will allow experiences that are causing problems to be 'digested' and stored appropriately in your brain." While concentrating on a particular emotion or physical sensation surrounding the traumatic event, the client is asked to focus his or her eye movements on the therapist's fingers as the therapist moves them from left to right and back again. Although some individuals report rapid results with this therapy, research has indicated that between 5 and 12 sessions are required to achieve lasting treatment effects. The treatment encompasses an eight-phase process.

Phase 1: History and Treatment Planning The therapist takes a thorough history and develops a treatment plan. The problem for which the client is seeking treatment and current symptoms are discussed. However, the client is not required to discuss the traumatic event in detail unless he or she chooses to do so. Instead, emphasis is placed on the emotions and physical sensations surrounding the traumatic event.

Phase 2: Preparation The therapist teaches the client certain self-care techniques (e.g., relaxation techniques) for dealing with emotional disturbances that may arise during or between sessions. Self-care is an important component of EMDR. The client must develop a sense of trust in the therapist during this phase.

Phase 3: Assessment The therapist asks the client to identify a specific scene or picture from the event identified in phase 1 that best represents the memory. The client is then directed to express a negative self-belief associated with the memory (e.g., "I am bad" or "I'm in danger"). The next step is to identify a self-statement that he or she would *rather* believe (e.g., "I am good" or "I'm safe now"). When the self-statements have been identified, the client is asked to rate the validity of each of the statements on the Validity of Cognition (VOC) scale from 1 (completely false) to 7 (completely true). The client is also asked to rank the disturbing emotions on the 0 to 10 Subjective Units of Disturbance (SUD) scale (with 0 meaning not disturbing at all and 10 meaning the worst feeling he or she has ever had).

Phase 4: Densensitization The client gives attention to the negative beliefs and disturbing emotions associated with the traumatic event while focusing his or her vision on the back-and-forth motion of the therapist's finger. All personal feelings and physical reactions experienced during this time are noted. Following each

set of rapid eye movements, the therapist reassesses the level of disturbance associated with the feelings, images, and beliefs. This desensitization process continues until the distress level (as measured by the SUD scale) is reduced to 0 or 1.

Phase 5: Installation The client gives attention to the positive belief that he or she has identified to replace the negative belief associated with the trauma. This is accomplished while simultaneously visually tracking the therapist's finger. Following each set of rapid eye movements, the client is asked to rate the positive belief on the VOC scale. The goal is to strengthen the positive belief or self-statement until it is accepted as completely true (a score of 7 on the VOC scale).

Phase 6: Body Scan When positive cognition has been strengthened, the therapist asks the client to concentrate on any lingering physical sensations. While focusing on the traumatic event, the client is asked to identify any areas of the body where residual tension is experienced. Because positive self-beliefs must be on a physical as well as an intellectual level, phase 6 is not complete until the client is able to think about or discuss the traumatic event (or the feelings associated with it) without experiencing bodily tension.

Phase 7: Closure Closure ensures that the client leaves each session feeling better than he or she felt at the beginning. If the processing that took place during the session is not complete, the therapist will direct the client through a variety of self-calming relaxation techniques to help him or her regain emotional equilibrium. The client is briefed about what to expect between sessions. Until processing of the trauma is complete, disturbing images, thoughts, and emotions may arise between therapy sessions. The therapist instructs the client to record these experiences in a journal so that they may be used as targets for processing in future therapy sessions.

Phase 8: Reevaluation Reevaluation begins each new therapy session. The therapist assesses whether the positive changes have been maintained, determines if previous target areas need reprocessing, and identifies any new target areas that need attention.

Clients often feel relief quite rapidly with EMDR. However, to achieve lasting results, it is important that each of the eight phases be completed. Treatment is not complete until "EMDR therapy has focused on the past memories that are contributing to the problem, the present situations that are disturbing, and what skills the client may need for the future" (EMDR Network, 2013).

Psychopharmacology

Antidepressants The selective serotonin reuptake inhibitors (SSRIs) are now considered first-line treatment

of choice for PTSD because of their efficacy, tolerability, and safety ratings (Sadock et al., 2015). Paroxetine and sertraline have been approved by the FDA for this purpose. The tricyclic antidepressants amitriptyline and imipramine have been supported by several well-controlled studies. MAO inhibitors (e.g., phenelzine) and trazodone have also been effective in the treatment of PTSD.

Anxiolytics Alprazolam has been prescribed for PTSD clients for its antidepressant and antipanic effects. Other benzodiazepines have also been used despite the absence of controlled studies demonstrating their efficacy in PTSD. Their addictive properties make them less desirable than some of the other medications in the treatment of posttrauma clients.

Buspirone, which has serotonergic properties similar to the SSRIs, may also be useful. Further controlled trials with this drug are needed to validate its efficacy in treating PTSD.

Antihypertensives The beta blocker propranolol and alpha$_2$-receptor agonist clonidine have been successful in alleviating some of the symptoms associated with PTSD. In clinical trials, marked reductions in nightmares, intrusive recollections, hypervigilance, insomnia, startle responses, and angry outbursts were reported with the use of these drugs.

Other Medications Carbamazepine, valproic acid, and lithium carbonate have been reported to alleviate symptoms of intrusive recollections, flashbacks, nightmares, impulsivity, irritability, and violent behavior in PTSD clients. Sadock and associates (2015) report that little positive evidence exists concerning the use of antipsychotics in PTSD. They suggest that these drugs "should be reserved for the short-term control of severe aggression and agitation" (p. 621).

Ketamine, an anesthetic agent which has demonstrated benefits in treatment of depression and obsessive-compulsive disorder, was found in clinical trials (Feder et al., 2014) to benefit some patients with PTSD. It is a modulator of glutaminergic activity at *N*-methyl-D-aspartate receptors and serotonergic activity at $5HT_1$ receptors that is believed to disrupt the fear associated with trauma. Currently, ketamine is not FDA approved for this use but is prescribed as an off-label use. It is administered intravenously at subanesthetic doses and usually involves a series of treatments. Jeffreys (2016) cautions that its effects are short term and there is potential for addiction.

The endocannabinoid system may be another avenue for treatment, since decreased levels of endogenous cannabinoids have been found in PTSD patients (Jeffreys, 2016). Although direct stimulation of this pathway has demonstrated negative effects on PTSD, indirect stimulation of this pathway might provide some additional treatment options.

Prazosin, an alpha$_1$ antagonist, has demonstrated benefit in reducing nightmares and enhancing normal dreaming patterns in clients with PTSD (Gore, 2015), and recent research has identified benefits for daytime PTSD symptoms as well (Jeffreys, 2016). Low-dose glucocorticoids are being studied for possible benefit in decreasing recall of traumatic memories, but more research is needed (Gore, 2015).

Adjustment Disorders

Various treatments are used for clients with adjustment disorders. The primary focus of intervention is to maximize the potential for adaptation.

Individual Psychotherapy

Individual psychotherapy is the most common treatment for adjustment disorder. Individual psychotherapy allows the client to examine the stressor that is causing the problem, possibly assign personal meaning to the stressor, and confront unresolved issues that may be exacerbating this crisis. Treatment works to remove these blocks to adaptation so that normal developmental progression can resume. Techniques are used to clarify links between the current stressor and past experiences and assist with the development of more adaptive coping strategies.

Family Therapy

The focus of treatment is shifted from the individual to the system of relationships in which the individual is involved. The maladaptive response of the identified client is viewed as symptomatic of a dysfunctional family system. All family members are included in the therapy, and treatment serves to improve the functioning within the family network. Emphasis is placed on communication, family rules, and interaction patterns among the family members.

Behavior Therapy

The goal of behavior therapy is to replace ineffective response patterns with more adaptive ones. The situations that promote ineffective responses are identified, and carefully designed reinforcement schedules along with role modeling and coaching are used to alter the maladaptive response patterns. This type of treatment is very effective when implemented in an inpatient setting where the client's behavior and its consequences may be more readily controlled.

Self-Help Groups

Group experiences, with or without a professional facilitator, provide an arena in which members may consider and compare their responses to individuals with similar life experiences. Members benefit from learning that they are not alone in their painful experiences. Hope is derived from knowing that others have survived and even grown from similar traumas. Members of the

group exchange advice, share coping strategies, and provide support and encouragement for each other.

Crisis Intervention

In crisis intervention, the therapist or other intervener becomes part of the individual's life situation. Because of increased anxiety, the individual with adjustment disorder is unable to problem-solve, so he or she requires guidance and support from another to help mobilize the resources needed to resolve the crisis. Crisis intervention is short term and relies heavily on orderly problem-solving techniques and structured activities that are focused on change. The ultimate goal of crisis intervention in the treatment of adjustment disorder is to resolve the immediate crisis, restore adaptive functioning, and promote personal growth.

Psychopharmacology

Adjustment disorder is not commonly treated with medications because (1) their effect may be temporary and only mask the real problem, interfering with the possibility of finding a more permanent solution; and (2) psychoactive drugs carry the potential for physiological and psychological dependence.

When the client with adjustment disorder has symptoms of anxiety or depression, the physician may prescribe antianxiety or antidepressant medication. These medications are considered only adjuncts to psychotherapy and should not be given as primary therapy. They are given to alleviate symptoms so that the individual may more effectively cope while attempting to adapt to the stressful situation.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Marissa, age 22, was born in a small town in Oklahoma. She lived there her whole life, even living at home while she attended a nearby college to earn a baccalaureate degree in education. She is an only child, and her parents were in their 40s when she was born. She was engaged throughout her college years to her high school sweetheart, Dave, who graduated 6 months ago from the state university with a degree in aeronautical engineering.

Upon his graduation, he accepted a position with NASA at Kennedy Space Center in Florida. Marissa and Dave were married 5 months ago and moved to a small apartment in Cape Canaveral, where Dave began his work with NASA. The plan was for Marissa to seek employment upon their arrival, but she has been unable to move ahead with those plans. She stays in the apartment most days, talking on the phone to her parents and crying about how much she misses them and her home in Oklahoma. She has met very few people and has no desire to do so. She sleeps a lot and has lost weight. She has been having severe headaches. Her husband has become very concerned about her and made an appointment for her with a private physician. Following a complete and unremarkable physical examination, the physician referred Marissa to the mental health clinic, where she was admitted to the day treatment center with a diagnosis of Adjustment Disorder with Depressed Mood.

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Marissa:

1. **Complicated grieving** related to feelings of loss associated with leaving her parents and her lifetime home.
   a. **Short-Term Goal:** Within 1 week, Marissa will express anger about the loss associated with her move.

   b. **Long-Term Goal**: Marissa will be able to verbalize behaviors associated with the normal stages of grief and identify her own position in the grief process, while progressing at her own pace toward resolution.
2. **Relocation stress syndrome** related to move away from parents and familiar environment in which she had spent her whole life.
   a. **Short-Term Goal:** Within 1 week, Marissa will verbalize at least one positive aspect regarding relocation to her new environment.
   b. **Long-Term Goal:** Within 1 month, Marissa will demonstrate positive adaptation to her new environment as evidenced by involvement in activities, expression of satisfaction with new acquaintances, and elimination of previously evident physical and psychological symptoms associated with the relocation.

PLANNING AND IMPLEMENTATION

COMPLICATED GRIEVING

The following nursing interventions have been identified for Marissa:

1. Determine the stage of grief in which Marissa is fixed. Identify behaviors associated with this stage.
2. Develop a trusting relationship with Marissa. Show empathy and caring. Be honest and keep all promises.
3. Convey an accepting attitude so that Marissa is not afraid to express her feelings openly.
4. Allow Marissa to express her anger. Do not become defensive if the initial expression of anger is displaced on nurse or therapist. Help Marissa explore angry feelings so that they may be directed toward the intended object or situation.
5. Help Marissa discharge pent-up anger through participation in large motor activities (e.g., brisk walks, jogging, physical exercises, or activity of her choice).

CASE STUDY AND SAMPLE CARE PLAN—cont'd

6. Explain to Marissa the normal stages of grief and the behaviors associated with each stage. Help her to understand that these feelings are normal and acceptable during a grief process.
7. Encourage Marissa to review her personal perception of the move. With support and sensitivity, point out the reality of the situation in areas where misrepresentations are expressed.
8. Help Marissa solve problems as she attempts to determine methods for more adaptive coping with the life change. Provide positive feedback for strategies identified and decisions made.
9. Encourage Marissa to reach out for spiritual support during this time in whatever form is desirable to her. Assess her spiritual needs and assist as necessary in the fulfillment of those needs.

RELOCATION STRESS SYNDROME
The following nursing interventions have been identified for Marissa:
1. Encourage Marissa to discuss feelings (concerns, fears, anger) regarding this relocation.
2. Encourage Marissa to discuss how the change will affect her life. Ensure that Marissa is involved in decision-making and problem-solving regarding the move.
3. Help Marissa identify positive aspects about the move.

4. Help Marissa identify resources within the new community from which assistance with various types of services may be obtained.
5. Identify groups within the community that specialize in helping individuals adapt to relocation. Examples include Newcomers' Club, Welcome Wagon International, and school and church organizations.
6. Refer Marissa to a support group (e.g., Depression and Bipolar Support Alliance [DBSA]).

EVALUATION
The outcome criteria for Marissa have been met. She is no longer having headaches and has regained some of her weight. She has joined a chapter of DBSA and has made some new acquaintances. She has applied to become a substitute teacher in the local school district, and she and Dave have joined the local Methodist church, where they have started to socialize with several couples their age. They have also adopted Molly, a 2-year-old mutt from the local shelter, who showers Marissa with love and keeps her company when no one else is around. They take daily walks together. Marissa still talks to her parents on the phone daily but no longer has feelings of despair about living so far away from them. Her parents provide encouragement and give her positive feedback for achieving a satisfactory adaptation to her new environment. They are planning a visit to see Marissa and Dave in the near future.

Summary and Key Points

- PTSD is the development of characteristic symptoms following exposure to an extreme traumatic stressor involving a personal threat to physical integrity or to the integrity of others. Symptoms may begin within the first 3 months after the trauma, or there may be a delay of several months or even years.
- The symptoms are associated with events that would be markedly distressing to almost anyone and include reexperiencing the trauma, a sustained high level of anxiety or arousal, or a general numbing of responsiveness.
- A disorder that is similar in terms of precipitating traumatic events and symptomatology to PTSD is ASD. In ASD, the symptoms are time limited, lasting up to 1 month following the trauma. If the symptoms last longer than 1 month, the diagnosis would be PTSD.
- Predisposing factors to trauma-related disorders include psychosocial, learning, cognitive, and biological influences.
- Adjustment disorders are relatively common. Some studies indicate they are the most commonly ascribed psychiatric diagnoses.
- Clinical symptoms associated with adjustment disorders include inability to function socially or occupationally in response to an identifiable stressor.

- Adjustment disorder is distinguished by the predominant features of the maladaptive response. These include depression, anxiety, mixed anxiety and depression, disturbance of conduct, and mixed disturbance of emotions and conduct.
- Of the two types of stressors discussed (i.e., sudden shock and continuous), more individuals respond with maladaptive behaviors to long-term continuous stressors.
- Treatment modalities for PTSD include cognitive therapy, prolonged exposure therapy, group and family therapy, eye movement desensitization and reprocessing, and psychopharmacology.
- Treatment modalities for adjustment disorders include individual psychotherapy, family therapy, behavior therapy, self-help groups, crisis intervention, and medications to treat anxiety or depression.
- Nursing care of individuals with trauma- and stressor-related disorders is accomplished using the steps of the nursing process.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. John, a veteran of the war in Iraq, is diagnosed with PTSD. He says to the nurse, "I can't figure out why God took my buddy instead of me." From this statement, the nurse assesses which of the following in John?
   a. Repressed anger
   b. Survivor's guilt
   c. Intrusive thoughts
   d. Spiritual distress

2. John, a veteran of the war in Iraq, is diagnosed with PTSD. He experiences a nightmare during his first night in the hospital. He explains to the nurse that he was dreaming about gunfire all around and people being killed. The nurse's most appropriate *initial* intervention is to:
   a. Administer alprazolam as ordered prn for anxiety.
   b. Call the physician and report the incident.
   c. Stay with John and reassure him of his safety.
   d. Have John listen to a tape of relaxation exercises.

3. John, a veteran of the war in Iraq, is diagnosed with PTSD. Which of the following therapy regimens would most appropriately be ordered for John?
   a. Paroxetine and group therapy
   b. Diazepam and implosion therapy
   c. Alprazolam and behavior therapy
   d. Carbamazepine and cognitive therapy

4. Which of the following may be influential in the predisposition to PTSD?
   a. Unsatisfactory parent-child relationship
   b. Excess of the neurotransmitter serotonin
   c. Distorted, negative cognitions
   d. Severity of the stressor and availability of support systems

5. Nina recently left her husband of 10 years. She was very dependent on him and is having difficulty adjusting to an independent lifestyle. She has been hospitalized with a diagnosis of adjustment disorder with depressed mood. What is the *priority* nursing diagnosis for Nina?
   a. Risk-prone health behavior related to loss of dependency
   b. Complicated grieving related to breakup of marriage
   c. Ineffective communication related to problems with dependency
   d. Social isolation related to depressed mood

6. Nina, who is depressed following the breakup of a very stormy marriage, says to the nurse, "I feel so bad. I thought I would feel better once I left, but I feel worse!" Which is the *best* response by the nurse?
   a. "Cheer up, Nina. You have a lot to be happy about."
   b. "You are grieving the loss of your marriage. It's natural for you to feel badly."
   c. "Try not to dwell on how you feel. If you don't think about it, you'll feel better."
   d. "You did the right thing, Nina. Knowing that should make you feel better."

7. Nina has been hospitalized with adjustment disorder with depressed mood following the breakup of her marriage. Which of the following is true regarding the diagnosis of adjustment disorder?
   a. Nina will require long-term psychotherapy to achieve relief.
   b. Nina likely inherited a genetic tendency for the disorder.
   c. Nina's symptoms will likely remit once she has accepted the change in her life.
   d. Nina probably would not have experienced adjustment disorder if she had a higher level of intelligence.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. The physician orders sertraline (Zoloft) for a client who is hospitalized with adjustment disorder with depressed mood. This medication is intended to:
   a. Increase energy and elevate mood.
   b. Stimulate the central nervous system.
   c. Prevent psychotic symptoms.
   d. Produce a calming effect.

9. An individual who is diagnosed with *adjustment disorder with disturbance of conduct* most likely:
   a. Violates the rights of others to feel better.
   b. Expresses symptoms that reveal a high level of anxiety.
   c. Exhibits severe social isolation and withdrawal.
   d. Is experiencing a complicated grieving process.

10. Emma, age 16, has recently been diagnosed with diabetes mellitus. She must watch her diet and take an oral hypoglycemic medication daily. She has become very depressed, and her mother reports that Emma refuses to change her diet and often skips her medication. Emma has been hospitalized for stabilization of her blood sugar. The psychiatric nurse practitioner has been called in as a consult. Which of the following nursing diagnoses by the psychiatric nurse would be a priority for Emma at this time?
    a. Anxiety related to hospitalization evidenced by noncompliance
    b. Low self-esteem related to feeling different from her peers evidenced by social isolation
    c. Risk for suicide related to new diagnosis of diabetes mellitus
    d. Risk-prone health behavior related to denial of seriousness of her illness evidenced by refusal to follow diet and take medication

11. Trauma-informed care is a philosophical approach that includes which of the following principles? (Select all that apply.)
    a. Nurses need to be aware of the potential for trauma in any client and provide care that minimizes the risk of revictimization or retraumatization.
    b. Medications need to be given before any other interventions are considered.
    c. Trauma-informed care highlights the importance of providing care that protects the physical, psychological, and emotional safety of the client.
    d. Trauma-informed care is based on the principle that traumas are not correlated with depression or increased risk for suicide.

TEST YOUR CRITICAL THINKING SKILLS

Alice, age 48, underwent a mastectomy of the right breast after her mammogram revealed a lump that proved malignant when biopsied. Since her surgery 6 weeks ago, Alice has refused to see any of her friends. She stays in her bedroom, speaks to her husband only when he speaks first, is having difficulty sleeping, and eats very little. She refuses to look at the mastectomy scar and has refused to see the Reach to Recovery representative who has tried several times to help fit her with a prosthesis. Her husband has become very worried about her and spoke to the family doctor, who recommended a psychiatrist. She has been admitted to the psychiatric unit with a diagnosis of adjustment disorder with depressed mood.
   Answer the following questions about Alice:

1. What would be the primary nursing diagnosis for Alice?
2. Describe a short-term goal and a long-term goal for Alice.
3. Discuss a priority nursing intervention in working with Alice.

OBJECTIVES

After reading this chapter, the student will be able to:

1. Discuss historical aspects and epidemiological statistics related to somatic symptom and dissociative disorders.
2. Describe various types of somatic symptom and dissociative disorders and identify symptomatology associated with each; use this information in client assessment.
3. Identify predisposing factors in the development of somatic symptom and dissociative disorders.
4. Formulate nursing diagnoses and goals of care for clients with somatic symptom and dissociative disorders.
5. Describe appropriate nursing interventions for behaviors associated with somatic symptom and dissociative disorders.
6. Evaluate the nursing care of clients with somatic symptom and dissociative disorders.
7. Discuss modalities relevant to treatment of somatic symptom and dissociative disorders.

HOMEWORK ASSIGNMENT

Please read the chapter and answer the following questions:

1. Past experience with serious or life-threatening physical illness, either personal or that of a close family member, can predispose an individual to what somatic symptom disorder?
2. In an individual with dissociative identity disorder, what most commonly precipitates transition from one personality to another?
3. Conversion symptoms most commonly occur in an individual for what reason?
4. Somatic symptom and dissociative disorders are the physical and behavioral responses to what unconscious phenomenon?

614

Disorders with primarily somatic symptoms are characterized by physical symptoms suggesting medical disease but without demonstrable organic pathology. For this reason, most clients with a somatic symptom or related disorder are seen in primary care and hospital settings rather than in mental health-care settings. It is important to note that the inability of modern medicine to determine the existence of pathophysiology to explain a client's symptoms is not sufficient to diagnose him or her with a mental illness. Somatic symptom and related disorders are classified as mental disorders by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* when the excessive focus on somatic symptoms is beyond any medical explanation *and* it causes significant distress and impairment in one's functioning (APA, 2013).

The *DSM-5* identifies a specific disorder called *somatic symptom disorder* and several related disorders including *illness anxiety disorder, conversion disorder, factitious disorders, psychological factors affecting other medical conditions*, and others (APA, 2013). The common focus of these diagnoses is distress and impairment secondary to somatic symptoms, as described previously. The prevalence of somatic symptom disorder in primary care settings has been estimated to be as high as 11 percent and hypochondriasis (no longer a diagnostic category in the *DSM-5* but similar to illness anxiety disorder) from 4 to 6 percent (Yates, 2014). The prevalence of conversion disorders, based on studies of hospital psychiatric consults, is estimated to be as high as 15 percent. The wide variation of these estimates highlights the difficulties associated with consensus about diagnosing and reporting these conditions.

Dissociative disorders are defined by a disturbance of or alteration in the usually integrated functions of consciousness, memory, and identity (Black & Andreasen, 2014). Dissociative responses occur when anxiety becomes overwhelming and the personality becomes disorganized. Defense mechanisms that normally govern consciousness, identity, and memory break down, and behavior occurs with little or no participation on the part of the conscious personality. Types of dissociative disorders described by the *DSM-5* include *depersonalization derealization disorder, dissociative amnesia, dissociative identity disorder,* and others.

This chapter focuses on disorders characterized by severe repressed anxiety that manifests as physical symptoms, fear of illness, and dissociative behaviors. Historical and epidemiological statistics are presented. Predisposing factors that have been implicated in the etiology of these responses provide a framework for studying the dynamics of somatic symptom and dissociative disorders. An explanation of the symptomatology of these disorders is presented as background

knowledge for assessing the client, and nursing care is described in the context of the nursing process. Additional treatment modalities are explored.

Historical Aspects

Historically, somatic symptom disorders were identified as *hysterical neuroses*. The concept of hysteria is at least 4,000 years old and probably originated in Egypt. The name has been in use since the time of Hippocrates.

Over the years, symptoms of hysterical neuroses have been associated with witchcraft, demonology, and sorcery; dysfunction of the nervous system; and unexpressed emotion. They have also historically been viewed as primarily an affliction of women. Critics have argued that the depiction of women as prone to hysteria not only is sexist but has interfered with women receiving adequate medical evaluation for symptoms. Somatic symptom disorders are thought to occur in response to repressed severe anxiety. Freud observed that under hypnosis, clients with hysterical neurosis could recall past memories and emotional experiences that would relieve their symptoms. This observation led to his proposal that unexpressed emotion can be "converted" into physical symptoms.

CORE CONCEPT
Dissociation
An unconscious defense mechanism in which there is separation of identity, memory, and cognition from affect; the segregation of ideas and memories about oneself from their emotional and historical underpinnings (Sadock, Sadock, & Ruiz, 2015; Venes, 2014).

Freud (1962) viewed dissociation as a type of repression, an active defense mechanism used to remove threatening or unacceptable mental contents from conscious awareness. He also described the defense of ego-splitting in the management of incompatible mental contents. Although the study of dissociative processes dates back to the 19th century, scientists still know remarkably little about the phenomena. Questions remain unanswered: Are dissociative disorders psychopathological processes or ego-protective devices? Are dissociative processes under voluntary control, or are they a totally unconscious effort? In either case, they may serve to reduce a person's awareness and anxiety associated with events that are perceived as extremely stressful.

While symptoms such as dissociation are often an unconscious defense mechanism, some individuals consciously fabricate symptoms. The syndrome of

fabricating symptoms for emotional gain was first described by Richard Asher in 1951 in an article in *The Lancet.* He described a pattern of behavior in which individuals fabricated or embellished their histories and signs and symptoms of illness. He termed this condition **Munchausen syndrome** after Baron Friedrich Hieronymus Freiherr von Munchhausen, a German cavalry officer and nobleman, who was known for his fabricated stories and fanciful exaggerations about himself (Asher, 1951). Currently the *DSM-5* describes these syndromes as **factitious disorders.** These include *factitious disorders imposed on self,* or when someone deceptively induces injury or illness in another person, *factitious disorder imposed on another.*

Epidemiological Statistics

The prevalence of somatic symptom disorder is estimated to be anywhere from 0.1 to 11.6 percent (Yates, 2014). Although historically this disorder has been thought to be more prevalent in women, Sadock and associates (2015) identify it as a disorder that affects men and women equally. The *DSM-5* (APA, 2013) suggests that the higher reported prevalence in women may be related to the fact that females tend to report somatic symptoms more often than males do.

Lifetime prevalence rates of conversion disorder vary widely. Statistics within the general population have ranged from 5 to 30 percent. The disorder occurs more frequently in women than in men and more frequently in adolescents and young adults than in other age groups. A higher prevalence exists in lower socioeconomic groups, rural populations, those with less education, and military personnel who have been exposed to combat situations (Black & Andreasen, 2014; Sadock et al., 2015).

The prevalence of illness anxiety disorder, closely associated with the now-deleted diagnosis of hypochondriasis, is especially difficult to establish because this disorder is new in the *DSM-5.* The best estimate is based on data about the prevalence of hypochondriasis, estimated at between 3 and 8 percent (APA, 2013). Some people who were previously diagnosed with hypochondriasis might better meet diagnostic criteria for somatic symptom disorder under this new classification. There are similarities in these two disorders, but in somatic symptom disorder, the primary symptom is significant somatic sensations, whereas in illness anxiety disorder, there are few to no somatic symptoms but anxiety or fear about having or acquiring an illness is a primary concern. More research is needed to better understand the epidemiological statistics for each of these disorders. Hypochondriasis was relabeled to illness anxiety disorder at least in part to eliminate myths and stigmas associated with the former diagnosis (Dimsdale, 2015). Illness anxiety disorder is equally common among men and women, and onset most commonly occurs in early adulthood. Data on the prevalence of factitious disorder is limited, so the frequency of the disorder is unknown. Estimates based on samples of hospital patients identify that about 1 percent meet criteria for factitious disorder (APA, 2013). Factitious disorder imposed on another is most often perpetrated by mothers against infants but accounts for less than 0.04 percent of reported cases of child abuse in the United States (Sadock et al., 2015).

Dissociative syndromes, although often portrayed in fictional media, are statistically quite rare. However, when they do occur, they may present dramatic clinical pictures of severe disturbance in normal personality functioning. Dissociative amnesia occurs most frequently under conditions of war or during natural disasters. In recent years, the number of reported cases has increased, possibly attributable to increased awareness of the phenomenon and subsequent identification of cases that were previously undiagnosed. It appears to be equally common in men and women. Dissociative amnesia can occur at any age but is difficult to diagnose in children because it is easily confused with inattention or oppositional behavior.

Estimates of the prevalence of dissociative identity disorder (DID, previously called *multiple personality disorder*) also vary. The disorder occurs from five to nine times more frequently in women than in men (Sadock et al., 2015). Onset likely occurs in childhood, although manifestations of the disorder may not be recognized until late adolescence or early adulthood.

The prevalence of severe episodes of depersonalization-derealization disorder is unknown. Single brief episodes may occur in as many as half of all adults, particularly when under severe psychosocial stress; when sleep deprived; during travel to unfamiliar places; or when intoxicated with hallucinogens, marijuana, or alcohol (Black & Andreasen, 2014). Symptoms usually begin in adolescence or early adulthood. The disorder is chronic, with periods of remission and exacerbation. The incidence of depersonalization-derealization disorder is high under conditions of sustained traumatization, such as in military combat or prisoner-of-war camps. It has also been reported in many individuals who endure near-death experiences.

Application of the Nursing Process

Background Assessment Data: Types of Somatic Symptom Disorders
Somatic Symptom Disorder

Somatic symptom disorder is a syndrome of multiple somatic symptoms that cannot be explained medically and are associated with psychosocial distress and frequent visits to health-care professionals to seek

assistance. Symptoms may be vague, dramatized, or exaggerated in presentation, and an excessive amount of time and energy is devoted to worry and concern about the symptoms. Individuals with somatic symptom disorder are so convinced that their symptoms are related to organic pathology that they adamantly reject and are often irritated by any implication that stress or psychosocial factors play a role in their conditions. The disorder is chronic, with symptoms beginning before age 30. Anxiety and depression are frequent comorbidities, and consequently, there is an increased risk for suicide attempts (Yates, 2014).

The disorder usually runs a fluctuating course, with periods of remission and exacerbation. Clients often receive medical care from several physicians, sometimes concurrently, leading to the possibility of dangerous treatment combinations. They have a tendency to seek relief through overmedicating with prescribed analgesics or antianxiety agents. Drug abuse and dependence are common complications of somatic symptom disorder. The *DSM-5* diagnostic criteria for somatic symptom disorder are presented in Box 29–1.

Illness Anxiety Disorder

Illness anxiety disorder is defined as an unrealistic or inaccurate interpretation of physical symptoms or sensations, leading to preoccupation about and fear of having a serious disease. The fear becomes disabling and persists despite appropriate reassurance that no organic pathology can be detected. Symptoms may be minimal or absent, but the individual is highly anxious about and suspicious of the presence of an undiagnosed, serious medical illness (APA, 2013).

Individuals with illness anxiety disorder are extremely conscious of bodily sensations and changes and may become convinced that a rapid heart rate indicates they have heart disease or that a small sore is skin cancer. They are profoundly preoccupied with their bodies and are totally aware of even the slightest change in feeling or sensation. The response to these small changes, however, is usually unrealistic and exaggerated.

Some individuals with illness anxiety disorder have a long history of "doctor shopping" and are convinced that they are not receiving the proper care. Others avoid seeking medical assistance because to do so would increase their anxiety to intolerable levels. Depression is common, and obsessive-compulsive traits frequently accompany the disorder. Preoccupation with the fear of serious disease may interfere with social or occupational functioning. Some individuals are able to function appropriately on the job, however, while limiting their physical complaints to non-work time.

Individuals with illness anxiety disorder are so apprehensive and fearful that they become alarmed at the slightest intimation of serious illness. Even reading about a disease or hearing that someone they know has been diagnosed with an illness precipitates alarm. Both somatic symptom disorder and illness anxiety disorder have similar features to what was previously called hypochondriasis, but the *DSM-5* identifies two separate disorders to distinguish between individuals who are primarily preoccupied with perceived

---

BOX 29–1 Diagnostic Criteria for Somatic Symptom Disorder

A. One or more somatic symptoms that are distressing or result in significant disruption in daily life.

B. Excessive thoughts, feelings, or behaviors related to the somatic symptoms or associated health concerns as manifested by at least one of the following:
  1. Disproportionate and persistent thoughts about the seriousness of one's symptoms.
  2. Persistently high level of anxiety about health or symptoms.
  3. Excessive time and energy devoted to these symptoms or health concerns.

C. Although any one symptom may not be continuously present, the state of being symptomatic is persistent (typically more than 6 months).

Specify if:

With predominant pain (the somatic symptoms predominantly involve pain)

Persistent (a persistent course is characterized by severe symptoms, marked impairment, and long duration [more than 6 months])

Specify current severity:

Mild (only one of the symptoms specified in Criterion B is fulfilled)

Moderate (two or more of the symptoms specified in Criterion B are fulfilled)

Severe (two or more of the symptoms specified in Criterion B are fulfilled, plus there are multiple somatic complaints [or one very severe somatic symptom])

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

physical symptoms (somatic symptom disorder) and those who are primarily focused on fear of illness in general (illness anxiety disorder).

The *DSM-5* diagnostic criteria for illness anxiety disorder are presented in Box 29–2.

Conversion Disorder (Functional Neurological Symptom Disorder)

Conversion disorder is a loss of or change in body function that cannot be explained by any known medical disorder or pathophysiological mechanism. There is likely a psychological component involved in the initiation, exacerbation, or perpetuation of the symptom, although it may or may not be identifiable.

Conversion symptoms affect voluntary motor or sensory functioning suggestive of neurological disease. Examples include paralysis, **aphonia** (inability to produce voice), seizures, coordination disturbance, difficulty swallowing, urinary retention, akinesia, blindness, deafness, double vision, **anosmia** (inability to perceive smell), loss of pain sensation, and hallucinations. Abnormal limb shaking with impaired or loss of consciousness that resembles epileptic seizures is another type of conversion disorder symptom, referred to as *psychogenic* or *nonepileptic seizures*. **Pseudocyesis** (false pregnancy) is a conversion symptom and may represent a strong desire to be pregnant.

The *DSM-5* clarifies that "although the diagnosis [of conversion disorder] requires that the symptom is not explained by neurological disease, it should not be made simply because results from investigations are normal or because the symptom is 'bizarre.' There must be clear evidence of incompatibility with neurological disease" (APA, 2013, p. 319). For example, if a client appears to be having a seizure but the EEG is normal, the eyes are closed and resist opening, and there is no urinary incontinence, conversion disorder may be diagnosed. Multiple causes likely play a role in etiology.

While not diagnostic of a conversion disorder, some clients display an apparent indifference to symptoms that seem very serious to others. This feature is coined *la belle indifference* (Sadock et al., 2015). Most symptoms of conversion disorder resolve within a few weeks. About 20 percent of individuals with the diagnosis have a relapse within 1 year. The *DSM-5* states the prognosis is better when the symptoms are of short duration, when the client accepts the diagnosis, when there is absence of comorbid physical disease, and when there are no identified maladaptive personality traits (APA, 2013). The *DSM-5* diagnostic criteria for conversion disorder are presented in Box 29–3.

Psychological Factors Affecting Other Medical Conditions

Psychological factors play a role in virtually all medical conditions. However, in this disorder, it is evident that psychological or behavioral factors are clearly implicated in the development, exacerbation, or delayed recovery from a medical condition.

The *DSM-5* diagnostic criteria for psychological factors affecting other medical conditions are presented in Box 29–4.

Factitious Disorder

Factitious disorders involve conscious, intentional feigning of physical or psychological symptoms (Black & Andreasen, 2014). Individuals with factitious disorder pretend to be ill in order to receive emotional care

---

BOX 29–2 **Diagnostic Criteria for Illness Anxiety Disorder**

A. Preoccupation with having or acquiring a serious illness.

B. Somatic symptoms are not present or, if present, are only mild in intensity. If another medical condition is present or there is a high risk for developing a medical condition (e.g., strong family history is present), the preoccupation is clearly excessive or disproportionate.

C. There is a high level of anxiety about health, and the individual is easily alarmed about personal health status.

D. The individual performs excessive health-related behaviors (e.g., repeatedly checks his or her body for signs of illness) or exhibits maladaptive avoidance (e.g., avoids doctors' appointments and hospitals).

E. Illness preoccupation has been present for at least 6 months, but the specific illness that is feared may change over that period of time.

F. The illness-related preoccupation is not better explained by another mental disorder, such as somatic symptom disorder, panic disorder, generalized anxiety disorder, body dysmorphic disorder, obsessive-compulsive disorder, or delusional disorder, somatic type.

Specify whether:

Care-seeking type: Medical care, including physician visits or undergoing tests and procedures, is frequently used.

Care-avoidant type: Medical care is rarely used.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

BOX 29–3 **Diagnostic Criteria for Conversion Disorder (Functional Neurological Symptom Disorder)**

A. One or more symptoms of altered voluntary motor or sensory function.
B. Clinical findings provide evidence of incompatibility between the symptom and recognized neurological or medical conditions.
C. The symptom or deficit is not better explained by another medical or mental disorder.
D. The symptom or deficit causes clinically significant distress or impairment in social, occupational, or other important areas of functioning or warrants medical evaluation.

Specify symptom type:

With weakness or paralysis
With abnormal movement
With swallowing symptoms
With speech symptom
With attacks or seizures
With anesthesia or sensory loss
With special sensory symptom
With mixed symptoms

Specify if:

Acute episode
Persistent

Specify if:

With psychological stressor
Without psychological stressor

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

BOX 29–4 **Diagnostic Criteria for Psychological Factors Affecting Other Medical Conditions**

A. A medical symptom or condition (other than a mental disorder) is present.
B. Psychological or behavioral factors adversely affect the general medical condition in one of the following ways:
   1. The factors have influenced the course of the medical condition as shown by a close temporal association between the psychological factors and the development or exacerbation of, or delayed recovery from, the medical condition.
   2. The factors interfere with the treatment of the medical condition (e.g., poor adherence).
   3. The factors constitute additional well-established health risks for the individual.
   4. The factors influence the underlying pathophysiology, precipitating or exacerbating symptoms or necessitating medical attention.
C. The psychological and behavioral factors in Criterion B are not better explained by another mental disorder (e.g., panic disorder, major depressive disorder, posttraumatic stress disorder).

Specify current severity:

Mild: Increases medical risk
Moderate: Aggravates underlying medical condition
Severe: Results in medical hospitalization or emergency room visit
Extreme: Results in severe, life-threatening risk

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

---

and support commonly associated with the role of "patient." Even though the behaviors are deliberate and intentional, there may be an associated compulsive element that diminishes personal control. Individuals with this disorder characteristically become skilled at presenting their "symptoms" so well that they successfully gain admission to hospitals and treatment centers. To accomplish this, they may aggravate existing symptoms, induce new ones, or even inflict painful injuries on themselves (Sadock et al., 2015). The

disorder has also been identified as *Munchausen syndrome*, and symptoms may be psychological, physical, or a combination of both.

The disorder may be imposed on oneself or on another person (previously called *factitious disorder by proxy*). In the latter case, physical symptoms are intentionally imposed on a person under the care of the perpetrator. Diagnosis of factitious disorder can be difficult, as individuals become very inventive in their quest to produce symptoms. "The most common case of factitious disorder by proxy involves a mother who deceives medical personnel into believing her child is ill" (Sadock et al., 2015, p. 492). This may be accomplished by lying about the child's medical history, manipulating data such as by contaminating laboratory samples, and inducing illness or injury in their child through use of substances or other physical assaults.

The *DSM-5* diagnostic criteria for factitious disorder are presented in Box 29–5.

Predisposing Factors Associated With Somatic Symptom and Related Disorders

Genetic

Studies have shown an increased incidence of somatic symptom disorder, conversion disorder, and illness anxiety disorder in first-degree relatives, implying a possible inheritable predisposition. In somatic symptom disorder, there is evidence of genetic overlap with some other mental disorders, including eating disorders (Soares & Grossman, 2012; Yates, 2014; Yutzy & Parish, 2008).

Biochemical

Studies have indicated that tryptophan catabolism may be abnormal in clients with somatic symptom disorders (Yate, 2014). Decreased levels of serotonin and endorphins may play a role in the sensation of pain.

Neuroanatomical

Brain dysfunction has been proposed by some researchers as a factor in factitious disorders (Sadock et al., 2015). The hypothesis is that impairment in information processing contributes to the aberrant behaviors associated with the disorder. Sadock and associates report that brain imaging studies have found hypometabolism in the dominant hemisphere, hypermetabolism in the nondominant hemisphere, and impaired hemispheric communication in conversion disorders (p. 474). Other reports of brain imaging studies have identified reduced volume of the amygdala as well as reduced connectivity between the amygdala and brain centers controlling executive and motor functions in one or more somatic symptom disorders (Yates, 2014).

Psychodynamic

Some psychodynamicists view illness anxiety disorder as an ego defense mechanism. Physical complaints are the expression of low self-esteem and feelings of worthlessness, because it is easier to feel something is

---

BOX 29–5 Diagnostic Criteria for Factitious Disorder

FACTITIOUS DISORDER IMPOSED ON SELF
A. Falsification of physical or psychological signs or symptoms, or induction of injury or disease, associated with identified deception.
B. The individual presents himself or herself to others as ill, impaired, or injured.
C. The deceptive behavior is evident even in the absence of obvious external rewards.
D. The behavior is not better explained by another mental disorder, such as delusional disorder or other psychotic disorder.

Specify:

Single episode

Recurrent episodes

FACTITIOUS DISORDER IMPOSED ON ANOTHER (PREVIOUSLY FACTITIOUS DISORDER BY PROXY)
A. Falsification of physical or psychological signs or symptoms, or induction of injury or disease in another, associated with identified deception.
B. The individual presents another individual (victim) to others as ill, impaired, or injured.
C. The deceptive behavior is evident even in the absence of obvious external rewards.
D. The behavior is not better explained by another mental disorder, such as delusional disorder or other psychotic disorder.

Note: The perpetrator, not the victim, receives this diagnosis.
Specify:

Single episode

Recurrent episodes

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

wrong with the body than to feel something is wrong with the self. Another psychodynamic view of illness anxiety disorder (as well as somatic symptom disorder, predominantly pain) is related to a defense against guilt. The individual views the self as "bad," based on real or imagined past misconduct, and considers physical suffering the deserved punishment required for atonement. This view has also been related to individuals with factitious disorders.

The psychodynamic theory of conversion disorder proposes that emotions associated with a traumatic event that the individual cannot express because of moral or ethical unacceptability are "converted" into physical symptoms. The unacceptable emotions are repressed and converted to a somatic symptom that is symbolic in some way of the original emotional trauma.

Some reports suggest that individuals with factitious disorders were victims of child abuse or neglect. Frequent childhood hospitalizations provided a reprieve from the traumatic home situation and a loving and caring environment that was absent in the child's family. This theory proposes that the individual with factitious disorder is attempting to recapture the only positive support he or she may have known by seeking out the environment in which it was received as a child. Regarding factitious disorder imposed on another, Sadock and associates (2015) have stated, "One apparent purpose of the behavior is for the caretaker to indirectly assume the sick role; another is to be relieved of the caretaking role by having the child hospitalized" (p. 492).

Family Dynamics

Some families have difficulty expressing emotions openly and resolving conflicts verbally. When this occurs, the child may become ill, and a shift in focus is made from the open conflict to the child's illness, leaving unresolved the underlying issues that the family cannot confront openly. Thus, **somatization** in the child brings some stability to the family as harmony replaces discord and the child's welfare becomes the common concern. The child in turn receives positive reinforcement for the illness. This shift in focus from family discord to concern for the child is sometimes called **tertiary gain.**

Learning Theory

Somatic complaints are often reinforced when the sick role relieves the individual from the need to deal with a stressful situation, whether it be within society or within the family. The sick person learns that he or she may avoid stressful obligations; may postpone unwelcome challenges; is excused from troublesome duties **(primary gain);** becomes the prominent focus of attention because of the illness **(secondary gain);** or relieves conflict within the family as concern is shifted to the ill person and away from the real issue

(tertiary gain). These types of positive reinforcements virtually guarantee repetition of the response.

Past experience with serious or life-threatening physical illness, either personal or that of close family members, can predispose an individual to illness anxiety disorder. Once an individual has experienced a threat to biological integrity, he or she may develop a fear of recurrence. This generates an exaggerated response to minor physical changes, leading to excessive anxiety and health concerns.

Transactional Model of Stress and Adaptation

The etiology of somatic symptom disorders is most likely influenced by multiple factors. In Figure 29–1, a graphic depiction of this theory of multiple causation is presented in the transactional model of stress and adaptation.

Background Assessment Data: Types of Dissociative Disorders

Dissociative Amnesia

> ### CORE CONCEPT
> **Amnesia**
> Partial or total, permanent or transient loss of memory. The term is often applied to episodes during which patients forget recent events (although they may conduct themselves appropriately) and after which no memory of the period persists. Such episodes may be caused by strokes, seizures, trauma, senility, alcoholism, or intoxication (Venes, 2014).

Dissociative amnesia is an inability to recall important personal information, usually of a traumatic or stressful nature, that is too extensive to be explained by ordinary forgetfulness and is not due to the direct effects of substance use or a neurological or other medical condition (APA, 2013). The *DSM-5* states that the most common types of dissociative amnesia are localized, selective, and generalized. Localized and selective amnesia are related to a specific stressful event. For example, the individual with **localized amnesia** is unable to recall all incidents associated with a stressful period. It may be broader than just a single event, such as the inability to remember months or years of child abuse (APA, 2013). In **selective amnesia,** the individual can recall only certain incidents associated with a stressful event for a specific period after the event. In **generalized amnesia,** the individual has amnesia for his or her identity and total life history.

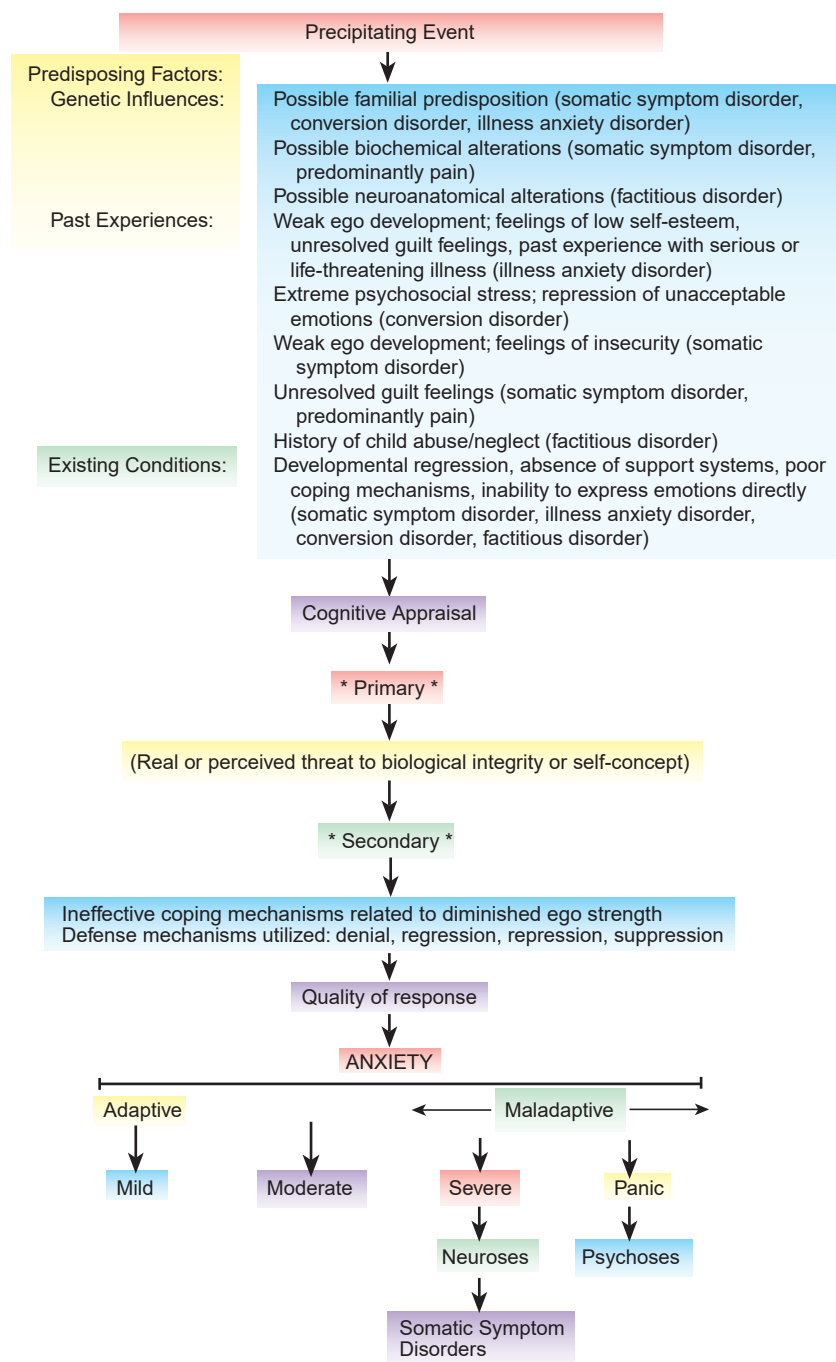
The individual with amnesia usually appears alert and may give no indication to observers that anything is wrong, although some clients may present


FIGURE 29–1 The dynamics of somatic symptom disorders using the transactional model of stress and adaptation.

with alterations in consciousness, with conversion symptoms, or in trance states. Clients suffering from amnesia are often brought to general hospital emergency departments by police who have found them wandering confusedly around the streets.

Onset of an amnestic episode usually follows severe psychosocial stress. Termination is typically abrupt and followed by complete recovery. Recurrences are unusual. A specific subtype of dissociative amnesia is *with dissociative fugue.* Dissociative **fugue** is characterized by a sudden, unexpected travel away from customary places or by bewildered wandering, with the inability to recall some or all of one's past. An individual in a fugue state may not be able to recall personal identity and sometimes assumes a new identity (Black & Andreasen, 2014).

The *DSM-5* diagnostic criteria for dissociative amnesia are presented in Box 29–6.

BOX 29–6 Diagnostic Criteria for Dissociative Amnesia

A. An inability to recall important autobiographical information, usually of a traumatic or stressful nature, that is inconsistent with ordinary forgetting. *Note*: Dissociative amnesia most often consists of localized or selective amnesia for a specific event or events; or generalized amnesia for identity and life history.

B. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

C. The disturbance is not attributable to the physiological effects of a substance (e.g., alcohol or other drug of abuse, a medication) or a neurological or other medical condition (e.g., partial complex seizures, transient global amnesia, sequelae of a closed head injury/traumatic brain injury, other neurological condition).

D. The disturbance is not better explained by dissociative identity disorder, posttraumatic stress disorder, acute stress disorder, somatic symptom disorder, or major or mild neurocognitive disorder.

Specify if:

With dissociative fugue (apparently purposeful travel or bewildered wandering that is associated with amnesia for identity or for other important autobiographical information)

Dissociative Identity Disorder

Dissociative identity disorder (DID) was formerly called multiple personality disorder and is characterized by the existence of two or more personality states in a single individual. These different personality states are sometimes referred to as *alter identities* or just *alters*. Only one of the personalities is evident at any given moment, and one of them is dominant most of the time over the course of the disorder. Each personality is unique and composed of a complex set of memories, behavior patterns, and social relationships that surface at different times. Transition from one personality state to another may be sudden or gradual and is sometimes quite dramatic. Sadock and associates (2015) state, "Patients often describe a profound sense of concretized internal division or personified internal conflicts between parts of themselves . . . these parts may have proper names or be designated by their predominant affect or function, for example, 'the angry one' or 'the wife'" (p. 460).

DID has been a controversial disorder since it gained attention after the 1976 movie *Sybil*, which portrayed the presumed true story of a woman who reported having 16 different personalities. Diagnosis of this disorder increased significantly in the years following the movie, and in 1980 the APA formally recognized the disorder as a psychiatric illness (Haberman, 2014). Since then, critics have reported that both the patient "Sybil" and her psychiatrist acknowledged her case as fabrication. Dr. David Speigel, a psychiatrist who was involved in promoting the American Psychiatric Association's adoption of DID as the preferred term for this condition, is quoted in Haberman's review (2014) as saying "[the term] multiple personality carries with it the implication that they really have more than one personality. The problem is fragmentation of identity, not that you really are 12 people . . . that you have not more than one but less than one personality."

Although questions persist about whether this disorder has been overdiagnosed, there are certainly individuals who present with fragmented identity. Most have been victims of severe childhood physical and sexual abuse. It is not uncommon for clients with DID to also manifest with symptoms of other dissociative disorders such as amnesia, fugue states, depersonalization, and derealization (Sadock et al., 2015). Generally, there is amnesia for the events that took place when another personality was being manifested, and clients report "gaps" in autobiographical histories, "lost time" or "blackouts." They may "wake up" in unfamiliar situations with no idea where they are, how they got there, or the identities of the people around them. They may be accused of lying when they deny remembering or being responsible for events or actions.

Dissociative identity disorder is not always incapacitating. Some individuals with DID maintain responsible positions, complete graduate degrees, and are successful spouses and parents before diagnosis and while in treatment. Before they are diagnosed with DID, many individuals are misdiagnosed with depression, borderline and antisocial personality disorders, schizophrenia, epilepsy, or bipolar disorder. The *DSM-5* diagnostic criteria for DID are presented in Box 29–7.

Depersonalization-Derealization Disorder

Depersonalization-derealization disorder is characterized by a temporary change in the quality of self-awareness, which often takes the form of feelings of unreality, changes in body image, feelings of detachment from the environment, or a sense of observing oneself from outside the body. For example, a soldier in recalling an experience in combat describes observing himself from a distance and wondering what he would do if *he* were in that situation. **Depersonalization** (a disturbance in the perception of oneself) is differentiated from **derealization,** which describes an alteration in the perception of the external environment. Both of

BOX 29–7 Diagnostic Criteria for Dissociative Identity Disorder

A. Disruption of identity characterized by two or more distinct personality states, which may be described in some cultures as an experience of possession. The disruption in identity involves marked discontinuity in sense of self and sense of agency, accompanied by related alterations in affect, behavior, consciousness, memory, perception, cognition, and/or sensory-motor functioning. These signs and symptoms may be observed by others or reported by the individual.

B. Recurrent gaps in the recall of everyday events, important personal information, and/or traumatic events that are inconsistent with ordinary forgetting.

C. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

D. The disturbance is not a normal part of a broadly accepted cultural or religious practice. *Note*: In children, the symptoms are not better explained by imaginary playmates or other fantasy play.

E. The symptoms are not attributable to the physiological effects of a substance (e.g., blackouts or chaotic behavior during alcohol intoxication) or another medical condition (e.g., complex partial seizures).

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

these phenomena also occur in a variety of psychiatric illnesses such as schizophrenia, depression, anxiety states, and neurocognitive disorders. As previously stated, the symptoms of depersonalization and derealization are very common. It is estimated that approximately half of all adults have experienced transient episodes of these symptoms, identified as the third-most commonly reported psychiatric symptoms after depression and anxiety (Sadock et al., 2015, p. 454). Diagnosis of the disorder is made only if the symptoms cause significant distress or impairment in functioning.

The *DSM-5* describes this disorder as persistent or recurrent episodes of depersonalization, derealization, or both (APA, 2013). There may be a mechanical or dreamlike feeling or a belief that the body's physical characteristics have changed. If derealization is present, objects in the environment are perceived as altered in size or shape. Other people in the environment may seem automated or mechanical.

These distorted perceptions are experienced as disturbing and often accompanied by anxiety, depression, fear of going insane, obsessive thoughts, somatic complaints, and an alteration in the subjective sense of time. The age of onset is typically late adolescence or early adulthood, and it is two to four times more common in women than in men (Sadock et al., 2015).

The *DSM-5* diagnostic criteria for depersonalization-derealization disorder are presented in Box 29–8.

Predisposing Factors Associated With Dissociative Disorders

Genetics

The overwhelming majority of adults with DID (85% to 97%) have a history of physical and sexual abuse. Although genetic factors are being studied, preliminary research does not show evidence of significant genetic contribution (Sadock et al., 2015, p. 458).

Neurobiological

Some clinicians have suggested a possible correlation between neurological alterations and dissociative disorders. Although available information is inadequate, dissociative amnesia may be related to neurophysiological

BOX 29–8 Diagnostic Criteria for Depersonalization-Derealization Disorder

A. The presence of persistent or recurrent depersonalization, derealization, or both:
  1. **Depersonalization:** Experiences of unreality, detachment, or being an outside observer with respect to one's thoughts, feelings, sensations, body, or actions (e.g., perceptual alterations, distorted sense of time, unreal or absent self, emotional and/or physical numbing).
  2. **Derealization:** Experiences of unreality or detachment with respect to surroundings (e.g., individuals or objects are experienced as unreal, dreamlike, foggy, lifeless, or visually distorted).

B. During the depersonalization or derealization experiences, reality testing remains intact.

C. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

D. The disturbance is not attributable to the physiological effects of a substance (e.g., a drug of abuse, medication) or another medical condition (e.g., seizures).

E. The disturbance is not better explained by another mental disorder, such as schizophrenia, panic disorder, major depressive disorder, acute stress disorder, posttraumatic stress disorder, or another dissociative disorder.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

dysfunction. Areas of the brain that have been associated with memory include the hippocampus, amygdala, fornix, mammillary bodies, thalamus, and frontal cortex.

Depersonalization has been evidenced with migraines and with marijuana use, responds to selective serotonin reuptake inhibitors (SSRIs), and is seen in cases where L-tryptophan, a serotonin precursor, is depleted. These facts suggest some level of serotonergic involvement in this dissociative symptom (Sadock et al., 2015). Some studies have suggested a possible link between DID and certain neurological conditions, such as temporal lobe epilepsy and severe migraine headaches. Electroencephalographic abnormalities have been observed in some clients with DID.

Psychodynamic Theory

Freud (1962) believed that dissociative behaviors occurred when individuals repressed distressing mental contents from conscious awareness. He believed that the unconscious was a dynamic entity in which repressed mental contents were stored and unavailable to conscious recall. Current psychodynamic explanations of dissociation are based on Freud's concepts. The repression of mental contents is believed to protect the client from extreme emotional pain triggered by either disturbing external circumstances or anxiety-provoking internal urges and feelings. In the case of depersonalization and derealization, the pain and anxiety are expressed as feelings of unreality or detachment from the environment of the painful situation.

Psychological Trauma

A growing body of evidence points to the etiology of dissociative disorders as a response to traumatic experiences that overwhelm the individual's capacity to cope by any means other than dissociation. In DID, these experiences are most often physical, sexual, or psychological abuse by a parent or significant other in the child's life. The most widely accepted explanation for DID is that it begins as a survival strategy to help children cope with horrifying sexual, physical, or psychological abuse and evolves into a fragmented identity as the victim struggles to integrate conflicting aspects of personality into a cohesive whole. Dissociative amnesia is frequently related to acute and extreme trauma but may also develop in the clinical presentation of DID or in response to combat trauma during wartime.

Transactional Model of Stress and Adaptation

The etiology of dissociative disorders is likely influenced by multiple factors. In Figure 29–2, a graphic depiction of this theory of multiple causation is presented in the transactional model of stress and adaptation.

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Table 29–1 presents a list of client behaviors and the NANDA nursing diagnoses that correspond to those behaviors, which may be used in planning care for clients with somatic symptom and dissociative disorders.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with somatic symptom and dissociative disorders.

The client:

- Effectively uses adaptive coping strategies during stressful situations without resorting to physical symptoms (*somatic symptom disorder*)
- Interprets bodily sensations rationally, verbalizes understanding of the significance of the irrational fear, and has decreased the number and frequency of physical complaints (*illness anxiety disorder and somatic symptom disorder*)
- Is free of physical disability and is able to verbalize understanding of the possible correlation between the loss of or alteration in function and extreme emotional stress (*conversion disorder*)
- Can recall events associated with a traumatic or stressful situation (*dissociative amnesia*)
- Can verbalize the extreme anxiety that precipitated the dissociation (*depersonalization-derealization disorder*)
- Can demonstrate more adaptive coping strategies to avert dissociative behaviors in the face of severe anxiety (*depersonalization-derealization disorder*)
- Verbalizes understanding of the existence of multiple personality states and the purposes they serve (*dissociative identity disorder*)
- Is able to maintain a sense of reality during stressful situations (*depersonalization-derealization disorder*)

Planning and Implementation

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Ineffective Coping

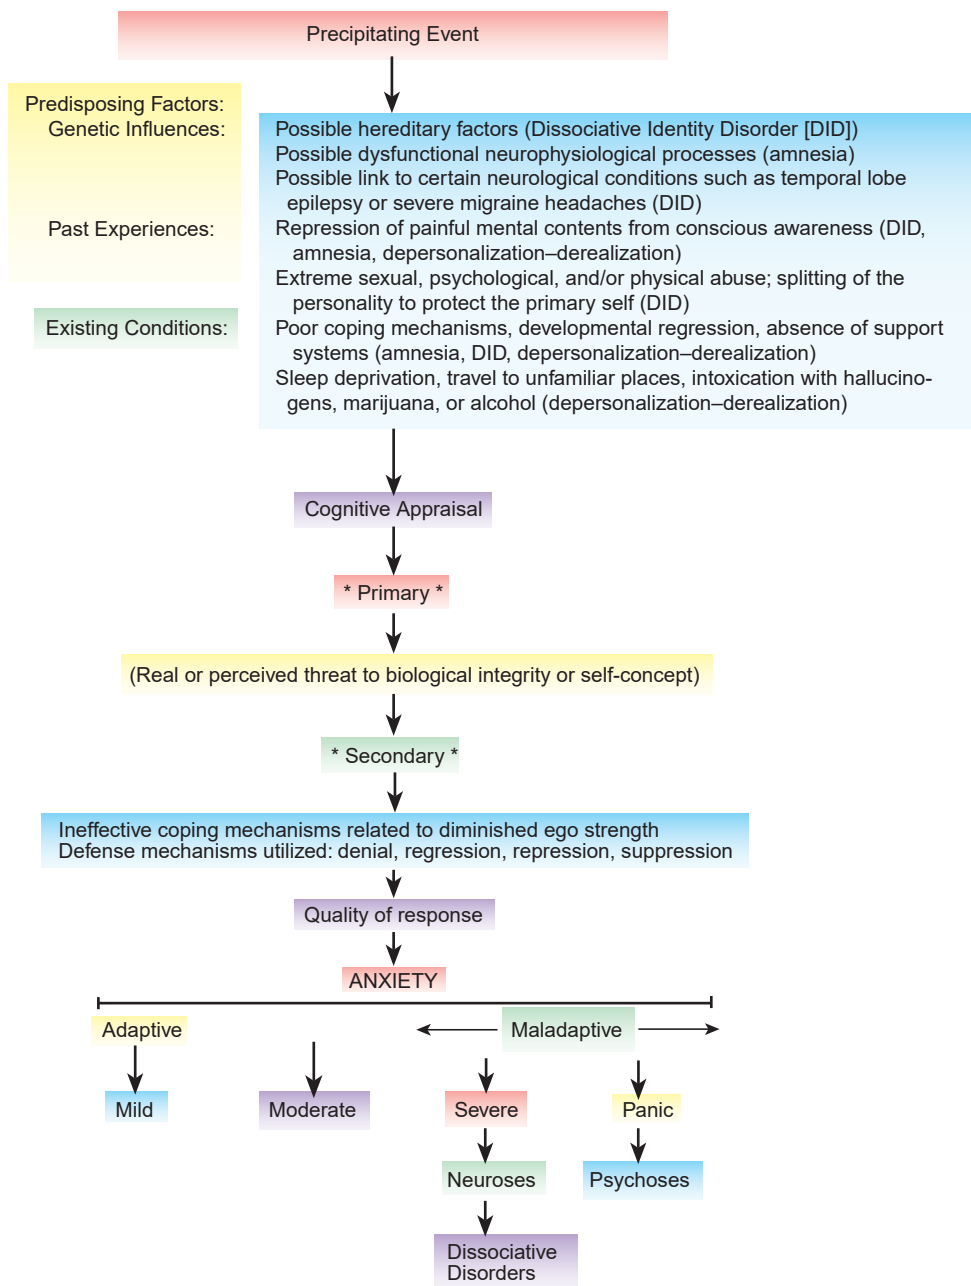
Ineffective coping is defined as the "inability to form a valid appraisal of the stressors, inadequate choices of practiced responses, and/or inability to use available resources" (Herdman & Kamitsuru, 2014, p. 326). This nursing diagnosis may be relevant to any somatic symptom and related disorders as well as to clients with dissociative disorders.


FIGURE 29–2 The dynamics of dissociative disorders using the transactional model of stress and adaptation.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Within (specified time), client will verbalize understanding of correlation between physical symptoms and psychological problems.

Long-term goal

■ By time of discharge from treatment, client will demonstrate ability to cope with stress by means other than preoccupation with physical symptoms.

Interventions

■ Monitor the physician's ongoing assessments, laboratory reports, and other data to maintain assurance that the possibility of organic pathology is clearly ruled out. Review findings with the client. Accurate medical assessment is vital for the provision of adequate and appropriate care. Honest explanation may help the client understand the psychological implications.

■ Recognize and accept that the physical complaint is real to the client even though no organic etiology can be identified. Denial of the client's feelings is

TABLE 2–2 Assigning Nursing Diagnoses to Behaviors Commonly Associated With Somatic Symptom and Dissociative Disorders	
BEHAVIORS	**NURSING DIAGNOSES**
Verbalization of numerous physical complaints in the absence of any pathophysiological evidence; focus on the self and physical symptoms *(somatic symptom disorder)*	Ineffective coping; chronic pain
History of "doctor shopping" for evidence of organic pathology to substantiate physical symptoms; statements such as, "I don't know why the doctor put me on the psychiatric unit. I have a physical problem" *(somatic symptom disorder)*	Deficient knowledge (psychological causes for physical symptoms)
Preoccupation with and unrealistic interpretation of bodily signs and sensations *(illness anxiety disorder)*	Fear (of having a serious disease)
Loss or alteration in physical functioning without evidence of organic pathology *(conversion disorder)* Alteration in the perception or experience of the self or the environment *(depersonalization-derealization disorder)*	Disturbed sensory perception*
Need for assistance to carry out self-care activities such as eating, dressing, maintaining hygiene, and toileting due to alteration in physical functioning *(conversion disorder)*	Self-care deficit
History of numerous exacerbations of physical illness; inappropriate or exaggerated behaviors; denial of emotional problems *(psychological factors affecting other medical conditions)*	Deficient knowledge (psychological factors affecting medical condition); Ineffective denial
Loss of memory *(dissociative amnesia)*	Impaired memory
Verbalizations of frustration over lack of control and dependence on others *(dissociative amnesia)*	Powerlessness
Unresolved grief; depression; self-blame associated with childhood abuse *(dissociative identity disorder [DID])*	Risk for suicide
Presence of more than one personality within the individual *(DID)*	Disturbed personality identity
Feigning of physical or psychological symptoms to gain attention *(factitious disorder)*	Ineffective coping

*This diagnosis has been resigned from the NANDA-I list of approved diagnoses. It is used in this instance because it is most compatible with the identified behaviors.

nontherapeutic and interferes with establishment of a trusting relationship.

■ Provide pain medication as prescribed by physician. Client comfort and safety are nursing priorities.

■ Identify gains that the physical symptoms are providing for the client: increased dependency, attention, and distraction from other problems. Identification of underlying motivation is important in assisting the client with problem resolution.

■ Initially, fulfill the client's most urgent dependency needs, but gradually withdraw attention to physical symptoms. Minimize time given in response to physical complaints. Anxiety and maladaptive behaviors will increase if dependency needs are ignored initially. Gradual withdrawal of positive reinforcement will discourage repetition of maladaptive behaviors.

■ Explain to the client that any new physical complaints will be referred to the physician and give no further attention to them. Follow up on the physician's assessment of the complaint. The possibility

of organic pathology must always be considered. Failure to do so could jeopardize client safety.

■ Encourage the client to verbalize fears and anxieties. Explain that attention will be withdrawn if rumination about physical complaints begins and follow through. Without consistency of limit setting, change will not occur.

■ Help the client recognize that physical symptoms often occur because of, or are exacerbated by, specific stressors. Discuss alternative coping strategies that client may use in response to stress (e.g., relaxation exercises, physical activities, assertiveness skills). The client may need help with problem-solving. Give positive reinforcement for adaptive coping strategies.

■ Have the client keep a diary of appearance, duration, and intensity of physical symptoms. A separate record of situations that the client finds especially stressful should also be kept. Comparison of these records may provide objective data from which to observe the relationship between physical symptoms and stress.

■ Help the client identify ways to achieve recognition from others without resorting to physical symptoms. Positive recognition from others enhances self-esteem and minimizes the need for attention through maladaptive behaviors.

■ Discuss how interpersonal relationships are affected by the client's narcissistic behavior. Explain how this behavior alienates others. The client may not realize how he or she is perceived by others.

■ Provide instruction in relaxation techniques and assertiveness skills. These approaches decrease anxiety and increase self-esteem, which facilitate adaptive responses to stressful situations.

Fear (of Having a Serious Disease)

Fear is defined as the "response to perceived threat that is consciously recognized as a danger" (Herdman & Kamitsuru, 2014, p. 336). This nursing diagnosis is particularly relevant to clients with illness anxiety disorder but may pertain also to clients with somatic symptom disorder and some dissociative disorders.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will verbalize that fears associated with bodily sensations are irrational (within time limit deemed appropriate for specific individual).

Long-term goal

■ Client interprets bodily sensations correctly.

Interventions

■ Monitor the physician's ongoing assessments and laboratory reports. Organic pathology must be clearly ruled out.

■ Refer all new physical complaints to the physician. To ignore all physical complaints could place the client's safety in jeopardy.

■ Assess the function the client's illness is fulfilling for him or her (e.g., unfulfilled needs for dependency, nurturing, caring, attention, or control). This information may provide insight into reasons for maladaptive behavior and provide direction for planning client care.

■ Identify times during which the preoccupation with physical symptoms worsens. Determine the extent of correlation of physical complaints with times of increased anxiety. The client may be unaware of the psychosocial implications of the physical complaints. Knowledge of the relationship is the first step in the process for creating change.

■ Convey empathy. Let the client know that you understand how a specific symptom may conjure up fears of previous life-threatening illness. Unconditional acceptance and empathy promote a therapeutic nurse-client relationship.

■ Initially allow the client a limited amount of time (e.g., 10 minutes each hour) to discuss physical symptoms. Because preoccupation with physical symptoms has been his or her primary method of coping for so long, complete prohibition of this activity would likely raise the client's anxiety level significantly, further exacerbating the behavior.

■ Help the client determine what techniques may be most useful for him or her to implement when fear and anxiety are exacerbated (e.g., relaxation techniques, mental imagery, thought-stopping techniques, physical exercise). All of these techniques are effective in reducing anxiety and may assist the client in the transition from focusing on fear of physical illness to the discussion of honest feelings.

■ Gradually increase the limit on amount of time spent each hour in discussing physical symptoms. If the client violates the limits, withdraw attention. Lack of positive reinforcement may help to extinguish the maladaptive behavior.

■ Encourage the client to discuss feelings associated with fear of serious illness. Verbalization of feelings in a nonthreatening environment facilitates expression and resolution of disturbing emotional issues. When the client can express feelings directly, there is less need to express them through physical symptoms.

■ Role-play the client's plan for dealing with the fear the next time it assumes control and before anxiety becomes disabling. Anxiety and fears are minimized when the client has achieved a degree of comfort through practicing a plan for dealing with stressful situations in the future.

Disturbed Sensory Perception

Disturbed sensory perception, no longer identified as a NANDA-I diagnosis, is retained here and may be defined as an impaired or exaggerated sensory perception. This may include an exaggerated sensation of pain, impairment of function or mobility without medical basis, other somatic sensations, and distorted perception of the self (depersonalization) or distorted perception of the environment (derealization). The nursing diagnosis of disturbed sensory perception is relevant to clients with somatic symptom disorders, conversion disorder symptoms, and depersonalization derealization disorder. Table 29–2 presents this nursing diagnosis in care plan format.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Table 29–2 | CARE PLAN FOR THE CLIENT WITH CONVERSION DISORDER

NURSING DIAGNOSIS: DISTURBED SENSORY PERCEPTION
RELATED TO: Repressed severe anxiety
EVIDENCED BY: Loss or alteration in physical functioning, without evidence of organic pathology

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client will verbalize understanding of emotional problems as a contributing factor to the alteration in physical functioning (within time limit appropriate for specific individual). **Long-Term Goal** • Client will demonstrate recovery of lost or altered function.	1. Monitor physician's ongoing assessments, laboratory reports, and other data to ensure that possibility of organic pathology is clearly ruled out.	1. Failure to do so may jeopardize client safety.
	2. Identify primary or secondary gains that the physical symptom may be providing for the client (e.g., increased dependency, attention, protection from experiencing a stressful event).	2. Primary and secondary gains are often etiological factors and may be used to assist in problem resolution.
	3. Do not focus on the disability, and encourage client to be as independent as possible. Intervene only when client requires assistance.	3. Positive reinforcement would encourage continual use of the maladaptive response for secondary gains, such as dependency.
	4. Maintain nonjudgmental attitude when providing assistance to the client. The physical symptom is not within the client's conscious control and is very real to him or her.	4. A judgmental attitude interferes with the nurse's ability to provide therapeutic care for the client.
	5. Do not reinforce the client's attempts to use the disability as a manipulative tool to avoid participation in therapeutic activities. Withdraw attention if client continues to focus on physical limitation.	5. Lack of reinforcement may help to extinguish the maladaptive response.
	6. Encourage the client to verbalize fears and anxieties. Help identify physical symptoms as a coping mechanism that is used in times of extreme stress.	6. Clients with conversion disorder are usually unaware of the psychological implications of their illness.
	7. Help client identify coping mechanisms that he or she could use when faced with stressful situations rather than retreating from reality with a physical disability.	7. Client needs assistance with problem-solving at this severe level of anxiety.
	8. Give positive reinforcement for identification or demonstration of alternative, more adaptive coping strategies.	8. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.

Short-term goal

■ The client will verbalize understanding of emotional problems as a contributing factor to the alteration in sensory perceptions (within time limit appropriate for specific individual).

Long-term goal

■ The client will demonstrate recovery of lost or altered function.

Interventions

■ Monitor the physician's ongoing assessments, laboratory reports, and other data to ensure that the possibility of organic pathology is clearly ruled out. Failure to do so may jeopardize the client's safety.

■ Identify primary or secondary gains that the physical symptom is providing for the client (e.g., increased dependency, attention, protection from experiencing a stressful event). These are considered to be etiological factors and may be used to assist in problem resolution.

■ Do not focus on the disability, and encourage the client to be as independent as possible. Intervene only when the client requires assistance. Positive reinforcement would encourage continued use of the maladaptive response for secondary gains, such as dependency.

■ Maintain a nonjudgmental attitude when providing assistance with self-care activities to the client. The physical symptom is not within the client's conscious control and is very real to him or her.

■ Do not reinforce the client's use of the disability as a manipulative tool to avoid participating in therapeutic activities. Withdraw attention if the client continues to focus on the physical limitation. Lack of reinforcement may help to extinguish the maladaptive response.

■ Encourage the client to verbalize fears and anxieties. Help identify physical symptoms as a coping mechanism that is used in times of extreme stress. Clients with conversion disorder are usually unaware of the psychological implications of their illness.

■ Help the client identify coping mechanisms that he or she could use when faced with stressful situations rather than retreating from reality with a physical disability. The client needs assistance with problem-solving at this severe level of anxiety.

■ Give positive reinforcement for identification or demonstration of alternative, more adaptive coping strategies.

■ Discuss ways the client may more adaptively respond to stress, and use role-play to practice using these new methods. Having practiced through role-play helps to prepare the client to face stressful situations by using these new behaviors when they occur in real life.

For clients experiencing depersonalization, also use the following interventions:

■ Provide support and encouragement during times of depersonalization. Clients manifesting these symptoms may express fear and anxiety. They do not understand the response and may express a fear of going insane. Support and encouragement from a trusted individual provide a feeling of security when fears and anxieties are manifested.

■ Explain the depersonalization behaviors and the purpose they usually serve for the client. This knowledge may help to minimize fears and anxieties associated with their occurrence. Help relate these behaviors to times of severe psychological stress that client has experienced. The client may be unaware that the occurrence of depersonalization behaviors is related to severe anxiety. Knowledge of this relationship is the first step in the process of behavioral change.

Deficient Knowledge (Psychological Factors Affecting Medical Condition)

Deficient knowledge is defined as "absence or deficiency of cognitive information related to a specific topic" (Herdman & Kamitsuru, 2014, p. 257). This nursing diagnosis may be relevant to clients with any somatic or related disorder as well as to clients with dissociative disorders.

Client Goals

■ Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Client will cooperate with plan for teaching provided by primary nurse.

Long-term goal

■ By time of discharge from treatment, client will be able to verbalize psychological factors affecting his or her physical condition.

Interventions

■ Assess the client's level of knowledge regarding effects of psychological problems on the body. An adequate database is necessary for the development of an effective teaching plan.

■ Assess the client's level of anxiety and readiness to learn. Learning does not occur beyond the moderate level of anxiety.

■ Discuss physical examinations and laboratory tests that have been conducted. Explain the purpose and results of each. Fear of the unknown may contribute to an elevated level of anxiety. The client has the right to know about and accept or refuse any medical treatment.

■ Explore the client's feelings and fears as he or she demonstrates readiness. Go slowly. These feelings may have been suppressed or repressed for so long that their disclosure may be a very painful experience. Be supportive. Expression of feelings in the presence of a trusted individual and in a nonthreatening environment may encourage the individual to confront unresolved issues.

■ Have the client keep a diary of appearance, duration, and intensity of physical symptoms. A separate record of situations the client finds especially stressful should also be kept. Comparison of these records may provide objective data from which to observe the relationship between physical symptoms and stress.

■ Help the client identify needs that are being met through the sick role. Together, formulate more adaptive means for fulfilling these needs. Practice by role-playing. Repetition through practice serves to reduce discomfort in the actual situation.

■ Provide instruction in assertiveness techniques, especially the ability to recognize the differences among passive, assertive, and aggressive behaviors and the importance of respecting the rights of others while protecting one's own basic rights. These skills will preserve the client's self-esteem while also improving his or her ability to form satisfactory interpersonal relationships.

■ Discuss adaptive methods of stress management, such as relaxation techniques, physical exercise, meditation, and breathing exercises. Use of these adaptive techniques may decrease appearance of physical symptoms in response to stress.

Impaired Memory

Impaired memory is defined as an "inability to remember or recall bits of information or behavioral skills" (Herdman & Kamitsuru, 2014, p. 259). This nursing diagnosis is particularly relevant in clients with dissociative disorders such as dissociative amnesia.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ The client will verbalize understanding that the loss of memory is related to a stressful situation and begin discussing the stressful situation with nurse or therapist.

Long-term goal

■ The client will recover deficits in memory and develop more adaptive coping mechanisms to deal with stressful situations.

Interventions

■ Obtain as much information as possible about the client from family and significant others if possible. Consider likes, dislikes, important people, activities, music, and pets. A comprehensive baseline assessment is necessary for the development of an effective plan of care.

■ Do not confront the client with information he or she does not appear to remember. Individuals who are exposed to painful information from which the amnesia is providing protection may decompensate even further into a psychotic state.

■ Instead, expose the client to stimuli that represent pleasant experiences from the past, such as smells associated with enjoyable activities, beloved pets, and music the client enjoys. As memory begins to return, engage the client in activities that may provide additional stimulation. Recall often occurs during activities that simulate life experiences.

■ Listen empathically when the client discusses situations that have been especially stressful and explore the feelings associated with those times. Verbalization of feelings in a nonthreatening environment may help the client come to terms with unresolved issues that may be contributing to the dissociative process.

■ Identify specific conflicts that remain unresolved and help the client identify possible solutions. Provide instruction regarding more adaptive ways to respond to anxiety. Unless these underlying conflicts are resolved, any improvement in coping behaviors must be viewed as temporary.

■ Provide positive feedback for decisions made. Respect the client's right to make those decisions independently and refrain from attempting to influence him or her toward those that may seem more logical. Independent choice provides a feeling of control, decreases feelings of powerlessness, and increases self-esteem.

Disturbed Personal Identity

Disturbed personal identity is defined as the "inability to maintain an integrated and complete perception of self" (Herdman & Kamitsuru, 2014, p. 268). This nursing diagnosis is particularly relevant for the client with dissociative identity disorder.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ The client will verbalize understanding about the existence of multiple personality states within the self.

■ The client will be able to recognize stressful situations that precipitate transition from one personality to another.

Long-term goals

■ The client will verbalize understanding of the reasons for fragmented identity.

■ The client will enter into and cooperate with long-term therapy, with the ultimate goal of integration into one personality.

Interventions

■ The nurse must develop a trusting relationship with the client. Trust is the basis of a therapeutic relationship. Listen nonjudgmentally when the client transitions from one personality state to another. Help the client understand the existence of the subpersonalities and the need each serves in the personal identity of the individual. The client may initially be unaware of the dissociative response. Knowledge of the needs each personality fulfills is the first step in the integration process and the client's ability to face unresolved issues without dissociation.

■ Help the client identify stressful situations that precipitate transition from one personality to another. Carefully observe and record these transitions. Identification of stressors is required to assist the client in responding more adaptively and eliminate the need for transition to another personality.

■ Use nursing interventions necessary to deal with maladaptive behaviors associated with individual subpersonalities. For example, if one personality is suicidal, precautions must be taken to guard against the client's self-harm. If another personality has a tendency toward physical hostility, precautions must be taken to protect others.

> **CLINICAL PEARL** It may be possible to seek assistance from one of the subpersonalities. For example, a strong-willed personality may help to control the behaviors of a suicidal personality.

■ Help subpersonalities understand that their "being" will not be destroyed, but rather integrated into a unified identity within the individual. Because the subpersonalities function as separate entities, the idea of total elimination generates fear and defensiveness.

■ Provide support during disclosure of painful experiences and reassurance when the client becomes discouraged with lengthy treatment.

Concept Care Mapping

The concept map care plan (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. Examples of concept map care plans for clients with somatic symptom and dissociative disorders are presented in Figures 29–3 and 29–4.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client with a somatic symptom disorder may be facilitated by gathering information using the following types of questions:

■ Can the client recognize signs and symptoms of escalating anxiety?

■ Can the client intervene with adaptive coping strategies to interrupt the escalating anxiety before physical symptoms are exacerbated?

■ Can the client verbalize an understanding of the correlation between physical symptoms and times of escalating anxiety?

■ Does the client have a plan for dealing with increased stress to prevent exacerbation of physical symptoms?

■ Does the client demonstrate a decrease in ruminations about physical symptoms?

■ Have fears of serious illness diminished?

■ Does the client demonstrate full recovery from previous loss or alteration of physical functioning?

Evaluation of the nursing actions for the client with a dissociative disorder may be facilitated by gathering information using the following types of questions:

■ Has the client's memory been restored?

■ Can the client connect occurrence of psychological stress to loss of memory?

■ Does the client discuss fears and anxieties with members of the staff in an effort toward resolution?

■ Can the client discuss the presence of various personalities within the self?

■ Can he or she verbalize why these personalities exist?

■ Can the client verbalize situations that precipitate transition from one personality to another?

■ Can the client maintain a sense of reality during stressful situations?

■ Can the client verbalize a correlation between stressful situations and the onset of depersonalization behaviors?

■ Can the client demonstrate more adaptive coping strategies for dealing with stress without resorting to dissociation?

Treatment Modalities

Somatic Symptom Disorders
Individual Psychotherapy

The goal of psychotherapy is to help clients develop healthy and adaptive behaviors and encourage them to move beyond their somatization and become able to manage their lives more effectively. The focus is on

Clinical Vignette: Veronica, age 51, has a long history of "doctor shopping" for numerous complaints of gastrointestinal distress, daily headaches, and abdominal pain. She has undergone numerous tests that show no evidence of pathophysiology. Her husband of 25 years recently died of a myocardial infarction (MI). Yesterday, she began having chest pains and was certain she was having a heart attack. Her daughter called 911, and Veronica was transported to the emergency department. The staff performed diagnostic studies and laboratory tests, which were all negative for pathophysiology. She was admitted to the psychiatric unit with a diagnosis of Somatic Symptom Disorder. The nurse develops the following concept map care plan for Veronica.

Signs and Symptoms
- Physical complaints
- Absence of pathophysiology
- Focus on self and physical symptoms

Signs and Symptoms
- Chest pains and fear of having a heart attack (following husband's sudden death from MI)

Nursing Diagnosis

Ineffective coping

Nursing Diagnosis

Fear (of dying as husband did from acute MI)

Nursing Actions
- Perform ongoing assessment.
- Accept that the symptoms are real to the client.
- Identify personal gains.
- Fulfill client's needs.
- Do not give positive reinforcement to symptoms.
- Limit amount of time client discusses symptoms.
- Teach adaptive coping strategies.

Nursing Actions
- Perform ongoing assessment.
- Refer all new physical complaints to physician.
- Discuss client fears and anxieties.
- Encourage verbalization of feelings associated with husband's death.
- Encourage participation in grief support group.

Medical Rx:
Duloxetine 60 mg q day for chronic pain/depression/anxiety

Outcomes:
- Client recognizes signs and symptoms of escalating anxiety
- Client is able to intervene before the exacerbation of physical symptoms

Outcomes:
- Client discusses feelings associated with husband's death
- Fears of own serious illness have diminished
- Client uses adaptive coping mechanisms to diminish fears/anxieties

FIGURE 29–3   Concept map care plan for a client with somatic symptom disorder.

personal and social difficulties that the client experiences in daily life as well as the achievement of practical solutions for these difficulties.

Treatment is initiated with a complete physical examination to rule out organic pathology. Clients may be more amenable to psychotherapeutic treatment, particularly stress management, when it is conducted in a medical setting. Frequent, regular physical examinations are recommended to reassure clients that their concerns are being heard (Sadock et al., 2015; Yates, 2014) and may also provide an ongoing opportunity for education and stress management. The use of psychotherapy in the treatment of illness anxiety disorder is controversial (Sadock et al., 2015). Individual

Clinical Vignette: Wanda, age 32, was diagnosed 5 years ago with Dissociative Identity Disorder. History revealed severe childhood physical and sexual abuse by both parents. Several personalities have surfaced during years of therapy: an aggressive personality (Jamie), a suicidal personality (Ida), and 4-year-old child (Anna). Yesterday, following a particularly intense session with her therapist, the personality "Ida" surfaced and swallowed an undisclosed number of sertraline tablets. Wanda's group-home leader called 911, and Wanda was transported to the emergency department (ED). Following stabilization in the ED, Wanda was admitted to the psychiatric unit. The nurse develops the following concept map care plan for Wanda.

Signs and Symptoms
- The presence of more than one personality within the individual

Signs and Symptoms
- Depression and anxiety
- Suicidal ideations (acted upon by personality "Ida")

Nursing Diagnosis

Disturbed personal identity

Nursing Diagnosis

Complicated grieving

Nursing Actions
- Develop trust with each personality.
- Help client understand need for subpersonalities.
- Identify situations that precipitate transition.
- Help subpersonalities understand that integration means unifying into one.
- Provide support with therapy.

Nursing Actions
- Convey an accepting attitude.
- Allow client to express anger in an appropriate manner.
- Explore with client the true source of the anger.
- Explain process and stages of grieving and client's position in the process.
- Until personalities are integrated, elicit assistance from personality "Jamie" to help control behavior of "Ida."

Outcomes:
- Verbalizes understanding of multiple personalities and purpose they serve
- Verbalizes knowledge of stress that precipitates transition
- Desires to participate in integration therapy

Outcomes:
- Verbalizes knowledge that anger is associated with maladaptive grieving
- Is able to discuss original source of the anger

FIGURE 29–4 Concept map care plan for a client with dissociative identity disorder.

insight-oriented psychotherapy has not been proven effective (Yates, 2014).

Group Psychotherapy

Group therapy may be helpful for somatic symptom disorders because it provides a setting where clients can share their experiences of illness, learn to verbalize thoughts and feelings, and be confronted by group members and leaders when they reject responsibility for maladaptive behaviors. It is the treatment of choice for both somatic symptom disorder and illness anxiety disorder, in part because it provides the social support and anxiety reduction that these clients need.

Cognitive-Behavioral Therapy (CBT) and Psychoeducation

Yates (2014) reports that several studies support CBT as an effective strategy for reducing depressive symptoms in clients with somatic diseases. Psychoeducation has also been identified as beneficial and includes

teaching the patient that the symptoms may be related to or exacerbated by stress and anxiety. This teaching should be done in the context of a trusting relationship between the health-care provider and the client because the client may resist the suggestion that physical symptoms could have a psychological foundation. Psychoeducation for family members and other support persons focuses on teaching these individuals to reward the client's autonomy, self-sufficiency, and independence while taking care not to reinforce passivity and dependence associated with the sick role. This process becomes more difficult when the client is very regressed and the sick role is well established. In conversion disorder, symptoms usually abate spontaneously, but behavior therapy may be beneficial.

Psychopharmacology

Based on studies of somatization disorder, medication treatment is not effective unless it used to treat underlying depression or anxiety (Sadock et al., 2015; Yates, 2014). When antidepressant therapy is warranted, SSRIs are generally preferred. Anxiety may be treated in the short term with antianxiety agents such as benzodiazepines, but long-term use should be avoided because of the potential for addiction.

In the treatment of conversion disorders, parenteral amobarbital or lorazepam may be helpful in revealing historical information related to trauma.

Dissociative Amnesia

Many cases of dissociative amnesia resolve spontaneously when the individual is removed from the stressful situation. For more refractory conditions, intravenous administration of amobarbital is useful in the retrieval of lost memories. Most clinicians recommend supportive psychotherapy to reinforce adjustment to the psychological impact of the retrieved memories and associated emotions.

In some instances, psychotherapy is used as the primary treatment. Techniques of persuasion and free or directed association are used to help the client remember. In other cases, hypnosis may be required to mobilize the memories. Hypnosis is sometimes facilitated by the use of pharmacological agents, such as sodium amobarbital. Supportive psychotherapy, group psychotherapy, and cognitive therapy may be employed once the memories have been obtained through hypnosis to help the client integrate the memories into his or her conscious state. Cognitive therapy has an added benefit of helping clients recall details about traumatic events when he or she begins to correct cognitive distortions about these traumas (Sadock et al., 2015).

Dissociative Identity Disorder

The goal of therapy for the client with DID is to optimize the client's function and potential. The achievement of **integration** (a blending of all the personalities into one) is usually considered desirable, but some clients choose not to pursue this lengthy therapeutic regimen. In these cases, resolution, or a smooth collaboration among the subpersonalities, may be all that is realistic.

Intensive long-term psychotherapy with the DID client is directed toward uncovering the underlying psychological conflicts, helping him or her gain insight into these conflicts, and striving to synthesize the various identities into one integrated personality. The therapist who engages in psychotherapy with this client must be skilled in various approaches, including insight-oriented psychotherapy, cognitive therapy, and especially trauma-informed and posttraumatic stress disorder (PTSD) treatment approaches. Clients are assisted to recall past traumas in detail. They must mentally reexperience the abuse that caused their illness. This process, called **abreaction,** or "remembering with feeling," is so painful that clients may actually cry, scream, and feel the pain that they felt at the time of the abuse.

During therapy, each personality is actively explored and encouraged to become aware of the others across previously amnestic barriers. Traumatic memories associated with the different personality manifestations, especially those related to childhood abuse, are examined. The course of treatment is often difficult and anxiety-provoking to client and therapist alike, especially when aggressive or suicidal personalities dominate. In these instances, brief periods of hospitalization may be necessary as an interim supportive measure.

When integration is achieved, the individual is able to integrate all the feelings, experiences, memories, skills, and talents that were previously in the command of the various personalities. He or she learns how to function effectively without the necessity for creating separate identities to cope with life. This is possible only after years of intense psychotherapy, and even then, recovery is often incomplete.

Depersonalization-Derealization Disorder

Information about the treatment of depersonalization-derealization disorder is sparse and inconclusive. Various psychiatric medications have been tried, both singly and in combination: antidepressants, mood stabilizers, anticonvulsants, and antipsychotics. Results have been sporadic at best. If other psychiatric disorders, such as schizophrenia, are evident, they too may be treated pharmacologically. For clients with evident intrapsychic conflict, analytically oriented insight psychotherapy may be useful. Some clients with depersonalization-derealization disorders have benefited from hypnotherapy or CBT.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Jake is a 54-year-old client of the psychiatric outpatient department of the VA Medical Center. At age 42, Jake was diagnosed with colon cancer and underwent a colon resection. Since that time, he has had regular follow-up exams, with no recurrence of the cancer and no residual effects. He did not require follow-up chemotherapy or radiation therapy. For 10 years, Jake has had yearly physical and laboratory examinations. He regularly complains to his family physician of mild abdominal pain, sensations of "fullness," "bowel rumblings," and what he calls a "firm mass," which he says he can sometimes feel in his lower left quadrant. The physician has performed x-rays of the entire gastrointestinal (GI) tract, an esophagoscopy, gastroscopy, and colonoscopy. All results were negative for organic pathology. Rather than being relieved, Jake appears resentful and disappointed that the physician has not been able to reveal a pathological problem. Jake's job is in jeopardy because of excessive use of sick leave. The family physician has referred Jake for psychiatric evaluation. Jake was admitted as an outpatient with the diagnosis of Illness Anxiety Disorder. He has been assigned to Lisa, a psychiatric nurse practitioner.

In her assessment, Lisa learns that Jake has pretty much lived his adult life in isolation. He was never close to his parents, who worked and seldom had time for Jake or his sister. Jake told Lisa, "My parents really didn't care about me. They were too busy taking care of the farm. Dad wanted me to take over the farm, but I was never interested. I liked working on cars, and went to vocational school to learn how to be a mechanic. I thought they would be proud of me, but they never cared. I think they only had kids so they would have some help on the farm. When I left home, they really didn't care if they ever saw me again." He has never been married nor had a really serious relationship. "Women don't like me much. I spend most of my time alone. I guess I don't really like people, and they don't really like me."

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Jake:

1. **Fear** (of cancer recurrence) related to history of colon cancer evidenced by numerous complaints of the GI tract and insistence that something is wrong despite objective tests that rule out pathophysiology.
   a. **Short-Term Goal:** Client will verbalize that fears associated with bodily sensations are irrational.
   b. **Long-Term Goal:** Client interprets bodily sensations correctly.
2. **Chronic low self-esteem** related to unfulfilled childhood needs for nurturing and caring evidenced by transformation of internalized anger into physical complaints and hostility toward others.
   a. **Short-Term Goal:** Within 2 weeks, client will verbalize aspects about self that he likes.

   b. **Long-Term Goal:** By discharge from treatment, client will demonstrate acceptance of self as a person of worth, as evidenced by setting realistic goals, limiting physical complaints and hostility toward others, and verbalizing positive prospects for the future.

PLANNING AND IMPLEMENTATION

FEAR (OF CANCER RECURRENCE)
The following nursing interventions have been identified for Jake:

1. Monitor the physician's ongoing assessments and laboratory reports to ensure that pathology is clearly ruled out.
2. Refer any new physical complaints to the physician.
3. Assess what function these physical complaints are fulfilling for Jake. Is it a way for him to get attention that he cannot get in any other way?
4. Show empathy for his feelings. Let him know that you understand how GI symptoms may bring about fears of the colon cancer.
5. Encourage Jake to talk about his fears of cancer recurrence. What feelings did he have when it was first diagnosed? How did he deal with those feelings? What are his fears at this time?
6. Have Jake keep a diary of the appearance of the symptoms. In a separate diary, have Jake keep a record of situations that create stress for him. Compare these two records. Correlate whether symptoms appear at times of increased anxiety.
7. Help Jake determine techniques that may be useful for him to implement when fear and anxiety are exacerbated (e.g., relaxation techniques; mental imagery; thought-stopping techniques; physical exercise).
8. Offer positive feedback when Jake responds to stressful situations with coping strategies other than physical complaints.

CHRONIC LOW SELF-ESTEEM
The following nursing interventions have been identified for Jake:

1. Convey acceptance and unconditional positive regard, and remain nonjudgmental at all times.
2. Encourage Jake to participate in decision-making regarding his care and in life situations.
3. Help Jake to recognize and focus on strengths and accomplishments. Minimize attention given to past (real or perceived) failures.
4. Encourage Jake to talk about feelings related to his unsatisfactory relationship with his parents.
5. Discuss things in his life that Jake would like to change. Help him determine what *can* be changed and what changes are not realistic.
6. Encourage participation in group activities and in therapy groups that offer simple methods of achievement. Give recognition and positive feedback for actual accomplishments.

7. Teach assertiveness techniques and effective communication techniques.
8. Offer positive feedback for appropriate social interactions with others. Role-play with Jake situations that he finds particularly stressful. Help him to understand that ruminations about himself and his health may cause others to reject him socially.
9. Help Jake to set realistic goals for his future.

EVALUATION

Some of the outcome criteria for Jake have been met, and some are ongoing. He has come to realize that the fears about his "symptoms" are not rational. He understands that the physician has performed adequate diagnostic procedures to rule out illness. He still has fears of cancer occurrence and discusses these fears with the nurse practitioner on a weekly basis. He has kept his symptoms and stressful situations diaries and has correlated the appearance of some of the symptoms to times of increased anxiety. He has started running and tries to use this as a strategy to keep the anxiety from escalating out of proportion and bringing on new physical symptoms. He continues to discuss feelings associated with his childhood, and the nurse has helped him see that he has had numerous accomplishments in his life, even though they were not recognized by his parents or others. He has joined a support group for depressed persons and states that he "has made a few friends." He has made a long-term goal of joining a church with the hope of meeting new people. He is missing fewer workdays because of illness, and his job is no longer in jeopardy.

Summary and Key Points

■ Somatic symptom and related disorders and dissociative disorders are associated with anxiety that occurs at the severe level. The anxiety is repressed and manifested in the form of symptoms and behaviors associated with these disorders.

■ Somatic symptom and related disorders affect about 4 to 8 percent (although estimates range from 0.1% to 11.6%) of the general population. Types of somatic disorders include somatic symptom disorder, illness anxiety disorder, conversion disorder, psychological factors affecting other medical conditions, factitious disorder, and other specified or unspecified somatic symptom and related disorders.

■ Somatic symptom disorder is manifested by physical symptoms that may be vague, dramatized, or exaggerated in presentation. No evidence of organic pathology can be identified.

■ Illness anxiety disorder is an unrealistic preoccupation with fear of having a serious illness. This disorder may follow a personal experience or the experience of a close family member with serious or life-threatening illness.

■ The individual with conversion disorder experiences a loss of or alteration in bodily functioning, unsubstantiated by medical or pathophysiological explanation. Psychological factors may be evident by the primary or secondary gains the individual achieves from experiencing the physiological manifestation.

■ With the diagnosis of psychological factors affecting medical condition, psychological or behavioral factors have been implicated in the development, exacerbation, or delayed recovery from a medical condition.

■ In factitious disorder, the individual falsifies physical or psychological signs or symptoms or induces injury on the self or another person in order to receive attention from medical personnel.

■ A dissociative response has been described as a defense mechanism to protect the ego in the face of overwhelming anxiety.

■ Dissociative responses result in an alteration in the normally integrative functions of identity, memory, or consciousness.

■ Classification of dissociative disorders includes dissociative amnesia, DID, depersonalization-derealization disorder, and other specified or unspecified dissociative disorders.

■ The individual with dissociative amnesia is unable to recall important personal information that is too extensive to be explained by ordinary forgetfulness.

■ The prominent feature of DID is the existence of two or more personality states within a single individual. An individual may have many personality states, each of which allows him or her to endure painful stimuli that the identity is too fragmented to integrate as one whole personality.

■ Depersonalization-derealization disorder is characterized by an alteration in the perception of oneself and/or the environment. Depersonalization is described as a feeling of unreality or detachment from one's body. Derealization is an experience of unreality or detachment with respect to one's surroundings.

■ Individuals with somatic symptom and dissociative disorders often receive initial health care in areas other than psychiatry.

■ Nurses can assist clients with these disorders by helping them understand the role of anxiety in symptom development and identify and establish new, more adaptive cognitive and behavior patterns. Nurses should provide trauma-informed care and be aware of resources for referral to specialists in trauma care and PTSD treatment.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Lorraine has been diagnosed with somatic symptom disorder. Which of the following symptom profiles would you expect when assessing Lorraine?
   a. Multiple somatic symptoms in several body systems
   b. Fear of having a serious disease
   c. Loss or alteration in sensorimotor functioning
   d. Belief that her body is deformed or defective in some way

2. Which of the following ego defense mechanisms describes the underlying psychodynamics of somatic symptom disorder?
   a. Denial of depression
   b. Repression of anxiety
   c. Suppression of grief
   d. Displacement of anger

3. Nursing care for a client with somatic symptom disorder would focus on helping her to:
   a. Eliminate the stress in her life.
   b. Discontinue her numerous physical complaints.
   c. Take her medication only as prescribed.
   d. Learn more adaptive coping strategies.

4. Lorraine, a client diagnosed with somatic symptom disorder, states, "My doctor thinks I should see a psychiatrist. I can't imagine why he would make such a suggestion." What is the most common basis for Lorraine's statement?
   a. She thinks her doctor wants to get rid of her as a client.
   b. She does not understand the correlation of symptoms and stress.
   c. She thinks psychiatrists are only for "crazy" people.
   d. She thinks her doctor has made an error in diagnosis.

5. Lorraine, a client diagnosed with somatic symptom disorder, tells the nurse about a pain in her side. She says she has not experienced it before. Which is the most appropriate response by the nurse?
   a. "I don't want to hear about another physical complaint. You know they are all in your head. It's time for group therapy now."
   b. "Let's sit down here together and you can tell me about this new pain you are experiencing. You'll just have to miss group therapy today."
   c. "I will report this pain to your physician. In the meantime, group therapy starts in 5 minutes."
   d. "I will call your physician and see if he will order a new pain medication for your side. The one you have now doesn't seem to provide relief. Why don't you get some rest for now?"

Review Questions—cont'd
Self-Examination/Learning Exercise

6. Ellen has a history of childhood physical and sexual abuse. She was diagnosed with dissociative identity disorder 6 years ago and has been admitted to the psychiatric unit following a suicide attempt. What is the primary nursing diagnosis for Ellen?
   a. Disturbed personal identity related to childhood abuse
   b. Disturbed sensory perception related to repressed anxiety
   c. Impaired memory related to disturbed thought processes
   d. Risk for suicide related to unresolved grief

7. In establishing trust with Ellen, a client with the diagnosis of dissociative identity disorder, the nurse must:
   a. Try to relate to Ellen as though she did not have multiple personalities.
   b. Listen nonjudgmentally and respond empathically when Ellen transitions to different personality states.
   c. Ignore behaviors that Ellen attributes to other subpersonalities.
   d. Explain to Ellen that he or she will work with her only if the primary personality is maintained.

8. What is the ultimate goal of therapy for a client with dissociative identity disorder?
   a. Integration of the personalities into one
   b. The ability to switch from one personality to another voluntarily
   c. The ability to select one personality as the dominant self
   d. Recognition that the various personalities exist

9. The ultimate goal of therapy for a client with dissociative identity disorder is most likely achieved through:
   a. Crisis intervention and directed association.
   b. Psychotherapy and hypnosis.
   c. Psychoanalysis and free association.
   d. Insight psychotherapy and dextroamphetamines.

10. Lucille has a diagnosis of illness anxiety disorder. Which of the following symptoms would be consistent with this diagnosis?
   a. Complains of a multitude of incapacitating physical symptoms
   b. Manifests with pseudoseizures or pseudocyesis
   c. Takes substances to induce vomiting in order to convince the nurse that she needs treatment
   d. Expresses persistent fears of having life-threatening disease
   e. All of the above

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Brand, R., Classen, C., Lanius, R., Loewenstein, R., McNary, S., Pain, C., & Putnam, F. (2009). A naturalistic study of dissociative identity disorder and dissociative disorder not otherwise specified patients treated by community clinicians. *Psychological Trauma: Theory, Research, Practice, and Policy, 1*(2), 153-171. doi:http://dx.doi.org/10.1037/a0016210

DESCRIPTION OF THE STUDY: This study examined an international sample of clients ($N = 280$) receiving a similar five-phase treatment model for dissociative disorders by community clinicians. The researchers sought to identify whether the treatment was as effective as treatments for PTSD and conditions comorbid with dissociative disorders.

RESULTS OF THE STUDY: In the late stages of this 30-month treatment program, the effects of treatment were similar to those of treatment for chronic PTSD associated with childhood trauma and depression comorbid with borderline personality disorder. In addition, patients and therapists reported fewer incidents of self-injury, fewer hospitalizations, higher levels of adaptive functioning, less dissociation, and fewer PTSD symptoms. The researchers conclude that considering the

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE—cont'd

prevalence, severity, chronicity and high costs of health care associated with dissociative disorders, extended treatment may be beneficial and justifies more research.

IMPLICATIONS FOR NURSING PRACTICE:

Awareness of evidence-based research is identified as an essential QSEN (Quality and Safety Education for Nurses) competency (QSEN Institute, 2014). Studies such as this one not only inform clinical practice for nurses in advanced practice roles but provide a foundation for registered nurses to educate patients about treatment options that have demonstrated efficacy. Patients can be educated that evidence supports the benefit of extended treatment for dissociative disorders. Sharing evidence-based information about treatment options may also encourage patients to follow through with a longer-term treatment program when there is evidence to support that it is effective.

TEST YOUR CRITICAL THINKING SKILLS

Tom was admitted to the psychiatric unit from the emergency department of a general hospital in the Midwest. The owner of a local bar called the police when Tom suddenly seemed to "lose control. He just went ballistic." The police reported that Tom did not know where he was or how he got there. He kept saying, "My name is John Brown, and I live in Philadelphia." When the police ran an identity check on Tom, they found that he was indeed John Brown from Philadelphia, and his wife had reported him missing a month ago. Mrs. Brown explained that about 12 months before his disappearance, her husband, who was a shop foreman at a large manufacturing plant, had been having considerable difficulty at work. He had been passed over for a promotion, and his supervisor was very critical of his work. Several of his staff had left the company for other jobs, and without enough help, Tom had been unable to meet shop deadlines. Work stress made him very difficult to live with at home. Previously an easygoing, extroverted individual, he became withdrawn and extremely critical of his wife and children. Immediately preceding his disappearance, he had had a violent argument with his 18-year-old son, who called Tom a "loser" and stormed out of the house to stay with some friends. It was the day after this argument that Tom disappeared. The psychiatrist assigns a diagnosis of Dissociative Amnesia, with dissociative fugue.

Answer the following questions related to Tom:

1. Describe the *priority* nursing intervention with Tom as he is admitted to the psychiatric unit.
2. What approach should be taken to help Tom with his problem?
3. What is the long-term goal of therapy for Tom?

voyeuristic disorder

OBJECTIVES

After reading this chapter, the student will be able to:

1. Describe developmental processes associated with human sexuality.
2. Discuss variations in sexual orientation.
3. Formulate nursing diagnoses and goals of care for clients with gender dysphoria.
4. Identify appropriate nursing interventions for clients with gender dysphoria.
5. Evaluate care of clients with gender dysphoria.
6. Discuss historical and epidemiological aspects of paraphilic disorders.
7. Identify various types of paraphilic disorders.
8. Discuss predisposing factors associated with the etiology of paraphilic disorders..
9. Describe the physiology of the human sexual response.
10. Conduct a sexual history.
11. Formulate nursing diagnoses, goals, and interventions for clients with sexual dysfunction disorders.
12. Identify topics for client/family education relevant to sexual dysfunction disorders.
13. Describe various treatment modalities for clients with sexual disorders.

HOMEWORK ASSIGNMENT

Please read the chapter and answer the following questions:

1. At about what age do children become aware of their own gender?
2. What types of psychosocial factors may predispose individuals to sexual desire disorders?
3. What medications have been implicated in the etiology of erectile disorder?
4. Which physiological mechanisms contribute to sexual dysfunctions?

Humans are sexual beings. Sexuality is a basic human need and an innate part of the total personality. It influences our thoughts, actions, and interactions and is involved in aspects of physical and mental health.

Society's attitude toward sexuality is changing. Clients are more open to seeking assistance in matters that pertain to sexuality. Although not all nurses need to be educated as sex therapists, they can readily integrate information on sexuality into the care they give by focusing on preventive, therapeutic, and educational interventions to assist individuals to attain, regain, or maintain sexual wellness.

This chapter focuses on disorders associated with sexual functioning and gender dysphoria. Primary consideration is given to the categories of paraphilic disorders and sexual dysfunctions as classified in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (American Psychiatric Association [APA], 2013). An overview of human sexual development throughout the life span is presented to help nurses better understand typical versus atypical desires and behaviors. Historical and epidemiological information associated with sexual disorders is included. Predisposing factors that have been implicated in the etiology of sexual disorders and gender dysphoria provide a framework for studying the dynamics of these conditions. Various medical treatment modalities are explored, and variations in sexual orientation are discussed.

Symptomatology is presented as background knowledge for assessing clients with sexual disorders and gender dysphoria. A tool for acquiring a sexual history is provided. Nursing care is described in the context of the nursing process.

CORE CONCEPT

Sexuality

Sexuality is the constitution and life of an individual relative to characteristics regarding intimacy. It reflects the totality of the person and does not relate exclusively to the sex organs or sexual behavior.

Development of Human Sexuality

Birth Through Age 12

Although the sexual identity of an infant is determined before birth by chromosomal factors and physical appearance of the genitals, postnatal factors can greatly influence the way developing children perceive themselves sexually. Masculinity and femininity as well as gender roles are, for the most part, culturally defined.

For example, differentiation of roles may be initiated at birth by painting a child's room pink or blue.

It is not uncommon for infants to touch and explore their genitals. In fact, research on infantile sexuality indicates that both male and female infants are capable of sexual arousal and **orgasm** (Berman & Berman, 2014).

By age 2 to 3 years, children know what gender they are. They know that they are like the parent of the same gender and different from the parent of the opposite gender and from other children of the opposite gender. They become acutely aware of anatomical gender differences during this time.

By age 4 or 5, children may engage in heterosexual play, such as "playing doctor." Through heterosexual play, children form a concept of relationships with a member of the opposite gender. It is not uncommon for children to act out in play behaviors they have seen in their parents or significant others, including touching, kissing, and arguing. Although these activities are a part of normal sexual development, they can sometimes signal issues such as sexual abuse. For example, if a child is engaging in play with other children that is nonconsensual, if there is a significant age discrepancy between the children involved, or if the language being used to describe the heterosexual play seems to be age-inappropriate, further assessment is warranted. Open, nonjudgmental communication such as, "Tell me more about where you learned this," encourages children to discuss issues about sexuality and provides a foundation for instruction.

Children increasingly gain experience with masturbation during childhood, although not all children masturbate during this period. Most children begin self-exploration and genital self-stimulation as soon as they are able to gain sufficient control over their physical movements (King & Regan, 2014).

Late childhood and preadolescence may be characterized by heterosexual or homosexual play. Generally, the activity involves no more than touching the other's genitals but may include a wide range of sexual behaviors (Masters, Johnson, & Kolodny, 1995). Girls at this age become interested in menstruation, and both genders are interested in learning about fertility, pregnancy, and birth. Interest in the opposite gender typically increases. Children of this age become self-conscious about their bodies and are concerned with physical attractiveness.

Children ages 10 to 12 are preoccupied with pubertal changes and the beginnings of romantic sexual attraction. Prepubescent boys may engage in group sexual activities such as genital exhibition or group masturbation. Homosexual sex play is not uncommon. Prepubescent girls may engage in some genital

exhibition, but they are usually not as preoccupied with the genitalia as are boys of this age.

Adolescence

Adolescence represents an acceleration in terms of biological changes and psychosocial and sexual development. This time of turmoil is challenged by awakening endocrine forces and a new set of psychosocial tasks. These tasks include issues relating to sexuality, such as how to deal with new or more powerful sexual feelings, whether to participate in various types of sexual behavior, how to recognize love, how to prevent unwanted pregnancy, and how to define age-appropriate gender roles.

Biologically, puberty begins for the female adolescent with breast enlargement, widening of the hips, and growth of pubic and ancillary hair. Onset of menstruation is variable but usually occurs between the ages of 11 and 13 years. Some children may begin menstruating as early as age 8. Malnutrition is one factor that influences a delay in onset of menses. In the male adolescent, growth of pubic hair and enlargement of the testicles begin at 12 to 16 years of age. Penile growth and the ability to ejaculate usually occur between the ages of 13 to 17. There is a marked growth of the body between ages 11 and 17, accompanied by the growth of body and facial hair, increased muscle mass, and a deeper voice.

Sexuality is slower to develop in the female than in the male adolescent. The notion that women show steady increases in sexual responsiveness that peak in their middle 20s or early 30s while sexual maturity for men is usually reached in the late teens dates back to Alfred Kinsey's research in the 1950s. However, it is more accurate to say that each person's sexuality is a unique, complex interplay among many variables. Masturbation is a common sexual activity among male and female adolescents.

Many individuals have their first experience with sexual intercourse during the adolescent years. According to data collected between September 2014 and December 2015, 41 percent of high school students surveyed admitted to having had sexual intercourse, and 43 percent said they did not use a condom the last time they had intercourse (Kann et al., 2016). Although the general trend has been toward safer sex practices in this age group, these statistics reflect an ongoing need for education about health risks and preventive measures. The American culture has ambivalent feelings about adolescent sexuality. Psychosexual development is desired, but most parents want to avoid anything that may encourage teenage sex. The rise in number of cases of sexually transmitted infections (STIs),

some of which are life threatening, also contributes to fears associated with unprotected sexual activity in all age groups.

In June 2006, the U.S. Food and Drug Administration (FDA) licensed Gardasil, the first vaccine developed to prevent cervical cancer and other diseases caused by certain strains of human papillomavirus (HPV). A second vaccine, Cervarix, was approved by the FDA in October 2009. If administered prior to exposure to HPV, these vaccines can protect women from ultimately developing cervical cancer caused by these specific strains. The Centers for Disease Control and Prevention (CDC) (2012) recommends routine administration of the vaccine to all girls aged 11 or 12 years with three doses of either vaccine. The vaccine is also recommended for girls and women aged 13 through 26 who have not already received the vaccine or have not completed all booster shots. In October 2011, the CDC's Advisory Committee on Immunization Practices (ACIP) recommended routine use of the quadrivalent vaccine, Gardasil, in males aged 11 or 12 years (CDC, 2011b). The ACIP also recommended vaccination for males aged 13 through 21 years who have not been vaccinated previously or who have not completed the 3-dose series; males aged 22 through 26 years may also be vaccinated. In 2015, a 9-valent HPV vaccine became available and was recommended by the ACIP as one of three HPV vaccines that may be used. This most current vaccine is identified as protective against 14 percent more HPV cancers for women and 5 percent more for men (Petrosky et al., 2015).

Some state legislatures have proposed making administration of the HPV vaccine mandatory for girls aged 9 to 12 years. However, some parents believe these types of laws circumvent their rights and may send the message that these young women are protected and thereby promote promiscuity. One recent study regarding this issue indicates that this concern is unfounded. Evidence has supported that HPV vaccination in the recommended age group was not associated with increased sexual activity–related outcomes or increase in unsafe sexual practices (Bednarczyk et al., 2012; Jena, Goldman, & Seabury, 2015). Currently, the controversy is ongoing, with supporters of a mandate saying that states have a rare opportunity to fight a cancer that kills 3700 American women every year, and to be effective, it must be given before a woman has been infected with the virus. But opponents say states—and parents—should be trying to prevent premarital sex instead of requiring a vaccination with the assumption that it is going to happen.

Adulthood

This period of the life cycle begins at approximately 20 years of age and continues to age 65. Sexuality

associated with older adults is discussed more thoroughly in Chapter 34, The Aging Individual.

Marital Sex

Choosing a partner is one of the major tasks in the early years of this life stage. Current cultural perspective reflects that marriage has survived as a mainstream institution. The United States has marriage rates of approximately 70 percent, although for the last decade, approximately 50 percent of marriages have ended in divorce (CDC, 2015). Changing attitudes about sex, living arrangement options, and marriage as a lifelong institution may be just a few of the factors contributing to this trend. Still, intimacy in marriage is one of the most common forms of sexual expression for adults. The average American couple has sex about two or three times per week in their 20s, with the frequency gradually declining to about once weekly for those 45 years of age and over. Many adults continue to masturbate even though they are married and have ready access to heterosexual sex. This behavior is perfectly normal, although it often evokes feelings of guilt and may be kept secret.

Extramarital Sex

Studies present widely variable results for surveys of extramarital sex. Even the most carefully conducted surveys are based on the reliability of self-reporting, and these reports may be skewed by people's hesitancy to acknowledge a behavior they perceive as contrary to societal expectations. King and Regan (2014) report estimates that about one-third of married men and one-fourth of married women have engaged in extramarital sex during their marriages. Allen and Atkins, as cited by Hughes (2012), analyzed data on 16,090 individuals over almost two decades from 1991 to 2008 to identify trends over time and concluded that about 17.7 percent of ever-married individuals and about 10 percent more men than women reported having an extramarital affair. They calculated the probability of divorce following an extramarital affair at 50 percent, but as Hughes notes, the factors within a marriage that contribute to extramarital affairs and ultimately to divorce are complex and multifaceted and therefore cannot be reduced to a simple cause-and-effect relationship.

Sex and the Single Person

Attitudes about sexual intimacy among singles—never married, divorced, or widowed—vary among individuals. Some single people pursue relationships, casual or committed, that they believe will enrich their lives. Others cherish their independent, single status and have no desire for marriage or a sexual partner.

Many divorced men and women return to having an active sex life following separation from their spouses. More widowed men than widowed women return to an active sex life after the loss of their partners, perhaps in part because men may be more comfortable choosing women partners younger than themselves, and also because widows outnumber widowers by more than 4 to 1 (Administration on Aging, 2013).

The "Middle" Years—40 to 65

With the advent of the middle years, a decrease in hormone production initiates a number of changes in the sex organs as well as in the rest of the body. The average age of naturally occurring menopause for women in North America is 51 years, although changes can be noted from about 40 to 60 years of age (Kingsberg & Krychman, 2016). The decrease in the amount of estrogen results in loss of natural vaginal lubrication, possibly making intercourse painful. Other symptoms may include insomnia, hot flashes, headaches, heart palpitations, and depression. Hormonal supplements may alleviate some of these symptoms, although controversy still exists within the medical community regarding the safety of menopausal hormone therapy.

With the decrease of androgen production during these years, men also experience sexual changes. The amount of ejaculate may decrease, and ejaculation may be less forceful. The testes decrease in size, and erections may be less frequent and less rigid. By age 50, the refractory period increases, and men may require 8 to 24 hours after orgasm before another erection can be achieved.

Biological drives decrease and interest in sexual activity may decrease during these middle years. A man's declining interest in sexual activity may be influenced by needing longer stimulation to reach orgasm and decreased intensity of pleasure. Women, however, stabilize at the same level of sexual activity as at the previous stage in the life cycle and often have a greater capacity for orgasm in middle adulthood than in young adulthood (Sadock, Sadock, & Ruiz, 2015).

Variations in Sexual Orientation

Several labels have been used to describe variations in sexual orientation. One current acronym, LGBTQIA, attempts to describe the range of preferences (including lesbian, gay, bisexual, transgender, queer, intersex, and asexual). The term *lesbian* refers to women with a homosexual orientation; *gay* refers to males with homosexual orientation; *bisexual* refers to people who are oriented to both heterosexual and homosexual relationships; *transgender* refers to individuals who are inclined toward a gender different from their biologically assigned gender; *queer* is a term that has more recently been identified within the LGBTQIA community to describe people who are either uncertain about or uncomfortable with conventional, binary

labels; *intersexual* relates to individuals who describe themselves as sexually ambiguous; and *asexual* refers to those who have no sexual orientation or preference. Together, those with minority orientations are often described as the "LGBTQIA community." The following discussion focuses on the most common of these orientations, homosexuality and bisexuality.

Homosexuality

Same-sex relationships exist in all known human cultures and all mammalian species for which it has been studied. The term **homosexuality** is derived from the Greek root *homo,* meaning "same," and refers to sexual preference for individuals of the same gender. The term **gay** is used to refer to men who prefer same-sex relationships. The term **lesbian** also has Greek roots and is used to identify females who prefer same-sex relationships. Most men in same-sex relationships prefer the term *gay* because it focuses less on the sexual aspects of the orientation. A heterosexual person may be commonly referred to as "straight."

To provide informed, supportive care to all patients, it is important to understand the evolution of medical information and societal perceptions regarding homosexuality. Beginning in the late 1800s, homosexuality was classified as a mental illness. This remained the case until 1973, when the APA finally removed the classification from the *DSM,* affirming that homosexuality was one expression of sexuality, not a mental disorder. Still, homosexuality remained classified as a mental disorder in the World Health Organization's *International Classification of Diseases* until 1992, when it was finally removed.

Despite the advances made within the medical and mental health communities, U.S. state legislation prohibiting sexual behavior that could not result in reproduction ("sodomy laws") was slower to change. In 2003, when these laws still remained in 13 states, the U.S. Supreme Court finally issued a broad-scoped decision that essentially invalidated all sodomy laws (King & Regan, 2014). Then, on June 26, 2015, the Supreme Court declared same-sex marriage legal in all 50 states. Justice Anthony Kennedy, who wrote the majority opinion, said of same-sex couples in the case: "They ask for equal dignity in the eyes of the law. The Constitution grants them that right" (Chappell, 2015).

Despite these recent changes, some experts believe that some Americans' attitudes toward homosexuals can still best be described as homophobic. *Homophobia* is a negative attitude toward or fear of homosexuality or nonheterosexuals. Homophobic behaviors include extreme prejudice against, abhorrence of, and discomfort around nonheterosexuals. The impact of these prejudices, beliefs, or behaviors can create a climate of fear or stress for members of the homosexual community and their families.

Health-care providers must ensure that those of all sexual orientations receive care with dignity, which is the right of every human being. In 2013, for the first time, the CDC collected health data based on sexual orientation in an effort to pursue a goal of the national initiative *Healthy People 2020* (Institute of Medicine, 2003) to improve the health, safety, and well-being of lesbian, gay, and bisexual (LGB) individuals (CDC, 2014). One of the research findings was a higher than average incidence of alcohol use (five or more drinks a day) in this population, suggesting that a good health assessment should include screening for substance abuse issues. Other studies have identified concerns about increased risks for suicide attempts and suicides among LGB individuals, especially in men (Mathy et al., 2011; Ploderl et al., 2013). Whether this risk is associated with sexual orientation itself or the stresses associated with being a stigmatized minority group, nurses play an important role in promoting the safety and well-being for this population by screening for depression and suicide ideation in each health-care encounter.

Relationship patterns are as varied among homosexuals as they are among heterosexuals. They may remain single or live with one partner for an extended period of time; they may divorce or remain married for a lifetime. As a nurse and health-care provider, what matters is understanding that variations in sexual orientation are commonplace, with no relationship whatsoever to mental illness. Unconditional acceptance of each individual is an essential component of compassionate, successful nursing.

Bisexuality

A bisexual person is not exclusively heterosexual or homosexual, but engages in sexual activity with members of both genders. Bisexuals are also sometimes referred to as *ambisexual.* According to the 2013 National Health Interview Survey (CDC, 2014) 0.4 percent men and 0.9 percent women identified themselves as bisexual.

A diversity of sexual preference exists among those who identify themselves as bisexual. Some individuals prefer men and women equally, whereas others have a preference for one gender but also accept sexual activity with the other gender. Some may alternate between homosexual and heterosexual activity for long periods; others may have both a male and a female lover at the same time. Whereas some individuals maintain their bisexual orientation throughout their lives, others may eventually become exclusively homosexual or heterosexual.

Gender Dysphoria

> ## CORE CONCEPT
> **Gender**
> The condition of being either male or female.

Gender identity is a person's sense of being male or female—that is, the awareness of one's masculinity or femininity. The term **cisgender** refers to a personal identity that is the same as the gender assigned at birth. **Transgender** describes a state in which an individual experiences incongruence between his or her biological/assigned gender and gender identity. Colloquially, this term is sometimes abbreviated to simply *trans*. Gender identity does not dictate to whom one is attracted: in other words, transgender individuals may or may not have same-sex couples relationships (Lowry & Vega, 2016). The *DSM-5* stipulates that a diagnosis of gender dysphoria, in addition to incongruence between assigned gender and expressed gender, requires that the client expresses significant distress in school, social, occupational, and performance functions for at least 6 months. It is not sufficient to make a diagnosis solely on a parent's or other people's discomfort with someone's gender identity. Changes in labeling and criteria for diagnosis reflect efforts within the psychiatric community to depathologize variances in gender. Stroumsa (2014) points out that there is increasing agreement among psychiatrists that transgender identity is not an "illness" to be "cured." However, when struggles with gender identity cause suffering, the individual may benefit from treatment. Although most cases of gender dysphoria begin in childhood, those who seek treatment may be of any age.

The *DSM-5* categorizes diagnosis of the condition in two groups: gender dysphoria in children and gender dysphoria in adolescents and adults. For purposes of this text, differentiation between the age groups is discussed, but the major focus is on gender dysphoria as it emerges in childhood. Nurses who work in areas of primary prevention with children can have the greatest effect in responding to the needs of this population.

There was a great deal of controversy in the psychiatric community about whether gender dysphoria should be included in the *DSM-5* (APA, 2013). The transgender community protested to the psychiatric work group that "different is not a disease." The work group attempted to address some of the concerns of the transgender community, taking into consideration the stigma associated with inclusion of the diagnosis but also the need for inclusion in terms of access to adequate treatment and care. If the diagnosis was not included, those who chose to seek medical-surgical and/or psychiatric treatment may have been denied third-party assistance. The term *gender dysphoria* was adopted to minimize the stigma connected to the previous label and emphasize the emotional component of the condition.

Course and Epidemiology

An estimated 1 in 30,000 men and 1 in 100,000 women identify as transgender (Sadock et al., 2015). In other words, most (approximately 75%) transgender individuals are biological males desiring reassignment to female gender (MTF), and the remaining 25 percent are females desiring to be male (FTM). Some transgender individuals choose to find ways of living with their cross-gender identity without surgically altering their bodies. Others have a strong desire to change their physical bodies to reflect their core gender identities. Transgender ideation and expression sometimes dissipates after early childhood; however, if it persists into adolescence, it appears to be an established identity.

Predisposing Factors

Biological Influences

The etiology of transgender identity is unknown. There is no significant evidence linking this condition to hormone or chromosome variations (Gooren, 2011). Some small postmortem studies of brain tissue have demonstrated that MTF transgender individuals (also referred to as *trans women*) had typically female patterns of sexual differentiation in both the stria terminalis and the hypothalamic uncinate nucleus, leading researchers to suggest that perhaps this is a sexual differentiation issue that affects the brain (Garcia-Falgueras & Swaab, 2008).

Family Dynamics

Gender roles are certainly culturally influenced as parents encourage masculine or feminine behaviors in their children. However, there is no clear evidence that psychological factors or family dynamics cause gender dysphoria (Gooren, 2011). Parents may present with anxiety over their child's gender-nonconforming behavior based on their attitudes and perceptions. Likewise, children may present with symptoms of anxiety and depression related to negative attitudes toward their gender-nonconforming behaviors. Interestingly, researchers have observed that many children who show gender-nonconforming behavior do not grow up to become transgender, and many people who identify themselves as transgender in adulthood were not identified as gender nonconforming in childhood (Sadock et al., 2015).

Application of the Nursing Process to Gender Dysphoria in Children

Background Assessment Data (Symptomatology)

Some children may resist wearing clothing or playing with toys that are typical for their assigned genders. This resistance is often part of normal childhood behavior. But when these behaviors persist into later childhood and adolescence, they may indicate a stable gender identity. Gender dysphoria is not diagnosed unless symptoms of distress emerge, such as marked distress associated with gender identity, concerns such as depression related to the desire to be the opposite gender, disgust with one's own genitals, or fear and anxiety related to others learning about their gender identity. These children may be subjected to teasing and rejection by their peers and disapproval from family members. This occurs early in childhood for boys but often does not occur before adolescence in girls, because masculine behavior in girls is more culturally accepted than feminine behavior in boys. Because of this rejection, interpersonal relationships are hampered. The *DSM-5* diagnostic criteria for gender dysphoria in children are presented in Box 30–1.

Diagnosis and Outcome Identification

Based on the data collected during the nursing assessment, possible nursing diagnoses for the child with gender dysphoria may include the following:

■ Impaired social interaction related to socially and culturally nonconforming behaviors
■ Low self-esteem related to rejection by peers and/or family members

The following criteria may be used for measurement of outcomes in the care of the child with gender dysphoria.

The client:

■ Demonstrates trust in a therapist
■ Demonstrates development of a close relationship with parents
■ Verbalizes positive self-esteem
■ Demonstrates evidence of social skills and assertive communication in relationship with family and peers
■ Verbalizes and demonstrates comfort with gender identity

Planning and Implementation

Table 30–1 provides a plan of care for the child with gender dysphoria. Nursing diagnoses are presented along with outcome criteria, appropriate nursing interventions, and rationales.

BOX 30–1 Diagnostic Criteria for Gender Dysphoria in Children

A. A marked incongruence between one's experienced/expressed gender and assigned gender, of at least 6 months' duration, as manifested by at least six of the following indicators (one of which must be Criterion A1):
  1. A strong desire to be of the other gender or an insistence that he or she is the other gender (or some alternative gender different from one's assigned gender).
  2. In boys (assigned gender), a strong preference for cross-dressing or simulating female attire; in girls (assigned gender), a strong preference for wearing only typical masculine clothing and a strong resistance to the wearing of typical feminine clothing.
  3. A strong preference for cross-gender roles in make-believe or fantasy play.
  4. A strong preference for the toys, games, or activities stereotypically used or engaged in by the other gender.
  5. A strong preference for playmates of the other gender.
  6. In boys (assigned gender), a strong rejection of typically masculine toys, games, and activities and a strong avoidance of rough-and-tumble play; or in girls (assigned gender), a strong rejection of typically feminine toys, games, and activities.
  7. A strong dislike of one's sexual anatomy.
  8. A strong desire for the primary and/or secondary sex characteristics that match one's experienced gender.
B. The condition is associated with clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Specify if:
  With a disorder of sex development (e.g., a congenital adrenogenital disorder such as congenital adrenal hyperplasia or androgen insensitivity syndrome).

Evaluation

The final step of the nursing process is to determine whether nursing interventions have been effective in achieving the intended outcomes. This evaluation process requires that the nurse reassess the client's behaviors and determine if the changes at which the interventions had been directed have occurred. For the child with gender dysphoria, this evaluation may be accomplished by using the following types of questions:

■ Does the client perceive that a problem existed that required a change in behavior for resolution?
■ What is the client's response to any negative peer reaction?
■ Can the client verbalize positive statements about self?
■ Can the client discuss past accomplishments without dwelling on the perceived failures?

Table 30–1 | CARE PLAN FOR THE CHILD WITH GENDER DYSPHORIA

NURSING DIAGNOSIS: INEFFECTIVE COPING ASSOCIATED WITH GENDER IDENTITY

RELATED TO: Biological factors or parenting patterns that encourage culturally unacceptable behaviors for assigned gender

EVIDENCED BY: Wearing clothing of and engaging in activities associated with the opposite gender; verbalized discomfort and distress related to assigned gender

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals • Client will verbalize knowledge of behaviors that are appropriate and culturally acceptable for assigned gender. • Client will verbalize personal feelings and behavior about assigned gender. • Parents will demonstrate knowledge about gender-nonconforming behaviors and gender dysphoria. Long-Term Goal • Client will express personal satisfaction and feelings of being comfortable within self-concept and gender identity.	1. Spend time with client and show positive regard. 2. Be aware of personal feelings and attitudes toward client and his or her behavior. 3. Educate parents about issues children face when engaging in gender-nonconforming behaviors and describe current knowledge about gender dysphoria. 4. Allow client to describe his or her perception of the problem.	1. Trust and unconditional acceptance are essential to the establishment of a therapeutic nurse–client relationship. 2. Attitudes influence behavior. The nurse must not allow negative attitudes to interfere with the effectiveness of interventions. 3. Including parents in the care plan for children is an important aspect of providing care for minor children. Providing current education to parents offers opportunities to discuss their roles and to provide supportive care. 4. It is important to know how the client perceives the problem before attempting to intervene.

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Socially and culturally nonconforming behaviors

EVIDENCED BY: Ridicule from peers and self-imposed social isolation

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client will verbalize possible reasons for ineffective interactions with others Long-Term Goal • Client will interact with others using behaviors that promote personal safety and self-esteem.	1. Once client feels comfortable with new behaviors in role-playing or one-to-one nurse–client interactions, new behaviors may be tried in group situations. If possible, remain with client during initial interactions with others. This intervention may include identification of safe and supportive peer groups. 2. Offer support if client is feeling hurt from peer ridicule. Matter-of-factly discuss behaviors that elicited the ridicule. Offer no personal reaction to the behavior.	1. The presence of a trusted individual provides security for client in a new situation and also provides the potential for feedback to client about his or her behavior. 2. Personal reaction from the nurse would be considered judgmental. Validation of client's feelings is important, yet it is also important that client understand why his or her behavior was the subject of ridicule and how to avoid it in the future.

Table 30–1	CARE PLAN FOR THE CHILD WITH GENDER DYSPHORIA–cont'd		
OUTCOME CRITERIA	**NURSING INTERVENTIONS**	**RATIONALE**
	3. The goal is to create a trusting, nonthreatening atmosphere for the client in an attempt to improve social interactions.	3. Long-term studies have not yet revealed the significance of therapy with these children for psychosexual relationship development in adolescence or adulthood. One variable that must be considered is the evidence of psychopathology within the families of these children.

NURSING DIAGNOSIS: LOW SELF-ESTEEM
RELATED TO: Rejection by peers
EVIDENCED BY: Lack of eye contact, negative self-evaluation, social withdrawal

OUTCOME CRITERIA	**NURSING INTERVENTIONS**	**RATIONALE**
Short-Term Goal • Client will verbalize positive statements about self, including past accomplishments and future prospects. Long-Term Goal • Client will verbalize and demonstrate behaviors that indicate self-satisfaction with gender identity, ability to interact with others, and a sense of self as a worthwhile person.	1. Encourage child to engage in activities in which he or she is likely to achieve success. 2. Help child to focus on aspects of his or her life for which positive feelings exist. Discourage rumination about situations that are perceived as failures or over which child has no control. Give positive feedback for these behaviors. 3. Help child identify behaviors or aspects of life he or she would like to change. If realistic, assist child in problem-solving ways to bring about the change. 4. Offer to be available for support to child when he or she is feeling rejected by peers.	1. Successful endeavors enhance self-esteem. 2. Rumination about perceived failures only further diminishes feelings of self-worth. Positive feedback increases self-esteem. 3. Having some control over his or her life may decrease feelings of powerlessness and increase feelings of self-worth and self-satisfaction. 4. Having an available support person who does not judge child's behavior and who provides unconditional acceptance assists child to progress toward acceptance of self as a worthwhile person.

■ Has the client shown progress toward accepting self as a worthwhile person regardless of others' responses to his or her behavior?

Treatment Issues

Determining whether a child is truly experiencing gender dysphoria should be done cautiously because gender-related behaviors vary widely in this age group. When this issue is identified as real gender dysphoria (e.g., the child is manifesting significant distress, symptoms of clinical depression, or suicidal ideation), treatment should include evaluation and management of concurrent mental health problems, social support systems, and in later childhood, nonjudgmental exploration of the individual's desires with regard to sexual reassignment.

Some practitioners still engage in treatment models that attempt to "repair" or change the person's gender

identity, but this approach is contrary to position statements by the American Psychiatric Association (Byne et al., 2012) and the practice guidelines established by the American Academy of Child and Adolescent Psychiatry (Adelson, 2012).

Another treatment model suggests that children who have differing gender identity are dysphoric only because of their image within the culture. In this view, children should be accepted as they see themselves—different from their assigned gender—and supported in their efforts to live as the gender in which they feel most comfortable. One option for treatment is pubertal delay for adolescents aged 12 to 16 years who have suffered with extreme lifelong gender dysphoria and who have supportive parents who encourage the child to pursue a desired change in gender (Adelson, 2012; Byne et al., 2012; Gibson & Catlin, 2010). A gonadotropin-releasing hormone agonist is administered to suppress changes associated with puberty. The treatment is reversible if the adolescent later decides not to pursue the gender change. When the medication is withdrawn, external sexual development proceeds, and the individual has avoided permanent surgical intervention. If he or she decides as an adult to advance to surgical intervention, pubertal delay may facilitate transition because secondary sex characteristics have not been clearly established. The type of treatment one chooses for gender dysphoria (if any) is a matter of personal choice. However, issues associated with mental health concerns, such as depression, anxiety, social isolation, anger, self-esteem, and parental conflict, must be addressed.

Children who demonstrate gender-nonconforming behaviors are often targets of bullying and violence. Nurses can play a key role in educating families and providing support to identify safe, supportive peer groups for these children (Nicholson & McGuiness, 2014).

Gender Dysphoria in Adolescents and Adults

An individual who identifies as transgender has anatomical characteristics of one gender but has the self-perception of being the opposite gender. Gender Dysphoria refers to a clinically significant mood disturbance related to transgender identity issues. Individuals with this disorder may not feel comfortable wearing the clothes of their assigned gender and often engage in cross-dressing. They may find their own genitals repugnant and may repeatedly seek treatment for hormonal and surgical gender reassignment. Depression and anxiety are common mood disturbances in this population, often attributed by the individual to his or her inability to live in the desired gender role. (Refer to the previous section on gender dysphoria in children for predisposing factors to this condition.)

Treatment Issues

Intervention with adolescents and adults with gender dysphoria is multifaceted. Evidence suggests that the longer people live with gender dysphoria before seeking treatment, the greater the likelihood of suicide attempts and completions (Nicholson & McGuiness, 2014). With a 41 percent lifetime prevalence of suicide attempts among transgender individuals and 33 percent identifying that they postponed preventive care because of discrimination or disrespect from health-care providers (Stroumsa, 2014), we must improve our abilities to provide holistic, nonjudgmental care. Adolescents rarely have the desire or motivation to alter their cross-gender roles, and in the interest of patient-centered care, nurses must listen carefully to the desires and treatment preferences expressed by the client. Some adults seek therapy to learn how to cope with their sexual identities, whereas others directly and immediately request hormonal therapy and surgical sex reassignment. The transgender person may intensely desire to have the genitalia and physical appearance of the assigned gender changed to conform to his or her gender identity. This change requires a great deal more than surgical alteration of physical features. In most cases, the individual must undergo extensive psychological testing and counseling as well as live in the role of the desired gender for up to 2 years before surgery.

Hormonal treatment is initiated during this period. Male clients receive estrogen, which results in a redistribution of body fat in a more "feminine" pattern, enlargement of the breasts, softening of the skin, and reduction in body hair. Women receive testosterone, which also causes a redistribution of body fat, growth of facial and body hair, enlargement of the clitoris, and deepening of the voice. Menstruation ceases (amenorrhea) within a few months of the advent of testosterone treatment.

Surgical treatment for MTF transgender reassignment involves removal of the penis and testes and creation of an artificial vagina. Care is taken to preserve sensory nerves in the area so that the individual may continue to experience sexual stimulation.

Surgical treatment for FTM transgender reassignment is more complex. A mastectomy and sometimes a hysterectomy are performed. A penis and scrotum are constructed from tissues in the genital

and abdominal area, the vaginal orifice is closed, and nerves are preserved to maintain sensation. A penile implant is used to attain erection.

Both men and women continue to receive maintenance hormone therapy following surgery. One study reported that after completion of gender reassignment, the satisfaction rate was 87 percent for MTF patients and 97 percent for FTM patients, and suicide rates decreased (Nicholson & McGuiness, 2014). Black and Andreasen (2014) state, "Many patients will continue to benefit from psychotherapy following surgery to assist them in adjusting to their new gender role" (p. 340).

Nursing care of the post-gender-reassignment surgical client is similar to that of most other postsurgical clients. Particular attention is given to maintaining comfort, preventing infection, preserving integrity of the surgical site, maintaining elimination, and meeting nutritional needs. Psychosocial needs may have to do with body image, fears and insecurities about relating to others, and being accepted in the new gender role. Meeting these needs can begin with nursing in a nonthreatening, nonjudgmental, healing atmosphere. For an example of communication that reflects a nonjudgmental, patient-centered approach, see "Real People, Real Stories: Erin."

Real People, Real Stories: Erin

Introduction: Patient-centered care is identified as an important competency for nurses and health-care professionals by the Institute of Medicine's 2003 report. Listening to the patient and his or her identified needs is a key way to develop this competency. Erin's story may not represent the experience of everyone who is transgender, but is presented here as an example of a health-care provider listening and encouraging a client to clarify her needs.

Nurse: Tell me about your background with regard to gender identity.

Erin: I didn't fit in as a boy and knew that, maybe as early as age 6. The only thing I was familiar with was drag queens on television, and they weren't me. Not until college did I recognize this thing called "transgender." In high school, I tried to overcompensate by listening to loud macho music, heavy metal. I had cross-dressed in theater settings but not outside of that.

Nurse: Did you experience any difficulties in school or relationships that were related to your gender identity?

Erin: There was bullying and some violence but not gender-role related, more because I was performing male roles but not very well, and teenagers are morons.

Nurse: What was it like in college after you learned about transgender identity?

Erin: In college was where I found a name for my feelings. I knew that trying to behave as a male was acting, and I didn't want to do that. I started experimenting with going out as a woman on Halloween. I was terrified though. What if I saw someone I knew? How would I explain this costume? What if I got beat up? I had an okay time. I went to a place where I wouldn't be recognized, but I was on guard all night.

Nurse: Did you have any support systems there?

Erin: I sought out safe spaces, largely gay spaces where I could spend some time "out" and figure out who would be safe to "come out" to. The first time I came out to someone not gay or transgender was difficult, and so I laid some hints and groundwork, doing more stereotypical stuff like baking and cooking. When I did formally come out I was very worked up and agitated, but to them it was a nonissue.

Nurse: So your friends were more accepting than you thought they would be! How about your family relationships?

Erin: I was living full time as a woman and attending grad school before I came out to my parents. They are pretty progressive. Dad was a chaplain who worked with AIDS patients early on. I'm not aware of any major conflicts with

Real People, Real Stories: Erin—cont'd

Dad; he might have wanted me to be more athletic but wasn't pushy, and I was an athlete in high school, running cross country and track. Again, I got very worked up, but if there was a negative reaction from them, I never saw it. I have one uncle who is a conservative Christian that I don't talk with much, but there's no overt conflict, just distance. I'm the oldest of three siblings, but my sisters don't live nearby. We're not very close and never have been. I'm closer to my mom than my sisters, and our relationship is okay. I've been enormously fortunate; I am the exception. Some people I know have been kicked out or even had their lives threatened by family members when they came out.

Nurse: What kinds of health care have you sought out related to your gender identity?

Erin: To make the transition more physical, I used "gray market" hormone therapies that I purchased online, in part for fear of expense because endocrinologists and psychologists were required to get the okay for hormone therapy from insurance, and the costs were prohibitive. I didn't have insurance. The hormones were effective but also shot down my libido. I took them for about three years.

Nurse: Have you ever been interested in or explored sexual reassignment surgery?

Erin: Sexual reassignment is not a priority for me, although it's not off the table. I'm ambivalent. I'm not sufficiently dysphoric that I feel like I need major surgeries or major expense.

Nurse: Have you ever sought counseling for mental health concerns?

Erin: I have had counseling on and off for stress and depression related to gender issues but not because I wanted counseling about gender identity. My counseling experiences were helpful in that I learned more effective life skills and coping skills. To find a counselor, I looked for a resource listed in a gay resources guide. With another counseling encounter, I was open during the intake assessment about my gender issues, and they assigned me to someone more familiar with transgender populations. So in general, I've had positive experiences with counseling.

Nurse: Are there any experiences you've had in seeking health care that were not positive?

Erin: I haven't encountered any health professionals who were overtly hostile. Sometimes they were unfamiliar with transgender populations or uncomfortable but not unwilling to work with me. Mostly I've encountered nonverbal signals of discomfort.

Nurse: What do you want or need most from health-care professionals when you seek them out?

Erin: I don't need for someone to know the latest things about reassignment surgery or hormone treatments; that stuff can be looked up. I need honesty about what someone knows or doesn't know and some reassurance that the person is engaged and interested in helping me. Asking about mood, social supports, and coping skills are important screening questions. If someone disrespects me, I would go somewhere else, but I don't ignore my health-care needs because of fear of disrespect or discrimination. I just don't care.

Nurse: That may be a testimony to your self-esteem.

Erin: I've been very fortunate with friends, family, and health-care workers with regard to their response to me, but since I am also somewhat "acting" in my performance as a female and I kind of live somewhere in between genders, some people might be uncomfortable or unfamiliar with that. But I think that that is probably a pretty common experience for transgender individuals.

Nurse: I have been concerned when I've read that there is a high incidence of depression and suicide attempts in transgender individuals. Have you ever struggled with depression or suicidal ideation?

Erin: I've been on antidepressants, and although I have had some decreased sex drive, it's a trade-off I'm willing to take. I have had periods where I didn't want to get out of bed or leave the house and periods in the past where I had suicide ideas but have never attempted. I realized that wasn't where I wanted to be, so I went back to therapy and got back on meds.

Nurse: That's so important! Depression can be a downward spiral, and getting some kind of help before it becomes too severe can be a lifesaving decision.

Sexual Disorders

Paraphilic Disorders

The term *paraphilia* is used to identify repetitive or preferred sexual fantasies or behaviors that involve (1) nonhuman objects, (2) suffering or humiliation of oneself or one's partner, or (3) nonconsenting persons (Black & Andreasen, 2014).

According to the *DSM-5*, a paraphilia is labeled a paraphilic *disorder* only when specific types of sexual fantasies or behaviors are recurrent over a period of at least 6 months and cause the individual clinically significant distress or impairment in social, occupational, or other important areas of functioning (APA, 2013). Many paraphilic behaviors are illegal sex acts, so an individual may come to the attention of legal authorities before he or she is introduced to psychiatric treatment for this disorder. The general prognosis for controlling or curing paraphilias is poor when associated with an early age of onset, high frequency of behaviors, lack of guilt about the act, and

substance abuse (Sadock et al., 2015). Nonetheless, Fedoroff (2016) notes that, contrary to popular opinion, when individuals with paraphilic disorders *seek* treatment, outcomes are frequently positive.

Epidemiological Statistics

Relatively limited data exist on the prevalence or course of paraphilic disorders. Most available information has been obtained from studies of incarcerated sex offenders and from outpatient psychiatric services for individuals with paraphilic disorders outside the criminal justice system. Data suggest that most people with paraphilic disorders who seek outpatient treatment do so for pedophilic disorder (45%), exhibitionistic disorder (25%), or voyeuristic disorder (12%).

Most individuals with paraphilic disorders are men, and the behavior is generally established in adolescence (Black & Andreasen, 2014). The behavior peaks between ages 15 and 25 and gradually declines so that, by age 50, the occurrence of paraphilic acts is very low, except for those behaviors that occur in isolation or with a cooperative partner. It is not uncommon for individuals with paraphilias to exhibit multiple paraphilias (APA, 2013).

Types of Paraphilic Disorders

The following types of paraphilic disorders are identified by the *DSM-5:*

Exhibitionistic Disorder

Exhibitionistic disorder is characterized by recurrent and intense sexual arousal (manifested by fantasies, urges, or behaviors of at least 6 months' duration) from the exposure of one's genitals to an unsuspecting individual (APA, 2013). Masturbation may occur during the exhibitionism. In most cases of exhibitionism, the perpetrators are men and the victims are women. Evidence has demonstrated that victims identify several negative outcomes as a consequence of the occurrence, including "feelings of violation, changes in behavior, and even long-term psychological distress" (Clark et al., 2016).

The urges for genital exposure intensify when the exhibitionist has excessive free time or is under significant stress. Most people who engage in exhibitionism have rewarding sexual relationships with adult partners but concomitantly expose themselves to others.

Fetishistic Disorder

Fetishistic disorder involves recurrent and intense sexual arousal (manifested by fantasies, urges, or behaviors of at least 6 months' duration) from the use of either inanimate objects or specific nongenital body part(s) (APA, 2013). A common sexual focus is on objects intimately associated with the human body (e.g., shoes, gloves, stockings). The fetish object is usually used during masturbation or incorporated into sexual activity with another person in order to produce sexual excitement.

Onset of a fetishistic disorder usually occurs during adolescence. The disorder is chronic, and the complication arises when the individual becomes progressively more intensely aroused by sexual behaviors that exclude a sexual partner. Requirement of the fetish object for sexual arousal may become so intense that to be without it results in impotence. The person with the fetish and his partner may become so distant that the partner eventually terminates the relationship.

Frotteuristic Disorder

Frotteuristic disorder is the recurrent and intense sexual arousal (manifested by urges, behaviors, or fantasies of at least 6 months' duration) involving touching or rubbing against a nonconsenting person (APA, 2013). Sexual excitement is derived from the actual touching or rubbing, not from the coercive nature of the act. Almost without exception, the gender of the frotteur is male.

The individual usually chooses to commit the act in crowded places, such as on buses or subways during rush hour. In this way, he can provide rationalization for his behavior should someone complain and can more easily escape arrest. The frotteur waits in a crowd until he identifies a victim, then he follows her and allows the rush of the crowd to push him against her. He fantasizes a relationship with his victim while rubbing his genitals against her thighs and buttocks or touching her genitalia or breasts with his hands. He often escapes detection because of the victim's initial shock and denial that such an act has been committed in this public place.

Pedophilic Disorder

The essential feature of **pedophilic disorder** is sexual arousal derived from prepubescent or early pubescent children equal to or greater than that derived from physically mature persons. *DSM-5* criteria specify that the behavior has lasted at least 6 months and is manifested by fantasies or sexual urges on which the individual has acted or which cause significant distress or impairment in social, occupational, or other important areas of functioning (APA, 2013). The age of the perpetrator with pedophilic disorder is at least 16 years, and he or she is at least 5 years older than the child victimized. This category of paraphilic disorder is the most common of sexual assaults.

Most child molestations involve genital fondling or oral sex. Vaginal or anal penetration of the child is most common in cases of incest. Sexual abuse of a child may include a wide range of behaviors,

including speaking to the child in a sexual manner, indecent exposure and masturbation in the presence of the child, and inappropriate touching or acts of penetration (oral, vaginal, and anal) (King & Regan, 2014). Onset usually occurs during adolescence, and the disorder is often chronic.

Sexual Masochism Disorder

The identifying feature of **sexual masochism disorder** is recurrent and intense sexual arousal (manifested by urges, behaviors, or fantasies of at least 6 months' duration) from the act of being humiliated, beaten, bound, or otherwise made to suffer (APA, 2013). These masochistic activities may be fantasized (e.g., being raped) and may be performed alone (e.g., self-inflicted pain) or with a partner (e.g., being restrained, spanked, or beaten by the partner). Some masochistic activities, particularly those involving sexual arousal by oxygen deprivation, have resulted in death. The disorder is usually chronic and can progress to the point at which the individual cannot achieve sexual satisfaction without masochistic fantasies or activities.

Sexual Sadism Disorder

The *DSM-5* identifies the essential feature of **sexual sadism disorder** as recurrent and intense sexual arousal (manifested by urges, behaviors, or fantasies of at least 6 months' duration) from the physical or psychological suffering of another individual (APA, 2013). The sadistic activities may be fantasized or acted on with a consenting or nonconsenting partner. In all instances, sexual excitation occurs in response to the suffering of the victim. Examples of sadistic acts include restraint, beating, burning, rape, cutting, torture, and even killing.

The course of the disorder is usually chronic, with the severity of the sadistic acts often increasing over time. Activities with nonconsenting partners are usually terminated by legal apprehension.

Transvestic Disorder

Transvestic disorder involves recurrent and intense sexual arousal (as manifested by fantasies, urges, or behaviors of at least 6 months' duration) from dressing in the clothes of the opposite gender. The individual is commonly a heterosexual man who keeps a collection of women's clothing that he intermittently uses to dress in when alone. The sexual arousal may be produced by an accompanying fantasy of the individual as a woman with female genitalia or merely by the view of himself fully clothed as a woman without attention to the genitalia. As with other paraphilias, it is identified as a *disorder* only when these urges and behaviors cause marked distress to the individual or interfere with social, occupational, or other important areas of functioning.

Voyeuristic Disorder

Voyeuristic disorder is identified by recurrent and intense sexual arousal (manifested by urges, behaviors, or fantasies of at least 6 months' duration) involving the act of observing an unsuspecting individual who is naked, in the process of disrobing, or engaging in sexual activity (APA, 2013). Sexual excitement is achieved through the act of looking, and no contact with the person is attempted. Masturbation usually accompanies the "window peeping" but may occur later as the individual fantasizes about the voyeuristic act.

Onset of voyeuristic behavior commonly occurs during adolescence, but the minimum age for a diagnosis of voyeuristic disorder is 18 years (APA, 2013). Many individuals who engage in this behavior enjoy satisfying sexual relationships with an adult partner. Few apprehensions occur because most targets of voyeurism are unaware that they are being observed.

Predisposing Factors to and Theories of Etiology in Paraphilic Disorders

Biological Factors

Many studies have identified biologic abnormalities in individuals with paraphilias. Two common findings are that 74 percent have abnormal hormone levels and 24 percent have chromosomal abnormalities (Sadock et al., 2015). Temporal lobe diseases, such as psychomotor seizures or tumors, have been implicated in some individuals with paraphilic disorder. Abnormal levels of androgens also may contribute to inappropriate sexual arousal. The majority of studies have involved violent sex offenders, and the results cannot accurately be generalized.

Psychoanalytic Theory

The psychoanalytic approach defines an individual with paraphilic disorder as one who has failed the normal developmental process toward heterosexual adjustment (Sadock et al., 2015). This occurs when the individual fails to resolve the Oedipal crisis and either identifies with the parent of the opposite gender or selects an inappropriate object for libido cathexis.

Behavioral Theory

The behavioral model hypothesizes that whether or not an individual engages in paraphilic behavior depends on the type of reinforcement he or she receives following the behavior. The initial act may be committed for various reasons. Some examples include recalling memories of experiences from an individual's early life (especially the first shared sexual experience), modeling behavior of others who have carried out paraphilic acts, mimicking sexual behavior

depicted in the media, and recalling past trauma such as one's own molestation (Sadock et al., 2015).

Once the initial act has been committed, the individual with paraphilic disorder consciously evaluates the behavior and decides whether to repeat it. A fear of punishment or perceived harm or injury to the victim, or a lack of pleasure derived from the experience, may extinguish the behavior. However, when negative consequences do not occur, when the act itself is highly pleasurable, or when the person with the paraphilic disorder immediately escapes and thereby avoids seeing any negative consequences experienced by the victim, the activity is more likely to be repeated.

Treatment Modalities for Paraphilic Disorders

Biological Treatment

Biological treatment of individuals with paraphilic disorders has focused on blocking or decreasing the level of circulating androgens. The most extensively used of the antiandrogenic medications are progestin derivatives that block testosterone synthesis or block androgen receptors. They do not influence the direction of sexual drive toward appropriate adult partners. Instead, they act to decrease libido by reducing serum testosterone levels to subnormal concentrations (Sadock et al., 2015). They are not meant to be the sole source of treatment and work best when given in conjunction with participation in individual or group psychotherapy.

Psychoanalytic Therapy

Psychoanalytic approaches have been tried in the treatment of paraphilic disorders. In this type of therapy, the therapist helps the client identify unresolved conflicts and traumas from early childhood. The therapy focuses on helping the individual resolve these early conflicts, thus relieving the anxiety that prevents him or her from forming appropriate sexual relationships. In turn, the individual has no further need for paraphilic fantasies.

Behavioral Therapy

Aversion therapy methods in the treatment of paraphilic disorders involve pairing noxious stimuli, such as electric shocks and bad odors, with the sexual impulse, which then diminishes. Behavioral therapy also includes skills training and cognitive restructuring in an effort to change the individual's maladaptive beliefs.

Other behavioral approaches to decreasing inappropriate sexual arousal have included *imaginal desensitization* and *satiation*. With imaginal desensitization, the client learns how to achieve a state of relaxation while recalling situations that triggered paraphilic behavior with the idea that relaxation will lead to less impulsivity in behavior. Satiation is a technique in which the postorgasmic individual repeatedly fantasizes deviant behaviors to the point of saturation with the deviant stimuli, consequently making the fantasies and behavior unexciting.

Role of the Nurse

Treatment of the person with a paraphilic disorder is often very frustrating for both the client and the therapist. Most individuals with paraphilic disorders deny that they have a problem and seek psychiatric care only after their inappropriate behavior comes to the attention of others. In secondary prevention, the focus is to diagnose and treat the problem as early as possible to minimize difficulties. One role of nurses may involve conducting a sexual history to identify the presence of paraphilic disorders. Developing skill in open, nonjudgmental communication when conducting a sexual history will help nurses assist clients to identify urges and behaviors that cause them distress. Individuals identified as suffering from paraphilic disorders should be referred to specialists who are accustomed to working with this population.

Nurses must also intervene to accomplish primary prevention. The focus of primary prevention in sexual disorders is to identify psychosocial stressors in childhood sexual development in an effort to prevent problems from developing. Again, developing skill in asking questions about sexual thoughts, concerns, and behaviors will enable nurses to provide interventions that encourage adaptive coping with stress and promote healthy sexual development.

Three major components of sexual development have been identified: (1) gender identity (one's sense of maleness or femaleness), (2) sexual responsiveness (arousal to appropriate stimuli), and (3) the ability to establish relationships with others. The questions that are asked in a sexual history collect information about the client's thoughts, feelings, and behaviors in each of these three domains, since distress in these areas may disrupt emotional, mental or behavioral health.

Nurses who work in pediatrics, psychiatry, public health, ambulatory clinics, schools, and any other facility requiring contact with children must be knowledgeable about human sexual development. Accurate assessment and early intervention by these nurses can substantially contribute to primary prevention of sexual disorders.

Sexual Dysfunctions

The Sexual Response Cycle

Because sexual dysfunctions occur as disturbances in any of the phases of the sexual response cycle, an

understanding of anatomy and physiology is a prerequisite to considerations of pathology and treatment.

- **Phase I—Desire:** During this phase, the desire to have sexual activity occurs in response to verbal, physical, or visual stimulation. Sexual fantasies can also bring about this desire.
- **Phase II—Excitement:** This is the phase of sexual arousal and erotic pleasure. Physiological changes occur. The male responds with penile tumescence and erection. Female changes include vasocongestion in the pelvis, vaginal lubrication, and swelling of the external genitalia.
- **Phase III—Orgasm:** Orgasm is identified as a peaking of sexual pleasure, with release of sexual tension and rhythmic contraction of the perineal muscles and reproductive organs. Orgasm in women is marked by simultaneous rhythmic contractions of the uterus, the lower third of the vagina, and the anal sphincter. In the man, a forceful emission of semen occurs in response to rhythmic spasms of the prostate, seminal vesicles, vas, and urethra.
- **Phase IV—Resolution:** If orgasm has occurred, this phase is characterized by disgorgement of blood from the genitalia, creating a sense of general relaxation and well-being. If orgasm is not achieved, resolution may take several hours, producing pelvic discomfort and a feeling of irritability.

After orgasm, men experience a refractory period that may last from a few minutes to many hours, during which time they cannot be stimulated to further orgasm. Commonly, the length of the refractory period increases with age. Because women have no refractory period, they may be capable of multiple and successive orgasms (Sadock et al., 2015).

Historical and Epidemiological Aspects Related to Sexual Dysfunction

Treatments for sexual dysfunction have existed in most cultures throughout history. Meditation, aphrodisiacs, and tonics (primarily alcohol) are just a few of the remedies that have been promoted in the past. Concurrent with the cultural changes occurring during the sexual revolution of the 1960s and 1970s came an increase in scientific research into sexual physiology and sexual dysfunctions. Masters and Johnson (1966; 1970) pioneered this work with their studies on human sexual response and the treatment of sexual dysfunctions. Currently, treatment of sexual dysfunctions has found a place in medicine, with medications, surgeries, and psychological treatments as some of the available options.

Sexual dysfunction consists of an impairment or disturbance in any of the phases of the sexual response cycle. No one knows exactly how many people experience sexual dysfunctions. Knowledge exists only about those who seek some kind of treatment for the problem, and they may be few in number compared with those who have a dysfunction but suffer quietly and never seek therapy.

In 1970, Masters and Johnson reported that 50 percent of all American couples suffered from some type of sexual dysfunction. In 1984, Robins and fellow researchers estimated that 24 percent of the U.S. population would experience a sexual dysfunction at some time in their lives. A 1999 landmark survey (Laumann, Paik, & Rosen, 1999) identified the prevalence of sexual dysfunctions at 43 percent for women and 31 percent for men, highlighting that these dysfunctions are more common than previously thought. Data related to prevalence of sexual problems in the United States based on a more recent survey identified that the most prevalent sexual problems for men were premature ejaculation and erectile difficulties; for women the most prevalent sexual problems were lack of sexual interest and lubrication difficulties (Laumann et al., 2009). This survey included 1491 men and women aged 40 to 80, and a significant finding was that less than 25 percent of the individuals with a sexual problem sought help from a health-care provider.

Types of Sexual Dysfunction

Erectile Disorder

Erectile disorder is characterized by marked difficulty in obtaining or maintaining an erection during sexual activity or a decrease in erectile rigidity that interferes with sexual activity (APA, 2013). The problem persists for at least 6 months and causes the individual significant distress. *Primary erectile disorder* refers to cases in which the man has never been able to have intercourse; *secondary erectile disorder* refers to cases in which the man has difficulty getting or maintaining an erection but has been able to have vaginal or anal intercourse at least once.

Female Orgasmic Disorder

Female orgasmic disorder is defined by the *DSM-5* as a marked delay in or infrequency or absence of orgasm during sexual activity (APA, 2013). It may also be characterized by a reduced intensity of orgasmic sensation. The condition, which is sometimes referred to as **anorgasmia,** has lasted at least 6 months and causes the individual significant distress. Women who can achieve orgasm through noncoital clitoral stimulation but are not able to experience it during coitus in the absence of manual clitoral stimulation are not necessarily categorized as anorgasmic.

A woman is considered to have *primary orgasmic disorder* when she has never experienced orgasm by any kind of stimulation. *Secondary orgasmic disorder* exists if the woman has experienced at least one orgasm, regardless of the means of stimulation, but is no longer able to do so.

Delayed Ejaculation

Delayed ejaculation is characterized by marked delay in ejaculation or marked infrequency or absence of ejaculation during partnered sexual activity (APA, 2013). The condition has lasted for at least 6 months and causes the individual significant distress. With this disorder, the man is unable to ejaculate even though he has a firm erection and has had more than adequate stimulation. The severity of the problem may range from only occasional problems ejaculating *(secondary disorder)* to a history of never having experienced an orgasm *(primary disorder)*. In the most common version, the man cannot ejaculate during coitus but may be able to ejaculate as a result of other types of stimulation.

Premature (Early) Ejaculation

The *DSM-5* describes **premature (early) ejaculation** as persistent or recurrent ejaculation occurring within 1 minute of beginning partnered sexual activity and before the person wishes it to occur (APA, 2013). The condition has lasted at least 6 months and causes the individual significant distress. The diagnosis should take into account factors that affect the duration of the excitement phase, such as the person's age, the novelty of the sexual partner, and frequency of sexual activity (Sadock et al., 2015).

Premature (early) ejaculation is the most common sexual disorder for which men seek treatment. It is particularly common among young men who have a very high sex drive and have not yet learned to control ejaculation.

Female Sexual Interest/Arousal Disorder

This disorder is characterized by a reduced or absent interest or pleasure in sexual activity (APA, 2013). The individual typically does not initiate sexual activity and is commonly unreceptive to partner's attempts to initiate. There is an absence of sexual thoughts or fantasies and absent or reduced arousal in response to sexual or erotic cues. The condition has persisted for at least 6 months and causes the individual significant distress.

Male Hypoactive Sexual Desire Disorder

This disorder is defined by the *DSM-5* as a persistent or recurrent deficiency or absence of sexual fantasies and desire for sexual activity. In making the judgment of deficiency or absence, the clinician considers factors that affect sexual functioning, such as age and life circumstances (APA, 2013). The condition has persisted for at least 6 months and causes the individual significant distress.

An individual's absolute level of sexual desire may not be the problem; rather, the problem may be a discrepancy between the partners' levels of desire. Conflict may occur if one partner wants to have sexual relations more often than the other does. Care must be taken not to label one partner as pathological when the problem actually lies in the conflicting desire levels.

Genito-Pelvic Pain/Penetration Disorder

With this disorder, the individual experiences considerable difficulty with vaginal intercourse and attempts at penetration. Pain is felt in the vagina, around the vaginal entrance and clitoris, or deep in the pelvis. Fear and anxiety are associated with anticipation of pain or vaginal penetration. A tensing and tightening of the pelvic floor muscles occurs during attempted penetration (APA, 2013). The condition may be *lifelong* (present since the individual became sexually active) or *acquired* (began after a period of relatively normal sexual function). It has persisted for at least 6 months and causes the individual clinically significant distress.

Substance/Medication-Induced Sexual Dysfunction

With these disorders, the sexual dysfunction developed after substance intoxication or withdrawal or after exposure to a medication (APA, 2013). The dysfunction may involve pain, impaired desire, impaired arousal, or impaired orgasm. Some substances and medications that can interfere with sexual functioning include alcohol, amphetamines, cocaine, opioids, sedatives, hypnotics, anxiolytics, antidepressants, antipsychotics, and antihypertensives, among others.

Predisposing Factors to Sexual Dysfunction

Biological Factors

Sexual Desire Disorders Studies have correlated decreased levels of serum testosterone with hypoactive sexual desire disorder in men. Evidence also suggests a relationship between serum testosterone and increased female libido (Sadock et al., 2015). Diminished libido has been observed in both men and women with elevated levels of serum prolactin (Wisse, 2015). Various medications have been implicated in the etiology of hypoactive sexual desire disorder, including antihypertensives, antipsychotics, antidepressants, anxiolytics, and anticonvulsants. Alcohol and cocaine have also been associated with impaired desire, especially after chronic use. In 2015, the FDA approved

the first drug for treatment of hypoactive sexual desire disorder in premenopausal women. This medication, flibanserin (Addyi), is a nonhormonal serotonin agonist and antagonist.

Sexual Arousal Disorders A decrease in estrogen levels when women are postpartum, postmenopausal, or receiving gonadotrophin-releasing hormone agonists may prohibit the vasocongestion and vaginal lubrication needed for painless intercourse. This may lead to decreased sexual desire (Basson, 2016; Kingsberg & Krychman, 2016). Various medications, particularly those with antihistaminic and anticholinergic properties, may also contribute to decreased ability for arousal in women.

Arteriosclerosis is a common cause of male erectile disorder as a result of arterial insufficiency (King & Regan, 2014). Various neurological disorders can contribute to erectile dysfunction as well. The most common neurologically based cause may be diabetes, which places men at high risk for neuropathy (Kim & Brosman, 2013). Other potential neurological causes include temporal lobe epilepsy and multiple sclerosis. Trauma (e.g., spinal cord injury, pelvic cancer surgery) can also result in erectile disorder. Several medications have been implicated in the etiology of this disorder, including antihypertensives, antipsychotics, antidepressants, and anxiolytics. Chronic use of alcohol has also been shown to be a contributing factor.

Orgasmic Disorders Some women report decreased ability to achieve orgasm following hysterectomy. Conversely, some report increased sexual activity and decreased sexual dysfunction following hysterectomy. Some medications (e.g., selective serotonin reuptake inhibitors [SSRIs]) may inhibit orgasm. Medical conditions such as depressive disorders, hypothyroidism, and diabetes mellitus may cause decreased sexual arousal and orgasm.

Biological factors associated with delayed male orgasm include surgery of the genitourinary tract (e.g., prostatectomy), neurological disorders (e.g., Parkinson's disease), and other diseases (e.g., diabetes mellitus). Medications that have been implicated include opioids, antihypertensives, antidepressants, and antipsychotics. Transient cases of the disorder may occur with excessive alcohol intake.

Although early ejaculation is commonly caused by psychological factors, general medical conditions or substance use may also be contributing influences. Physical factors are often involved in cases of secondary dysfunction. Examples include a local infection, such as prostatitis, or a degenerative neural disorder, such as multiple sclerosis.

Sexual Pain Disorders A number of organic factors can contribute to painful intercourse in women, including intact hymen, episiotomy scar, vaginal or urinary tract infection, ligament injuries, endometriosis, or ovarian cysts or tumors. Painful intercourse in men may also be caused by various organic factors. For example, infection caused by poor hygiene under the foreskin of an uncircumcised man can cause pain. Phimosis, a condition in which the foreskin cannot be pulled back, can also cause painful intercourse. An allergic reaction to various vaginal spermicides or irritation caused by vaginal infections may be a contributing factor. Finally, various prostate problems may cause pain on ejaculation.

Psychosocial Factors

Sexual Desire Disorders A variety of individual and relationship factors may contribute to hypoactive sexual desire disorder. Individual factors include fears associated with sex; history of sexual abuse and trauma; chronic stress, anxiety, depression; and aging-related concerns (e.g., changes in physical appearance). Among the relationship causes are interpersonal conflicts; current physical, verbal, or sexual abuse; extramarital affairs; and desire or practices that differ from those of one's partner. In general, the presence of sexual desire is influenced by sexual drives, self-esteem, accepting oneself as a sexual person, good stress management, and good relationship skills; disruption in any of these areas can contribute to lower desire (Sadock et al., 2015).

Sexual Arousal Disorders A number of psychological factors have been cited as possible impediments to female arousal. They include doubt, guilt, fear, anxiety, shame, conflict, embarrassment, tension, disgust, irritation, resentment, grief, hostility toward partner, and a puritanical or moralistic upbringing. Sexual abuse has been identified as a significant risk factor for desire and arousal disorders in women.

Problems with male sexual arousal may be related to chronic stress, anxiety, or depression. Developmental factors that hinder the ability to be intimate, that lead to a feeling of inadequacy or distrust, or that develop a sense of being unloving or unlovable may also result in impotence. Relationship factors that may affect erectile functioning include lack of attraction to one's partner, anger toward one's partner, or being in a relationship that is not characterized by trust. Regardless of the etiology of the erectile dysfunction, once it occurs the man may become increasingly anxious about his next sexual encounter. This anticipatory anxiety about achieving and maintaining an erection may then perpetuate the problem.

Orgasmic Disorders Numerous psychological factors are associated with inhibited female orgasm. They

include fears of becoming pregnant or damage to the vagina, rejection by the sexual partner, hostility toward men, and feelings of guilt regarding sexual impulses (Sadock et al., 2015). Various developmental factors may also have relevance to orgasmic dysfunction. Examples include negative messages about sexuality from family; religion and culture; unwanted sexual experiences; or punishment for childhood sexual experimentation (Donahey, 2016).

Psychological factors are also associated with inhibited male orgasm (delayed ejaculation). In the primary disorder (in which the man has never experienced orgasm), the man often comes from a rigid, puritanical background. He perceives sex as sinful and the genitals as dirty, and he may have conscious or unconscious incest wishes and associated guilt (Sadock et al., 2015). In the case of secondary disorder (previously experienced orgasms that have now stopped), interpersonal difficulties are usually implicated. There may be some ambivalence about commitment, fear of pregnancy, or unexpressed hostility.

Premature ejaculation may be related to a lack of physical awareness on the part of a sexually inexperienced man. The ability to control ejaculation occurs as a gradual maturing process with a sexual partner in which foreplay becomes more give-and-take "pleasuring" rather than strictly goal-oriented. The man becomes aware of the sensations and learns to delay the point of ejaculatory inevitability. Relationship problems, negative cultural conditioning, anxiety over intimacy, and lack of comfort in the sexual relationship may also contribute to this disorder.

Sexual Pain Disorders Penetration disorders may occur in response to genito-pelvic pain experienced for various organic reasons stated in the "Biological Factors" section. Involuntary constriction within the vagina occurs in response to anticipatory pain, making intercourse difficult or impossible. The diagnosis does not apply if the etiology is determined to be due to another medical condition.

A variety of psychosocial factors have been identified in clients with sexual pain disorder. Clinicians report that frequently an individual with this disorder has been raised in a strict religious environment where sex was associated with sin (Sadock et al., 2015). Early traumatic sexual experiences (e.g., rape or incest) may also contribute to penetration disorder. Other etiological factors that may be important include painful childhood experiences with surgical, dental, or pelvic examination; phobias associated with pregnancy, STIs, or cancer; and catastrophizing or fear of pain (Bergeron, Rosen, & Corsini-Munt, 2016; King & Regan 2014; Sadock et al., 2015).

Application of the Nursing Process to Sexual Disorders

Assessment

Most assessment tools for taking a general nursing history contain some questions devoted to sexuality. Nurses may feel uncomfortable obtaining information about this subject. However, accurate data must be collected if problems are to be identified and resolutions attempted. Sexual health is an integral part of physical and emotional well-being. The nursing history is incomplete if items directed toward sexuality are not included.

Most nurses are not required to obtain a sexual history as in depth as the one presented in this chapter. However, for certain clients, a more extensive sexual history is required, including those who have medical or surgical conditions that may affect their sexuality; clients with infertility problems, STIs, or complaints of sexual inadequacy; clients who are pregnant or have gynecological problems; those seeking information on abortion or family planning; and individuals in premarital, marital, and psychiatric counseling.

The best approach for taking a sexual history is a nondirective one, meaning it is best to use the sexual history outline as a guideline but allow the interview to progress in a natural, less restrictive manner. The order of the questions should be adjusted according to the client's needs as identified during the interview. A nondirective approach allows time for the client to interject information related to feelings or concerns about his or her sexuality.

The language used should be understandable to the client. If he or she uses terminology that is unfamiliar, ask for clarification. Take level of education and cultural influences into consideration. Hispanic and Indian clients, for example, tend to be reluctant to talk about sexual matters and may feel more comfortable with a nurse of the same sex. In some cultures (such as Hispanic, Pakistani, and Arabic), discussing sexual matters with a male child requires the father rather than the mother to be present (Giger, 2017).

The nurse's attitude must convey warmth, openness, honesty, and objectivity. Personal feelings, attitudes, and values should be clarified and should not interfere with acceptance of the client. The nurse must remain nonjudgmental, which is conveyed by listening in an interested, matter-of-fact manner without overreacting to any information the client may present.

The content outline for a sexual history presented in Box 30–2 is not intended to be used as a rigid questionnaire but as a guideline from which the nurse may select appropriate topics for gathering information about the client's sexuality. The outline should be individualized according to client needs.

BOX 30–2 Sexual History Outline

The questions in this outline are a guide to identify issues that require further assessment and should not necessarily be followed in a rigid order. Rather, they provide a foundation for exploration of sexual health concerns in the context of a therapeutic nurse–client relationship.

The nurse initiates this assessment by

1. Acknowledging that he or she will be asking very personal questions about sexual health and activities.
2. Stating that the reason for asking these questions is to assist with any sexual health issues or concerns the patient may have.

PRESENT CONCERNS

Are there any specific concerns about sexuality or sexual health that you would like to discuss? If so, tell me more about these concerns.

GENERAL ASSESSMENT

Are you currently sexually active?

If no, have you ever been sexually active?

If yes, when was your last sexual encounter?

For Women

Contraceptive use? Presently? If so, for how long? If in the past, what were the dates?

Is there any possibility that you might now be pregnant?

Previous pregnancies? Any problems associated with pregnancies or childbirth?

When was your last menstrual period? Regular/irregular? Pain or heavy bleeding? Bleeding between periods?

SEXUAL HEALTH AND RISKS FOR SEXUALLY TRANSMITTED INFECTIONS (STIS)
Partners

How many sexual partners have you had within the last 12 months?

What are the gender(s) of your sexual partners within the last 12 months?

If you had only one partner, what was the length of the relationship?

If you had multiple partners, what was the history of encounters with past partners, drug use, condom use, safety considerations?

Practices

What kinds of sexual activities do you participate in? Genital? Anal? Oral?

Do you use any forms of protection against STIs? How often? What kinds?

Past History

Have you ever been diagnosed with an STI?

If so, how was it treated? Have you had any recurrent symptoms?

Have any current or past partners been diagnosed with an STI?

If so, were you tested for the same STIs?

Have you ever been tested for HIV?

Symptoms

Have you been aware of any painful urination, discharge, itching, swelling, pain, or skin changes on or around genitalia?

Do you have any other symptoms of concern, such as pain, rashes, or any other symptoms we haven't yet discussed?

HISTORY OF SEXUAL TRAUMA

Have any of your sexual encounters, past or present, been nonconsensual?

If so, please share whatever you feel comfortable telling me about this history.

Do you have any current concerns for your safety or well-being?

SEXUAL DYSFUNCTIONS

What medications are you currently taking, including over-the-counter and herbal remedies?

Are you aware of any changes in sexual function or desire since you began taking any of these medications?

What surgeries, medical treatments, or illnesses have you had?

Are you aware of any changes in sexual function or desire as a result of these?

How would you describe your level of satisfaction with your sexual responsiveness and sexual relationships?

Is sexual activity ever the source of pain, discomfort, or bleeding?

OTHER CONCERNS

Are there any other practices, urges, or concerns about sexuality or sexual health that you would like to discuss?

Adapted from Centers for Disease Control (CDC). (2011a). A guide to taking a sexual history [CDC Publication: 99-8445]. Retrieved from https://www.cdc.gov/std/treatment/sexualhistory.pdf

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. The following nursing diagnoses may be used for the client with sexual disorders:

■ Sexual dysfunction related to depression and conflict in relationship or certain biological or psychological contributing factors to the disorder, evidenced by loss of sexual desire or ability to perform.

■ Ineffective sexuality pattern related to conflicts with sexual orientation or variant preferences, evidenced by expressed dissatisfaction with sexual behaviors.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with sexual disorders.

The client:

- Correlates stressful situations that decrease sexual desire
- Communicates with partner about sexual situation without discomfort
- Verbalizes ways to enhance sexual desire
- Verbalizes resumption of sexual activity at level satisfactory to self and partner
- Correlates variant behaviors with times of stress
- Verbalizes fears about abnormality and inappropriateness of sexual behaviors
- Expresses desire to change variant sexual behavior
- Participates and cooperates with extended plan of behavior modification
- Expresses satisfaction with own sexuality pattern

Planning and Implementation

Table 30–3 provides a plan of care for the client with sexual disorders. Nursing diagnoses are presented, along with outcome criteria, appropriate nursing interventions, and rationales.

Concept Care Mapping

The concept map care plan is an innovative approach to planning and organizing nursing care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing). It is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with a sexual disorder is presented in Figure 30–1.

Client and Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. A list of topics for client and family education relevant to sexual disorders is presented in Box 30–3.

Evaluation

Reassessment is necessary to determine whether selected interventions have been successful in helping the client overcome problems with sexual functioning.

Table 30–3 | CARE PLAN FOR THE CLIENT WITH A SEXUAL DISORDER

NURSING DIAGNOSIS: SEXUAL DYSFUNCTION

RELATED TO: Depression and conflict in relationship; biological or psychological contributing factors to the disorder

EVIDENCED BY: Loss of sexual desire or ability to perform

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals • Client will identify stressors that may contribute to loss of sexual function within 1 week.	1. Assess client's sexual history and previous level of satisfaction in sexual relationship.	1. Client history establishes a database from which to work and provides a foundation for goal setting.
OR • Client will discuss pathophysiology of disease process that contributes to sexual dysfunction within 1 week.	2. Assess client's perception of the problem.	2. Client's idea of what constitutes a problem may differ from that of the nurse. It is the client's perception on which the goals of care must be established.
• *(For a client with permanent dysfunction due to disease process)* Client will verbalize willingness to seek professional assistance from a sex therapist to learn alternative ways of achieving sexual satisfaction with partner by [time is individually determined].	3. Help client determine time dimension associated with onset of the problem, and discuss what was happening in life situation at that time.	3. Stress in all areas of life will affect sexual functioning. Client may be unaware of correlation between stress and sexual dysfunction.
	4. Assess client's mood and level of energy.	4. Depression and fatigue decrease client's desire and enthusiasm for participation in sexual activity.
Long-Term Goal • Client will resume sexual activity at a level satisfactory to self and partner by [time is individually determined].	5. Review medication regimen; observe for side effects.	5. Many medications can affect sexual functioning. Evaluation of drug and individual response is important to ascertain whether drug is responsible for the problem.

Continued

Table 30–3 | CARE PLAN FOR THE CLIENT WITH A SEXUAL DISORDER–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	6. Encourage client to discuss the disease process that may be contributing to sexual dysfunction. Ensure that client is aware that alternative methods of achieving sexual satisfaction exist and can be learned through sex counseling if he or she and the partner desire to do so.	6. Client may be unaware of alternatives, leading to feelings of hopelessness about current situation. Education regarding various available options may increase feelings of self-worth and offer hope for the future.
	7. Provide information regarding sexuality and sexual functioning.	7. Increasing knowledge and correcting misconceptions can decrease feelings of powerlessness and anxiety and facilitate problem resolution.
	8. Refer for additional counseling or sex therapy if required.	8. Client and partner may need additional or more in-depth assistance if problems in sexual relationship are severe or remain unresolved.

NURSING DIAGNOSIS: INEFFECTIVE SEXUALITY PATTERN

RELATED TO: Conflicts with sexual orientation or variant preferences

EVIDENCED BY: Expressed dissatisfaction with sexual behaviors (e.g., voyeurism; transvestism)

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals • Client will verbalize aspects about sexuality that he or she would like to change. • Client and partner will communicate with each other ways in which each believes their sexual relationship could be improved. Long-Term Goals • Client will express satisfaction with own sexuality pattern. • Client and partner will express satisfaction with the sexual relationship.	1. Take sexual history, noting client's expression of areas of dissatisfaction with sexual pattern.	1. Knowledge of what client perceives as the problem is essential for providing the type of assistance he or she may need.
	2. Assess areas of stress in client's life, and examine relationship with sexual partner.	2. Variant sexual behaviors are often associated with added stress in client's life. The relationship with his or her partner may deteriorate as the individual eventually gains sexual satisfaction only from variant practices.
	3. Note cultural, social, ethnic, racial, and religious factors that may contribute to conflicts regarding variant sexual practices.	3. Client may be unaware of the influence these factors exert in creating feelings of discomfort, shame, and guilt regarding sexual attitudes and behavior.
	4. Be accepting and nonjudgmental.	4. Sexuality is a very personal and sensitive subject. Client is more likely to share this information if he or she does not fear being judged by the nurse.
	5. Assist therapist in a plan of behavior modification to help client who desires to decrease variant sexual behaviors.	5. Individuals with paraphilic disorders are treated by specialists who have experience in modifying variant sexual behaviors. Nurses can

Table 30–3 | CARE PLAN FOR THE CLIENT WITH A SEXUAL DISORDER—cont'd		
OUTCOME CRITERIA	**NURSING INTERVENTIONS**	**RATIONALE**
		intervene by providing assistance with implementation of the plan for behavior modification.
	6. If altered sexuality patterns are related to illness or medical treatment, provide information to client and partner regarding correlation between the illness and the sexual alteration. Explain possible modifications in usual sexual pattern that client and partner may try in an effort to achieve a satisfying sexual experience despite the limitation.	6. Client and his or her partner may be unaware of alternative possibilities for achieving sexual satisfaction, or anxiety associated with the limitation may interfere with rational problem-solving.
	7. Teach client that sexuality is a normal human response and is not synonymous with any one sexual act; that it reflects the totality of the person and does not relate exclusively to sex organs or sexual behavior. Client must understand that *sexual* feelings are *human* feelings.	7. If client feels abnormal or unlike everyone else, self-concept is likely to be very low—even worthless. Helping client to understand that, even though the behavior is variant, the feelings and motivations are common, may help to increase feelings of self-worth and desire to change behavior.

Evaluation may be facilitated by gathering information using the following types of questions.

For the client with sexual dysfunction:

■ Has the client identified life situations that promote feelings of depression and decreased sexual desire?
■ Can he or she verbalize ways to deal with this stress?
■ Can the client satisfactorily communicate with sexual partner about the problem?
■ Have the client and sexual partner identified ways to enhance sexual desire and the achievement of sexual satisfaction for both?
■ Are the client and partner seeking assistance with relationship conflict?
■ Do both partners agree on what the major problem is? Do they have the motivation to attempt change?
■ Do the client and partner verbalize an increase in sexual satisfaction?

For the client with variant sexual behaviors:

■ Can the client correlate an increase in variant sexual behavior to times of severe stress?
■ Has the client been able to identify those stressful situations and verbalize alternative ways to deal with them?

■ Does the client express a desire to change variant sexual behavior and a willingness to cooperate with extended therapy to do so?
■ Does the client express an understanding about the normalcy of sexual feelings, aside from the inappropriateness of his or her behavior?
■ Are expressions of increased self-worth evident?

Treatment Modalities for Sexual Dysfunctions

Sexual Desire Disorders

Hypoactive Sexual Desire Disorder

Hypoactive sexual desire disorder has been treated in both men and women with the administration of testosterone. The masculinizing side effects make this approach unacceptable to women, and the evidence that it increases libido in men is inconclusive. In 2015, the FDA approved the first treatment specifically for sexual desire disorder in premenopausal women. The medication, flibanserin (Addyi), is a serotonin receptor agonist, but how it works to improve sexual desire is unknown (FDA, 2015). This drug has also been associated with severe hypotension and syncope and can be particularly serious in patients who drink alcohol during treatment. For these reasons, it carries a black

Clinical Vignette: Harry (age 60) and Sally (age 58) have been married for 35 years. They have come to the mental health clinic for couples therapy because they are having problems in their sexual relationship. They tell the psychiatric nurse practitioner that they once had an active, satisfying sexual relationship, but Sally admits that although she still loves Harry, she no longer has a desire for sex. She states that she must create sexual fantasies or view sexual videos to become aroused and that this makes her feel uncomfortable and "dirty." Harry desires sex with Sally but has lately developed some difficulties with erectile dysfunction. The nurse develops the following concept map care plan for Harry and Sally.

Signs and Symptoms
- Loss of sexual desire or function

Signs and Symptoms
- Expressed dissatisfaction with sexual behaviors

Nursing Diagnosis

Sexual dysfunction

Nursing Diagnosis

Ineffective sexuality pattern

Nursing Actions
- Assess history and previous satisfaction with sexual relationship
- Assess clients' perceptions of the problem
- Review medication regimen
- Provide information about sexual functioning
- Refer couple to sex therapist

Nursing Actions
- Assess areas of dissatisfaction with sexual pattern
- Assess relationship with sexual partner
- Assess predisposing factors that may create conflicts
- Be accepting and nonjudgmental
- Help clients understand that alternative practices are acceptable

Medical Rx (Harry): Sildenafil 50 mg 1 hr before sexual activity

Outcomes:
- Clients identify factors that interfere with sexual functioning
- Clients communicate with each other about sexual relationship and ways for both to achieve satisfaction

Outcomes:
- Clients verbalize understanding of acceptability of alternative sexual practices
- Clients express desire to resume satisfactory sexual relationship
- Clients participate in plan of therapy proposed by sex therapist

FIGURE 30–1 Concept map care plan for clients with sexual disorders.

box warning and may be prescribed only by practitioners who are certified to prescribe this medication. Basson (2016) identifies mental and relationship health as major factors determining sexual desire. Cognitive behavior therapy to identify and correct maladaptive thoughts and behaviors along with relationship therapy to improve communication and relationship skills have both been identified as effective psychological interventions.

If partner incompatibility is the suspected cause of hypoactive sexual desire disorder, the therapist may choose to shift from dealing with the sexual issue to helping a couple identify and deal with their incompatibility. Examples of incompatibility may include different preferences for type, amount, or frequency of sexual activities as well as conflicts around the emotional and physical expectations associated with sex.

Sexual Arousal Disorders

Female Sexual Interest/Arousal Disorder

The goal of treatment for female sexual interest/arousal disorder is to reduce the anxiety associated with sexual activity. Masters and Johnson (1970) reported successful results using their behaviorally oriented **sensate focus** exercises to treat this disorder. These exercises strive to reduce the goal-oriented demands of intercourse on both men and women, thus reducing performance pressures and anxiety associated with possible failure. The exercises include touching activities that initially exclude genital stimulation in order to increase comfort with physical intimacy and reduce anxiety associated with sexual performance.

The couple is instructed to take turns caressing each other's bodies. Initially, they are to avoid touching breasts and genitals and to focus on the sensations of being touched. The caressing progresses to include touching of the breasts and genitals, to touching each other simultaneously, and eventually to include intercourse. These non-goal-oriented exercises promote the sensual side of sexual interaction in a nonpressured, nonevaluative way (Masters et al., 1995).

Erectile Disorder

Sensate focus has also been used effectively for erectile disorder in men. Clinicians widely agree that even when significant organic factors have been identified, psychological factors may also be present and must be considered in treatment. The general public and the medical community agree that organic causes should be ruled out first, but nonetheless, biological factors influence a man's psychological state and psychosocial factors affect physiology (Levine, 2016). Not surprisingly, several studies support the benefits of combination medical and psychological therapy (Althof & Rosen, 2010). Group therapy, individual therapy, psychoeducation, and self-instruction manuals with telephone assistance from a therapist are some of the psychological interventions that have been used successfully in reducing the anxiety that may contribute to erectile difficulties. These studies demonstrated the added benefit of decreasing discontinuation rates and increasing sexual satisfaction compared to medical interventions alone.

Several medications have been approved by the FDA for the treatment of erectile disorder. They include avanafil (Stendra), sildenafil (Viagra), tadalafil (Cialis), and vardenafil (Levitra, Staxyn). These newer impotence agents block the action of phosphodiesterase-5 (PDE5), an enzyme that breaks down cyclic guanosine monophosphate, a compound required to produce an erection. This action only occurs, however, in the presence of nitric oxide, which is released during sexual arousal. PDE5 inhibitors do not result in sexual arousal. They work to achieve penile erection in the presence of sexual arousal. Adverse effects may include headache, facial flushing, indigestion, nasal congestion, dizziness, and visual changes (mild color tinges and blurred vision) (Vallerand, Sanoski, & Deglin, 2016).

In 2005, the FDA ordered that the manufacturers of these medications add a warning to their labels. This action was taken in response to 43 cases of sudden vision loss by individuals taking the drugs. It is not possible to ascertain whether the medications are responsible for nonarteritic ischemic optic neuropathy, a condition in which blood flow to the optic nerve is blocked. More recently, the FDA has issued an additional warning associated with PDE5, the risk of sudden hearing loss (Kim & Brosman, 2013). PDE5 inhibitors are contraindicated in concurrent use with nitrates. In 2016, the FDA identified an emerging trend in which many over-the-counter products, often marketed as dietary supplements for sexual enhancement or improved energy, were found to have sildenafil or sildenafil-like ingredients as well as controlled substances and other untested active ingredients. In the first 9 months of 2016, the FDA issued public

notifications for more than 30 such products (a fraction of the number of products on the market) with warnings about potential dangers and drug interactions (FDA, 2017).

Yohimbine is a natural remedy used to treat erectile dysfunction and as such is not subject to FDA guidelines for medicines. Effectiveness does not necessarily equate with safety, so caution is advised when using such alternative medicines. Excessive doses can cause significant toxicity, and concomitant use with foods containing tyramine can lead to hypertensive crisis (Vallerand, Sanosky, & Deglin, 2016).

Althof and Rosen (2010) report that 90 percent of men with erectile dysfunction are being treated with PDE5 inhibitors, and the remaining 10 percent are treated with intraurethral suppositories; intra-cavernossal injections (both prostaglandin preparations); combination drugs that include papaverine phentolamine,and alprostadil vacuum tumescence therapy; and/or penile prosthesis surgery. Penile prostheses are usually reserved for erectile disorders that have not responded to other treatments. Two basic types are currently available: a bendable silicone implant and an inflatable device. The bendable variety requires a relatively simple surgical technique for insertion of silicone rods into the erectile areas of the penis. This results in a perpetual state of semierection for the client. The inflatable penile prosthesis produces an erection only when desired, and the appearance of the penis in both the flaccid and erect states is completely normal. Potential candidates for penile implantation should undergo careful psychological and physical screening. Although penile implants do not enable the client to recover the ability to ejaculate or to have an orgasm, men with prosthetic devices have generally reported satisfaction with their subsequent sexual functioning.

Orgasmic Disorders

Female Orgasmic Disorder

Many substances affect sexual function and the achievement of orgasm, so a thorough assessment for smoking, alcohol use, recreational drug use, and prescription medication is critical to effective treatment of female orgasmic disorder. Antidepressants, particularly SSRIs, can adversely affect orgasmic responsiveness, so treatment may include changes to the prescription drug regimen (Donahey, 2016).

Because anxiety may contribute to the lack of orgasmic ability in women, sensate focus is often advised to reduce anxiety, increase awareness of physical sensations, and transfer communication skills from the verbal to the nonverbal domain. Other therapeutic techniques include directed masturbation, vibrator use, bibliotherapy, communication skills training, visualization, and Kegel exercises (Donahey, 2016).

Treatment for secondary anorgasmia (in which the client has had orgasms in the past but is now unable to achieve them) focuses on the couple and their relationship. Therapy with both partners is essential to successful treatment of this disorder.

Delayed Ejaculation

Treatment for delayed ejaculation is very similar to that described for the anorgasmic woman. A combination of sensate focus and masturbatory training has been used with a high degree of success in the Masters and Johnson clinic. Treatment for male orgasmic disorder almost always includes the sexual partner.

Early Ejaculation

Masters and associates (1995) advocate what they suggest is a highly successful technique for the treatment of early ejaculation. Sensate focus is used with progression to genital stimulation. When the man reaches the point of imminent ejaculation, the woman is instructed to apply the "squeeze" technique: applying pressure at the base of the glans penis with her thumb and first two fingers. Pressure is held for about 4 seconds and then released. This technique is continued until the man is no longer on the verge of ejaculating. This technique is practiced during subsequent periods of sexual stimulation. Many other psychological therapies have been advanced as beneficial for treating early ejaculation, but the squeeze method is the only one with demonstrated evidence of effectiveness. However, even this treatment's effectiveness appears to be short term (Waldinger, 2016).

No medication has been approved by the FDA for the treatment of early ejaculation, but a number of studies have shown efficacy for this disorder with SSRIs (Benson et al., 2013). Some individuals may achieve positive results with single dosing prior to sexual relations, whereas others may require regular daily dosing to achieve an adequate blood level.

Genito-Pelvic Pain/Penetration Disorder

Treatment for painful intercourse begins with a thorough physical and gynecological examination. When organic pathology has been eliminated, the client's fears and anxieties underlying sexual functioning are investigated. Systematic desensitization has been used successfully to decrease fears and anxieties associated with painful intercourse.

Treatment of penetration disorder begins with education of the woman and her sexual partner regarding the anatomy and physiology of the disorder (i.e., what exactly is occurring during the vaginal reflex and possible etiologies). The involuntary nature of the disorder is stressed in an effort to alleviate the sexual partner's perception that this occurrence is an act of willful withholding by the woman.

Psychological treatment options with evidence of effectiveness include intensive exposure therapy, cognitive-behavioral therapy (CBT), and biofeedback (Bergeron et al., 2016). Bergeron and associates (2016) also report that in a 2.5-year follow-up study, CBT was equal over time to surgical interventions in alleviating pain during intercourse, according to client self-reports. In general, they recommended a multidisciplinary treatment approach for these disorders but note that, on the basis of the effectiveness of CBT, surgical interventions might be avoidable.

In systematic desensitization, the client is taught a series of tensing and relaxing exercises aimed at relaxation of pelvic musculature. This is followed by a procedure involving the systematic insertion of dilators of graduated sizes until the woman is able to accept the penis into the vagina without discomfort.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Emma's obstetrician/gynecologist (OB/GYN) has referred her to the mental health clinic with a diagnosis of postpartum depression. Emma (age 30) tells Carol, the psychiatric nurse practitioner, that she and her husband Brett (age 32) have been married for 2 years and that she gave birth 4 months ago to their first child, a boy they named Jason. Jason has been a difficult baby, was diagnosed with colic, and is wakeful and cries much of the time. Emma is sleep deprived and continuously fatigued. Emma states, "I'm not depressed. I'm just exhausted! Brett is a computer analyst and is gone from home about 10 hours a day. When he gets home, we do what we can to put some dinner together and take care of Jason at the same time. By 9 o'clock, I'm ready to collapse, and Brett wants to go to bed and make love. I just don't have the energy. It's starting to cause a lot of friction in our marriage. Brett gets so angry when I refuse his advances. He also gets angry when I passively comply with his advances. To be honest, I'm just not interested in sex anymore. I certainly don't want to risk another pregnancy. But I also don't want to risk losing my husband. We used to have such a great sexual relationship, but that seems like a lifetime ago. I don't know what to do!"

NURSING DIAGNOSIS AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnosis for Emma: **Sexual dysfunction** related to extreme fatigue and depressed mood, evidenced by loss of sexual desire.
a. **Short-term goals:**
   ■ Client will identify ways to receive respite from child care.
   ■ Client will identify ways to devote time to regain satisfactory sexual relationship with husband.
b. **Long-term goal:**
   ■ Client will resume sexual activity at a level satisfactory to herself and her husband.

PLANNING AND IMPLEMENTATION

SEXUAL DYSFUNCTION
The following nursing interventions have been identified for Emma:

1. Take Emma's sexual history.
2. Determine the previous level of satisfaction in current sexual relationship.
3. Assess Emma's perception of the problem.
4. Suggest alternative strategies for resolution of the problem. (Because of Emma's fatigue and mild depression, she may not be able to adequately problem-solve the situation without assistance.)
   a. Respite from child care (e.g., babysitting service, Mom's Day Out program, sharing babysitting with other mothers or grandparents).
   b. Schedule regular "date nights" with husband.
   c. Schedule periodic weekends away with husband.
5. Provide information regarding sexuality and sexual functioning.
6. Discuss with Emma her fear of pregnancy. Provide information about various methods of contraception.
7. Make referral to sex therapist if Emma requests this service.

EVALUATION

The outcome criteria for Emma have been met. She was able to identify ways to receive respite from child care. She takes Jason to Mom's Day Out at her church every Friday morning. She now has an agreement with another new mother to trade one afternoon a week of babysitting duties. She inquired at the local community college in the department of early childhood education for names of students who would be interested in babysitting. Gina, a 19-year-old sophomore at the college, now babysits for Emma and Brett every Wednesday evening while they have a "date night." And one weekend a month, Brett's widowed mother stays with Jason while Emma and Brett have time away together. Emma's OB/GYN prescribed oral contraceptives, and Emma's fear of pregnancy has subsided. Her mood has lifted and she looks forward to her free time and time alone with her husband. She reports that her sexual desire has increased and that she and Brett now enjoy a satisfactory sexual relationship. She also states that she feels she is giving more quality care to Jason now that she has the periods of respite to which she looks forward every week.

Summary and Key Points

- Human sexuality influences all aspects of physical and mental health. Clients are becoming more open to discussing matters pertaining to sexuality, and it is therefore important for nurses to integrate information on sexuality into the care they give. This can be done by focusing on preventive, therapeutic, and educational interventions to assist individuals to attain, regain, or maintain sexual wellness.
- Variations in sexual orientation include lesbian, gay, bisexual, transgender, queer, intersexual (ambiguous), and asexual (LGBTQIA).
- Gender dysphoria occurs when one's transgender identity influences clinically significant distress in emotional, social, occupational, and performance functions.
- Individuals with gender dysphoria experience extreme discomfort in the assigned gender and desire to be, or insist that they are, the opposite gender.
- Paraphilic disorders are a group of behaviors involving sexual activity with nonhuman objects or with nonconsenting partners or that involve suffering to others.
- Types of paraphilic disorders include exhibitionistic, fetishistic, frotteuristic, pedophilic, sexual masochism, sexual sadism, transvestic, and voyeuristic disorders.
- Sexual dysfunctions are disturbances that occur in any of the phases of the normal human sexual response cycle.

- Types of sexual dysfunctions include sexual desire, sexual arousal, orgasmic, and sexual pain disorders.
- Biological treatment of paraphilic disorders involves decreasing the level of circulating androgens.
- Psychoanalytic treatment of paraphilic disorders focuses on helping the individual resolve early conflicts, thus relieving the anxiety that prevents him or her from forming appropriate sexual relationships.
- Psychological therapy for paraphilic disorders includes use of aversion therapy, behavior therapy, imaginal desensitization, and satiation.
- Nurses may best become involved in the treatment of paraphilic disorders at the primary level of prevention.
- Treatment of sexual dysfunction disorders involves a variety of techniques, including CBT, systematic desensitization, and sensate focus exercises.
- Several medications are available for the treatment of erectile disorder. These include sildenafil (Viagra), tadalafil (Cialis), avanafil (Stendra), and vardenafil (Levitra, Staxyn). Others include prostaglandin preparations and combination drugs that may include papaverine, phentolamine, and alprostadil.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Anne, age 24, and her husband are seeking treatment at the sex therapy clinic. They have been married for 3 weeks and have never had sexual intercourse together. Pain and vaginal tightness prevent penile entry. Sexual history reveals Anne was raped when she was 15 years old. The physician would most likely assign which of the following diagnoses to Anne?
   a. Female orgasmic disorder
   b. Genito-pelvic pain/penetration disorder
   c. Female sexual interest/arousal disorder
   d. Sexual aversion disorder

Review Questions—cont'd
Self-Examination/Learning Exercise

2. Based on the scenario presented in question 1, which of the following would be the most appropriate *nursing* diagnosis for Anne?
   a. Pain related to vaginal constriction
   b. Ineffective sexuality patterns related to inability to have vaginal intercourse
   c. Sexual dysfunction related to history of sexual trauma
   d. Complicated grieving related to loss of self-esteem because of rape

3. A client comes to the mental health clinic with a complaint of lack of sexual desire. In the initial interview, what assessments would the nurse make? (Select all that apply.)
   a. Mood
   b. Level of energy
   c. Medications being taken
   d. Previous level of sexual activity

4. Which of the following medications may be prescribed for early ejaculation?
   a. Paroxetine
   b. Tadalafil
   c. Diazepam
   d. Imipramine

5. Carla watches her neighbor through his window each night as he undresses for bed. Later, she fantasizes about having sex with him. This is an example of which paraphilic disorder?
   a. Exhibitionistic disorder
   b. Voyeuristic disorder
   c. Frotteuristic disorder
   d. Pedophilic disorder

6. Frank drives his car up to a strange woman, stops, and asks her for directions. As she is explaining, he reveals his erect penis to her. This is an example of which paraphilic disorder?
   a. Sexual sadism disorder
   b. Sexual masochism disorder
   c. Frotteuristic disorder
   d. Exhibitionistic disorder

7. Tim, age 18, babysits for his 11-year-old neighbor, Jeff. Six months ago, Tim began fondling Jeff's genitals. They now engage in mutual masturbation each time they are together. This is an example of which paraphilic disorder?
   a. Fetishistic disorder
   b. Pedophilic disorder
   c. Exhibitionistic disorder
   d. Voyeuristic disorder

8. Fred rides a crowded subway every day. He stands beside a woman he finds very attractive. Just as the subway is about to stop, he places his hand on her breast and rubs his genitals against her buttock. As the door opens, he dashes out and away. Later, he fantasizes she is in love with him. This is an example of which paraphilia?
   a. Voyeuristic disorder
   b. Sexual sadism disorder
   c. Frotteuristic disorder
   d. Exhibitionistic disorder

Review Questions—cont'd
Self-Examination/Learning Exercise

9. A client with erectile disorder has a new prescription for sildenafil. The nurse who is providing education about this medication tells the client that which of the following are common side effects of this medication? (Select all that apply.)
   a. Headache
   b. Facial flushing
   c. Constipation
   d. Nasal congestion
   e. Indigestion

TEST YOUR CRITICAL THINKING SKILLS

Lindsey was hospitalized on the psychiatric unit with a depressive disorder. During her nursing assessment interview, she stated, "According to my husband, I can't do anything right—not even have sex." When asked to explain further, Lindsey said she and her husband had been married for 17 years. She said that in the beginning, they experienced a mutually satisfying sexual relationship and "made love" two or three times a week. Their daughter was born after they had been married 2 years, followed 2 years later by the birth of their son. They now have two teenagers (ages 15 and 13) who, by Lindsey's admission, require a great deal of her time and energy. She says, "I'm too tired for sex. And, besides, the kids might hear. I would be so embarrassed if they did. I walked in on my parents having sex once when I was a teenager, and I thought I would die! And my parents never mentioned it. It was just like it never happened! It was so awful! But sex is just so important to my husband, though, and we haven't had sex in months. We argue all the time about it. I'm afraid it's going to break us up."

Answer the following questions related to Lindsey.

1. Regarding her sexual relationship problem, what would be the nursing diagnosis for Lindsey?

2. What interventions for this problem might the nurse include in the treatment plan for Lindsey?

3. Regarding this problem, what would be a realistic goal for which Lindsey might strive?

Communication Exercises

Jamie is a 19-year-old male who came to the mental health clinic with complaints of worsening depression and feeling like he wants to die. He tells the nurse that he thinks he has gender issues, since he feels like a woman trapped in a man's body. What would be the appropriate response by the nurse at this point?

Jamie tells the nurse "I can't continue to live in this body, and I've been thinking of taking hormones to become more feminine." What would be an appropriate response by the nurse?

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Mitchell, K., Jones, K.G., Wellings, K., Johnson, A.M., Graham, C.A., Datta, J., & Mercer, C. (2015). Estimating the prevalence of sexual function problems: The impact of morbidity criteria. *Journal of Sex Research, 53*(8), 955-967. doi:10.1080/00224499.2015.1089214

DESCRIPTION OF THE STUDY: This was a large, stratified probability survey ($N = 11,509$) designed to identify the prevalence of sexual dysfunctions using the *DSM-5* criteria. These diagnostic criteria were more stringent than those in the *DSM-IV-TR,* and the diagnosis of sexual dysfunctions historically has been criticized for medicalizing mild and transient sexual problems that are

"sufficiently common to be considered normal." The *DSM-5* added more stringent criteria, stating that symptoms must be present for at least 6 months and must occur at least 75 percent of the time.

RESULTS OF THE STUDY: The results of the study supported that the more stringent criteria did indeed identify clinically significant syndromes; 38.2 percent of men and 22 percent of women reported sexual dysfunctions, but only 4.2 and 3.6 percent respectively met DSM-V criteria. The study also found that depression and anxiety were contributing factors in sexual dysfunction, unemployment was a contributor for men, and nonvolitional sex was a

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE–cont'd

contributing factor for women. Religiosity was not found to contribute to these dysfunctions, but the researchers report that this factor was difficult to firmly assess. Only about a third of those who met criteria for a clinically significant sexual dysfunction sought help. The researchers conclude that while historically the prevalence of sexual dysfunctions has been overstated, the numbers are still large (8.9 million in the United States and 1.8 million in the United Kingdom).

IMPLICATIONS FOR NURSING PRACTICE: This study broadens nurses' understanding of the prevalence of and contributing factors in sexual dysfunction. The finding that only a third of men and women reported their concerns to health-care providers supports the need for nurses to conduct a thorough sexual history and assessment. It also supports that asking relevant questions about the duration and frequency of a client's symptoms is helpful in prioritizing the clinical significance of the disorder.

Eating Disorders

31

CORE CONCEPTS

Anorexia

Body Image

Bulimia

KEY TERMS

amenorrhea	binging	lanugo
anorexia nervosa	bulimia nervosa	obesity
binge eating disorder	emaciated	purging

OBJECTIVES
After reading this chapter, the student will be able to:

1. Identify and differentiate among several eating disorders.
2. Discuss epidemiological statistics related to eating disorders.
3. Describe symptomatology associated with anorexia nervosa, bulimia nervosa, and obesity, and use the information in client assessment.
4. Identify predisposing factors in the development of eating disorders.
5. Formulate nursing diagnoses and outcomes of care for clients with eating disorders.
6. Describe appropriate interventions for behaviors associated with eating disorders.
7. Identify topics for client and family teaching relevant to eating disorders.
8. Evaluate the nursing care of clients with eating disorders.
9. Discuss various modalities relevant to treatment of eating disorders.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Anorexia nervosa may be associated with a primary dysfunction of which brain structure?
2. What is the level of body mass index (BMI) that is associated with the definition of obesity?
3. Individuals with anorexia nervosa have a "distorted body image." What does this mean?
4. What physiological signs may be associated with the excessive vomiting of the purging syndrome?

Nutrition is required to sustain life, and most individuals acquire nutrients from eating food; however, nutrition and life sustenance are not the only reasons most people eat food. Indeed, in an affluent culture, life sustenance may not even be a consideration. It is sometimes difficult to remember that many people in the affluent American culture, as well as all over the world, are starving from lack of food.

The hypothalamus contains the appetite regulation center within the brain. This complex neural system regulates the body's ability to recognize when it is hungry and when it has been sated. Some studies

have shown evidence of serotonin and norepinephrine dysfunction in individuals with eating disorders. These neurotransmitters both play a role in regulating eating behavior (Sadock, Sadock, & Ruiz, 2015).

Society and culture also have substantial influence on eating behaviors. Eating is a social activity; seldom does an event of any social significance occur without the presence of food. Yet society and culture also influence how people, especially women, should look. History reveals regular fluctuation in what society has considered desirable in the human female body. Archives and historical paintings from the 16th and 17th centuries reveal that plump, full-figured women were considered fashionable and desirable. In the Victorian era, beauty was characterized by a slender, wan appearance that continued through the flapper era of the 1920s. During the Depression era and World War II, the full-bodied woman was again admired, only to be superseded in the late 1960s by the image of the superthin models propagated by the media, which remains the ideal of today. As it has been said, "A woman can't be too rich or too thin." Eating disorders, as we know them, can refute this concept.

This chapter explores the disorders associated with undereating and overeating. Because psychological or behavioral factors play a potential role in the presentation of these disorders, they fall well within the realm of psychiatry and psychiatric nursing. Epidemiological statistics are presented along with factors that have been implicated in the etiology of anorexia nervosa, bulimia nervosa, and binge eating disorder. An explanation of the symptomatology is presented as background knowledge for assessing the client with an eating disorder. Nursing care is described in the context of the nursing process. Various treatment modalities are explored.

Epidemiological Factors

Reports have indicated that the prevalence of **anorexia nervosa** has increased since the mid-20th century, both in the United States and in Western Europe. Studies indicate a prevalence rate for anorexia nervosa among young women in the United States of approximately 1 percent (Black & Andreasen, 2014). The disorder occurs predominantly in females 12 to 30 years of age. Fewer than 10 percent of cases are male, but this percentage may be underestimated due to a biased view of anorexia nervosa as solely a female disorder. See the Real People, Real Stories feature for Vic's perspective about his experience with having an eating disorder.

Social interests may also play a role in the prevalence of eating disorders. Among females, ballet training carries a seven times greater risk of developing anorexia

nervosa, and among males, the evidence of eating disorders is more prevalent among those participating in wrestling sports; a minority continue to have symptoms beyond their involvement in the sport (Sadock et al., 2015). Anorexia nervosa was once believed to be more prevalent in the higher socioeconomic classes, but evidence is lacking to support this hypothesis.

Bulimia nervosa is more prevalent than anorexia nervosa, with estimates up to 4 percent of young women (Black & Andreasen, 2014). Onset of bulimia nervosa occurs in late adolescence or early adulthood. Among college women, about 20 percent experience transient bulimic symptoms during the college years (Sadock et al., 2015). Cross-cultural research suggests that bulimia nervosa occurs primarily in societies that place emphasis on thinness as the model of attractiveness for women and where an abundance of food is available.

Binge eating disorder is defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* as recurrent episodes of eating significantly more than most people would eat in a similar time period under similar circumstances (APA, 2013). These episodes occur at least once a week for at least 3 months. This is the most common eating disorder and affects women twice as often as men (Sadock et al., 2015), with prevalence estimated at 4 percent of the U.S. population (Balodis, Grilo, & Potenza, 2015). Weight gain leading to obesity is a major health risk associated with this disorder. It is estimated that approximately 50 to 75 percent of people seeking medical attention for severe obesity have a binge eating disorder (Sadock et al., 2015).

Obesity has been defined as a body mass index (BMI) (weight/height^2) of 30 or greater. In the United States, statistics indicate that among adults 20 years of age and older, 69 percent are overweight, 35 percent of whom fall in the obese range (Centers for Disease Control and Prevention [CDC], 2015). The percentage of obese individuals is higher in African Americans and Latino Americans than among the white population (CDC, 2015). There is a correlation between low income and obesity in women, but most obese adults are not in the low-income group. Among women, there is a correlation between lower level of education and obesity, but no such correlation exists among men (CDC, 2015). Interestingly, the *DSM-5* does not include obesity as a mental disorder, stating the rationale that "a range of genetic, physiological, behavioral, and environmental factors that vary across individuals contributes to the development of obesity; thus obesity is not considered a mental disorder" (APA, 2013, p. 329). The *DSM-5* also notes, however, that obesity is a significant problem in several mental disorders (at least in part related to side effects of psychotropic

Real People, Real Stories: Living With an Eating Disorder

(Following is an excerpt of our conversation.)

Karyn: First of all, I appreciate your willingness to share your story.

Vic: I want to talk about this because there is such a stigma associated with being a guy and having an eating disorder. And it's hard for guys to find a support group of people who really "get it."

Karyn: What has your experience been with encountering stigma?

Vic: Well, my weight has sometimes been really high and sometimes very low. I fluctuate between anorexia and bulimia. So when my weight is really low, people have presumed I have AIDS. And in general, because eating disorders are presumed to be a female disorder, people have assumed I was gay. In high school, I was very heavy and the guys on the football team teased me a lot. I talked to my girlfriend at the time, and she suggested I try purging. I was using food and alcohol for comfort, but then I had to purge. I started working out a lot, and when I started getting compliments on my appearance, I began binging and purging every day and drinking alcohol. It was a stress relief for a while, but then it just wasn't working anymore and I still hated my appearance. To this day, there's not one thing I like about my appearance even though my physician is happy with my current weight. I was hiding it from my family for some time: wearing baggy clothes and two sets of clothes so people wouldn't

see my flaws. The behaviors are very isolating. When I tried to talk to my dad. he just told me to be a man . . . but there was a lot of physical and emotional abuse from him, so I didn't get support there.

Karyn: Where have you found support?

Vic: My mom and my fiancée are my biggest supports, but it's a struggle to find support with other guys who have eating disorders, and I feel like they would really understand. I tried to start a support group on Facebook, and no one responded. I have an individual counselor who knows a lot about eating disorders, and I have a family practice physician, and they are both helpful. It's just not the same as having the support of others who are having the same experiences that you are.

Karyn: Have you ever been engaged in group treatment specifically for eating disorders?

Vic: I tried, at one point, but most insurances don't cover eating disorder treatment, or the treatment program doesn't take insurance. I went into treatment in 2009 for alcohol rehabilitation, and they didn't address the eating disorder. In fact, they kind of force you to eat and tell you that you'll probably gain weight as you go through rehab, so the bulimia kicked in again for me because I didn't want to get fat like the other people in recovery. But I've been sober since 2009, and I take Vivitrol injections (to manage alcohol dependence) once a month; it blocks the pleasure centers.

Karyn: And has that been effective?

Vic: Oh yes, definitely. And my AA buddies are very supportive, but they don't see food as a similar issue to alcohol, so they don't really see a need to discuss that. Plus, you can't abstain from food like you can from alcohol. And society itself can be a trigger: television, all the messages that you need to be a certain way, picnics, going out to eat, grocery stores, talking about food, et cetera. And I think I have an element of "people pleasing" in my personality, so I'm always worried about what other people are thinking about me.

Karyn: It's not uncommon for people with eating disorders to also have depression and sometimes have suicide thoughts. Have you ever been in that place?

Vic: Yeah, once last year I took an overdose of pills with some alcohol, but I called some friends and they got me in to get help.

Karyn: Do you still have times when you have those thoughts?

Vic: No. I'm doing really well right now. I still dabble from time to time with "the behavior" [Vic described this as his term for binging/purging or calorie restriction, stating that sometimes using the words can be a trigger for him], but not like before when I was taking up to 20 laxatives a day and my whole day was preoccupied with planning "the behaviors." I'm working in a setting that treats dual diagnosis clients, and I am hopeful that there may be opportunities to establish peer support groups for men with eating disorders, much like what exists in AA for alcohol recovery. As a guy, you just can't go to a group that is all women and talk

medications) and that obesity may be a risk factor for the development of illnesses such as depression. Binge eating disorder, which *is* identified as a mental illness, carries a high risk for weight gain and obesity.

Application of the Nursing Process

Background Assessment Data: Anorexia Nervosa

> **CORE CONCEPT**
> **Anorexia**
> Prolonged loss of appetite.

> **CORE CONCEPT**
> **Body Image**
> A subjective concept of one's physical appearance based on the personal perceptions of self and the reactions of others.

Anorexia nervosa is characterized by a morbid fear of obesity. Symptoms include gross distortion of body image, preoccupation with food, and refusal to eat. The term *anorexia* is actually a misnomer. It was initially believed that individuals with anorexia nervosa did not experience sensations of hunger. However, research indicates that they do indeed suffer from pangs of hunger, and it is only with food intake of less than 200 calories per day that hunger sensations cease.

The distorted body image is manifested by the individual's perception of being "fat" when he or she is obviously underweight or even **emaciated** (excessively thin). Weight loss is usually accomplished by reduction in food intake and often extensive exercising. Self-induced vomiting and the abuse of laxatives or diuretics may occur.

Weight loss is excessive, with some individuals who present for health-care services weighing less than 85 percent of expected weight. Other symptoms include hypothermia, bradycardia, hypotension with orthostatic changes, peripheral edema, **lanugo** (fine, neonatal-like hair growth), and a variety of metabolic changes. **Amenorrhea** (absence of menstruation) usually follows weight loss, but sometimes it happens early in the disorder before severe weight loss has occurred.

Individuals with anorexia nervosa may be obsessed with food. For example, they may hoard or conceal food, talk about food and recipes at great length, or prepare elaborate meals for others, only to restrict themselves to limited low-calorie food intake. Compulsive behaviors such as hand washing may also be present.

Age at onset is usually early to late adolescence, and psychosexual development is often delayed. Feelings of depression and anxiety often accompany the disorder. In fact, some studies have suggested a possible interrelationship between eating disorders and affective disorders. Box 31–1 outlines the *DSM-5* diagnostic criteria for anorexia nervosa.

Background Assessment Data: Bulimia Nervosa

> **CORE CONCEPT**
> **Bulimia**
> Excessive, insatiable appetite.

Bulimia nervosa is an episodic, uncontrolled, compulsive, rapid ingestion of large quantities of food over a short period of time **(binging),** followed by inappropriate compensatory behaviors to rid the body of the excess calories. The food consumed during a binge often has high caloric content, a sweet taste, and a soft or smooth texture that can be eaten rapidly, sometimes even without being chewed (Sadock et al., 2015). The binging episodes often occur in secret and are usually terminated only by abdominal discomfort,

sleep, social interruption, or self-induced vomiting. Although the eating binges may bring pleasure while they are occurring, self-degradation and depressed mood commonly follow.

To rid the body of the excessive calories, the individual engages in **purging** behaviors (self-induced vomiting or the misuse of laxatives, diuretics, or enemas) or other inappropriate compensatory behaviors, such as fasting or excessive exercise. Among these individuals, there is a persistent overconcern with personal appearance, particularly regarding how they believe others perceive them. Weight fluctuations are common because of the alternating binges and fasts. However, most individuals with bulimia are within a normal weight range—some slightly underweight, some slightly overweight.

Excessive vomiting and laxative or diuretic abuse may lead to problems with dehydration and electrolyte imbalance. Gastric acid in the vomitus also contributes to the erosion of tooth enamel. In rare instances, the individual may experience tears in the gastric or esophageal mucosa. Some individuals develop calluses on the dorsal surface of their hands, typically on knuckles, secondary to long-term self-induced vomiting. This feature is called *Russell's sign* after the British psychiatrist who first described it. It cannot be a reliable diagnostic symptom, however, since many individuals with purging behavior are able to induce vomiting without using their hands.

Common comorbidities include mood disorders, anxiety disorders, or substance abuse, most frequently involving central nervous central (CNS) stimulants or alcohol. About 50 percent of those with bulimia nervosa have had a history of anorexia nervosa (Sadock et al., 2015). The *DSM*-5 diagnostic criteria for bulimia nervosa are presented in Box 31–2.

Background Assessment Data: Binge Eating Disorder

Individuals with binge eating disorder have episodes of binge eating that may be similar to those with bulimia nervosa; however, binge eating disorder is absent of compensatory purging. As a result, this client is at risk for substantial weight gain. The episodes of eating are considered binges when they occur over a defined period of time, usually less than 2 hours (APA, 2013). Food consumption not only is rapid but often continues to the point that the individual feels uncomfortably full. Interpersonal stressors, low self-esteem, and boredom are identified as possible triggers. Typically, clients describe their eating as out of control. There is often accompanying guilt and depression. As many as 50 percent of individuals with binge eating disorder have a history of depression (Jaret, 2010). Another difference between bulimia nervosa and binge eating disorder is that rates of improvement are consistently higher among individuals with binge eating disorder than among those with bulimia nervosa

BOX 31–2 Diagnostic Criteria for Bulimia Nervosa

A. Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:
1. Eating, in a discrete period of time (e.g., within any 2-hour period) an amount of food that is definitely larger than most individuals would eat during a similar period of time and under similar circumstances.
2. A sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating).

B. Recurrent inappropriate compensatory behaviors in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, or other medications; fasting; or excessive exercise.

C. The binge eating and inappropriate compensatory behaviors both occur, on average, at least once a week for 3 months.

D. Self-evaluation is unduly influenced by body shape and weight.

E. The disturbance does not occur exclusively during episodes of anorexia nervosa.

Specify if:

In partial remission
In full remission

Specify current severity:

Mild: An average of 1–3 episodes of inappropriate compensatory behaviors per week.
Moderate: An average of 4–7 episodes of inappropriate compensatory behaviors per week.
Severe: An average of 8–13 episodes of inappropriate compensatory behaviors per week.
Extreme: An average of 14 or more episodes of inappropriate compensatory behaviors per week.

(APA, 2013). The *DSM-5* diagnostic criteria for binge eating disorder are presented in Box 31–3.

Predisposing Factors and Theories of Etiology Associated With Anorexia Nervosa, Bulimia Nervosa, and Binge Eating Disorder

Biological Influences

Genetics A hereditary predisposition to eating disorders has been hypothesized on the basis of family histories and an apparent association with other disorders for which the likelihood of genetic influences exists. Some studies identify higher concordance rates in monozygotic than in dizygotic twins (Sadock et al, 2015). Anorexia nervosa is more common among sisters of those with the disorder than among the general population, but social factors such as modeling and mimicking may influence these relationships. Several studies have reported a higher than expected frequency of mood and substance use disorders among first-degree biological relatives of individuals with eating disorders (Puri & Treasaden, 2011).

Neuroendocrine Abnormalities Some speculation has occurred regarding a primary hypothalamic dysfunction in anorexia nervosa. Support for this hypothesis is gathered from the fact that many people with anorexia experience amenorrhea before the onset of starvation and significant weight loss.

Neurochemical Influences Neurochemical influences in bulimia may be associated with the neurotransmitters serotonin and norepinephrine. This hypothesis has been supported by the positive response these individuals have shown to therapy with the selective serotonin reuptake inhibitors (SSRIs). Some evidence also exists to indicate that low levels of the neurotransmitter serotonin (5-hydroxytryptamine [5-HT]) may play a role in compulsive eating (Uçeyler et al., 2010). Studies have found high levels of endogenous opioids in the spinal fluid of clients with anorexia, promoting the speculation that these chemicals may contribute to denial of hunger (Sadock et al., 2015). Some of these individuals have been shown to gain weight when given naloxone, an opioid antagonist. Questions still remain as to whether neurochemical changes are causal or are an outcome of the body's reaction to changes in nutrition and mood.

The etiology of binge eating disorder is unknown. Brain imaging studies of people with binge eating disorders reveal increased activity in the orbitofrontal cortex, the centers associated with reward and pleasure responses such as those seen in response to substances of abuse (Balodis et al., 2015). This has supported the hypothesis that binge eating disorder may be an illness of addiction.

Psychodynamic Influences

Psychodynamic theories suggest that the development of an eating disorder is rooted in an unfulfilled sense of separation-individuation. When events occur that threaten the vulnerable ego, feelings of lack of control over one's body (self) emerge. Behaviors associated with food and eating provide feelings of control over one's life.

BOX 31–3 Diagnostic Criteria for Binge Eating Disorder

A. Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:
  1. Eating, in a discrete period of time (e.g., within any 2-hour period), an amount of food that is definitely larger than what most people would eat in a similar period of time under similar circumstances
  2. A sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating)
B. The binge eating episodes are associated with 3 (or more) of the following:
  1. Eating much more rapidly than normal
  2. Eating until feeling uncomfortably full
  3. Eating large amounts of food when not feeling physically hungry
  4. Eating alone because of feeling embarrassed by how much one is eating
  5. Feeling disgusted with oneself, depressed, or very guilty after overeating
C. Marked distress regarding binge eating is present.
D. The binge eating occurs, on average, at least once a week for 3 months.
E. The binge eating is not associated with the recurrent use of inappropriate compensatory behavior as in bulimia nervosa and does not occur exclusively during the course of bulimia nervosa or anorexia nervosa.

Specify if:

In partial remission
In full remission

Specify current severity:

Mild: 1–3 binge eating episodes per week
Moderate: 4–7 binge eating episodes per week
Severe: 8–13 binge eating episodes per week
Extreme: 14 or more binge eating episodes per week

Family Influences

Historically, parents of children with eating disorders have been presumed to be overcontrolling and perfectionistic, causing pathology in their children. This theory has been problematic, at least in part because not all siblings in the same family develop eating disorders. There is not sufficient evidence to support these claims, and they may have contributed to a resistance toward seeking health care based on parents' fear that they will be judged as the cause of the problem. The American Academy for Eating Disorders has published a position statement (2009) that includes the following:

> The AED stands firmly against any model of eating disorders in which family influences are seen as the primary cause of eating disorders, condemns statements that blame families for their child's illness, and recommends that families be included in the treatment of younger patients, unless this is clearly ill-advised on clinical grounds.

Both perfectionistic and depressive tendencies do appear to be common in clients with anorexia nervosa, but Sadock and associates (2015) offer this explanation:

> Many anorectic patients feel that oral desires are greedy and unacceptable; therefore these desires are projectively disavowed . . . parents respond to the refusal to eat by becoming frantic about whether

the patient is actually eating. The patient can then view the parents as the ones who have unacceptable desires and can projectively disavow them.

Certainly conflicts arise in a family when a child is starving himself or herself, but it has become clear that family members need to be involved in treatment rather than shunned or blamed. Family-based approaches such as the Maudsley approach are supported by clinical evidence.

Background Assessment Data: Body Mass Index

Assessment for the presence of an eating disorder requires an understanding of the measurements for BMI. The following formula is used to determine an individual's BMI:

$$\text{Body mass index} = \frac{\text{Weight (kg)}}{\text{Height (m)}^2}$$

The BMI range for normal weight is 20 to 24.9. Studies by the National Center for Health Statistics indicate that *overweight* is defined as a BMI of 25.0 to 29.9 (based on U.S. Dietary Guidelines for Americans). Based on criteria of the World Health Organization, *obesity* is defined as a BMI of 30.0 or greater. These guidelines, which were released by the National Heart,

Lung, and Blood Institute in July 1998, markedly increased the number of Americans considered overweight. The average American woman has a BMI of 26, and fashion models typically have BMIs of 18. Anorexia nervosa is characterized by a BMI of 17 or lower. In extreme anorexia nervosa the BMI may be less than 15. Table 31–1 presents an example of some BMIs based on weight (in pounds) and height (in inches).

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Table 31–2 presents a list of client behaviors and the NANDA-I nursing diagnoses that correspond to those behaviors, which may be used in planning care for clients with eating disorders.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with eating disorders:

The client:

- Has achieved and maintained an expected BMI for age with consideration for body build, weight history, and any physiological disturbances (APA, 2013, p. 340)
- Has vital signs, blood pressure, and laboratory serum studies within normal limits
- Verbalizes importance of adequate nutrition
- Verbalizes knowledge regarding consequences of fluid loss caused by self-induced vomiting (or laxative/diuretic abuse) and importance of adequate fluid intake (anorexia nervosa, bulimia nervosa)
- Verbalizes events that precipitate anxiety and demonstrates techniques for its reduction
- Verbalizes ways in which he or she may gain more control of the environment and thereby reduce feelings of powerlessness
- Expresses less preoccupation with own appearance (anorexia nervosa, bulimia nervosa)
- Demonstrates ability to take control of own life without resorting to maladaptive eating behaviors (anorexia nervosa, bulimia nervosa, binge eating disorder)
- Has established a healthy pattern of eating for weight control, and weight loss toward a desired goal is progressing (binge eating disorder)
- Verbalizes plans for maintenance of weight control and relapse prevention (binge eating disorder)

Planning and Implementation

In most instances, individuals with eating disorders are treated on an outpatient basis, but in some cases hospitalization becomes necessary. Assessment findings that may necessitate hospitalization include the following:

- **Malnutrition:** Twenty percent below expected weight for height recommended for inpatient treatment; 30 percent below expected weight for height recommended for long-term intensive treatment (Sadock et al., 2015)
- **Dehydration:** Assessment includes thirst, orthostatic hypotension, tachycardia, elevated sodium levels, and other symptoms
- **Severe electrolyte imbalance:** Potassium levels below 3 mmol/L, phosphate levels below 3 mg/dL, magnesium levels below 1.4 mEq/L
- **Cardiac arrhythmia:** ST segment and T wave changes usually related to electrolyte imbalances
- **Severe bradycardia:** Below 50 beats per minute
- **Hypothermia:** Body temperature below 96.8
- **Hypotension:** A pattern of low blood pressure or orthostatic hypotension (20 mm Hg or greater drop in systolic blood pressure with positional changes and pulse rate increase by 20 or more beats)
- **Suicidal ideation** (see Chapter 17, Suicide Prevention, for an in-depth discussion of suicide risk assessment)

In addition to the physical assessment parameters listed previously, when an eating disorder is suspected, a general assessment includes asking patients about their eating patterns and body image, their dieting patterns, whether or not they feel driven to be thin, exercise patterns, and any use of substances including diet pills, laxatives, or diuretics (Micula-Gondek & Lackamp, 2011). Evidence of calluses on the dorsum of the hands, parotid enlargement, mouth ulcers, dental caries, and edema may also be assessment findings in the patient with purging behaviors.

The following section presents a group of selected nursing diagnoses, with short- and long-term goals and nursing interventions for each.

Imbalanced Nutrition: Less Than Body Requirements/Deficient Fluid Volume (Risk for or Actual)

Imbalanced nutrition: less than body requirements is defined as "intake of nutrients insufficient to meet metabolic needs" (Herdman & Kamitsuru, 2014, p. 161). *Deficient fluid volume* is defined as "decreased intravascular, interstitial, and/or intracellular fluid" (p. 177). Table 31–3 presents these nursing diagnoses in care plan format.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

TABLE 31–1 Body Mass Index (BMI) Chart

HEIGHT (INCHES)	BMI 19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40

TABLE 31–2	**Assigning Nursing Diagnoses to Behaviors Commonly Associated With Eating Disorders**	
BEHAVIORS	**NURSING DIAGNOSES**
Refusal to eat; abuse of laxatives, diuretics, and/or diet pills; loss of 15 percent of expected body weight; pale conjunctiva and mucous membranes; poor muscle tone; amenorrhea; poor skin turgor; electrolyte imbalances; hypothermia; bradycardia; hypotension; cardiac irregularities; edema	Imbalanced nutrition: Less than body requirements
Decreased fluid intake; abnormal fluid loss caused by self-induced vomiting; excessive use of laxatives, enemas, or diuretics; electrolyte imbalance; decreased urine output; increased urine concentration; elevated hematocrit; decreased blood pressure; increased pulse rate; dry skin; decreased skin turgor; weakness	Deficient fluid volume
Minimizes symptoms; unable to admit impact of disease on life pattern; does not perceive personal relevance of symptoms; does not perceive personal relevance of danger	Denial
Compulsive eating; excessive intake in relation to metabolic needs; sedentary lifestyle; weight 20 percent over ideal for height and frame; BMI of 30 or more	Obesity
Distorted body image; views self as fat, even in the presence of normal body weight or severe emaciation; denies that problem with low body weight exists; difficulty accepting positive reinforcement; self-destructive behavior (self-induced vomiting, abuse of laxatives or diuretics, refusal to eat); preoccupation with appearance and how others perceive it *(anorexia nervosa, bulimia nervosa)* Verbalization of negative feelings about the way he or she looks and the desire to lose weight *(obesity)* Lack of eye contact; depressed mood *(all)*	Disturbed body image/Low self-esteem
Increased tension; increased helplessness; overexcited; apprehensive; fearful; restlessness; poor eye contact; increased difficulty taking oral nourishment; inability to learn	Anxiety (moderate to severe)

Table 31–3 | CARE PLAN FOR CLIENT WITH EATING DISORDERS: ANOREXIA NERVOSA AND BULIMIA NERVOSA

NURSING DIAGNOSES: IMBALANCED NUTRITION: LESS THAN BODY REQUIREMENTS/DEFICIENT FLUID VOLUME (RISK FOR OR ACTUAL)

RELATED TO: Refusal to eat/drink; self-induced vomiting; abuse of laxatives/diuretics

EVIDENCED BY: Loss of weight; poor muscle tone and skin turgor; lanugo; bradycardia; hypotension; cardiac arrhythmias; pale, dry mucous membranes

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals: • Client will gain *x* pounds per week (amount to be established by client, nurse, and dietitian) • Client will drink 125 mL of fluid each hour during waking hours. Long-Term Goal: • By time of discharge from treatment, client will exhibit no signs or symptoms of malnutrition or dehydration.	1. For the client who is emaciated and is unable or unwilling to maintain an adequate oral intake, the physician may order a liquid diet to be administered via nasogastric tube. Nursing care of the individual receiving tube feedings should be administered according to established hospital protocol. 2. For the client who is able and willing to consume an oral diet, the dietitian will determine	1. Without adequate nutrition, a life-threatening situation exists. 2. Adequate calories are required to allow a weight gain of 2–3 pounds per week.

Table 31–3 | CARE PLAN FOR CLIENT WITH EATING DISORDERS: ANOREXIA NERVOSA AND BULIMIA NERVOSA–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	the appropriate number of calories required to provide adequate nutrition and realistic weight gain.	
	3. Explain to the client that privileges and restrictions will be based on compliance with treatment and direct weight gain. Do not focus on food and eating.	3. The real issues have little to do with food or eating patterns. Focus on the control issues that have precipitated these behaviors.
	4. Weigh client daily (without the client observing the numbers on the scale) immediately upon arising and following first voiding. Always use same scale, if possible. Keep strict record of intake and output. Assess skin turgor and integrity regularly. Assess moistness and color of oral mucous membranes.	4. These assessments are important measurements of nutritional status and provide guidelines for treatment.
	5. Stay with client during established time for meals (usually 30 min) and for at least 1 hour following meals.	5. Lengthy mealtimes put excessive focus on food and eating and provide client with attention and reinforcement. The hour following meals may be used to discard food stashed from tray or to engage in self-induced vomiting.
	6. If weight loss occurs, enforce restrictions.	6. Restrictions and limits must be established and carried out consistently to avoid power struggles, to encourage client compliance with therapy, and to ensure client safety.
	7. Ensure that the client and family understand that if nutritional status deteriorates, tube feedings will be initiated. This is implemented in a matter-of-fact, nonpunitive way.	7. This intervention is carried out for the client's safety and protection from a life-threatening condition.
	8. Encourage the client to explore and identify the true feelings and fears that contribute to maladaptive eating behaviors.	8. Emotional issues must be resolved if these maladaptive responses are to be eliminated.

Short-term goals

- The client will gain ___ pounds per week (amount to be established by client, nurse, and dietitian).
- The client will drink 125 mL of fluid each hour during waking hours.

Long-term goal

- By time of discharge from treatment, the client will exhibit no signs or symptoms of malnutrition or dehydration.

Interventions

- For the client who is emaciated and is unable or unwilling to maintain an adequate oral intake, the physician may order a liquid diet to be administered via nasogastric tube. Without adequate nutrition, a life-threatening situation exists. Nursing care of the individual receiving tube feedings should be administered according to established hospital procedures.
- For the client who is able and willing to consume an oral diet, the dietitian should determine the appropriate number of calories required to provide adequate nutrition and realistic (according to body structure and height) weight gain.
- Explain the program of behavior modification to client and family. Explain that privileges and restrictions will be based on compliance with treatment and direct weight gain.
- Do not focus on food and eating specifically. Instead, focus on the emotional issues that have precipitated these behaviors.
- Do not discuss food or eating with the client once protocol has been established. Do, however, offer support and positive reinforcement for obvious improvements in eating behaviors.
- Keep a strict record of intake and output. Weigh the client daily immediately on arising and following first voiding. Always use the same scale, if possible. Weighing a client in such a way that the client cannot see the numbers on a scale may be beneficial in reducing his or her focus on daily weight fluctuations or evidence of weight gain.
- Assess vital signs, including blood pressure with positional changes to evaluate for orthostatic hypotension and pulse to evaluate for bradycardia. Bradycardia may be more pronounced at rest, so regular assessment during these times is especially important.
- Assess skin turgor and integrity regularly. Assess moistness and color of oral mucous membranes. The condition of the skin and mucous membranes provides valuable data regarding client hydration. Discourage the client from bathing every day if the skin is very dry.

- Sit with the client during mealtimes for support and to observe the amount ingested. A limit (usually 30 minutes) should be imposed on time allotted for meals. Without a time limit, meals can become lengthy, drawn-out sessions, providing the client with attention based on food and eating.
- The client should be observed for at least 1 hour following meals. The client may use this time to discard food that has been stashed from the food tray or to engage in self-induced vomiting. He or she may need to be accompanied to the bathroom if self-induced vomiting is suspected.
- If weight loss occurs, enforce restrictions. Restrictions and limits must be established and carried out consistently to avoid power struggles and encourage client compliance with therapy.
- Ensure that the client and family understand that if nutritional status deteriorates, tube feedings will be initiated. This is implemented in a matter-of-fact, nonpunitive way, for the client's safety and protection from a life-threatening condition.
- Encourage the client to explore and identify the true feelings and fears that contribute to maladaptive eating behaviors. Emotional issues must be resolved if these maladaptive responses are to be eliminated.

Denial

Denial is defined as a "conscious or unconscious attempt to disavow the knowledge or meaning of an event to reduce anxiety and/or fear, leading to the detriment of health" (Herdman & Kamitsuru, p. 335).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

- The client will verbalize understanding of the correlation between emotional issues and maladaptive eating behaviors (within time deemed appropriate for individual client).

Long-term goal

- By time of discharge from treatment, the client will demonstrate the ability to discontinue use of maladaptive eating behaviors and to cope with emotional issues in a more adaptive manner.

Interventions

- Establish a trusting relationship with the client by being honest, accepting, and available and by keeping all promises. Convey unconditional positive regard.
- Acknowledge the client's anger at feelings of loss of control brought about by the established eating

regimen associated with the program of behavior modification. Anger is a normal human response and should be expressed in an appropriate manner. Feelings that are not expressed remain unresolved and add an additional component to an already serious situation.

- Avoid arguing or bargaining with the client who is resistant to treatment. State matter-of-factly which behaviors are unacceptable and how privileges will be restricted for noncompliance. It is essential that all staff members are consistent with this intervention.
- Encourage the client to verbalize feelings regarding his or her role within the family and issues related to dependence/independence, the intense need for achievement, and sexuality. Help the client recognize how maladaptive eating behaviors may be related to these emotional issues. Discuss ways in which he or she can gain control over these problematic areas of life without resorting to maladaptive eating behaviors.

Obesity

Obesity is defined as a condition in which an individual accumulates abnormal or excessive fat for age and gender that exceeds overweight (Herdman & Kamitsuru, p. 163).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

- Client will verbalize understanding of what must be done to lose weight.

Long-term goal

- Client will demonstrate a change in eating patterns that results in a steady weight loss.

Interventions

- Encourage the client to keep a diary of food intake. A food diary provides the opportunity for the client to gain a realistic picture of the amount of food ingested and provides a database on which to tailor the dietary program.
- Discuss feelings and emotions associated with eating. This helps to identify when the client is eating to satisfy an emotional need rather than a physiological one.
- With input from the client, formulate an eating plan that includes food from the required food groups with emphasis on low-fat intake. It is helpful to keep the plan as similar as possible to the client's usual eating pattern. The diet must eliminate calories while maintaining adequate nutrition. The client is more likely to stay on the eating plan if he or she is able to participate in its creation and it deviates as little as possible from usual types of foods.

- Identify realistic incremental goals for weekly weight loss. Reasonable weight loss (1 to 2 pounds per week) results in more lasting effects. Excessive, rapid weight loss may result in fatigue and irritability and ultimately lead to failure in meeting goals for weight loss. Motivation is more easily sustained by meeting "stair-step" goals.
- Plan a progressive exercise program tailored to individual goals and choice. Exercise may enhance weight loss by burning calories and reducing appetite, increasing energy, toning muscles, and enhancing sense of well-being and accomplishment. Walking is an excellent choice for overweight individuals.
- Discuss the probability of reaching plateaus when weight remains stable for extended periods. The client should know this is likely to happen as changes in metabolism occur. Plateaus cause frustration, and the client may need additional support during these times to remain on the weight-loss program.
- Provide instruction about medications to assist with weight loss if ordered by the physician. Appetite-suppressant drugs and others that have weight loss as a side effect may be helpful to someone who is severely overweight. They should be used for this purpose for only a short period while the individual attempts to adjust to the new pattern of eating.

Disturbed Body Image/Low Self-Esteem

Disturbed body image is defined as "confusion in mental picture of one's physical self" (Herdman & Kamitsuru 2014, p. 275). *Low self-esteem* is defined as "negative self-evaluating/feelings about self or self-capabilities" (p. 271).

Client Goals (for the Client With Anorexia Nervosa or Bulimia Nervosa)

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

- The client will verbally acknowledge misperception of body image as "fat" within specified time (depending on severity and chronicity of condition).

Long-term goal

- By the time of discharge from treatment, the client will demonstrate an increase in self-esteem as manifested by verbalizing positive aspects of self and exhibiting less preoccupation with own appearance as a more realistic body image is developed.

Client Goals (for the Client With Binge Eating Disorder and Associated Obesity)

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ The client will begin to accept self based on self-attributes rather than on appearance.

Long-term goal

■ The client will pursue loss of weight as desired.

Interventions

For the client with anorexia nervosa or bulimia nervosa:

■ Help the client develop a realistic perception of body image and relationship with food. Compare specific measurement of the client's body with the client's perceived calculations. There may be a large discrepancy between the actual body size and the client's perception of his or her body size. The client needs to recognize that the misperception of body image is unhealthy and that maintaining control through maladaptive eating behaviors is dangerous—even life threatening.

■ Promote feelings of control within the environment through participation and independent decision-making. Through positive feedback, help the client learn to accept self as is, including weaknesses as well as strengths. The client must come to understand that he or she is a capable, autonomous individual who can perform outside the family unit and is not expected to be perfect. Control of his or her life must be achieved in other ways besides dieting and weight loss.

■ Help the client realize that perfection is unrealistic, and explore this need with him or her. As the client begins to feel better about self, identifies positive self-attributes, and develops the ability to accept certain personal inadequacies, the need for unrealistic achievement should diminish.

For the client with binge eating disorder and associated obesity:

■ Assess the client's feelings and attitudes about overeating and obesity. Obesity and compulsive eating behaviors may have deep-rooted psychological implications, such as compensation for lack of love and nurturing or a defense against intimacy.

■ Ensure that the client has privacy during self-care activities. The obese individual may be sensitive or self-conscious about his or her body.

■ Have the client recall coping patterns related to food in family of origin, and explore how these may affect current situation. Parents are role models for their children. Maladaptive eating behaviors may have been learned within the family system and are supported through positive reinforcement. Food may be substituted by the parent for affection and love, and eating is associated with a feeling of satisfaction, becoming the primary defense.

■ Determine the client's motivation for developing healthier patterns of eating. O'Melia (2014) stresses that traditional obesity management strategies, which typically include diets and food restriction, are less effective with binge eating disorder because the primary concern is developing healthier approaches to eating and reducing or eliminating binging behavior. Weight loss would be a secondary outcome. The individual may harbor repressed feelings of hostility that may be expressed inwardly on the self. Because of a poor self-concept, the person often has difficulty with relationships. When the motivation is to lose weight for someone else, healthier eating is less likely to be sustainable.

■ Help the client identify positive self-attributes. Focus on strengths and past accomplishments unrelated to physical appearance. It is important that self-esteem not be tied solely to size of the body. The client needs to recognize that obesity need not interfere with positive feelings regarding self-concept and self-worth.

■ Refer the client to a support or therapy group. Support groups can provide companionship, increase motivation, decrease loneliness and social ostracism, and give practical solutions to common problems. Group therapy can be helpful in dealing with underlying psychological concerns.

Concept Care Mapping

The concept map care plan (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. Examples of concept map care plans for clients with eating disorders are presented in Figures 31–1 and 31–2.

Client and Family Education

The role of client teacher is important in the psychiatric area, as it is in all areas of nursing. It is essential to include the family in education and treatment unless there are overriding reasons not to do so. A list of topics for client and family education relevant to eating disorders is presented in Box 31–4.

Evaluation

Evaluation of the client with an eating disorder requires a reassessment of the behaviors for which the client

Clinical Vignette: Alice, age 18, graduated from high school 6 months ago. She is 5´10˝ tall and had frequently been teased by her peers because of her height. She lived in a rural community and was often ridiculed for her plan to become a model after graduation. But Alice was determined, and instead of going to college, she moved to New York City to pursue her dream. However, at the first modeling agency, she was told that she would never be accepted for modeling at her weight (140 pounds) and to come back when she had lost at least 15 pounds. She was devastated but steadfast in her determination to succeed. She cut her calories to 500 a day, exercised relentlessly, took over-the-counter laxatives and diuretics, and engaged in self-induced vomiting when she ate more than she felt she should. She became weak and chronically fatigued but persisted until yesterday when she collapsed at the gym and the owner called 911. She was admitted to the psychiatric unit weighing 118 pounds, with poor skin turgor, blood pressure 75/45, and pulse 60 and irregular. She tells the nurse, "I can't be a model unless I get thin! Everyone at home will think I'm a failure!" The nurse develops the following concept map care plan for Alice.

Signs and Symptoms
- Weight loss
- Poor skin turgor
- Bradycardia
- Hypotension
- Cardiac arrhythmias

Signs and Symptoms
- Inability to admit the impact of maladaptive eating behaviors on her health

Signs and Symptoms
- Distorted body image
- Self-deprecating thoughts
- Unrealistic need to excel and "prove" herself to former peers
- Depressed mood/ anxiety at thoughts of possible failure

Nursing Diagnosis
Imbalanced nutrition: less than body requirements

Nursing Diagnosis
Ineffective denial

Nursing Diagnosis
Disturbed body image/ Low self-esteem

Nursing Actions
- Determine needed nutritional requirements.
- Explain behavior modification plan.
- Measure weights and I&O daily.
- Assess skin turgor and mucous membranes.
- Stay with client during meals and for 1 hr following meals.

Nursing Actions
- Develop trusting relationship; give positive regard.
- Do not bargain; explain that privileges and consequences are based on compliance with therapy and weight gain.
- Encourage client to verbalize feelings and unresolved issues.
- Help her understand the negative consequence to current eating behaviors.

Nursing Actions
- Help client develop realistic perception of body image.
- Allow client independent decision-making.
- Give positive feedback.
- Help client accept self.
- Convey knowledge that perfection is unrealistic.

Medical Rx: Fluoxetine 20 mg q day

Outcomes
- Client gains 2–3 lb/wk
- No signs of malnutrition or dehydration
- Consumes adequate calories
- Does not stash food or self-induce vomiting

Outcomes
- Client verbalizes that eating behaviors are maladaptive
- Client verbalizes understanding that current eating behaviors are life threatening

Outcomes
- Client acknowledges that image of body as "fat" is a misperception
- Client verbalizes positive self-attributes

FIGURE 31–1 Concept map care plan for a client with anorexia nervosa.

sought treatment. Behavioral change will be required on the part of both the client and family members. The following types of questions may provide assistance in gathering data required for evaluating whether the nursing interventions have been effective in achieving the goals of therapy.

For the client with anorexia nervosa or bulimia nervosa:

■ Has the client steadily gained 2 to 3 pounds per week to at least 80 percent of expected body weight for age and size?

■ Is the client free of signs and symptoms of malnutrition and dehydration?

Clinical Vignette: Harriet, age 20, has been overweight since childhood. Her mother and sister were both of normal weight, but her mother always said, "Harriet took after her dad's side of the family." Through her teens, she tried innumerable times to lose weight, only to lose a few pounds and then gain back more. In college, out from under the watchful eye of her mother, she has gained even more weight. She has never had a date. Her sister is engaged to be married in 6 months and has asked Harriet to be her maid of honor. Harriet has come to the university student health center to seek assistance with weight loss. She is 5´4˝ tall and weighs 204 pounds. She tells the nurse, "I hate the way I look. I can't be in my sister's wedding looking like this!" The nurse develops the following concept map care plan for Harriet.

Signs and Symptoms
- Weight of more than 20 percent over expected body weight for age and height
- BMI >30

Signs and Symptoms
- Verbalizes negative feelings about looks
- Verbalizes desire to lose weight

Nursing Diagnosis
Imbalanced nutrition: more than body requirements

Nursing Diagnosis
Disturbed body image/ Low self-esteem

Nursing Actions
- Encourage client to keep food diary.
- Discuss feelings associated with eating.
- Establish healthy, low-calorie food plan.
- Set realistic weight-loss goals.
- Plan exercise program.
- Discuss possibility of plateaus.
- Instruct about medication.

Nursing Actions
- Assess attitude and feelings about weight.
- Explore past eating behaviors.
- Assess source and level of motivation.
- Focus on strengths and past accomplishments unrelated to physical appearance.
- Refer to support/therapy group.

Medical Rx: Belviq 10 mg bid

Outcomes
- Client has established healthy eating pattern
- Client has established daily exercise routine
- Client is losing ~2 lb per week
- Client verbalizes plans for future maintenance of weight control

Outcomes
- Client verbalizes self-attributes not associated with physical appearance
- Client attends regular support group for assistance with weight management

FIGURE 31–2 Concept map care plan for a client with obesity.

- Does the client consume adequate calories as determined by the dietitian?
- Have there been any attempts to stash food from the tray to discard later?
- Have there been any attempts to self-induce vomiting?
- Has the client admitted that a problem exists and that eating behaviors are maladaptive?

- Have behaviors aimed at manipulating the environment been discontinued?
- Is the client willing to discuss the real issues concerning family roles, sexuality, dependence/ independence, and the need for achievement?
- Does the client understand how he or she has used maladaptive eating behaviors in an effort to achieve a feeling of some control over life events?

BOX 31–4 Topics for Client/Family Education Related to Eating Disorders

NATURE OF THE ILLNESS

1. Symptoms of anorexia nervosa
2. Symptoms of bulimia nervosa
3. Symptoms of binge eating disorder
4. What constitutes obesity
5. Causes of eating disorders
6. Effects of the illness or condition on the body
7. Behaviors that may reinforce unhealthy responses such as television and social media, peer focus on clothing sizes, eating, and weight. Internet sources have become a means for sharing information among people with anorexia about how the individual can distract parents and health-care providers from recognizing the extent of weight loss. Family members can learn more about some of these behaviors to look out for and may want to monitor their child's use of Internet and social media resources.

MANAGEMENT OF THE ILLNESS

1. Principles of nutrition (foods for maintenance of wellness)
2. Ways client may feel in control of life (aside from eating)
3. Importance of expressing fears and feelings, rather than holding them inside
4. Alternative coping strategies (to maladaptive eating behaviors)
5. For the obese client:
   a. How to plan a reduced-calorie, nutritious diet
   b. How to read food content labels
   c. How to establish a realistic weight loss plan
   d. How to establish a planned program of physical activity
6. Correct administration of prescribed medications
7. Indication for and side effects of prescribed medications
8. Relaxation techniques
9. Problem-solving skills
10. Discuss the Maudsley approach for treatment of anorexia nervosa as an evidence-based option for family involvement in the recovery program

SUPPORT SERVICES

■ Has the client acknowledged that perception of body image as "fat" is incorrect?

For the client with binge eating disorder and associated obesity:

■ Has the client shown a steady weight loss since starting the new eating plan?
■ Does the client verbalize a relapse prevention plan to avoid triggers and abstain from binging?

■ Does the client verbalize positive self-attributes not associated with body size or appearance?

For the client with anorexia, bulimia, or binge eating disorder and associated obesity:

■ Has the client been able to develop a more realistic perception of body image?
■ Has the client acknowledged that past self-expectations may have been unrealistic?

■ Does client accept self as less than perfect?
■ Has the client developed adaptive coping strategies to deal with stress without resorting to maladaptive eating behaviors?

Quality and Safety Education for Nurses (QSEN)

The Institute of Medicine (IOM) (now the National Academy of Medicine), in its 2003 report *Health Professions Education: A Bridge to Quality,* challenged faculties of medicine, nursing, and other health professions to ensure that their graduates have achieved a core set of competencies in order to meet the needs of the 21st-century health-care system. These competencies include *providing patient-centered care, maintaining safety, working in interdisciplinary teams, employing evidence-based practice, applying quality improvement,* and *utilizing informatics.* A QSEN teaching strategy is included in Box 31–5. The use of this type of activity is intended to arm the instructor and the student with guidelines for attaining the knowledge, skills, and attitudes necessary for achievement of quality and safety competencies in nursing.

Treatment Modalities

The immediate aim of treatment in eating disorders is to restore the client's nutritional status. Complications of emaciation, dehydration, and electrolyte imbalance can lead to death. Once the physical condition is no longer life threatening, other treatment modalities may be initiated.

Behavior Modification

Efforts to change the maladaptive eating behaviors of clients with anorexia nervosa and bulimia nervosa have become the widely accepted treatment. The importance of instituting a behavior modification program with these clients is to ensure that the program does not "control" them. Issues of control are central in these disorders, so for the program to be successful, the client must perceive that he or she is

---

BOX 31–5 QSEN TEACHING STRATEGY

Assignment: Using Evidence to Address Clinical Problems
Intervention With a Client Who Fears Gaining Weight (Anorexia Nervosa)

Competency Domain: Evidence-Based Practice

Learning Objectives: Student will:
• Differentiate clinical opinion from research and evidence summaries.
• Explain the role of evidence in determining the best clinical practice for intervening with clients who do not want to eat.
• Identify gaps between what is observed in the treatment setting to what has been identified as best practice.
• Discriminate between valid and invalid reasons for modifying evidence-based clinical practice based on clinical expertise or other reasons.
• Participate effectively in appropriate data collection and other research activities.
• Acknowledge own limitations in knowledge and clinical expertise before determining when to deviate from evidence-based best practices.

Strategy Overview:
1. Investigate the research related to intervening with a client who does not want to eat.
2. Identify best practices described in the literature. How were these best practices determined?
3. Compare and contrast staff intervention with best practices described in the literature.
4. Investigate staff perceptions related to intervening with a client who is refusing to eat.
5. How has the client developed these perceptions?
6. Do staff members view any problems associated with their practice versus best practice described in the literature? If so, how would they like to see the problem addressed?
7. Describe ethical issues associated with intervening with a client who does not want to eat.
8. What is your personal perception regarding the best evidence available to date related to intervening with a client who has anorexia nervosa? Are there situations that you can think of when you might deviate from the best practice model?
9. What questions do you have about intervening with a client who has anorexia nervosa that are not being addressed by current researchers?

Adapted from teaching strategy submitted by Pamela M. Ironside, Associate Professor, Indiana University School of Nursing, Indianapolis, IN. © 2009 QSEN; http://qsen.org. With permission.

in control of the treatment. The Maudsley approach, an evidence-based program for the treatment of adolescents with anorexia nervosa, modifies this concept in that the first phase of treatment is designed to encourage parental control of eating, with control returned to the adolescent once he or she demonstrates readiness and ability to establish control in healthier ways.

Successes have been observed when the client with anorexia nervosa is allowed to contract for privileges based on weight gain. The client has input into the care plan and can clearly see what the treatment choices are. The client has control over eating, over the amount of exercise pursued, and even over whether or not to induce vomiting. Goals of therapy, along with the responsibilities of each for goal achievement, are agreed on by client and staff.

Staff and client also agree on a system of rewards and privileges that can be earned by the client, who is given ultimate control. He or she has a choice of whether or not to abide by the contract, a choice of whether or not to gain weight, and a choice of whether or not to earn the desired privilege.

This method of treatment gives a great deal of autonomy to the client. It must be understood, however, that these behavior modification techniques are helpful for weight restoration only. Adjunctive individual psychotherapy and/or family psychoeducation may be required to prevent or reduce further morbidity. Cognitive-behavioral therapy (CBT) and dialectical behavior therapy (DBT) have demonstrated benefits in clients with anorexia, bulimia, and binge eating disorders (Black & Andreasen, 2014; O'Melia, 2014; Wright, Thase, & Beck, 2008).

By confronting irrational thinking patterns and associated feelings, CBT and DBT strive to eliminate the emotional components associated with unhealthy eating patterns.

Individual Therapy

Although individual psychotherapy is not the therapy of choice for eating disorders, it may be an adjunct to a comprehensive, multifaceted treatment approach when underlying comorbid psychological problems are contributing to the maladaptive behaviors. In supportive psychotherapy, the therapist encourages the client to explore unresolved conflicts and recognize the maladaptive eating behaviors as defense mechanisms to ease emotional pain. The goals are to resolve personal issues and establish more adaptive coping strategies for dealing with stressful situations.

Family Treatment: The Maudsley Approach

The Maudsley approach is one of the few evidence-based treatment approaches for teens with anorexia nervosa. This approach actively involves the family in each step of the process. In some of the first controlled studies of this method, 90 percent of clients showed improvement compared to 36 percent of those in individual therapies (Le Grange, 2005). The treatment program is conducted in an intensive outpatient program and involves three phases of treatment. Phase I is focused on weight restoration, and in this phase the parents are actively engaged in establishing the rules and guidelines around eating. Parents often need substantial support during this phase because they typically encounter frequent power struggles with their child. When the client accepts parental demands for increased food intake, demonstrates steady weight gain, and there is a change in the mood of the family (i.e., relief at having taken charge of the eating disorder; both adolescents and their parents identify reduced anxiety), phase II is ready to begin (LeGrange & Lock, no date). In this phase, control of maintaining weight gain is returned to the adolescent. Once he or she demonstrates ability to maintain above 95 percent of ideal weight, the shift to phase III focuses on assisting the adolescent to develop a healthy self-identity. This includes incorporating CBT and DBT skills, which have demonstrated effectiveness in treating this condition.

Psychopharmacology

Research has not yet identified a medication that results in definitive improvement of anorexia nervosa (Sadock et al., 2015). Trials of fluoxetine (Prozac) have shown some evidence of weight gain and, in general, SSRIs may be beneficial in the treatment of comorbid depression, but they also carry a black-box warning about risk of increasing suicide ideation in adolescents. The anticholinergic side effects of tricyclic antidepressants, including orthostatic hypotension, may be problematic for patients who are already at risk for these symptoms. It is important to recognize that depression and other mood and cognitive symptoms can be a symptom of malnutrition and starvation. When nutrition is restored those symptoms often improve.

Fluoxetine has been found useful in the treatment of bulimia nervosa (Schatzberg, Cole, & DeBattista, 2010). A dosage of 60 mg/day (triple the usual antidepressant dosage) was found to be most effective. It is possible that fluoxetine, an SSRI, may decrease the craving for carbohydrates, thereby decreasing the incidence of binge eating, which is often associated with consumption of large amounts of carbohydrates. Other antidepressants, such as imipramine (Tofranil), desipramine (Norpramin), amitriptyline (Elavil), nortriptyline (Aventyl), and phenelzine

(Nardil), also have been shown effective in controlled treatment studies (Sadock et al., 2015)

High-dose SSRIs have demonstrated some efficacy in promoting weight loss for clients with binge eating disorder, but the weight loss was temporary and weight *gain* typically occurred after the medication was discontinued (Sadock et al., 2015). Remember, too, that weight loss is a secondary symptom of binge eating disorder. An effective medication needs to also manage the symptom of binging. Two medications, topiramate and lisdexamfetamine (a dopamine-norepinephrine reuptake inhibitor, originally used in the treatment of attention-deficit/hyperactivity disorder) have demonstrated benefits in reducing incidents of both binge eating and weight loss (Balodis et al., 2015). Most studies reveal that medication in combination with CBT is more beneficial than medication alone (Sadock et al., 2015).

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

When Katie fainted in history class, she was taken to the university health center by her roommate, Ashley. Ashley told the nurse that Katie has been taking a lot of over-the-counter laxatives and diuretics. She also said that Katie often self-induced vomiting when she felt that she had eaten too much. After an initial physical assessment, the nurse in the university health center referred Katie to the mental health clinic.

At the mental health clinic, Katie weighed 110 pounds and measured 5 feet 6 inches. She admitted to the psychiatric nurse that she tried to keep her weight down by dieting, but sometimes she got so hungry that she would overeat, and then she felt the need to self-induce vomiting to get rid of the calories. "I really don't like doing it, but lots of the girls do. In fact, that is where I got the idea. I always thought I was too fat in high school, but the competition wasn't so great there. Here all the girls are so pretty—and so thin! It's the only way I can keep my weight down!"

Katie also admitted that she hoards food in her dorm room and that she eats when she is feeling particularly anxious and depressed (often during the night). She admitted to having eaten several bags of potato chips and whole packages of cookies in a single sitting. She sometimes drives to the local hamburger stand in the middle of the night, orders several hamburgers, fries, and milkshakes, and consumes them as she sits in her car alone. She stated that she feels so much better while she is eating these foods but then feels panicky after they have been consumed. That is when she self-induces vomiting. "Then I feel more depressed, and the only thing that helps is eating! I feel so out of control!"

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnosis for Katie:

Ineffective coping related to feelings of helplessness, low self-esteem, and lack of control in life situation.

- **Short-Term Goal:** Client will identify and discuss fears and anxieties with the nurse.
- **Long-Term Goal:** Client will identify adaptive coping strategies that can be realistically incorporated into her lifestyle, thereby eliminating binging and purging in response to anxiety.

PLANNING AND IMPLEMENTATION

INEFFECTIVE COPING

The following nursing interventions have been identified for Katie.

- Establish a trusting relationship with Katie. Be honest and accepting. Show unconditional positive regard.
- Help Katie identify the situations that produce anxiety and discuss how she coped with these situations before she began binging and purging.
- Help Katie identify the emotions that precipitate binging (e.g., fear, boredom, anger, loneliness).
- Once these high-risk situations have been identified, help her identify alternate behaviors, such as exercise, a hobby, or a warm bath.
- Encourage Katie to express feelings that have been suppressed because they were considered unacceptable. Help her identify healthier ways to express those feelings.
- Use role-play with Katie to deal with feelings and experiment with new behaviors.
- Explore the dynamics of Katie's family and encourage family involvement for support with Katie's consent.
- Teach the concepts of good nutrition, and the importance of healthy eating patterns in overall wellness.
- Consult with the physician about a prescription for fluoxetine for Katie.
- Help Katie find a support group for individuals with eating disorders. Encourage regular attendance in this group.

EVALUATION

The outcome criteria for Katie have been met. She discussed with the nurse the feelings that triggered binging episodes and the situations that precipitated those feelings. She has joined a support group of individuals with eating disorders and now has a "buddy" that she may call (even in the middle of the night) when she is feeling like binging. She has started riding her bicycle regularly and goes to the fitness center when she is feeling especially anxious. She still sees the mental health nurse weekly and continues to discuss her fears and anxieties. The urges to binge at stressful times have not disappeared completely. However, they have decreased in frequency, and Katie is now able to choose more adaptive strategies for dealing with stress.

Summary and Key Points

■ The incidence of eating disorders has continued to increase since the middle of the 20th century.

■ Individuals with anorexia nervosa, a disorder characterized by a morbid fear of obesity and a gross distortion of body image, literally can starve themselves to death.

■ The individual with anorexia nervosa believes he or she is fat even when emaciated. The disorder is commonly accompanied by depression and anxiety.

■ Bulimia nervosa is an eating disorder characterized by the consumption of huge amounts of food, usually in a short period of time and often in secret.

■ With bulimia nervosa, tension is relieved and pleasure felt during the time of the binge but is soon followed by feelings of guilt and depression.

■ Individuals with bulimia nervosa "purge" themselves of the excessive intake with self-induced vomiting or the misuse of laxatives, diuretics, or enemas. They also are subject to mood and anxiety disorders.

■ Binge eating disorder is characterized by the consumption of huge amounts of food by an individual who feels a lack of control over the eating behavior. It differs from bulimia nervosa in that the individual does not engage in behaviors to rid the body of the excess calories.

■ Compulsive eating can result in obesity, which is defined by the National Institutes of Health as a BMI of 30.

■ Obesity predisposes the individual to many health concerns, and at the morbid level (a BMI of 40), the weight alone can contribute to increases in morbidity and mortality.

■ Predisposing factors to eating disorders include genetics, physiological factors, family dynamics, and environmental and lifestyle factors.

■ Treatment modalities for eating disorders include behavior modification, individual psychotherapy, cognitive-behavioral therapy, family treatment (such as the Maudsley approach), and psychopharmacology.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Some obese individuals take amphetamines to suppress appetite and help them lose weight. Which of the following is an adverse effect associated with use of amphetamines that makes this practice undesirable?
   a. Bradycardia
   b. Amenorrhea
   c. Tolerance
   d. Convulsions

2. The Maudsley approach to treatment of adolescents with anorexia nervosa advances which of the following fundamental concepts?
   a. Family should be actively involved in each phase of treatment.
   b. Parents should be prohibited from involvement in helping their child eat more, since there are often control issues.
   c. Adolescents need to work on developing healthy self-identities before they can begin to gain weight.
   d. Individual psychotherapy is the most effective treatment for adolescents with anorexia nervosa.

3. John has sought help for his concern that he is binge eating and feels like it has "gotten out of control." He asks the nurse what can be done to help him. Which of these is the most accurate response?
   a. Nothing can be done.
   b. Some medications and psychological treatments have demonstrated effectiveness in reducing binge eating behaviors.
   c. The primary problem is obesity. I can help you set up a calorie-restricted diet.
   d. Medications can help with weight loss, but there are no medications effective for reducing binge eating.

Review Questions—cont'd
Self-Examination/Learning Exercise

4. Emma, age 14, has just been admitted to the psychiatric unit for anorexia nervosa. She is emaciated and refusing to eat. What is the primary nursing diagnosis for Emma?
   a. Complicated grieving
   b. Imbalanced nutrition: Less than body requirements.
   c. Interrupted family processes
   d. Anxiety (severe)

5. Which of the following physical manifestations would you expect to assess in a client suffering from anorexia nervosa?
   a. Tachycardia, hypertension, hyperthermia
   b. Bradycardia, hypertension, hyperthermia
   c. Bradycardia, hypotension, hypothermia
   d. Tachycardia, hypotension, hypothermia

6. The nurse is caring for a client who has been hospitalized with anorexia nervosa and is severely malnourished. The client continues to refuse to eat. What is the most appropriate response by the nurse?
   a. "You know that if you don't eat, you will die."
   b. "If you continue to refuse to take food orally, you will be fed through a nasogastric tube."
   c. "You might as well leave if you are not going to follow your therapy regimen."
   d. "You don't have to eat if you don't want to. It is your choice."

7. Which medication has been used with some success in clients with anorexia nervosa?
   a. Lorcaserin (Belviq)
   b. Diazepam (Valium)
   c. Fluoxetine (Prozac)
   d. Carbamazepine (Tegretol)

8. Marissa is hospitalized on the psychiatric unit. She has a history and current diagnosis of bulimia nervosa. Which of the following symptoms would be congruent with Marissa's diagnosis?
   a. Binging, purging, obesity, hyperkalemia
   b. Binging, purging, normal weight, hypokalemia
   c. Binging, laxative abuse, amenorrhea, severe weight loss
   d. Binging, purging, severe weight loss, hyperkalemia

9. A hospitalized client with bulimia nervosa has stopped vomiting in the hospital and tells the nurse she is afraid she is going to gain weight. Which is the most appropriate response by the nurse?
   a. "Don't worry. The dietitian will ensure you don't get too many calories in your diet."
   b. "Don't worry about your weight. We are going to work on other problems while you are in the hospital."
   c. "I understand that you are concerned about your weight, and we will talk about the importance of good nutrition, but for now I want you to tell me about your recent invitation to join the National Honor Society. That's quite an accomplishment."
   d. "You are not fat, and the staff will ensure that you do not gain weight while you are in the hospital, because we know that is important to you."

10. Mandy presents in the emergency department with complaints of suicidal ideation. The following data is collected by the nurse. Which of these assessment findings suggests that bulimia nervosa might be a health problem? (Select all that apply.)
    a. Mandy's parotid glands appear enlarged.
    b. Mandy's teeth have a "moth eaten" pattern of tooth decay.
    c. Mandy reports that she takes laxatives daily.
    d. Mandy's weight is within the expected range.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

DESCRIPTION OF THE STUDY: Almost 69 percent of adults in the United States are overweight, and more than 35 percent of those are within the range of obesity. Obesity has become a leading health concern that impacts both physical and psychological health. Because attitudes can affect behaviors negatively, the authors undertook this study to determine the implicit or unconscious attitudes of nursing and psychology students toward overweight individuals in medical and nonmedical contexts. Study participants included 90 students in upper division nursing and psychology programs at the University of Alaska Anchorage. Mean age was 25 years. The majority were white. Others reported their race as Alaska Native or American Indian, African American, Asian, Hispanic, and Filipino. Attitudes were measured using an implicit association test (IAT) that measures how readily a target concept and an attribute are associated by analyzing reaction times. Participants sat at computers with dominant hand on response pad with the following instructions: "Please press the *blue* key as quickly as possible if you see a *thin* or *normal weight* person, or if you see a *positive* attribute used to describe a person. Please press the *yellow* key if you see an *overweight* person, or if you see a *negative* attribute used to describe a person." Attitudes were measured according to rapidity of response time in relation to associating images of overweight individuals with positive words and normal-weight or thin individuals with negative words (the inconsistent stereotype) as compared to associating positive words with thin or normal-weight individuals and negative words with obese or overweight individuals (the consistent stereotype). Scenarios exhibited individuals in both medical settings (patients) and nonmedical settings.

RESULTS OF THE STUDY: Students enrolled in a social psychology class analyzed the data for a class assignment. Results indicated a statistically significant implicit bias toward overweight individuals by both the nursing students and the psychology students. A stronger weight bias was noted when the target stimulus in the scenario was female than when the target stimulus was male. No significant differences in degree of bias toward weight were found between nursing and psychology students or between subjects in medical versus nonmedical settings.

IMPLICATIONS FOR NURSING PRACTICE: The authors suggest:

Providing education and support to overweight individuals is central to nursing practice in a society struggling to manage obesity. Negative stereotypes or beliefs about these individuals may result in poor patient care. Therefore, nurses and other healthcare professionals must be aware of personal biases and work to develop methods to address weight-related issues in a therapeutic manner. (p. 3504)

TEST YOUR CRITICAL THINKING SKILLS

Janice, a high school sophomore, wanted desperately to become a cheerleader. She practiced endlessly before tryouts, but she was not selected. A week later, her boyfriend, Roy, broke up with her to date another girl. Janice, who was 5 feet 3 inches tall and, at that time, weighed 110 pounds, decided it was because she was too fat. She began to exercise at every possible moment. She skipped meals and tried to keep her daily consumption to no more than 300 calories. She lost a great deal of weight but became very weak. She felt cold all of the time and wore sweaters in the warm weather. She collapsed during her physical education class at school and was rushed to the emergency department. On admission, she weighed 90 pounds. She was emaciated and anemic. The physician admitted her with a diagnosis of anorexia nervosa.

Answer the following questions about Janice:

1. What will be the *primary* consideration in her care?
2. How will treatment be directed toward helping her gain weight?
3. How will the nurse know if Janice is using self-induced vomiting to rid herself of food consumed at meals?

Communication Exercises

1. Helena was admitted to the psychiatric unit with a diagnosis of severe anorexia nervosa. After completing a meal, she asks the nurse to be excused so she can use the restroom. How would the nurse respond to Helena's request?

2. John has been seeking counseling for a binge eating disorder. When the nurse is weighing him, John states, "I hate myself. I should never have let myself get like this. I'm completely out of control." What would be the most empathic response by the nurse?

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *personality*.
2. Compare stages of personality development according to Sullivan, Erikson, and Mahler.
3. Identify various types of personality disorders.
4. Discuss historical and epidemiological statistics related to various personality disorders.
5. Describe symptomatology associated with borderline personality disorder and antisocial personality disorder, and use these data in client assessment.
6. Identify predisposing factors for borderline personality disorder and antisocial personality disorder.

7. Formulate nursing diagnoses and goals of care for clients with borderline personality disorder and antisocial personality disorder.
8. Describe appropriate nursing interventions for behaviors associated with borderline personality disorder and antisocial personality disorder.
9. Evaluate nursing care of clients with borderline personality disorder and antisocial personality disorder.
10. Discuss various modalities relevant to treatment of personality disorders.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What are the primary psychosocial predisposing factors to avoidant personality disorder?
2. How should a nurse care for the self-inflicted wounds of a client with borderline personality disorder?
3. What are some of the types of family dynamics that may predispose a person to antisocial personality disorder?

CORE CONCEPT

Personality

The totality of emotional and behavioral characteristics that are particular to a specific person and that remain somewhat stable and predictable over time.

The word *personality* is derived from the Greek term *persona*. It was originally used to describe the theatrical mask worn by some dramatic actors at the time. Over the years, it lost its connotation of pretense and illusion and came to represent the person behind the mask—the "real" person.

Personality *traits* may be defined as characteristics with which an individual is born or develops early in life. They influence the way he or she perceives and relates to the environment and remain stable over time. Personality *disorders* occur when these traits deviate markedly from the expectations of the individual's culture, become rigid and inflexible, contribute to maladaptive patterns of behavior or impairment in functioning, and lead to distress (American Psychiatric Association [APA], 2013). The most common symptoms occurring in personality disorders are impairment in interpersonal relationship functions (41%), dysfunctions in cognition (30%), affect (18%), and impulse control (6%) (Bornstein et al., 2014). In specific types of personality disorders, such as paranoid and schizotypal personality disorders, cognitive symptoms may appear more prominently. In other types, such as borderline personality and antisocial personality disorders, interpersonal dysfunctions may predominate (Bornstein et al., 2014). Virtually all individuals exhibit some behaviors associated with the various personality disorders from time to time. As previously stated, it is only when significant functional impairment occurs in response to these personality characteristics that the individual is thought to have a personality disorder.

Personality development occurs in response to a number of biological and psychological influences. These variables include (but are not limited to) heredity, temperament, experiential learning, and social interaction. A number of theorists have attempted to provide information about personality development. Most suggest that it occurs in an orderly, stepwise fashion. These stages overlap, however, as maturation occurs at different rates in different individuals. The theories of Sullivan (1953), Erikson (1963), and Mahler (Mahler, Pine, & Bergman, 1975) are presented at length in the chapter Theoretical Models of Personality Development available online at DavisPlus. The stages of personality development according to these three theorists are compared in Table 32–1. The nurse should understand "normal" personality development before learning about what is considered maladaptive.

Historical and epidemiological aspects of personality disorders are discussed in this chapter. Predisposing

	30 to 65 years: To achieve the life goals established for oneself, while also considering the welfare of future generations	
	65 years to death: To review one's life and derive meaning from both positive and negative events, while achieving a positive sense of self-worth In late, older adulthood (80 years and beyond) an additional stage of development, *transcendence*, refers to a period in which one develops a broader sense of one's meaning and spirituality that transcends themselves.	

factors that have been implicated in the etiology of personality disorders are presented. Symptomatology is explained to provide background knowledge for assessing clients with personality disorders.

Individuals with personality disorders are not often treated in acute care settings for the personality disorder as their primary psychiatric diagnosis. However, many clients with other psychiatric and medical diagnoses manifest symptoms of personality disorders. Nurses are likely to encounter clients with these personality characteristics in all health-care settings.

Nurses working in psychiatric settings are likely to encounter clients with borderline and antisocial personality characteristics. The behavior of clients with **borderline personality disorder** (BPD) is very unstable, and hospitalization is often required as a result of attempts at self-injury. The client with antisocial personality disorder may enter the psychiatric arena as a result of judicially ordered evaluation. Psychiatric intervention may be an alternative to imprisonment for antisocial behavior if it is deemed potentially helpful.

Nursing care of clients with BPD or antisocial personality disorder is presented in this chapter in the context of the nursing process. Various medical treatment modalities for personality disorders are explored.

Historical Aspects

In the fourth century BC, Hippocrates concluded that all disease stemmed from an excess of or imbalance among four bodily humors: yellow bile, black bile, blood, and phlegm. Hippocrates identified four fundamental personality styles that he concluded stemmed from excesses in the four humors: the irritable and hostile choleric (yellow bile), the pessimistic melancholic (black bile), the overly optimistic and extraverted sanguine (blood), and the apathetic phlegmatic (phlegm).

In 1801, the medical profession first recognized that personality disorders, apart from psychosis, were cause for their own special concern with the realization that an individual can behave irrationally even when the powers of intellect are intact. Nineteenth-century psychiatrists embraced the term *moral insanity,* the concept of which defines what we know today as personality disorders.

Historically, individuals with personality disorders have been labeled as "bad" or "immoral" and as deviants in the range of normal personality dimensions. The events and sequences that result in pathology of the personality are complicated and difficult to unravel. Continued study is needed to facilitate understanding of this complex behavioral phenomenon.

A major difficulty for psychiatrists has been the establishment of a classification of personality disorders. Ten specific types of personality disorders are identified in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (APA, 2013). The APA has proposed a new, complex diagnostic system to identify impairments in personality functioning specifically related to the dimensions of *self* and *interpersonal relations* and to personality *trait domains and facets*. This system is very specific and addresses symptoms that may differ not only among personality disorders but also among individuals with the same personality disorder. This

trait-specific diagnostic methodology is described in the *DSM-5* as an alternative approach to diagnosis of personality disorder and is recommended for further study.

The current diagnostic system classifies the personality disorders into three clusters according to description of personality traits. These include the following:

1. **Cluster A:** Behaviors described as odd or eccentric
   a. Paranoid personality disorder
   b. Schizoid personality disorder
   c. Schizotypal personality disorder
2. **Cluster B:** Behaviors described as dramatic, emotional, or erratic
   a. Antisocial personality disorder
   b. Borderline personality disorder
   c. Histrionic personality disorder
   d. Narcissistic personality disorder
3. **Cluster C:** Behaviors described as anxious or fearful
   a. Avoidant personality disorder
   b. Dependent personality disorder
   c. Obsessive-compulsive personality disorder

Types of Personality Disorders

Paranoid Personality Disorder
Definition and Epidemiological Statistics

Paranoid personality disorder is defined as a pattern of pervasive mistrust and suspiciousness of others, and misinterpretation of others' motives as malevolent (APA, 2013, p. 649). This pattern begins by early adulthood and remains present in a variety of contexts. Prevalence has been estimated at 1 to 4 percent of the general population, and often is diagnosed only when the individual seeks treatment for a mood or anxiety disorder (Black & Andreasen, 2014). The disorder is more commonly diagnosed in men than in women.

Clinical Picture

Individuals with paranoid personality disorder are constantly on guard, hypervigilant, and ready for any real or imagined threat. They appear tense and irritable. They have developed a hard exterior and become immune or insensitive to the feelings of others. They avoid interactions with other people lest they be forced to relinquish some of their own power. They always feel that others plan to take advantage of them.

They are extremely oversensitive and tend to misinterpret even minute cues within the environment, magnifying and distorting them into thoughts of trickery and deception. Because they trust no one, they are constantly "testing" the honesty of others. Their intimidating manner provokes exasperation and anger in almost everyone with whom they come in contact.

Individuals with paranoid personality disorder maintain their self-esteem by attributing their shortcomings to others. They do not accept responsibility for their own behaviors and feelings and project this responsibility onto others. They are envious and hostile toward those who are highly successful and believe the only reason they are not as successful is because they have been treated unfairly. People who are paranoid are extremely vulnerable and constantly on the defensive. Any real or imagined threat can release hostility and anger fueled by animosities from the past. The desire for reprisal and vindication is so intense that a possible loss of control can result in aggression and violence. These outbursts are usually brief, and the paranoid person soon regains the external control, rationalizes the behavior, and reconstructs the defenses central to his or her personality pattern.

The *DSM-5* diagnostic criteria for paranoid personality disorder are presented in Box 32–1.

BOX 32–1 Diagnostic Criteria for Paranoid Personality Disorder

A. A pervasive distrust and suspiciousness of others such that their motives are interpreted as malevolent, beginning by early adulthood and present in a variety of contexts, as indicated by four (or more) of the following:
   1. Suspects, without sufficient basis, that others are exploiting, harming, or deceiving him or her
   2. Is preoccupied with unjustified doubts about the loyalty or trustworthiness of friends or associates
   3. Is reluctant to confide in others because of unwarranted fear that the information will be used maliciously against him or her
   4. Reads hidden demeaning or threatening meanings into benign remarks or events
   5. Persistently bears grudges (i.e., is unforgiving of insults, injuries, or slights)
   6. Perceives attacks on his or her character or reputation that are not apparent to others and is quick to react angrily or to counterattack
   7. Has recurrent suspicions, without justification, regarding fidelity of spouse or sexual partner
B. Does not occur exclusively during the course of schizophrenia, a bipolar disorder or depressive disorder with psychotic features, or another psychotic disorder and is not attributable to the physiological effects of another medical condition.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

Predisposing Factors

Research has indicated a possible hereditary link in paranoid personality disorder. Studies have revealed a higher incidence of paranoid personality disorder among relatives of clients with schizophrenia than among control subjects (Sadock, Sadock, & Ruiz, 2015).

Psychological predisposing factors, as is the case with many personality disorders, include a history of childhood trauma including neglect. People with paranoid personality disorder may have been subjected to parental antagonism and harassment. They learned to perceive the world as harsh and unkind, a place calling for protective vigilance and mistrust. They entered the world with a "chip-on-the-shoulder" attitude and were met with many rebuffs and rejections from others. Anticipating humiliation and betrayal by others, they learned to defend themselves by attacking first.

Schizoid Personality Disorder

Definition and Epidemiological Statistics

Schizoid personality disorder is characterized primarily by a profound defect in the ability to form personal relationships. People with this condition are often seen by others as eccentric, isolated, or lonely (Sadock et al., 2015). These individuals display a lifelong pattern of social withdrawal, and their discomfort with human interaction is apparent. The prevalence of schizoid personality disorder is difficult to determine because, as with many other personality disorders, it may go undiagnosed unless it is recognized when the individual seeks health care for other reasons. Estimates within the general population vary between 3 and 5 percent. Many people with the disorder are never observed in a clinical setting. Gender ratio of the disorder is unknown, although it is diagnosed more frequently in men.

Clinical Picture

People with schizoid personality disorder appear cold, aloof, and indifferent to others. They typically have a long-standing history of engaging in primarily solitary activities or engaging more with animals than people. They prefer to work in isolation and are unsociable, with little need or desire for emotional ties. They are able to invest enormous affective energy in intellectual pursuits.

In the presence of others, they appear shy, anxious, or uneasy. They are inappropriately serious about everything and have difficulty acting in a lighthearted manner. Their behavior and conversation exhibit little or no spontaneity. Typically, they are unable to experience pleasure, and their affect is commonly bland and constricted.

The *DSM-5* diagnostic criteria for schizoid personality disorder are presented in Box 32–2.

Predisposing Factors

Although the role of heredity in the etiology of schizoid personality disorder is unclear, introversion appears to be a highly inheritable characteristic. Further studies are required before definitive statements can be made. Psychosocially, the development of schizoid personality is probably influenced by early interactional patterns that the person found cold and unsatisfying. The childhoods of these individuals have often been characterized as bleak, cold, and lacking empathy and nurturing. A child brought up with this type of parenting may develop schizoid personality traits if that child possesses a temperamental disposition that is shy, anxious, and introverted.

Schizotypal Personality Disorder

Definition and Epidemiological Statistics

Individuals with **schizotypal personality disorder** were once described as "latent schizophrenics." Their

---

BOX 32–2 Diagnostic Criteria for Schizoid Personality Disorder

A. A pervasive pattern of detachment from social relationships and a restricted range of expression of emotions in interpersonal settings, beginning by early adulthood and present in a variety of contexts, as indicated by four (or more) of the following:
   1. Neither desires nor enjoys close relationships, including being part of a family
   2. Almost always chooses solitary activities
   3. Has little, if any, interest in having sexual experiences with another person
   4. Takes pleasure in few, if any, activities
   5. Lacks close friends or confidants other than first-degree relatives
   6. Appears indifferent to the praise or criticism of others
   7. Shows emotional coldness, detachment, or flattened affectivity
B. Does not occur exclusively during the course of schizophrenia, a bipolar disorder or depressive disorder with psychotic features, another psychotic disorder, or autism spectrum disorder and is not attributable to the physiological effects of another medical condition.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

behavior is odd and eccentric but does not decompensate to the level of schizophrenia. Schizotypal personality is marked by symptoms that are closer to those of schizophrenia than those in schizoid personality. The former individuals show significant peculiarities in thinking, behavior, and appearance. Studies indicate that schizotypal personality disorder has a prevalence of around 3 percent (Sadock et al., 2015).

Clinical Picture

Individuals with schizotypal personality disorder are aloof and isolated and behave in a bland and apathetic manner. Magical thinking, ideas of reference, illusions, and depersonalization are part of their everyday world. Examples include superstitiousness; belief in clairvoyance, telepathy, or "sixth sense"; as well as beliefs that "others can feel my feelings."

The speech pattern is sometimes bizarre. People with this disorder often cannot orient their thoughts logically and become lost in personal irrelevancies and tangential asides that seem vague and digress from the topic at hand. This feature only further alienates them from others.

Under stress, these individuals may decompensate and demonstrate psychotic symptoms, such as delusional thoughts, hallucinations, or bizarre behaviors, but these are usually of brief duration (Sadock et al., 2015). They often talk or gesture to themselves, as if "living in their own world." Their affect is bland or inappropriate, such as laughing at their own problems or at a situation that most people would consider sad.

The *DSM-5* diagnostic criteria for schizotypal personality disorder are presented in Box 32–3.

Predisposing Factors

Evidence suggests that schizotypal personality disorder is more common among the first-degree biological relatives of people with schizophrenia than among the general population. It is now considered part of the genetic spectrum of schizophrenia (APA, 2013). Twin studies reveal a higher incidence in monozygotic twins than dizygotic twins (Sadock et al., 2015).

Psychological and environmental factors may also interact with genetic vulnerability in the development of schizotypal personality traits. One recent study (Hur et al., 2016) found that individuals with schizotypal personality disorder demonstrated reduced activation of brain areas responsive to motion perception and executive control of perception. These findings may explain a biological basis for the peculiar ways that individuals with schizotypal personality disorder behave in social situations. Affective blandness, peculiar behaviors, and discomfort with interpersonal relationships may provoke other children to avoid relationships with them, or worse, engage in bullying, which reinforces their withdrawal from others. Having failed repeatedly to cope with these adversities, they withdraw and reduce contact with individuals and situations that evoked sadness and humiliation. Their new inner world provides them with a more significant and potentially rewarding existence than the one experienced in reality.

Antisocial Personality Disorder

Definition and Epidemiological Statistics

Antisocial personality disorder is a pattern of socially irresponsible, exploitative, and guiltless behavior that reflects a general disregard for the rights of others.

BOX 32–3 **Diagnostic Criteria for Schizotypal Personality Disorder**

A. A pervasive pattern of social and interpersonal deficits marked by acute discomfort with, and reduced capacity for, close relationships as well as by cognitive or perceptual distortions and eccentricities of behavior, beginning by early adulthood and present in a variety of contexts, as indicated by five (or more) of the following:
   1. Ideas of reference (excluding delusions of reference)
   2. Odd beliefs or magical thinking that influences behavior and is inconsistent with subcultural norms (e.g., superstitiousness, belief in clairvoyance, telepathy, or "sixth sense;" in children and adolescents, bizarre fantasies or preoccupations)
   3. Unusual perceptual experiences, including bodily illusions
   4. Odd thinking and speech (e.g., vague, circumstantial, metaphorical, overelaborate, or stereotyped)
   5. Suspiciousness or paranoid ideation
   6. Inappropriate or constricted affect
   7. Behavior or appearance that is odd, eccentric, or peculiar
   8. Lack of close friends or confidants other than first-degree relatives
   9. Excessive social anxiety that does not diminish with familiarity and tends to be associated with paranoid fears rather than negative judgments about self
B. Does not occur exclusively during the course of schizophrenia, a bipolar disorder or depressive disorder with psychotic features, another psychotic disorder, or autism spectrum disorder.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

These individuals exploit and manipulate others for personal gain and are unconcerned with obeying the law. They have difficulty sustaining consistent employment and developing stable relationships. This is one of the oldest and best-researched personality disorders and has been included in all editions of the *Diagnostic and Statistical Manual of Mental Disorders*. In the United States, prevalence is estimated to be about 3 percent in the general population, but in prison populations, the prevalence is 50 percent or higher (Hatchett, 2015). It is more common in men than in women, among the lower socioeconomic classes, and especially among highly mobile inhabitants of impoverished urban areas. The *DSM*-5 currently identifies antisocial personality and psychopathy as synonymous terms, but recent research reveals that these are better understood as distinct disorders (Hatchett, 2015; Thompson, Ramos, & Willett, 2014). Substance use disorder is commonly identified as a comorbid disorder.

The clinical picture, predisposing factors, nursing diagnoses, and interventions for care of clients with antisocial personality disorder are presented later in this chapter.

Borderline Personality Disorder
Definition and Epidemiological Statistics

BPD is characterized by a pattern of intense and chaotic relationships, with affective instability and fluctuating attitudes toward other people. These individuals are impulsive, are directly and indirectly self-destructive, and lack a clear sense of identity. Prevalence of BPD is estimated at 1 to 2 percent of the population. It is generally estimated to be twice as common in women than in men (Sadock et al., 2015), and some have identified female-to-male ratios as high as 4 to 1 (Lubit, 2016).

The clinical picture, predisposing factors, nursing diagnoses, and interventions for care of clients with BPD are presented later in this chapter.

Histrionic Personality Disorder
Definition and Epidemiological Statistics

Histrionic personality disorder is characterized by colorful, dramatic, and extroverted behavior in excitable, emotional people. They have difficulty maintaining long-lasting relationships, although they require constant affirmation of approval and acceptance from others. This often gives rise to seductive, flirtatious behavior in efforts to reassure themselves of their attractiveness and gain approval. Prevalence of the disorder is thought to be about 2 to 3 percent, and it is more common in women than in men.

Clinical Picture

People with histrionic personality disorder tend to be self-dramatizing, attention-seeking, overly gregarious, and seductive. They use manipulative and exhibitionistic behaviors in their demands to be the center of attention. People with histrionic personality disorder often demonstrate, to an extreme, what our society tends to foster and admire in its members: to be well liked, successful, popular, extroverted, attractive, and sociable. However, beneath these surface characteristics is a driven quality—an all-consuming need for approval and a desperate striving to be conspicuous and evoke affection or attract attention at all costs. Failure to evoke the attention and approval they seek often results in feelings of dejection and anxiety.

Individuals with this disorder are highly distractible and flighty by nature. They have difficulty paying attention to detail. They can portray themselves as carefree and sophisticated on the one hand and as inhibited and naive on the other. They tend to be highly suggestible, impressionable, and easily influenced by others. They are strongly dependent.

Interpersonal relationships are fleeting and superficial. The person with histrionic personality disorder, having failed throughout life to develop the richness of inner feelings and without resources from which to draw, lacks the ability to provide another with genuinely sustained affection. Somatic complaints are not uncommon in these individuals, and fleeting episodes of psychosis may occur during periods of extreme stress.

The *DSM-5* diagnostic criteria for histrionic personality disorder are presented in Box 32–4.

Predisposing Factors

Heredity may be a factor because the disorder is apparently more common among first-degree biological relatives of people with the disorder than in the general population. Some traits may be inherited, whereas others are related to a combination of genetic predisposition and childhood experiences. But at present, the cause or causes are unknown.

From a psychosocial perspective, learning experiences may contribute to the development of histrionic personality disorder. The child may have learned that positive reinforcement was contingent on the ability to perform parentally approved and admired behaviors. It is likely that the child rarely received either positive or negative feedback. Parental acceptance and approval came inconsistently and only when the behaviors met parental expectations.

Narcissistic Personality Disorder
Definition and Epidemiological Statistics

Persons with **narcissistic personality disorder** have an exaggerated sense of self-worth. They lack empathy and are hypersensitive to the evaluation of others. They believe that they have the inalienable right to receive special consideration and that their desire is sufficient justification for possessing whatever they seek.

BOX 32–4 Diagnostic Criteria for Histrionic Personality Disorder

A pervasive pattern of excessive emotionality and attention seeking, beginning by early adulthood and present in a variety of contexts, as indicated by five (or more) of the following:

1. Is uncomfortable in situations in which he or she is not the center of attention
2. Interaction with others is often characterized by inappropriate sexually seductive or provocative behavior
3. Displays rapidly shifting and shallow expression of emotions
4. Consistently uses physical appearance to draw attention to self
5. Has a style of speech that is excessively impressionistic and lacking in detail
6. Shows self-dramatization, theatricality, and exaggerated expression of emotion
7. Is suggestible (i.e., easily influenced by others or circumstances)
8. Considers relationships to be more intimate than they actually are

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

This diagnosis appeared for the first time in the third edition of the *Diagnostic and Statistical Manual of Mental Disorders*. However, the concept of narcissism has its roots in the 19th century. It was viewed by early psychoanalysts as a normal phase of psychosexual development. The prevalence of narcissistic personality disorder is estimated at 1 to 6 percent (Sadock et al., 2015). It is diagnosed more often in men than in women.

Clinical Picture

Individuals with narcissistic personality disorder appear to lack humility, be overly self-centered, and exploit others to fulfill their own desires. They often do not conceive of their behavior as being inappropriate or objectionable. Because they view themselves as "superior" beings, they believe they are entitled to special rights and privileges.

Although often grounded in grandiose distortions of reality, their moods are usually optimistic, relaxed, cheerful, and carefree. This can easily change, however, because of fragile self-esteem. If they do not meet self-expectations, do not receive the positive feedback they expect from others, or draw criticism from others, they may respond with rage, shame, humiliation, or dejection. They may turn inward and fantasize rationalizations that convince them of their continued stature and perfection.

The exploitation of others for self-gratification results in impaired interpersonal relationships. In selecting a mate, narcissistic individuals frequently choose a person who will provide them with the praise and positive feedback that they require and who will not ask much from their partner in return.

The *DSM-5* diagnostic criteria for narcissistic personality disorder are presented in Box 32–5.

Predisposing Factors

Although the causes are unknown, psychodynamic theories have suggested that narcissistic personality disorder evolves from a parent-child dynamic of either excessive pampering or excessive criticism

---

BOX 32–5 Diagnostic Criteria for Narcissistic Personality Disorder

A pervasive pattern of grandiosity (in fantasy or behavior), need for admiration, and lack of empathy, beginning by early adulthood and present in a variety of contexts, as indicated by five (or more) of the following:

1. Has a grandiose sense of self-importance (e.g., exaggerates achievements and talents, expects to be recognized as superior without commensurate achievements)
2. Is preoccupied with fantasies of unlimited success, power, brilliance, beauty, or ideal love
3. Believes that he or she is "special" and unique and can only be understood by, or should associate with, other special or high-status people (or institutions)
4. Requires excessive admiration
5. Has a sense of entitlement (i.e., unreasonable expectations of especially favorable treatment or automatic compliance with his or her expectations)
6. Is interpersonally exploitative (i.e., takes advantage of others to achieve his or her own ends)
7. Lacks empathy: is unwilling to recognize or identify with the feelings and needs of others
8. Is often envious of others or believes that others are envious of him or her
9. Shows arrogant, haughty behaviors or attitudes

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

(Mayo Clinic, 2014). Children may then grow to project an image of invulnerability and self-sufficiency that conceals their true sense of emptiness and contributes to their inability to feel deep emotion.

Sadock and associates (2015) identify the propensity for an increase in narcissistic personality disorders among children whose parents had the disorder. Children may evolve into adults with narcissistic personality disorder through role modeling parent behavior, or as Sadock and associates suggest, these traits may be caused by a narcissistic parent's imparting an unrealistic omnipotence, grandiosity, beauty, and talent to their children.

Narcissism may also develop from an environment in which parents attempt to live their lives vicariously through their child. They expect the child to achieve the things they did not achieve, possess that which they did not possess, and have life better and easier than they did. The child is not subjected to the requirements and restrictions that may have dominated the parents' lives and thereby grows up believing he or she is above that which is required for everyone else.

Genetics and environment may both have a role in the development of narcissistic personality disorder. Research has identified a decreased volume of gray matter in areas of the brain responsible for empathy, emotional regulation, compassion, and cognitive functions (Gregory, 2016).

Avoidant Personality Disorder

Definition and Epidemiological Statistics

The individual with **avoidant personality disorder** is extremely sensitive to rejection and thus may lead a very socially withdrawn life. It is not that he or she is asocial; in fact, there may be a strong desire for companionship. The extreme shyness and fear of rejection, however, create the need for unusually strong assurances of unconditional acceptance. Prevalence of the disorder in the general population is about 2 to 3 percent, and it appears to be equally common in men and women.

Clinical Picture

Individuals with this disorder are awkward and uncomfortable in social situations. From a distance, others may perceive them as timid, withdrawn, or perhaps cold and strange. Those who have closer relationships with them, however, soon learn of their sensitivities, touchiness, evasiveness, and mistrustful qualities.

Their speech is usually slow and constrained, with frequent hesitations, fragmentary thought sequences, and occasional confused and irrelevant digressions. They are often lonely and express feelings of being unwanted. They view others as critical, betraying, and humiliating. They desire to have close relationships but avoid connecting with others because of their fear of being rejected. Depression, anxiety, and anger at oneself for failing to develop social relations are commonly experienced.

The *DSM-5* diagnostic criteria for avoidant personality disorder are presented in Box 32–6.

Predisposing Factors

There is no clear cause of avoidant personality disorder. Contributing factors are most likely a combination of biological, genetic, and psychosocial influences. Some infants who exhibit traits of hyperirritability, crankiness, tension, and withdrawal behaviors may possess a temperamental disposition toward an avoidant pattern later in life.

Psychosocial influences may include childhood trauma or neglect leading to fears of abandonment or views of the world as a hostile and dangerous place.

Dependent Personality Disorder

Definition and Epidemiological Statistics

Dependent personality disorder is characterized by lack of self-confidence and extreme reliance on others to take responsibility for them, sometimes to the point

---

BOX 32–6 Diagnostic Criteria for Avoidant Personality Disorder

A pervasive pattern of social inhibition, feelings of inadequacy, and hypersensitivity to negative evaluation, beginning by early adulthood and present in a variety of contexts, as indicated by four (or more) of the following:

1. Avoids occupational activities that involve significant interpersonal contact, because of fears of criticism, disapproval, or rejection
2. Is unwilling to get involved with people unless certain of being liked
3. Shows restraint within intimate relationships because of the fear of being shamed or ridiculed
4. Is preoccupied with being criticized or rejected in social situations
5. Is inhibited in new interpersonal situations because of feelings of inadequacy
6. Views self as socially inept, personally unappealing, or inferior to others
7. Is unusually reluctant to take personal risks or to engage in any new activities because they may prove embarrassing

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

of intense discomfort with being alone for even a brief period (Sadock et al., 2015). This mode of behavior is evident in the tendencies to allow others to make decisions, feel helpless when alone, act submissively, subordinate needs to others, tolerate mistreatment by others, demean oneself to gain acceptance, and fail to function adequately in situations that require assertive or dominant behavior.

Clinical Picture

Individuals with dependent personality disorder have a notable lack of self-confidence that is often apparent in their posture, voice, and mannerisms. They are typically passive and acquiescent to the desires of others. They are overly generous and thoughtful and underplay their own attractiveness and achievements. They may appear to others to "see the world through rose-colored glasses," but when alone, they may feel pessimistic, discouraged, and dejected. Others are not made aware of these feelings; their "suffering" is done in silence.

Individuals with dependent personality disorder assume the passive and submissive role in relationships. They are willing to let others make their important decisions. Should a dependent relationship end, they feel fearful and vulnerable because they lack confidence in their ability to care for themselves. They may hastily and indiscriminately attempt to establish another relationship with someone they believe can provide them with the nurturance and guidance they need.

They avoid positions of responsibility and become anxious when forced into them. They have feelings of low self-worth and are easily hurt by criticism and disapproval. They will do almost anything, even if it is unpleasant or demeaning, to earn the acceptance of others.

The *DSM-5* diagnostic criteria for dependent personality disorder are presented in Box 32–7.

Predisposing Factors

An infant may be genetically predisposed to a dependent temperament. Twin studies measuring submissiveness have shown a higher correlation between identical twins than fraternal twins.

Psychosocially, dependency is fostered in infancy when stimulation and nurturance are experienced exclusively from one source. The infant becomes attached to one source to the exclusion of all others. If this exclusive attachment continues as the child grows, the dependency is nurtured. A problem may arise when parents become overprotective and discourage independent behaviors on the part of the child. Parents who make new experiences unnecessarily easy for the child and refuse to allow him or her to learn by experience encourage their child to give up efforts at achieving autonomy. Dependent behaviors may be subtly rewarded in this environment, and the child may come to fear a loss of love or attachment from the parental figure if independent behaviors are attempted.

Obsessive-Compulsive Personality Disorder
Definition and Epidemiological Statistics

Individuals with **obsessive-compulsive personality disorder** are very serious and formal and have difficulty expressing emotions. They are overly disciplined, perfectionistic, and preoccupied with rules. They are inflexible about the way in which things must be done and have a devotion to productivity to the exclusion of personal pleasure. An intense fear of making mistakes leads to difficulty with decision-making. The disorder is relatively common and occurs more often in men than in women. Within the family constellation, it appears to be most common in oldest children. Recurrent obsessions and compulsions are absent in this personality disorder; if the client presents with

---

BOX 32–7 Diagnostic Criteria for Dependent Personality Disorder

A pervasive and excessive need to be taken care of that leads to submissive and clinging behavior and fears of separation, beginning by early adulthood and present in a variety of contexts, as indicated by five (or more) of the following:

1. Has difficulty making everyday decisions without an excessive amount of advice and reassurance from others
2. Needs others to assume responsibility for most major areas of his or her life
3. Has difficulty expressing disagreement with others because of fear of loss of support or approval (*Note:* Do not include realistic fears of retribution.)
4. Has difficulty initiating projects or doing things on his or her own (because of a lack of self-confidence in judgment or abilities rather than a lack of motivation or energy)
5. Goes to excessive lengths to obtain nurturance and support from others, to the point of volunteering to do things that are unpleasant
6. Feels uncomfortable or helpless when alone because of exaggerated fears of being unable to care for himself or herself
7. Urgently seeks another relationship as a source of care and support when a close relationship ends
8. Is unrealistically preoccupied with fears of being left to take care of himself or herself

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

such symptoms, they are diagnosed with obsessive-compulsive *disorder* rather than obsessive compulsive *personality* disorder (Sadock et al., 2015). Prevalence is estimated at anywhere from 2 to 8 percent.

Clinical Picture

Individuals with obsessive-compulsive personality disorder are inflexible and lack spontaneity. They are meticulous and work diligently and patiently at tasks that require accuracy and discipline. They are especially concerned with matters of organization and efficiency and tend to be rigid and unbending about rules and procedures.

Social behavior tends to be polite and formal. They are very "rank conscious," a characteristic that is reflected in their contrasting behaviors with "superiors" as opposed to "inferiors." They tend to be very solicitous to and ingratiating with authority figures. With subordinates, however, the compulsive person can become quite autocratic and condemnatory, often appearing pompous and self-righteous.

People with obsessive-compulsive personality disorder typify the "bureaucratic personality," the so-called company man. They see themselves as conscientious, loyal, dependable, and responsible and are contemptuous of people whose behavior they consider frivolous and impulsive. Emotional behavior is considered immature and irresponsible.

Although on the surface these individuals appear to be calm and controlled, underneath this exterior lies a great deal of ambivalence, conflict, and hostility. Individuals with this disorder commonly use the defense mechanism of reaction formation. Not daring to expose their true feelings of defiance and anger, they withhold these feelings so strongly that the opposite feelings come forth. The defenses of isolation, intellectualization, rationalization, and undoing are also commonly evident.

The *DSM-5* diagnostic criteria for obsessive-compulsive personality disorder are presented in Box 32–8.

Predisposing Factors

Genetic vulnerability may be a predisposing factor, since it is noted to occur more frequently in first-degree biological relatives than in the general population (Sadock et al., 2015). In the psychoanalytical view, the individual with obsessive-compulsive personality disorder was reared in an overly controlled environment. These parents expect their children to live up to imposed standards of conduct and condemn them if they do not. Praise for positive behaviors is bestowed on the child with much less frequency than punishment for undesirable behaviors. In this environment, individuals become experts in learning what they must *not* do to avoid punishment and condemnation rather than what they *can* do to achieve attention and praise. They learn to heed rigid restrictions and rules. Positive achievements are expected, taken for granted, and only occasionally acknowledged by their parents, whose comments and judgments are limited to pointing out transgressions and infractions of rules.

Application of the Nursing Process

Borderline Personality Disorder (Background Assessment Data)

Historically, there have been clients who did not classically conform to the standard categories of neuroses or psychoses. The designation "borderline"

BOX 32–8 Diagnostic Criteria for Obsessive-Compulsive Personality Disorder

A pervasive pattern of preoccupation with orderliness, perfectionism, and mental and interpersonal control, at the expense of flexibility, openness, and efficiency, beginning by early adulthood and present in a variety of contexts, as indicated by four (or more) of the following:

1. Is preoccupied with details, rules, lists, order, organization, or schedules to the extent that the major point of the activity is lost
2. Shows perfectionism that interferes with task completion (e.g., is unable to complete a project because his or her own overly strict standards are not met)
3. Is excessively devoted to work and productivity to the exclusion of leisure activities and friendships (not accounted for by obvious economic necessity)
4. Is overconscientious, scrupulous, and inflexible about matters of morality, ethics, or values (not accounted for by cultural or religious identification)
5. Is unable to discard worn-out or worthless objects even when they have no sentimental value
6. Is reluctant to delegate tasks or to work with others unless they submit to exactly his or her way of doing things
7. Adopts a miserly spending style toward both self and others; money is viewed as something to be hoarded for future catastrophes
8. Shows rigidity and stubbornness

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

was introduced to identify clients who seem to fall on the border between the two categories. Other terminology that has been used in an attempt to identify this disorder includes *ambulatory schizophrenia, pseudoneurotic schizophrenia,* and *emotionally unstable personality.* When the term *borderline* was first proposed for inclusion in the third edition of the *DSM,* some psychiatrists feared it might be used as a "wastebasket" diagnosis for difficult-to-treat clients. However, a specific set of criteria, listed in Box 32–9, has been established for diagnosing what has been described as "a consistent and stable course of unstable behavior."

Clinical Picture

Individuals with BPD always seem to be in a state of crisis and have frequent mood swings (although there may also be comorbid bipolar disorder). Their affect is one of extreme intensity, and their behavior reflects frequent changeability, within days, hours, or even minutes. They are sometimes described as "thriving on chaos," since they frequently generate chaos, particularly in interpersonal relationships. Often these individuals exhibit a single, dominant affective tone, such as depression, which may give way periodically to anxious agitation or inappropriate outbursts of anger.

Chronic Depression

Depression is so common in clients with this disorder that before the inclusion of BPD in the *DSM,* many of these clients were diagnosed with depressive disorder. Depression may be rooted in feelings of abandonment by the mother in early childhood (see "Predisposing Factors"). Underlying the depression is a sense of rage that is sporadically turned inward on the self

and externally on the environment. Seldom is the individual aware of the true source of these feelings until well into long-term therapy.

Inability to Be Alone

Because of this chronic fear of abandonment, clients with BPD have little tolerance for being alone. They prefer a frantic search for companionship, no matter how unsatisfactory, to sitting with feelings of loneliness, emptiness, and boredom (Sadock et al., 2015).

Patterns of Interaction

Clinging and Distancing

The client with BPD commonly exhibits a pattern of interaction with others characterized by clinging and distancing behaviors. When clients are clinging to another individual, they may exhibit helpless, dependent, or even childlike behaviors. They want to spend all their time with this person and express a frequent need to talk with and often seek constant reassurance from him or her. Impulsive behaviors, even self-mutilation, may result when they cannot be with this chosen individual. Distancing behaviors are characterized by hostility, anger, and devaluation of others, arising from a feeling of discomfort with closeness. Distancing behaviors also occur in response to separations, confrontations, or attempts to limit certain behaviors. Devaluation of others is manifested by discrediting or undermining their strengths and personal significance.

Splitting

Splitting is a primitive ego defense mechanism common in people with BPD. It arises from their lack of achievement of **object constancy** and is manifested by

---

BOX 32–9 Diagnostic Criteria for Borderline Personality Disorder

A pervasive pattern of instability of interpersonal relationships, self-image, and affects, and marked impulsivity beginning by early adulthood and present in a variety of contexts, as indicated by five (or more) of the following:

1. Frantic efforts to avoid real or imagined abandonment (*Note:* Do not include suicidal or self-mutilating behavior covered in criterion 5.)
2. A pattern of unstable and intense interpersonal relationships characterized by alternating between extremes of idealization and devaluation
3. Identity disturbance: markedly and persistently unstable self-image or sense of self
4. Impulsivity in at least two areas that are potentially self-damaging (e.g., spending, sex, substance abuse, reckless driving, binge eating) (*Note:* Do not include suicidal or self-mutilating behavior covered in criterion 5.)
5. Recurrent suicidal behavior, gestures, or threats, or self-mutilating behavior
6. Affective instability due to marked reactivity of mood (e.g., intense episodic dysphoria, irritability, or anxiety, usually lasting a few hours and only rarely more than a few days)
7. Chronic feelings of emptiness
8. Inappropriate, intense anger or difficulty controlling anger (e.g., frequent displays of temper, constant anger, recurrent physical fights)
9. Transient, stress-related paranoid ideation or severe dissociative symptoms

---

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

an inability to integrate and accept both positive and negative feelings. In their view, people—including themselves—and life situations are either all good or all bad. For example, a nurse-patient relationship may be perceived as very intense and overvalued (e.g., "no one else in the world can help me the way you do") until the individual with BPD feels threatened in any way, the cause of which could be as simple as a perception that the nurse looked at him or her with a different expression or was not immediately available to spend time with the individual. Because this individual also struggles with emotional regulation, suddenly the nurse is devalued, valuing is shifted to another nurse, and the image of the former nurse changes from beneficent caregiver to hateful and cruel persecutor. These shifting allegiances and valuing/devaluing responses can generate conflict, anger, and frustration in staff members (or in any interpersonal relationships) unless this dynamic is clearly understood and managed appropriately.

Manipulation

In their efforts to prevent the separation they so desperately fear, clients with this disorder become masters of manipulation. Virtually any behavior becomes an acceptable means of achieving the desired result: relief from separation anxiety. Playing one individual against another is a common ploy to allay these fears of abandonment.

Self-Destructive Behaviors

Repetitive self-mutilating behaviors are classic manifestations of BPD. About 75 percent of individuals with BPD have a history of at least one deliberate act of self-harm and the prevalence rate for completed suicides is around 9 percent (Lubit, 2016). Although these acts can be fatal, most commonly they are manipulative gestures designed to elicit a rescue response from significant others. Suicide attempts are quite common and result from feelings of abandonment following separation from a significant other. The endeavor is often attempted, however, with a measure of "safety," such as swallowing pills in an area where the person will surely be discovered by others or swallowing pills and making a phone call to report the deed to someone.

Other types of destructive behaviors include cutting, scratching, and burning. Various theories abound regarding why these individuals are able to inflict pain on themselves. One hypothesis suggests they may have higher levels of endorphins in their bodies than most people, thereby increasing their threshold for pain. Another theory relates to the individual's personal identity disturbance. It proposes that since many of the self-mutilating behaviors take place when the individual is in a state of depersonalization and derealization, he or she does not initially feel the pain. The mutilation continues until pain is felt in an attempt to counteract the feelings of unreality. Some clients with BPD have reported that "to feel pain is better than to feel nothing." The pain validates their existence.

Impulsivity

Individuals with BPD have poor impulse control based on primary process functioning. Impulsive behaviors associated with BPD include substance abuse, gambling, promiscuity, reckless driving, and binging and purging. Many times these behaviors occur in response to real or perceived feelings of abandonment.

Predisposing Factors to Borderline Personality Disorder

Biological Influences

BPD, once thought an entirely psychodynamic illness, has been the focus of much current research revealing a wealth of information about the neurobiological underpinnings of this illness. Current research clearly identifies that BPD evolves through a complex interplay of environmental factors, brain anatomy and function, genetics, and epigenetics (Pier et al., 2016).

Biochemical Clients with BPD have a high incidence of major depressive episodes, and antidepressants have demonstrated benefits in some cases (Sadock et al., 2015). This fact and supporting information from brain imaging studies have led to the hypothesis that serotonin and/or norepinephrine dysregulation may contribute to the development of BPD. As stated elsewhere, questions remain about whether these dysfunctions contribute to the development of such disorders or whether they are a neurochemical response to intense emotional states.

Genetic An increased prevalence of major depression and substance use disorders in first-degree relatives of individuals with BPD suggests that there are complex genetic vulnerabilities as well as environmental influences (Sadock et al., 2015). Clients with BPD are five times more likely to have a first-degree relative with BPD, and many studies have shown personality traits such as impulsivity, affect lability, and neuroticism to be heritable (MacIntosh, Godbout, & Dubash, 2015). Epigenetic studies have identified changes to the oxytocin system (related to being a carrier of a specific allele) as associated with negative perceptions of others, increased stress markers, decreased empathy, confidence, and positivity (Pier et al., 2016). Treatment with oxytocin has demonstrated some benefits but requires more research.

Neurobiological Magnetic resonance imaging studies to assess anatomical and functional activities in the brain have identified several factors associated with BPD. Decreases in the volume of the left amygdala and right hippocampus are apparent. The left amygdala,

left hippocampus, and posterior cingulate cortex show heightened activation, and the prefrontal cortex shows decreased activation during the processing of negative emotions (Pier et al., 2016).

Psychosocial Influences

Childhood Trauma Research about specific *types* of trauma that predispose one to the development of BPD is inconsistent, but there is clear and strong evidence that they are linked (MacIntosh et al., 2015). In some instances, this disorder has been likened to posttraumatic stress disorder (PTSD) in response to childhood trauma and abuse. In fact, BPD has been considered a controversial diagnosis because of the many apparent overlaps with PTSD, but, as MacIntosh and associates (2015) cite, other research (Hodges et al., 2013) demonstrates that the complexity of symptoms seen in BPD does not fit with general profiles of PTSD sufferers. Ford and Courtois (2014) cite several studies identifying a 30 to 40 percent comorbidity of PTSD and BPD and indicating that about 85 percent of those diagnosed with BPD were initially diagnosed with PTSD. In these cases, the BPD symptoms persisted after remission of PTSD symptoms. Comorbid substance use disorders may also complicate the differentiation of symptoms and treatment needs. Thorough assessment to identify the multiple psychosocial influences in BPD is clearly essential.

Developmental Factors

Theory of Object Relations According to Mahler's theory of object relations (Mahler et al., 1975), infants pass through six phases from birth to 36 months, when a sense of separateness from the parenting figure is finally established. Between the ages of 16 to 24 months (phase 5, the rapprochement phase), children become acutely aware of their separateness, and because this is frightening, they look to the mother for "emotional refueling" and to maintain a sense of security while at the same time beginning to explore their separateness and independence. (See Table 32–1 for a more detailed outline of Mahler's theory.)

According to object relations theorists, the individual with BPD becomes fixed in the rapprochement phase of development. This occurs when the child shows increasing separation and autonomy. The mother, who feels secure in the relationship as long as the child is dependent, begins to feel threatened by the child's increasing independence. The mother may be experiencing her own fears of abandonment. In response to separation behaviors, the mother withdraws the emotional support or "refueling" that is so vitally needed during this phase for the child to feel secure. Instead, the mother rewards clinging, dependent behaviors and punishes (withholding emotional support) independent behaviors. With his or her sense of emotional survival at stake, the child learns to behave in a manner that satisfies the parental wishes. The child develops an internal conflict based on fear of abandonment. He or she wants to achieve independence common to this stage of development but fears that the mother will withdraw emotional support as a result. This unresolved fear of abandonment remains with the child into adulthood. Unresolved grief for the nurturing they failed to receive results in internalized rage that manifests in the depression so common in people with BPD.

Other research looking at attachment issues in childhood suggest that childhood maltreatment, particularly neglect, may be associated with reactive attachment disorder, which results in the development of neurocognitive deficits, particularly temporal limbic dysfunction; the symptoms of BPD with regard to unhealthy attachment in relationships may be related, at least in part, to these neurocognitive deficits rooted in childhood development disruptions (Minzenberg, Poole, & Vinogradov, 2008; Pier et al., 2016).

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Table 32–2 presents a list of client behaviors and the NANDA-I nursing diagnoses that correspond to these behaviors, which may be used in planning care for clients with BPD.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of clients with BPD.

The client:

- Has not harmed self
- Seeks out staff when desire for self-mutilation is strong
- Is able to identify true source of anger
- Expresses anger appropriately
- Relates to more than one staff member
- Completes activities of daily living independently
- Does not manipulate one staff member against the other in order to fulfill own desires

Planning and Implementation

The following section presents a group of selected nursing diagnoses common to clients with BPD, with short- and long-term goals and nursing interventions for each.

Risk for Self-Mutilation/Risk for Self-Directed or Other-Directed Violence

Risk for self-mutilation is defined as "vulnerable to deliberate self-injurious behavior causing tissue damage with

TABLE 32–2 Assigning Nursing Diagnoses to Behaviors Commonly Associated With Borderline Personality Disorder	
BEHAVIORS	**NURSING DIAGNOSES**
Risk factors: History of self-injurious behavior; history of inability to plan solutions; impulsivity; irresistible urge to damage self; feels threatened with loss of significant relationship	**Risk for self-mutilation**
Risk factors: History of suicide attempts; suicidal ideation; suicidal plan; impulsiveness; childhood abuse; fears of abandonment; internalized rage	**Risk for self-directed violence; Risk for suicide**
Risk factors: Body language (e.g., rigid posture, clenching of fists and jaw, hyperactivity, pacing, breathlessness, threatening stances); history of childhood abuse; impulsivity; transient psychotic symptomatology	**Risk for other-directed violence**
Depression; persistent emotional distress; rumination; separation distress; traumatic distress; verbalizes feeling empty; inappropriate expression of anger	**Complicated grieving**
Alternating clinging and distancing behaviors; staff splitting; manipulation	**Impaired social interaction**
Feelings of depersonalization and derealization	**Disturbed personal identity**
Transient psychotic symptoms (disorganized thinking; misinterpretation of the environment); increased tension; decreased perceptual field	**Anxiety (severe to panic)**
Dependent on others; excessively seeks reassurance; manipulation of others; inability to tolerate being alone	**Chronic low self-esteem**

the intent of causing nonfatal injury to attain relief of tension" (Herdman & Kamitsuru, 2014, p. 414). *Risk for self-directed or other-directed violence* is defined as "vulnerable to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to self or others" (pp. 410–411).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ The client will seek out a staff member if feelings of harming self or others emerge.
■ The client will not harm self or others.

Long-term goal

■ The client will not harm self or others.

Interventions

■ Observe the client's behavior frequently. Do this through routine activities and interactions; avoid appearing watchful and suspicious. Close observation is required so that intervention can occur if required to ensure the client's (and others') safety.
■ Encourage the client to seek out a staff member when the urge for self-mutilation is experienced. Discussing feelings of self-harm with a trusted individual provides some relief to the client. An attitude of acceptance of the client as a worthwhile individual is conveyed.

■ If self-mutilation occurs, care for the client's wounds in a matter-of-fact manner. Do not give positive reinforcement to this behavior by offering sympathy or additional attention. Lack of attention to the maladaptive behavior may decrease repetition of its use.
■ Encourage the client to talk about feelings he or she was having just before this behavior occurred. To problem-solve the situation with the client, knowledge of the precipitating factors is important.
■ Act as a role model for the appropriate expression of angry feelings, and give positive reinforcement to the client when attempts to appropriately express anger are made. It is vital that the client expresses angry feelings because suicide and other self-destructive behaviors are often viewed as a result of anger turned inward on the self.
■ Remove all dangerous objects from the client's environment so that he or she may not purposefully or inadvertently use them to inflict harm to self or others.
■ Try to redirect violent behavior with physical outlets for the client's anxiety (e.g., punching bag, jogging). Physical exercise is a safe and effective way of relieving pent-up tension.
■ Have sufficient staff available to indicate a show of strength to the client if it becomes necessary. This conveys to the client evidence of control over the situation and provides some physical security for staff.
■ Administer tranquilizing medications as ordered by the physician, or obtain an order if necessary.

Monitor the client for effectiveness of the medication and for the appearance of adverse side effects. Some patients show disinhibition with this class of drugs (Sadock et al., 2015). Tranquilizing medications such as anxiolytics or antipsychotics may have a calming effect on the client and thus prevent aggressive behaviors.

■ If the client is not calmed by "talking down" or by medication, use of mechanical restraints may be necessary. The avenue of the "least restrictive alternative" must be selected when planning interventions for a violent client. Restraints should be used only as a last resort, after all other interventions have been unsuccessful, and the client is clearly at risk of harm to self or others. Trauma-informed care should always be the foundation for decisions about appropriate intervention.

■ If restraint is deemed necessary, ensure that sufficient staff is available to assist. Follow protocol established by the institution. As agitation decreases, assess the client's readiness for restraint removal or reduction. Remove one restraint at a time while assessing the client's response. This minimizes the risk of injury to client and staff.

■ If warranted by high acuity of the situation, staff may need to be assigned on a one-to-one basis. Because of their extreme fear of abandonment, clients with BPD should not be left alone at a stressful time, as it may cause an acute rise in anxiety and agitation levels.

Complicated Grieving

Complicated grieving is defined as "a disorder that occurs after the death of a significant other [or any other loss of significance to the individual], in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment" (Herdman & Kamitsuru, p. 339). Table 32–3 presents this nursing diagnosis in care plan format.

Table 32–3 | CARE PLAN FOR THE CLIENT WITH BORDERLINE PERSONALITY DISORDER

NURSING DIAGNOSIS: COMPLICATED GRIEVING

RELATED TO: Maternal deprivation during rapprochement phase of development (internalized as a loss, with fixation in anger stage of grieving process); possible childhood physical or sexual abuse

EVIDENCED BY: Depressed mood, acting-out behaviors

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Within 5 days, the client discusses with nurse or therapist maladaptive patterns of expressing anger. Long-Term Goal • By time of discharge from treatment, the client is able to identify the true source of angry feelings, accept ownership of these feelings, and express them in a socially acceptable manner, in an effort to satisfactorily progress through the grieving process.	1. Convey an accepting attitude—one that creates a nonthreatening environment for client to express feelings. Be honest and keep all promises. 2. Identify the function that anger, frustration, and rage serve for client. Allow him or her to express these feelings within reason. 3. Encourage client to discharge pent-up anger through participation in large motor activities (e.g., brisk walks, jogging, physical exercises, volleyball, punching bag, exercise bike). 4. Explore with client the true source of the anger. This is a painful therapy that often leads to regression as client deals with the feelings of early abandonment or issues of abuse.	1. An accepting attitude conveys to client that you believe he or she is a worthwhile person. Trust is enhanced. 2. Verbalization of feelings in a nonthreatening environment may help client come to terms with unresolved issues. 3. Physical exercise provides a safe and effective method for discharging pent-up tension. 4. Reconciliation of the feelings associated with this stage is necessary before progression through the grieving process can continue.

Table 32–3 | CARE PLAN FOR THE CLIENT WITH BORDERLINE PERSONALITY DISORDER—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	5. As anger is displaced onto the nurse or therapist, caution must be taken to guard against the negative effects of countertransference. These are very difficult clients who have the capacity for eliciting a whole array of negative feelings from the therapist.	5. The existence of negative feelings by the nurse or therapist must be acknowledged, but they must not be allowed to interfere with the therapeutic process.
	6. Explain the behaviors associated with the normal grieving process. Help client recognize his or her position in this process.	6. Knowledge of the acceptability of the feelings associated with normal grieving may help to relieve some of the guilt that these responses generate.
	7. Help client understand appropriate ways to express anger. Give positive reinforcement for behaviors used to express anger appropriately. Act as a role model. It is important to let client know when he or she has done something that has generated angry feelings in you.	7. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors. Role-modeling ways to express anger in an appropriate manner is a powerful learning tool.
	8. Set limits on acting-out behaviors and explain consequences of violation of those limits. Be supportive, yet consistent and firm, in caring for this client.	8. Client lacks sufficient self-control to limit maladaptive behaviors, so assistance is required. Without consistency on the part of all staff members working with this client, a positive outcome will not be achieved.

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Within 5 days, the client will discuss with nurse or therapist maladaptive patterns of expressing anger.

Long-term goal

■ By the time of discharge from treatment, the client will be able to identify the true source of angry feelings, accept ownership of these feelings, and express them in a socially acceptable manner, in an effort to satisfactorily progress through the grieving process.

Interventions

■ Convey an accepting attitude—one that creates a nonthreatening environment for the client to express feelings. Be honest and keep all promises. An accepting attitude conveys to the client that you believe he or she is a worthwhile person. Trust is enhanced.

■ Identify the function that anger, frustration, and rage serve for the client. Allow him or her to express these feelings within reason. Verbalization of feelings in a nonthreatening environment may help the client come to terms with unresolved issues.

■ Encourage the client to discharge pent-up anger through participation in large motor activities (e.g., brisk walks, jogging, physical exercises, volleyball, punching bag, exercise bike). Physical exercise provides a safe and effective method for discharging pent-up tension.

■ Explore with the client the true source of anger. This is painful therapy that often leads to regression as the client deals with feelings of early abandonment

or abuse. It seems that sometimes the client must "get worse before he or she can get better." Reconciliation of the feelings associated with this stage is necessary before progression through the grieving process can continue.

■ As anger is displaced onto the nurse or therapist, caution must be taken to guard against the negative effects of countertransference. These behaviors have the capacity to elicit an array of negative feelings from the caregiver. The existence of negative feelings by the nurse or therapist must be acknowledged but must not be allowed to interfere with the therapeutic process.

■ Explain the behaviors associated with the normal grieving process. Help the client recognize his or her position in this process. Knowledge of the acceptability of the feelings associated with normal grieving may help to relieve some of the guilt that these responses generate.

■ Help the client understand appropriate ways of expressing anger. Give positive reinforcement for behaviors used to express anger appropriately. Act as a role model. It is appropriate to let the client know when he or she has done something that has generated angry feelings in you. Role-modeling ways to express anger in an appropriate manner is a powerful learning tool.

■ Clearly identify expected behaviors within the milieu and set limits on behaviors that are in violation of stated expectations with clearly stated consequences. For example, the nurse states clearly to the patient on admission that physical contact among patients is not permitted. When the patient is noticed putting her arm around a male patient, the nurse clarifies the limit, indicates that this is not acceptable behavior, and communicates that if the behavior continues, the patient will not be permitted to continue participating in the current activity. Be supportive, yet consistent and firm, in caring for this client. The client lacks sufficient self-control to limit maladaptive behaviors, so assistance is required. Without consistency on the part of all staff members working with this client, a positive outcome will not be achieved.

Impaired Social Interaction

Impaired social interaction is defined as "insufficient or excessive quantity or ineffective quality of social exchange" (Herdman & Kamitsuru, 2014, p. 301).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goal

■ Within 5 days, the client will discuss with the nurse or therapist behaviors that impede the development of satisfactory interpersonal relationships.

Long-term goal

■ By the time of discharge from treatment, the client will interact appropriately with others in the therapy setting in both social and therapeutic activities (evidencing a discontinuation of splitting and clinging and distancing behaviors).

Interventions

■ Encourage the client to examine these behaviors and associated feelings (to recognize that they are occurring). He or she may be unaware of splitting or of clinging and distancing patterns of interaction with others. Recognition must take place before change can occur. For example, when a client begins to recognize that he or she feels less anxious when engaging in disruptive behaviors, a foundation is laid for exploring healthier strategies for anxiety reduction.

■ Help the client understand that you will be available, without reinforcing dependent behaviors. Knowledge of your availability may provide needed security.

■ Rotate staff members who work with the client to avoid the development of dependence on particular individuals. The client must learn to relate to more than one staff member in an effort to decrease the use of splitting and diminish fears of abandonment. Communication and consistency among the staff team members in adherence to the established plan of care is essential to minimize opportunities for the client to successfully manipulate or split staff members.

■ With the client, explore feelings that relate to fears of abandonment and engulfment. Help him or her understand that clinging and distancing behaviors are engendered by these fears. Exploration of feelings with a trusted individual may help the client come to terms with unresolved issues.

■ Help the client understand how these behaviors interfere with satisfactory relationships. He or she may be unaware of how others perceive these behaviors and why they are not acceptable.

■ Help the client work toward achievement of object constancy. Be available without promoting dependency. Give positive reinforcement for independent behaviors. The client must resolve fears of abandonment to establish satisfactory intimate relationships.

■ Provide education, support, and referral resources for family members and significant others who may also experience anger and frustration at failed attempts to navigate interpersonal relationships with the client. Research has shown that family members of these clients often report feeling excluded and discriminated against by health-care providers (Lawn, Diped, & McMahon, 2015).

Concept Care Mapping

The concept map care plan is an innovative approach to planning and organizing nursing care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing). It is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with BPD is presented in Figure 32–1.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client with BPD may be facilitated by gathering information using the following types of questions:

- Has the client been able to seek out staff when feeling the desire for self-harm?
- Has the client avoided self-harm?
- Can the client correlate times of desire for self-harm to times of elevation in level of anxiety?
- Can the client discuss feelings with staff (particularly feelings of depression and anger)?
- Can the client identify the true source toward which the anger is directed?
- Can the client verbalize understanding of the basis for his or her anger?
- Can the client express anger appropriately?
- Can the client function independently?
- Can the client relate to more than one staff member?
- Can the client verbalize the knowledge that the staff members will return and are not abandoning him or her when leaving for the day?
- Can the client separate from the staff in an appropriate manner?
- Can the client delay gratification and refrain from manipulating others in order to fulfill own desires?
- Can the client verbalize resources within the community from whom he or she may seek assistance in times of extreme stress?

NOTE: The client with BPD is at high risk for stigmatization, even among health-care professionals (Black, Pfhol, & Blum, 2011; McNee, Donogue, & Coppola, 2014; Weight & Kendal, 2013; Westwood & Baker, 2010). Client behaviors such as manipulating, lying, and splitting violate the nurse's sense of success in establishing a trusting relationship with this individual and may culminate in negative or distancing behaviors from the nurse. The following guidelines are helpful in decreasing negative attitudes and stigmatization of this client:

- Understand the disorder and the impact of childhood trauma on the dynamics of the client's behavior to develop an approach of compassion and convey hopefulness that this is a treatable condition.
- Recognize that even brief encounters with a client during short hospital stays provide an opportunity to convey connectedness and a sense that they are valued. This is particularly important since the client with BPD is interpersonally hypersensitive, fears abandonment, and has had a history of instability in interpersonal relationships (Helleman et al., 2014).
- Frequently reflect on your feelings in response to client behavior. For example, self-harming behaviors by the client frequently generate feelings of anger and frustration in nurses when the behavior seems to be manipulative rather than a sign of true distress. These feelings may culminate in the nurse distancing themselves from the client (Westwood & Baker, 2010). Indeed, self-harming behaviors may be used as a tool for manipulating others *and* they are a sign of true distress.
- Develop a clear model of communication and intervention among team members for the hospitalized client with BPD. Consistency in intervention helps to model healthy interpersonal skills for the client and may minimize successful efforts at splitting staff members. In addition, when health-care team members develop strong communication skills with each other, it provides a foundation for discussing and confronting negative attitudes toward the client and promotes culture change. For example, McNee and associates (2014) developed a commitment among team members that they would avoid using phrases like "acting out" or "attention-seeking" since these reinforced a culture of negativity toward the client.

Antisocial Personality Disorder (Background Assessment Data)

In the *DSM-I,* antisocial behavior was categorized as a "sociopathic or psychopathic" reaction that could be symptomatic of any of several underlying personality disorders. The *DSM-II* represented it as a separate personality type, a distinction that has been retained in

Clinical Vignette: Clara, age 37, was diagnosed with Borderline Personality Disorder when she was 22 years old. She has had counseling with the same therapist since the initial diagnosis. She suffers from chronic depression and unstable personality. Two days ago, at her regular counseling session, the therapist told Clara that in 1 month she was getting married and would be moving across the country with her new husband. She told Clara that she would help her find a new therapist. Clara became hysterical and shouted, "You can't leave me! I don't want another therapist!" That evening, Clara's husband, Bill, found her sitting in a pool of blood in the bathroom, having sliced the back of both calves with a razor blade. Bill took Clara to the hospital where she is well known by the staff. Her wounds were treated in the emergency department, and she was transferred to the psychiatric unit. She clings to the admitting nurse saying, "Please don't leave. You're the best nurse here. You're the only one I can talk to." The nurse develops the following concept map care plan for Clara.

Signs and Symptoms

Risk factor:
• Unresolved fears of abandonment

Signs and Symptoms

• Depressed mood
• Acting-out behaviors

Signs and Symptoms

• Clinging and distancing behaviors
• Staff splitting

Nursing Diagnosis

Risk for self-mutilation

Nursing Diagnosis

Complicated grieving

Nursing Diagnosis

Impaired social interaction

Nursing Actions

• Observe client's behavior frequently.
• Secure verbal no-harm contract from client.
• Care for wounds matter-of-factly.
• Encourage verbalization of feelings.
• Make environment safe.
• Act as role model.

Nursing Actions

• Create trusting relationship.
• Encourage appropriate expression of anger.
• Explore true source of anger.
• Teach stages of grief.
• Set limits on acting-out behavior.
• Give positive feedback.

Nursing Actions

• Examine inappropriate behaviors.
• Encourage independence and give positive reinforcement.
• Explore fears.
• Explain inappropriateness of these behaviors.
• Rotate staff.

Medical Rx:
Olanzapine 5 mg bid
Fluoxetine 20 mg daily

Outcomes

• Client has not harmed self
• Seeks out staff when desire for self-mutilation occurs

Outcomes

• Client expresses anger appropriately
• Understands stages of grief and the need for personal progression through this process

Outcomes

• Relates to more than one staff member
• Completes ADLs independently
• Does not manipulate staff against each other

FIGURE 32–1 Concept map care plan for a client with borderline personality disorder.

subsequent editions. The *DSM-5* diagnostic criteria for antisocial personality disorder are presented in Box 32–10.

Individuals with antisocial personality disorder are seldom seen in most clinical settings, and when they are, it is commonly a way to avoid legal consequences. Sometimes they are admitted to the health-care system by court order for psychological evaluation. Most frequently, however, these individuals are encountered in prisons, jails, and rehabilitation services.

Although the *DSM-5* continues to identify antisocial personality disorder as synonymous with psychopathy, recent evidence is beginning to distinguish these as separate entities (Anderson et al., 2014; APA, 2013; Thompson et al., 2014; Verona & Patrick, 2015). Antisocial personality disorder as a distinct

BOX 32–10 Diagnostic Criteria for Antisocial Personality Disorder

A. A pervasive pattern of disregard for and violation of the rights of others occurring since age 15 years, as indicated by three (or more) of the following:
  1. Failure to conform to social norms with respect to lawful behaviors as indicated by repeatedly performing acts that are grounds for arrest
  2. Deceitfulness, as indicated by repeated lying, use of aliases, or conning others for personal profit or pleasure
  3. Impulsivity or failure to plan ahead
  4. Irritability and aggressiveness, as indicated by repeated physical fights or assaults
  5. Reckless disregard for safety of self or others
  6. Consistent irresponsibility, as indicated by repeated failure to sustain consistent work behavior or honor financial obligations
  7. Lack of remorse, as indicated by being indifferent to or rationalizing having hurt, mistreated, or stolen from another
B. Individual is at least 18 years.
C. There is evidence of conduct disorder with onset before age 15 years.
D. The occurrence of antisocial behavior is not exclusively during the course of schizophrenia or bipolar disorder.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

entity is identified as characterized by *behaviors* that are reactive to perceived threats, control, and a negative affect; psychopathy is described as *personality traits* that include low fear, low empathy, domination, callous cruelty, and emotional insensitivity (Thompson et al, 2014; Verona & Patrick, 2015). Those with either diagnosis may be considered prone to violence, but with different etiologies and potentially different responses in treatment. For the purpose of this text, they are discussed together as antisocial personality disorder.

Clinical Picture

Antisocial personality disorder is a pattern of socially irresponsible, exploitative, and guiltless behavior that reflects a general disregard for the rights of others. Individuals with antisocial personality disorder exploit and manipulate others for personal gain and are unconcerned with obeying the law. They have difficulty sustaining consistent employment and developing stable relationships. They appear cold and callous, often intimidating others with their brusque and belligerent manner. They tend to be argumentative and, at times, cruel and malicious. They lack warmth and compassion and are often suspicious of these qualities in others.

Individuals with antisocial personality have a very low tolerance for frustration, act impulsively, and are unable to delay gratification. They are restless and easily bored, often taking chances and seeking thrills as if they were immune to danger. Their pattern of impulsivity may be manifested in failure to plan ahead culminating in sudden job, residence, or relationship changes (APA, 2013).

When things go their way, individuals with this disorder act cheerful, even gracious and charming. But because of their low tolerance for frustration, this pleasant exterior can change very quickly. When momentary desires are challenged, they are likely to become furious and vindictive. Easily provoked to attack, their first inclination is to demean and dominate. They believe that "good guys finish last," and they show contempt for the weak and underprivileged. They exploit others to fulfill their own desires, showing no trace of shame or guilt for their behavior.

Individuals with antisocial personalities see themselves as victims, using projection, devaluing, and denial as primary ego defense mechanisms. They do not accept responsibility for the consequences of their behavior. Instead, the perception of victimization by others justifies their malicious behavior, lest they be the recipient of unjust persecution and hostility from others. Physical attacks or other acts of aggression are not uncommon.

Satisfying interpersonal relationships are not possible because individuals with antisocial personalities have learned to trust only themselves. They have a philosophy that "it's every man for himself" and that one should stop at nothing to avoid being manipulated by others. They may disregard their safety and that of others through reckless sexual activity, substance use, reckless driving, or child neglect (APA, 2013).

One of the most distinctive characteristics of individuals with antisocial personality is their tendency to ignore conventional authority and rules. They act as though established social norms and guidelines for self-discipline and cooperative behavior do not apply to them. They are flagrant in their disrespect for the law and for the rights of others.

Predisposing Factors to Antisocial Personality Disorder

Biological Influences

Antisocial personality is more common among first-degree biological relatives of those with the disorder

than among the general population. Twin and adoptive studies have implicated the role of genetics in antisocial personality disorder, especially for the personality traits of callousness and unemotional responses, which may be more definitive of psychopathy (Thompson et al., 2014). Interestingly, other antisocial behaviors among twins seemed to be more environmentally influenced, so based on current evidence, this is a complex disorder with both genetic and environmental influences. Recent research has suggested that a particular gene, *MAOA,* may be moderated after exposure to violence such as child maltreatment, physical abuse, or sexual abuse (Oullett-Morin et al., 2016). Moderation of this gene is believed to be associated with the eventual development of differential features of antisocial personality, although the authors note that more research is needed. Nonetheless, it lends support to the idea that a complex interaction of genetics and environment is involved in the development of antisocial personality disorder.

Characteristics associated with temperament in the newborn may be significant in the predisposition to antisocial personality disorder. Parents who bring children with behavior disorders to clinics often report that the child displayed temper tantrums from infancy and would become furious when awaiting a bottle or a diaper change. As these children mature, they commonly develop a bullying attitude toward other children. Parents report that they are undaunted by punishment and generally quite unmanageable.

The likelihood of developing antisocial personality disorder is increased if the individual had attention-deficit/hyperactivity disorder and conduct disorder as a child (APA, 2013). Other brain imaging studies have identified deficits in prefrontal cortex gray matter, which regulates cognitive control and inhibition, and decreased activity in the amygdala, which is responsible for modulating fearful or threatening stimuli. Still other studies have identified dysregulation of neurotransmitters (dopamine and serotonin), and endocrine abnormalities (testosterone and cortisol) in individuals with antisocial personality disorder, which may be related to the symptoms of impulsivity (Thompson et al., 2014). Neuropsychological studies have demonstrated an increased reactivity to environmental irritants and cues that may be triggers for disinhibition (Verona & Patrick, 2015).

Family Dynamics

Antisocial personality disorder frequently arises from a chaotic home environment. Parental deprivation during the first 5 years of life appears to be a critical predisposing factor in the development of antisocial personality disorder. Separation due to parental delinquency appears to be more highly correlated with the disorder than is parental loss from other causes.

Studies have shown that antisocial personality disorder in adulthood is highly associated with physical abuse and neglect, teasing, and lack of parental bonding in childhood (Krastins et al., 2014; Kolla et al., 2013). Severe physical abuse was particularly correlated to violent offending, triggering the development of a pattern of reactive aggression that is persistent over one's lifetime (Kolla et al., 2013). The abuse also contributes to the development of antisocial behavior in that it provides a model for behavior and may result in injury to the child's central nervous system, thereby impairing the child's ability to function appropriately. Although a diagnosis of antisocial personality disorder is only made when the client is at least 18 years old, these behavioral patterns are often seen earlier in childhood and adolescence. When they are identified in children and adolescents, the diagnosis is *conduct disorder,* and the common symptoms are bullying, fighting, physical cruelty to animals, destruction of property and theft, and others (APA, 2013). Whether better identification and early intervention might prevent more dangerous behavior in adulthood is yet to be determined through ongoing research.

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Table 32–4 presents a list of client behaviors and the NANDA-I nursing diagnoses that correspond to those behaviors, which may be used in planning care for clients with antisocial personality disorder.

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the client with antisocial personality disorder.

The client:

- Discusses angry feelings with staff and in group sessions
- Has not harmed self or others
- Can rechannel hostility into socially acceptable behaviors
- Follows rules and regulations of the therapy environment
- Can verbalize which of his or her behaviors are not acceptable
- Shows regard for the rights of others by delaying gratification of own desires when appropriate

TABLE 32–4 Assigning Nursing Diagnoses to Behaviors Commonly Associated With Antisocial Personality Disorder	
BEHAVIORS	**NURSING DIAGNOSES**
Risk factors: Body language (e.g., rigid posture, clenching of fists and jaw, hyperactivity, pacing, breathlessness, threatening stances); cruelty to animals; rage reactions; history of childhood abuse; history of violence against others; impulsivity; substance abuse; negative role-modeling; inability to tolerate frustration	Risk for other-directed violence
Disregard for societal norms and laws; absence of guilty feelings; inability to delay gratification; denial of obvious problems; grandiosity; hostile laughter; projection of blame and responsibility; ridicule of others; superior attitude toward others	Defensive coping
Manipulation of others to fulfill own desires; inability to form close, personal relationships; frequent lack of success in life events; passive-aggressiveness; overt aggressiveness (hiding feelings of low self-esteem)	Chronic low self-esteem
Inability to form a satisfactory, enduring, intimate relationship with another; dysfunctional interaction with others; use of unsuccessful social interaction behaviors	Impaired social interaction
Demonstration of inability to take responsibility for meeting basic health practices; history of lack of health-seeking behavior; demonstrated lack of knowledge regarding basic health practices; lack of expressed interest in improving health behaviors	Ineffective health maintenance

■ Does not manipulate others in an attempt to increase feelings of self-worth
■ Verbalizes understanding of knowledge required to maintain basic health needs

Planning and Implementation

The following section presents a group of selected nursing diagnoses common to clients with antisocial personality disorder, with short- and long-term goals and nursing interventions for each.

Risk for Other-Directed Violence

Risk for other-directed violence is defined as "vulnerable to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to others" (Herdman & Kamitsuru, 2014, p. 410).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ Within 3 days, the client will discuss angry feelings and situations that precipitate hostility.
■ The client will not harm others.

Long-term goal

■ The client will not harm others.

Interventions

■ Convey an accepting attitude toward this client. Feelings of rejection are undoubtedly familiar to him or her. Work on development of trust. Be honest, keep all promises, and convey the message to the client that it is not *him* or *her* but the *behavior* that is unacceptable. An attitude of acceptance promotes feelings of self-worth. Trust is the basis of a therapeutic relationship. Be alert, however, to the tendency of this client to manipulate others. Do not misconstrue charm or compliments as indicative of mutual trust. Maintaining clear, professional boundaries is essential.
■ Maintain a low level of stimuli in the client's environment (low lighting, few people, simple decor, low noise level). A stimulating environment may increase agitation and promote aggressive behavior.
■ Observe the client's behavior frequently through routine activities and interactions; avoid appearing watchful and suspicious. Close observation is required so that intervention can occur if needed to ensure the client's (and others') safety.
■ Remove all dangerous objects from the client's environment so that he or she may not purposefully or inadvertently use them to inflict harm to self or others.
■ Help the client identify the true object of his or her hostility (e.g., "You seem to be upset with . . ."). Because of weak ego development, the client may misuse the defense mechanism of displacement. Helping him or her recognize this in a nonthreatening manner may help reveal unresolved issues so that they may be confronted.
■ Encourage the client to gradually verbalize hostile feelings. Verbalization of feelings in a nonthreatening environment may help the client come to terms with unresolved issues.

■ Explore with the client alternative ways of handling frustration (e.g., large motor skills that channel hostile energy into socially acceptable behavior). Physically demanding activities help to relieve pent-up tension.

■ The staff should maintain and convey a calm attitude toward the client. Anxiety is contagious and can be transferred from staff to client. A calm attitude provides the client with a feeling of safety and security.

■ Have sufficient staff available to present a show of strength to the client if necessary. This conveys to the client evidence of control over the situation and provides some physical security for the staff.

■ Administer tranquilizing medications as ordered by the physician or obtain an order if necessary. Monitor the client for effectiveness of the medication as well as for appearance of adverse side effects. Antianxiety agents (e.g., lorazepam, chlordiazepoxide, oxazepam) produce a calming effect and may help to allay hostile behaviors. (NOTE: Medications are not often prescribed for clients with antisocial personality disorder because of these individuals' strong susceptibility to addictions.)

■ If the client is not calmed by "talking down" or by medication, use of mechanical restraints may be necessary. The avenue of the "least restrictive alternative" must be selected when planning interventions for a violent client. Restraints should be used only as a last resort, after all other interventions have been unsuccessful, and when the client is clearly at risk of harm to self or others.

■ If restraint is deemed necessary, ensure that sufficient staff is available to assist. Follow protocol established by the institution.

■ As agitation decreases, assess the client's readiness for restraint removal or reduction. Remove one restraint at a time while assessing the client's response. This minimizes the risk of injury to client and staff.

Defensive Coping

Defensive coping is defined as "repeated projection of falsely positive self-evaluation based on a self-protective pattern that defends against underlying perceived threats to positive self-regard" (Herdman & Kamitsuru, 2014, p. 324).

Client Goals

Outcome criteria include short- and long-term goals. Time lines are individually determined.

Short-term goals

■ Within 24 hours after admission, the client will verbalize understanding of treatment setting rules and regulations and the consequences for violation.

■ The client will verbalize personal responsibility for difficulties experienced in interpersonal relationships within (time period reasonable for client).

Long-term goals

■ By the time of discharge from treatment, the client will be able to cope more adaptively by delaying gratification of own desires and following rules and regulations of the treatment setting.

■ By the time of discharge from treatment, the client will demonstrate ability to interact with others without becoming defensive, rationalizing behaviors, or expressing grandiose ideas.

Interventions

■ From the onset, the client should be made aware of which behaviors are acceptable and which are not. Explain consequences of violation of the limits. A consequence must involve something of value to the client. All staff must be consistent in enforcing these limits. Consequences should be administered in a matter-of-fact manner immediately following the infraction. Because the client cannot (or will not) impose own limits on maladaptive behaviors, these behaviors must be delineated and enforced by staff. Undesirable consequences may help to decrease repetition of these behaviors.

■ The ideal goal would be for this client to eventually internalize societal norms, beginning with a step-by-step, "either/or" approach on the unit (*either* you do [don't do] this, *or* this will occur). Explanations must be concise, concrete, and clear, with little or no capacity for misinterpretation.

> **CLINICAL PEARL**
>
> Do not attempt to coax or convince the client to do the "right thing." Do not use the words "You should (or shouldn't) . . ."; instead, use the words "You will be expected to. . . ."

■ Provide positive feedback or reward for acceptable behaviors. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors.

■ In an attempt to assist the client to delay gratification, increase the length of time requirement for acceptable behavior in order to achieve the reward. For example, 2 hours of acceptable behavior may be exchanged for a phone call; 4 hours of acceptable behavior for 2 hours of television; 1 day of acceptable behavior for a recreational therapy bowling activity; 5 days of acceptable behavior for a weekend pass.

■ A milieu unit provides the appropriate environment for the client with antisocial personality. The

democratic approach, with specific rules and regulations, community meetings, and group therapy sessions, emulates the type of societal situation in which the client must learn to live. Feedback from peers is often more effective than confrontation from an authority figure. The client learns to follow the rules of the group as a positive step in the progression toward internalizing the rules of society.

■ Help the client gain insight into his or her own behavior. Often, these individuals deny that their behavior is inappropriate. For example, rationalizing may be reflected in statements such as, "The owner of this store has so much money, he'll never miss the little bit I take. He has everything, and I have nothing. It's not fair! I deserve to have some of what he has." The client must come to understand that certain behaviors will not be tolerated within society and that severe consequences are imposed on those individuals who refuse to comply. The client must *want* to change behavior before he or she can be helped. One of the difficulties posed in interventions for personality disorders is that often the behaviors are ego-syntonic; in other words, the client may not perceive these behaviors as requiring change.

■ Talk about past behaviors with the client. Discuss which are acceptable by societal norms and which are not. Help the client identify ways in which he or she has exploited others and the benefits versus consequences of previous behavior. Explore the client's insight into feelings associated with his or her behavior. An attempt may be made to enlighten the client to the sensitivity of others by promoting self-awareness in an effort to help the client gain insight into his or her own behavior.

■ Throughout the relationship with the client, maintain an attitude of "It is not *you*, but *your behavior*, that is unacceptable." An attitude of acceptance promotes feelings of dignity and self-worth.

Concept Care Mapping

The concept map care plan care (see Chapter 9) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with antisocial personality disorder is presented in Figure 32–2.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the client with antisocial personality disorder may be facilitated by gathering information using the following types of questions:

■ Does the client recognize when anger is getting out of control?
■ Can the client seek out staff instead of expressing anger in an inappropriate manner?
■ Can the client use other sources for rechanneling anger (e.g., physical activities)?
■ Has harm to others been avoided?
■ Can the client follow rules and regulations of the therapeutic milieu with little or no reminding?
■ Can the client verbalize which behaviors are appropriate and which are not?
■ Does the client express a desire to change?
■ Can the client delay gratification of own desires in deference to those of others when appropriate?
■ Does the client refrain from manipulating others to fulfill own desires?
■ Does the client fulfill activities of daily living willingly and independently?
■ Can the client verbalize methods of achieving and maintaining optimal wellness?
■ Can the client verbalize community resources from which he or she can seek assistance with daily living and health-care needs when required?

Treatment Modalities

Few would argue that treatment of individuals with personality disorders is difficult and may even seem impossible. Personality characteristics are learned very early in life and may be genetically influenced. Many of the symptoms of a personality disorder are viewed by the individual as ego-syntonic, so there may be little motivation to seek treatment or to explore change. It is not surprising, then, that these enduring patterns of behavior may take years to change, if change occurs. The main treatment modalities for personality disorders are psychosocial and pharmacological, but most of the available evidence comes from studies of borderline and antisocial personality disorders.

Comorbid conditions are common in most personality disorders, and there is evidence that treating these conditions may have positive outcomes. For example, Hatchett (2015) identifies that, in a review of the literature, psychosocial interventions for clients with antisocial personality disorder lack both treatment efficacy and clinical utility; however, treatment of comorbid substance use disorder has demonstrated positive outcomes. Further, when individuals with antisocial personality disorder have comorbid depression, they are more likely to persevere with treatment. This may be related to the fact that symptoms

Clinical Vignette: Hank, age 32, is the oldest of five children of a single mother, each of whom had a different father. He was physically abused by his mother's boyfriends, did not attend school regularly, and eventually dropped out in 10th grade. He has a history of violence, always carries a weapon (gun or knife) on his person, and threatens to use it if he is challenged in his attempts to fulfill his own desires. He has had numerous skirmishes with the law: shoplifting, auto theft, possession and sale of heroin and cocaine, and, most recently, armed robbery of a liquor store. He was identified by his image on the store's surveillance camera. Because of his long history of criminal behavior, the judge has ordered that Hank undergo psychological testing before he is sentenced. On the psychiatric unit, he says to the nurse, "Why am I here? I'm not crazy! And I've never hurt anybody! I don't belong in this loony bin!" The nurse develops the following concept map care plan for Hank.

Signs and Symptoms

Risk factors:
- Rage reactions
- Negative role modeling
- History of violence

Signs and Symptoms
- Disregard for societal norms and laws
- Absence of guilt
- Inability to delay gratification

Nursing Diagnosis

Risk for other-directed violence

Nursing Diagnosis

Defensive coping

Nursing Actions
- Provide unconditional acceptance.
- Keep environmental stimuli low.
- Observe behavior routinely.
- Make environment safe.
- Explore true object of anger.
- Gradually encourage appropriate expression of anger.
- Provide show of strength, if necessary.
- Give meds as ordered.
- Restrain if required.

Nursing Actions
- Explain acceptable behaviors and consequences of violation.
- Explain clearly what is expected of client.
- Provide positive feedback and rewards for acceptable behaviors.
- Provide milieu environment.
- Promote insight development.
- Maintain attitude of acceptance.

Medical Rx:
Lorazepam 2 mg
q 6h prn for agitation

Outcomes
- Client has not harmed self or others
- Discusses angry feelings with staff
- Engages in physical exercise to rechannel hostile feelings

Outcomes
- Demonstrates socially acceptable behavior on the unit
- Is able to delay personal gratification
- Does not manipulate others for own desires

FIGURE 32–2   Concept map care plan for a client with antisocial personality disorder.

of depression are considered undesirable (not ego-syntonic) and therefore may promote interest in improvement. He notes that this review should not be interpreted as meaning that a client's personality disorder is untreatable. Instead, Hatchett cites the conclusion of Skeem and associates (2011) that this client should be identified as "high risk" and requiring intensive treatment to maximize public safety.

Whereas Hatchett (2015) reviewed the literature specifically related to treatment for antisocial personality disorders, other literature reviews identify that, for personality disorders in general, there is strong evidence of the effectiveness of psychotherapeutic interventions (Papaioannou, Brazier, & Parry, 2013, Stoffers et al., 2012); again, the bulk of research focuses on borderline and antisocial personality disorders

(Bateman, 2014). Still other researchers identify that treatment focused on tackling the defense mechanisms associated with each personality disorder may be a more effective way to mediate improvement (Perry, Presniak, & Olson, 2013). For example, therapy focused on exploring the dissociation common in patients with BPD or exploring the defense mechanism of devaluing others, as seen in clients with antisocial personality, may promote overall improvement in symptoms. There is general agreement that all treatment modalities for personality disorders require intensive long-term plans of care. Selection of intervention is generally based on the area of greatest dysfunction, such as cognition, affect, behavior, or interpersonal relations. Following is a brief description of various types of therapies and the disorders to which they are customarily suited.

Individual Psychotherapy

Depending on the therapeutic goals, psychotherapy with personality disorders may be time-limited interpersonal psychotherapy or may involve long-term psychoanalytic therapy. Interpersonal psychotherapy may be particularly appropriate because personality disorders largely reflect problems in interpersonal relationship skills.

Long-term psychotherapy attempts to understand and modify the maladjusted behaviors, cognition, and affects of clients with personality disorders that dominate their personal lives and relationships.

Milieu or Group Therapy

This treatment is especially appropriate for individuals with antisocial personality disorder, who respond more adaptively to support and feedback from peers. In milieu or group therapy, feedback from peers is more effective than one-to-one interaction with a therapist.

Group therapy—particularly homogenous supportive groups that emphasize the development of social skills—may also be helpful in overcoming social anxiety and developing interpersonal trust and rapport in clients with avoidant personality disorder.

Cognitive-Behavioral Therapy

Behavioral strategies offer reinforcement for positive change. Social skills training and assertiveness training teach alternative ways to deal with frustration. Cognitive strategies help the client recognize and correct distorted and irrational thinking patterns. Davidson and associates (2009) found that the addition of cognitive-behavioral therapy to usual treatment for clients with antisocial personality disorders afforded a reduction in both verbal and physical aggression. There is also limited evidence that cognitive therapy is beneficial for clients with schizotypal personality disorder (Bateman, 2014).

Dialectical Behavior Therapy

Dialectical behavior therapy (DBT) is a type of psychotherapy originally developed by Marsha Linehan, PhD, specifically as a treatment for the chronic self-injurious and parasuicidal behavior of clients with BPD (Sadock et al., 2015). Rooted in a belief that the primary problem for this client is emotional dysregulation (a kind of emotional reactivity to perceived threats), DBT has become a well-established treatment for clients with BPD. It is a complex, eclectic treatment that combines the concepts of cognitive, behavioral, and interpersonal therapies with Eastern mindfulness practices. The four primary modes of treatment in DBT include the following:

1. **Group skills training:** In these groups, clients are taught skills relevant to the problems experienced by people with BPD, such as core mindfulness skills, interpersonal effectiveness skills, emotion modulation skills, and distress tolerance skills (Kiehn & Swales, 2013).
2. **Individual psychotherapy:** Weekly sessions address dysfunctional behavioral patterns, personal motivation, and skills strengthening.
3. **Telephone contact:.** The therapist is available to the client by telephone, according to limits set by the therapist but usually for 24 hours a day. Kiehn and Swales (2013) state, "Telephone contact is to give the patient help and support in applying the skills that she is learning to her real life situation between sessions and to help her find ways of avoiding self-injury."
4. **Therapist consultation/team meeting:** Therapists meet regularly to review their work with their clients. These meetings are focused specifically on providing support for each other, keeping the therapists motivated, and providing effective treatment to their clients. DBT has been well studied, and the evidence supports the benefits of this treatment for clients with BPD. O'Connell and Dowling (2014), citing a review of seven studies (Binks et al., 2006), report:

> Despite the difficulty in treating people with BPD, if the person with BPD engaged in their treatment plan, there was a reduction in anxiety levels, depression, self-harm, hospital admission, and the use of prescribed medication. (p. 522)

This method of treatment is now being used with other disorders, including substance use disorders, eating disorders, schizophrenia, and PTSD (Sadock et al., 2015). Bateman (2014) cautions, however, that of the many interventions specialized for the treatment of personality disorders, improvement is more often evidenced by symptom reduction rather than significant improvements in social functioning.

Psychopharmacology

Psychopharmacology may be helpful in some instances. Although these drugs have no effect in the direct treatment of the disorder itself, some symptomatic relief can be achieved. Among the cluster A disorders, there has been limited evidence of the benefits of antipsychotic medication in the treatment of schizotypal personality disorder, but the risk to benefit ratio is unclear (Bateman, 2014).

For the treatment of BPD, symptom-targeted pharmacotherapy has been identified as an important adjunct. Antipsychotic medications show benefit in treating cognitive-perceptual symptoms, selective serotonin reuptake inhibitors show some benefit in treating emotional dysregulation, and mood-stabilizing agents have shown some benefit in treating emotional dysregulation and impulsive and aggressive symptoms (Bateman, 2014). As mentioned previously, some current research identifies the benefits of adjunctive oxytocin therapy (Pier et al., 2016).

For antisocial personality disorder, pharmacotherapy is generally not recommended unless it is being used to treat a comorbid condition. Among the cluster C group of personality disorders, no randomized trials have been published that support pharmacological treatment for these disorders (Bateman, 2014).

Caution must be given to prescribing medications outside of a structured setting because of the high risk for substance abuse by these individuals.

CASE STUDY AND SAMPLE CARE PLAN

NURSING HISTORY AND ASSESSMENT

Anthony, age 34, has been admitted to the psychiatric unit with a diagnosis of antisocial personality disorder. He was recently arrested and convicted for armed robbery of a convenience store and attempted murder of the store clerk. Due to the actions of the store clerk, who quickly alerted police, and to the store surveillance camera, Anthony was identified and apprehended within hours of the crime. The judge has ordered physical, neurological, and psychiatric evaluations before sentencing Anthony.

Anthony was physically and psychologically abused as a child by his alcoholic father. He was suspended from high school because of failing grades and habitual truancy. He has a long history of arrests, beginning with shoplifting at age 7, progressing in adolescence to burglary, auto theft, and sexual assault, and finally to armed robbery and attempted murder. He was on probation when he committed his latest crime.

On the psychiatric unit, Anthony is loud, belligerent, and uncooperative. When Julie, his admitting nurse, arrives to work the evening shift on Anthony's second hospital day, he says to her, "I'm so glad you are finally here. You are the best nurse on the unit. I can't talk to anyone but you. These people are nothing but a bunch of loonies around here—and that includes staff as well as patients! Maybe you and I could walk down to the coffee shop together later. Are you married? I'd sure like to get to know you better after I get out of this nut house!"

NURSING DIAGNOSES AND OUTCOME IDENTIFICATION

From the assessment data, the nurse develops the following nursing diagnoses for Anthony:

A. **Risk for other-directed violence** related to history of violence against others and history of childhood abuse.
   a. **Short-Term Goals:** Client will discuss angry feelings and situations that precipitate hostility. Client will not harm others.
   b. **Long-Term Goal:** Client will not harm others.

B. **Defensive coping** related to low self-esteem, dysfunctional nuclear family, underdeveloped ego and superego, evidenced by absence of guilt feelings, disregard for societal laws and norms, inability to delay gratification, superior attitude toward others, denial of problems, and projection of blame and responsibility.
   a. **Short-Term Goal:** Client will verbalize understanding of unit rules and regulations and consequences for violation of them.
   b. **Long-Term Goals:** Client will be able to delay gratification and follow rules and regulations of the unit. Client will verbalize personal responsibility for own actions and behaviors.

PLANNING AND IMPLEMENTATION

RISK FOR OTHER-DIRECTED VIOLENCE

The following nursing interventions have been identified for Anthony.

1. Develop a trusting relationship with Anthony by conveying an accepting attitude. Ensure that he understands it is not him but his behavior that is unacceptable.
2. Try to keep excess stimuli out of the environment. Speak to Anthony in a calm, quiet voice.
3. Observe Anthony's behavior regularly through routine activity so that he does not become suspicious and angry about being watched. This is important so that if hostile and aggressive behaviors are observed, intervention may prevent harm to Anthony, staff members, and/or other patients.
4. Sit with Anthony and encourage him to talk about his anger and hostile feelings. Help him understand where these feelings originate and who is the true target of the hostility.
5. Help him develop adaptive ways of dealing with frustration, such as exercise and other physical activities.
6. Administer tranquilizing medication as ordered by the physician.

CASE STUDY AND SAMPLE CARE PLAN—cont'd

7. If Anthony should become out of control and mechanical restraints become necessary, ensure that sufficient staff is available to intervene. Do not use restraints as a punishment, but only as a last resort, protective measure for Anthony and the other patients.

DEFENSIVE COPING

The following nursing interventions have been identified for Anthony.

1. Explain to Anthony which of his behaviors are acceptable on the unit and which are not. Simply state that unacceptable behaviors will not be tolerated.
2. Determine appropriate consequences for violation of these limits (e.g., no TV or movies; no phone calls; time-out room). Ensure that all staff members follow through with these consequences.
3. Do not be taken in by Anthony's attempts to flatter or "charm" staff members. Compliments from Anthony are another form of manipulative behavior. Explain to Anthony that you will not accept these types of comments from him, and if they continue, impose consequences.
4. Encourage Anthony to talk about his past misdeeds. Try to help him understand how he would feel if someone treated him in the manner that he has treated others.

EVALUATION

The outcome criteria for Anthony have only partially been met. Personality characteristics such as those of Anthony's are deep rooted and enduring. He is not likely to change. Unless testing reveals a serious, treatable medical problem, Anthony will probably continue to suffer legal consequences and prison sentences until he develops insight and willingness to engage in behavior change. During his time on the psychiatric unit, harm to self and others has been avoided. He has discussed his anger and hostile feelings with Julie and other staff members. He continues to become belligerent when told that he cannot smoke on the unit and must wait for someone to escort him to the smoking area. He yells at the other patients and calls them "nut cases." He refuses to take responsibility for his actions and blames negative behavioral outcomes on others. He has begun a regular exercise program in the fitness room and receives positive feedback from the staff for this attempt to integrate healthier coping strategies.

Summary and Key Points

- Clients with personality disorders are undoubtedly some of the most difficult individuals health-care workers are likely to encounter.
- Personality characteristics are formed very early in life and are difficult, if not impossible, to change. In fact, some clinicians believe the therapeutic approach is not to try to change the characteristics but rather to decrease the inflexibility of the maladaptive traits and reduce their interference with everyday functioning and meaningful relationships.
- The concept of a personality disorder has been present throughout the history of medicine. Problems have arisen in the attempt to establish a classification system for these disorders.
- The *DSM-5* identifies 10 individual personality disorders: antisocial, avoidant, borderline, histrionic, dependent, narcissistic, obsessive-compulsive, paranoid, schizoid, and schizotypal.
- Nursing care of the client with a personality disorder is accomplished using the steps of the nursing process.

- Other treatment modalities include interpersonal psychotherapy, psychoanalytical psychotherapy, milieu or group therapy, cognitive-behavioral therapy, dialectical behavior therapy, and psychopharmacology.
- Individuals with BPD may enter the health-care system because of their instability and frequent attempts at self-destructive behavior.
- The individual with antisocial personality disorder may become part of the health-care system to avoid legal consequences or because of a court order for psychological evaluation.
- Nurses who work in all types of clinical settings should be familiar with the characteristics associated with personality disorders.
- Nurses working in psychiatry must be knowledgeable about appropriate intervention with these clients, for it is unlikely that they will encounter a greater professional challenge than these clients present.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Kim has a diagnosis of borderline personality disorder. She often exhibits alternating clinging and distancing behaviors. The most appropriate nursing intervention with this type of behavior would be to:
   a. Encourage Kim to establish trust in one staff person, with whom all therapeutic interaction should take place.
   b. Secure a verbal contract from Kim that she will discontinue these behaviors.
   c. Withdraw attention if these behaviors continue.
   d. Rotate staff members who work with Kim so that she will learn to relate to more than one person.

2. Kim, a client diagnosed with borderline personality disorder, manipulates the staff in an effort to fulfill her own desires. All of the following may be examples of manipulative behaviors in the borderline client *except:*
   a. Refusal to stay in room alone, stating, "It's so lonely."
   b. Asking Nurse Jones for cigarettes after 30 minutes, knowing the assigned nurse has explained she must wait 1 hour.
   c. Stating to Nurse Jones, "I really like having you for my nurse. You're the best one around here."
   d. Cutting arms with razor blade after discussing dismissal plans with physician.

3. "Splitting" by the client with BPD denotes:
   a. Evidence of precocious development.
   b. A primitive defense mechanism in which the client sees objects as all good or all bad.
   c. A brief psychotic episode in which the client loses contact with reality.
   d. Two distinct personalities within the borderline client.

4. According to Margaret Mahler, predisposition to BPD occurs when developmental tasks go unfulfilled in which of the following phases?
   a. Autistic phase, during which the child's needs for security and comfort go unfulfilled.
   b. Symbiotic phase, during which the child fails to bond with the mother.
   c. Differentiation phase, during which the child fails to recognize a separateness between self and mother.
   d. Rapprochement phase, during which the mother withdraws emotional support in response to the child's increasing independence.

5. Jack is a new client on the psychiatric unit with a diagnosis of antisocial personality disorder. Which of the following characteristics would you expect to assess in Jack?
   a. Lack of guilt for wrongdoing
   b. Insight into his own behavior
   c. Ability to learn from past experiences
   d. Compliance with authority

6. Milieu therapy is a good choice for clients with antisocial personality disorder because it:
   a. Provides a system of punishment and rewards for behavior modification.
   b. Emulates a social community in which the client may learn to live harmoniously with others.
   c. Provides mostly one-to-one interaction between the client and therapist.
   d. Provides a very structured setting in which the clients have very little input into the planning of their care.

7. In evaluating the progress of Jack, a client diagnosed with antisocial personality disorder, which of the following behaviors would be considered the most significant indication of positive change?
   a. Jack got angry only once in group this week.
   b. Jack was able to wait a whole hour for a cigarette without verbally abusing the staff.
   c. On his own initiative, Jack sent a note of apology to a man he had injured in a recent fight.
   d. Jack stated that he would no longer start any more fights.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. Which of the following behavioral patterns is characteristic of individuals with narcissistic personality disorder?
   a. Overly self-centered and exploitative of others
   b. Suspicious and mistrustful of others
   c. Rule conscious and disapproving of change
   b. Anxious and socially isolated

9. Jessica is a nurse who was floated to the psychiatric unit to cover for a staff nurse who called out sick. She encounters a patient diagnosed with BPD, and the patient states, "Thank goodness they sent you to the unit. No one else here has taken the time to listen to my concerns." This may be an example of which symptom common in BPD?
   a. Impulsivity
   b. Self-harming behaviors
   c. Dissociation
   d. Splitting

10. Which of the following behavioral patterns is characteristic of individuals with schizotypal personality disorder?
    a. Belittling themselves and their abilities
    b. A lifelong pattern of social withdrawal
    c. Suspicious and mistrustful of others
    b. Overreacting inappropriately to minor stimuli

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Brook, J., Lee. J.Y., Rubenstone, E., Brook, D., & Finch, S. (2014). Triple comorbid trajectories of tobacco, alcohol, and marijuana use as predictors of antisocial personality disorder and generalized anxiety disorder among urban adults. *American Journal of Public Health, 104*(8), 1413-1420. doi:10.2105/AJPH.2014.301880

DESCRIPTION OF THE STUDY: As part of the Harlem longitudinal development study, 816 urban youth of African American and Puerto Rican heritage were studied from the age of 19 until 32 years of age to evaluate the likelihood that those who were multi-substance users (alcohol, tobacco, and marijuana) were at greater risk for developing antisocial personality disorder (ASPD) and/or generalized anxiety disorder (GAD) in adulthood. The authors note that previous research has supported a relationship between multi-substance use and the development of ASPD. Evidence has also shown that psychosocial outcomes are worse when there is multi-substance abuse versus use of only one substance.

RESULTS OF THE STUDY: The concomitant use of tobacco, alcohol, and marijuana did significantly increase the likelihood of developing antisocial personality disorder in adulthood. A surprising finding was that, contrary to other research studies, this population did not show a decline in substance use after the mid-20s (as is typical of other populations), suggesting that these co-occurring problems may be more persistent for this population. The authors hypothesize that this may be related to less conventional ties (such as family or institutions) and more exposure to deviant peers, drug abusers, and antisocial behavior.

IMPLICATIONS FOR NURSING PRACTICE: Understanding the evidence base for treatment issues relevant to specific cultural and ethnic groups provides the nurse with a foundation for providing culturally sensitive and informed care. This study highlights risks for African American and Puerto Rican youth in urban settings, and the findings suggest that earlier intervention and treatment of comorbid substance use disorders may be effective in decreasing the likelihood of antisocial personality disorders in adulthood as well as decreasing their risk for longer-standing substance use disorders. Nursing assessment, particularly among adolescents, should include assessment for multi-substance use as well as for evidence of conduct disorder behavior and treatment should focus on addressing all substances.

TEST YOUR CRITICAL THINKING SKILLS

Dana, age 32, was diagnosed with borderline personality disorder when she was 26 years old. Her husband took her to the emergency department when he walked into the bathroom and found her cutting her legs with a razor blade. At that time, assessment revealed that Dana had a long history of self-mutilation, which she had carefully hidden from her husband and others. Dana began long-term psychoanalytical psychotherapy on an outpatient basis. Therapy revealed that Dana had been physically and sexually abused as a child by both her mother and her father, both now deceased. She admitted to having chronic depression, and her husband related episodes of rage reactions. Dana has been hospitalized on the psychiatric unit for a week because of suicidal ideations. After making a no-suicide contract with the staff, she is allowed to leave the unit on pass to keep a dental appointment that she made a number of weeks ago. She has just returned to the unit and says to her nurse, "I just took 20 Desyrel while I was sitting in my car in the parking lot."

Answer the following questions related to Lana:

1. The nurse is well acquainted with Dana and believes this is a manipulative gesture. How should the nurse handle this situation?
2. What is the priority nursing diagnosis for Dana?
3. Dana likes to "split" the staff into "good guys" and "bad guys." What is the most important intervention for splitting by a person with borderline personality disorder?

💬 Communication Exercises

1. Nathan, age 37, has been admitted to the hospital for a psychiatric evaluation after being arrested for armed robbery of a convenience store. He has a history of encounters with law enforcement since early adolescence. He has been diagnosed with antisocial personality disorder. Nathan says to the nurse, "Hey pretty lady! Where have you been all my life?"
   • How would the nurse respond appropriately to this statement by Nathan?
2. "I really got a bum rap! I had no intentions of hurting anyone. The gun only had one bullet in it! I just wanted to scare that clerk into giving me a few bucks! Just my bad luck an off-duty cop had to walk in about that time."
   • How would the nurse respond appropriately to this statement by Nathan?
3. "You're really cute. Are you married? I'm pretty sure my lawyer can get me out of this rap, and I'll be a free man! Why don't you give me your phone number and I'll call you sometime. We could go out and have some fun!"
   • How would the nurse respond appropriately to this statement by Nathan?

🎬 MOVIE CONNECTIONS

Psychiatric Mental Health Nursing of Special Populations

33

Children and Adolescents

CHAPTER OUTLINE

KEY TERMS

aggression	echolalia	negativism
clinging	impulsivity	palilalia

OBJECTIVES
After reading this chapter, the student will be able to:

1. Identify psychiatric disorders that commonly have their onset in infancy, childhood, or adolescence.
2. Discuss predisposing factors implicated in the etiology of intellectual disability, autism spectrum disorder, attention-deficit/hyperactivity disorder, conduct disorder, oppositional defiant disorder, Tourette's disorder, and separation anxiety disorder.
3. Identify symptomatology and use the information in the assessment of clients with the aforementioned disorders.

4. Identify nursing diagnoses common to clients with these disorders and select appropriate nursing interventions for each.
5. Discuss relevant criteria for evaluating nursing care of clients with selected infant, childhood, and adolescent psychiatric disorders.
6. Describe treatment modalities relevant to selected disorders of infancy, childhood, and adolescence.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What maternal prenatal activity has been associated with attention-deficit/hyperactivity disorder (ADHD) in children?
2. What antidepressant medication has been used with some success in treating ADHD?

3. Neuroimaging brain studies in children with Tourette's disorder have consistently found dysfunction in what area of the brain?
4. What are some family behaviors that have been implicated as influential in the development of separation anxiety disorder?

This chapter examines various disorders in which symptoms usually first become evident during infancy, childhood, or adolescence. However, some of the disorders discussed in this chapter may appear later in life, and symptoms associated with other disorders, such as major depressive disorder or bipolar disorder, may appear in childhood or adolescence.

All nurses working with children or adolescents should be knowledgeable about "normal" stages of growth and development. Theoretical Models of Personality Development, a bonus chapter available online at DavisPlus, discusses this topic. At best, the developmental process is one that is fraught with challenges. Behavioral responses are individual and idiosyncratic. They are, indeed, *human* responses.

Whether or not a child's behavior indicates emotional problems is often difficult to determine. Guidelines for making such a determination should consider appropriateness of the behavior regarding age and cultural norms and whether the behavior interferes with adaptive functioning. This chapter focuses on the nursing process in care of clients with intellectual disability, autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder (ADHD), conduct disorder, oppositional defiant disorder (ODD), Tourette's disorder, and separation anxiety disorder. Additional treatment modalities are included.

Neurodevelopmental Disorders

Intellectual Disability (Intellectual Developmental Disorder)

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* defines intellectual disability as a "disorder with onset during the developmental period that includes both intellectual and adaptive functioning deficits in conceptual, social, and practical domains" (American Psychiatric Association [APA], 2013, p. 33). The incidence rate in the general population is about 1 percent (APA, 2013). Onset of intellectual and adaptive deficits occurs during the developmental period. Level of severity (mild, moderate, severe, or profound) is based on adaptive functioning within the three domains. General intellectual functioning is measured by both clinical assessment and an individual's performance on intelligence quotient (IQ) tests. Adaptive functioning refers to the person's ability to adapt to the requirements of daily living and the expectations of his or her age and cultural group. The *DSM-5* diagnostic criteria for intellectual disability are presented in Box 33–1.

Predisposing Factors

The etiology of intellectual disability may be primarily biological, primarily psychosocial, a combination of

---

BOX 33–1 Diagnostic Criteria for Intellectual Disability (Intellectual Developmental Disorder)

Intellectual disability (intellectual developmental disorder) is a disorder with onset during the developmental period that includes both intellectual and adaptive functioning deficits in conceptual, social, and practical domains. The following three criteria must be met:

A. Deficits in intellectual functions, such as reasoning, problem-solving, planning, abstract thinking, judgment, academic learning, and learning from experience, confirmed by both clinical assessment and individualized, standardized intelligence testing.
B. Deficits in adaptive functioning that result in failure to meet developmental and sociocultural standards for personal independence and social responsibility. Without ongoing support the adaptive deficits limit functioning in one or more activities of daily life, such as communication, social participation, and independent living, across multiple environments, such as home, school, work, and community.
C. Onset of intellectual and adaptive deficits during the developmental period.

---

both, or in some instances unknown. Regardless of etiology, the common factors are significant impairments in intellectual functions and social adaptation.

Genetic Factors

Genetic factors are implicated as the cause of intellectual disability in approximately 5 percent of cases. These factors include inborn errors of metabolism, such as Tay-Sachs disease, phenylketonuria, and hyperglycinemia. Also included are chromosomal disorders, such as Down syndrome and Klinefelter's syndrome, and single-gene abnormalities, such as fragile X syndrome, tuberous sclerosis, and neurofibromatosis.

Disruptions in Embryonic Development

Conditions that result in early alterations in embryonic development account for approximately 30 percent of intellectual disability cases. Damages may occur in response to toxicity associated with maternal ingestion of alcohol or other drugs. For example, fetal alcohol syndrome has been identified as one

of the leading preventable causes of intellectual disability. Maternal illnesses and infections during pregnancy (e.g., rubella, cytomegalovirus) and complications of pregnancy (e.g., toxemia, uncontrolled diabetes) also can result in congenital intellectual disability (Sadock, Sadock, & Ruiz, 2015).

Pregnancy and Perinatal Factors

Approximately 10 percent of cases of intellectual disability are the result of circumstances that occur during pregnancy (e.g., fetal malnutrition, viral and other infections, and prematurity) or during the birth process. Examples of the latter include trauma to the head incurred during the process of birth, placenta previa or premature separation of the placenta, and prolapse of the umbilical cord.

General Medical Conditions Acquired in Infancy or Childhood

General medical conditions acquired during infancy or childhood account for approximately 5 percent of cases of intellectual disability. They include infections, such as meningitis and encephalitis; poisonings, such as from insecticides, medications, and lead; and physical trauma, such as head injuries, asphyxiation, and hyperpyrexia (Sadock et al., 2015).

Sociocultural Factors and Other Mental Disorders

Between 15 and 20 percent of cases of intellectual disability may be attributed to deprivation of nurturance and social stimulation and to impoverished environments associated with poor prenatal and perinatal care and inadequate nutrition. Additionally, other mental disorders, such as ASD, can result in intellectual disability.

Recognition of the cause and period of inception provides information regarding what to expect in terms of behavior and potential. However, each child is different, and consideration must be given on an individual basis.

Application of the Nursing Process to Intellectual Disability

Background Assessment Data (Symptomatology)

The degree of severity of intellectual disability may be measured by the client's IQ level. Four levels have been delineated: mild, moderate, severe, and profound. The various behavioral manifestations and abilities associated with each of these levels of severity are outlined in Table 33–1.

Nurses should assess and focus on each client's strengths and individual abilities. Knowledge regarding level of independence in the performance of self-care activities is essential to the development of an adequate plan for nursing care.

Nursing Diagnosis

Selection of appropriate nursing diagnoses for the client with intellectual disability depends largely on the degree of severity of the condition and the client's capabilities. Possible nursing diagnoses include the following:

- Risk for injury related to altered physical mobility or aggressive behavior
- Self-care deficit related to altered physical mobility or lack of maturity
- Impaired verbal communication related to developmental alteration
- Impaired social interaction related to speech deficiencies or difficulty adhering to conventional social behavior
- Delayed growth and development related to isolation from significant others, inadequate environmental stimulation, genetic factors
- Anxiety (moderate to severe) related to hospitalization and absence of familiar surroundings
- Defensive coping related to feelings of powerlessness and threat to self-esteem
- Ineffective coping related to inadequate coping skills secondary to developmental delay

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with intellectual disability.

The client:

- Has experienced no physical harm
- Has had self-care needs fulfilled
- Interacts with others in a socially appropriate manner
- Has maintained anxiety at a manageable level
- Is able to accept direction without becoming defensive
- Demonstrates adaptive coping skills in response to stressful situations

Planning and Implementation

Table 33–2 provides a plan of care for the child with intellectual disability using selected nursing diagnoses, outcome criteria, and appropriate nursing interventions and rationales.

Although this plan of care is directed toward the individual client, it is essential that family members or primary caregivers participate in the ongoing care of the client with intellectual disability. They need to receive information regarding the scope of the condition, realistic expectations and client potentials, methods for modifying behavior as required, and community resources from which they may seek assistance and support.

TABLE 33–1	Developmental Characteristics of Intellectual Developmental Disorder by Degree of Severity			
LEVEL (IQ)	**ABILITY TO PERFORM SELF-CARE ACTIVITIES**	**COGNITIVE/EDUCATIONAL CAPABILITIES**	**SOCIAL/COMMUNICATION CAPABILITIES**	**PSYCHOMOTOR CAPABILITIES**
Mild (50–70)	Capable of independent living with assistance during times of stress.	Capable of academic skills to sixth-grade level. As adult can achieve vocational skills for minimum self-support.	Capable of developing social skills. Functions well in a structured, sheltered setting.	Psychomotor skills usually not affected, although may have some slight problems with coordination.
Moderate (35–49)	Can perform some activities independently. Requires supervision.	Capable of academic skill to second-grade level. As adult may be able to contribute to own support in sheltered workshop.	May experience some limitation in speech communication. Difficulty adhering to social convention may interfere with peer relationships.	Motor development is fair. Vocational capabilities may be limited to unskilled gross motor activities.
Severe (20–34)	May be trained in elementary hygiene skills. Requires complete supervision.	Unable to benefit from academic or vocational training. Profits from systematic habit training.	Minimal verbal skills. Wants and needs often communicated by acting-out behaviors.	Poor psychomotor development. Able to perform only simple tasks under close supervision.
Profound (below 20)	No capacity for independent functioning. Requires constant aid and supervision.	Unable to profit from academic or vocational training. May respond to minimal training in self-help if presented in the close context of a one-to-one relationship.	Little, if any, speech development. No capacity for socialization skills.	Lack of ability for both fine and gross motor movements. Requires constant supervision and care. May be associated with other physical disorders.

(2015). *Synopsis of psychiatry: Behavioral sciences/clinical psychiatry* (11th ed.). Philadelphia: Lippincott Williams & Wilkins.

Table 33–2 | CARE PLAN FOR THE CHILD WITH INTELLECTUAL DISABILITY

NURSING DIAGNOSIS: RISK FOR INJURY

RELATED TO: Altered physical mobility or aggressive behavior

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short- and Long-Term Goal • Client does not experience injury.	1. Create a safe environment for client. 2. Ensure that small items are removed from area where client will be ambulating and that sharp items are out of reach. 3. Store items that client uses frequently within easy reach. 4. Pad side rails and headboard of client with history of seizures. 5. Prevent physical aggression and acting out behaviors by learning to recognize signs that client is becoming agitated.	1–5. Client safety is a nursing priority.

Table 33–2 | CARE PLAN FOR THE CHILD WITH INTELLECTUAL DISABILITY–cont'd

NURSING DIAGNOSIS: SELF-CARE DEFICIT

RELATED TO: Altered physical mobility or lack of maturity

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client is able to participate in aspects of self-care. Long-Term Goal • Client has all self-care needs met.	1. Identify aspects of self-care that may be within client's capabilities. Work on one aspect of self-care at a time. Provide simple, concrete explanations. Offer positive feedback for efforts. 2. When one aspect of self-care has been mastered to the best of client's ability, move on to another. Encourage independence but intervene when client is unable to perform.	1. Positive reinforcement enhances self-esteem and encourages repetition of desirable behaviors. 2. Client comfort and safety are nursing priorities.

NURSING DIAGNOSIS: IMPAIRED VERBAL COMMUNICATION

RELATED TO: Developmental alteration

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client establishes trust with caregiver and a means of communication of needs. Long-Term Goal • Client's needs are being met through established means of communication. • If client cannot speak or communicate by other means, needs are met by caregiver's anticipation of client's needs.	1. Maintain consistency of staff assignment over time. 2. Anticipate and fulfill client's needs until satisfactory communication patterns are established. Learn (from family, if possible) special words client uses that are different from the norm. Identify nonverbal gestures or signals that client may use to convey needs if verbal communication is absent. Practice these communications skills repeatedly.	1. Consistency of staff assignments facilitates trust and the ability to understand client's actions and communications. 2. Some children with intellectual disability, particularly at the severe level, can learn only by systematic habit training.

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Speech deficiencies or difficulty adhering to conventional social behavior

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client attempts to interact with others in the presence of trusted caregiver. Long-Term Goal • Client is able to interact with others using behaviors that are socially acceptable and appropriate to developmental level.	1. Remain with client during initial interactions with others on the unit. 2. Explain to other clients the meaning behind some of client's nonverbal gestures and signals. Use simple language to explain to client which behaviors are acceptable and which are not. Establish a procedure for behavior modification with rewards for appropriate behaviors and aversive reinforcement for inappropriate behaviors.	1. Presence of a trusted individual provides a feeling of security. 2. Positive, negative, and aversive reinforcements can contribute to desired changes in behavior. These privileges and penalties are individually determined as staff learns client's likes and dislikes.

Evaluation

Evaluation of care given to the client with intellectual disability should reflect positive behavioral changes. Evaluation is accomplished by determining if the goals of care (as identified previously) have been met through implementation of the nursing actions selected. The nurse reassesses the plan and makes changes as required. Reassessment data may include information gathered by asking the following questions:

- Have nursing actions providing for the client's safety been sufficient to prevent injury?
- Have all of the client's self-care needs been fulfilled? Can he or she fulfill some of these needs independently?
- Has the client been able to communicate needs and desires so that he or she can be understood?
- Has the client learned to interact appropriately with others?
- When regressive behaviors surface, can the client accept constructive feedback and discontinue the inappropriate behavior?
- Has anxiety been maintained at a manageable level?
- Has the client learned new coping skills through behavior modification? Does the client demonstrate evidence of increased self-esteem because of the accomplishment of these new skills and adaptive behaviors?
- Have primary caregivers been taught realistic expectations of the client's behavior and methods for attempting to modify unacceptable behaviors?
- Have primary caregivers been given information regarding various resources from which they can seek assistance and support within the community?

CORE CONCEPT

Autism Spectrum Disorder

A heterogenous group of neurodevelopmental syndromes characterized by a wide range of communication impairments and restricted, repetitive behaviors (Sadock et al., 2015).

Autism Spectrum Disorder

Clinical Findings

In the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision* (APA, 2000), the category of autism spectrum disorder (ASD) encompasses a broad spectrum of associated diagnoses that included autistic disorder, Rett's disorder, childhood disintegrative disorder, pervasive developmental disorder not otherwise specified, and Asperger's disorder. The *DSM-5* groups these disorders into a single diagnostic category—autism spectrum disorder. The diagnosis is adapted to each individual by clinical specifiers (e.g., level of severity, verbal abilities) and associated features (e.g., known genetic disorders, epilepsy, intellectual disability) (APA, 2013). ASD is characterized by a withdrawal of the child into an internal fantasy world of his or her own creation. The child has abnormal or impaired development in social interaction and communication and a restricted repertoire of activity and interests, some of which may be considered somewhat bizarre.

Epidemiology and Course

The Autism and Developmental Disabilities Monitoring (ADDM) Network estimates that 1 in 68 children in the United States is identified with ASD and reports that this number has increased 123 percent since 2002 (Centers for Disease Control and Prevention [CDC], 2016a). ASD occurs about five times more often in boys than in girls. Almost half (46%) of individuals with ASD have an average or above average IQ. Onset of the disorder occurs in early childhood, and in most cases it runs a chronic course, with symptoms persisting into adulthood.

Predisposing Factors

Neurological Implications

Imaging studies have revealed a number of alterations in major brain structures of individuals with ASD. Total brain volume, the size of the amygdala, and the size of the striatum have all been identified as enlarged in about 9 to16 percent of children younger than age 4 with ASD. There is also evidence of a decrease in size over time (Hazlett et al., 2011; Kranjac, 2016; Sadock et al., 2015). Sadock and associates identify that this pattern of change in total brain volume over time lends support for the hypothesis that there are critical periods in the brain's plasticity that, when disrupted, may contribute to the development of ASD. These findings related to brain plasticity also support that early recognition and intervention can be meaningful in improving functional abilities over time. Recent in vitro stem cell reprogramming research is beginning to identify the cellular mechanisms responsible for early brain overgrowth and the subsequent disruptions in neural connectivity that may yield valuable information about causes and treatment options (Marchetto et al., 2016).

Genetics

Research has revealed strong evidence that genetic factors play a significant role in the etiology of ASD. About 15 percent of ASD cases are related to a known genetic mutation; in most cases, its expression is related to multiple genes (Sadock et al., 2015). Genetic

studies have identified genes that are linked to both autism and schizophrenia, suggesting the two conditions are related (Gilman et al., 2012), although researchers identify that the mutations that occur in each disease lead to functional differences. Kranjac (2016) reports that rare genetic variants such as copy number variations increase the risk for autism by 20 to 60 percent. Familial and twin studies have also supported genetic influences. DNA studies have implicated areas on several chromosomes containing genes that may contribute to the development of ASD. Genetic studies have also identified disruptions in serotonin (5-HT). Because 5-HT is important in brain development, changes in 5-HT may be associated with enlargement in the brain (Sadock et al., 2015).

Prenatal and Perinatal Influences

Some of the prenatal risk factors associated with development of ASD include advanced parental age, fetal exposure to valproate, gestational diabetes, and gestational bleeding (APA, 2013; Sadock et al., 2015). Perinatal influences include low birth weight, obstetrical complications (particularly those associated with neonatal hypoxia), hyperbilirubinemia, congenital malformation, and ABO or Rh factor incompatibilities (Sadock et al., 2015). Exposure to environmental toxins, including air pollution and pesticides, showed the strongest links to ASD when it occurred during preconception, gestational, and early childhood stages (Rossignol & Frye, 2016).

Application of the Nursing Process to Autism Spectrum Disorder

Background Assessment Data (Symptomatology)

The symptomatology presented here is common among children with ASD, but it is important to understand these disorders along a spectrum with varying levels of functionality. Some individuals who meet criteria for ASD may be highly functional and highly intelligent despite communication impairments and repetitive or restrictive behaviors. The dramatic increase in prevalence of ASD has led to research focused on differential and common features along the continuum as well on etiological factors. This information is important in creating an accurate plan of care for the client. Because ASD is a *spectrum* disorder, the symptomatology described here should be understood on a continuum ranging from mild to severe.

Impairment in Social Interaction Children with ASD have difficulty forming interpersonal relationships with others. They show little interest in people and often do not respond to others' attempts at interaction. As infants, they may have an aversion to affection and physical contact. As toddlers, the attachment to a significant adult may be either absent or manifested as exaggerated adherence behaviors. In childhood, a lack of spontaneity is manifested in less cooperative play, less imaginative play, and fewer friendships. Those children with minimal handicaps may progress to the point of recognizing other children as part of their environment, but they struggle, nonetheless, in interpersonal relationships. Social interaction is further impaired by deficits in ability to accurately process others' feelings or affect. Higher-functioning children may recognize their difficulty with social skills even though they may desire friendship. In one study (Strunz et al., 2015), researchers noted that as these relational struggles unfold into adulthood, it is difficult at times to distinguish ASD from personality disorders because there are disruptions in interpersonal relationships within both groups. They found that the differential features in ASD were less extroversion, less openness to experience, increased inhibition, and increased compulsivity than among those with personality disorders.

Impairment in Communication and Imaginative Activity Both verbal and nonverbal skills are affected. In more severe ASD, language may be totally absent or characterized by immature structure or idiosyncratic utterances whose meaning is clear only to those who are familiar with the child's past experiences. Nonverbal communication, such as facial expression or gestures, may be absent or socially inappropriate. Sometimes children with ASD are misinterpreted as being deaf as a result of their lack of response to sounds, while other children may overreact to sound or other stimuli. In some cases, children with ASD demonstrate special abilities, such as fluent reading skills while still in preschool (Sadock et al., 2015). The pattern of play is often restricted and repetitive.

Restricted Activities and Interests Even minor changes in the environment are often met with resistance or sometimes with agitated irritability. Attachment to or extreme fascination with objects that move or spin (e.g., fans) is common. Stereotyped body movements (hand-clapping, rocking, whole-body swaying) and verbalizations (repetition of words or phrases) are typical. Diet abnormalities may include eating only a few specific foods or consuming an excessive amount of fluids. Self-injurious behaviors, such as head banging or biting the hands or arms, may be evident. Harrop and associates (2014) studied children with ASD compared to children without this disorder and found that all children demonstrated some repetitive behaviors as part of their development of skill mastery, but children with ASD displayed a wider range of repetitive behaviors in many different circumstances.

The *DSM-5* diagnostic criteria for ASD are presented in Box 33–2. The criteria specify a range of behaviors, with varying levels of severity, thus addressing the spectrum of symptomatology associated with this diagnosis.

Nursing Diagnosis

Based on data collected during the nursing assessment, possible nursing diagnoses for the client with ASD include the following:

■ Risk for self-mutilation or self injury related to neurological, cognitive, or social deficits
■ Impaired social interaction related to inability to trust; neurological alterations, evidenced by lack of responsiveness to, or interest in, people
■ Impaired verbal communication related to withdrawal into the self; neurological alterations, evidenced by inability or unwillingness to speak; lack of nonverbal expression
■ Disturbed personal identity related to neurological alterations; delayed developmental stage, evidenced by difficulty separating own physiological and emotional needs and personal boundaries from those of others

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with ASD.

BOX 33–2 Diagnostic Criteria for Autism Spectrum Disorder

A. Persistent deficits in social communication and social interaction across multiple contexts, as manifested by the following, currently or by history (examples are illustrative, not exhaustive):
   1. Deficits in social-emotional reciprocity, ranging, for example, from abnormal social approach and failure of normal back-and-forth conversation; to reduced sharing of interests, emotions, or affect; to failure to initiate or respond to social interactions.
   2. Deficits in nonverbal communicative behaviors used for social interaction, ranging, for example, from poorly integrated verbal and nonverbal communication; to abnormalities in eye contact and body language or deficits in understanding and use of gestures; to a total lack of facial expressions and nonverbal communication.
   3. Deficits in developing, maintaining, and understanding relationships, ranging, for example, from difficulties adjusting behavior to suit various social contexts; to difficulties in sharing imaginative play or in making friends; to absence of interest in peers.

Specify current severity:

Severity is based on social communication impairments and restricted, repetitive patterns of behavior.

B. Restricted, repetitive patterns of behavior, interests, or activities, as manifested by at least two of the following, currently or by history (examples are illustrative, not exhaustive):
   1. Stereotyped or repetitive motor movements, use of objects, or speech (e.g., simple motor stereotypies, lining up toys or flipping objects, echolalia, idiosyncratic phrases).
   2. Insistence on sameness, inflexible adherence to routines, or ritualized patterns of verbal or nonverbal behavior (e.g., extreme distress at small changes, difficulties with transitions, rigid thinking patterns, greeting rituals, need to take same route or eat same food every day).
   3. Highly restricted, fixated interests that are abnormal in intensity or focus (e.g., strong attachment to or preoccupation with unusual objects, excessively circumscribed or perseverative interests).
   4. Hyper- or hypo-reactivity to sensory input or unusual interest in sensory aspects of environment (e.g., apparent indifference to pain/temperature, adverse response to specific sounds or textures, excessive smelling or touching of objects, visual fascination with lights or movement).

Specify current severity:

Severity is based on social communication impairments and restricted, repetitive patterns of behavior.

C. Symptoms must be present in the early developmental period (but may not become fully manifest until social demands exceed limited capacities, or may be masked by learned strategies in later life).
D. Symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning.
E. These disturbances are not better explained by intellectual disability (intellectual developmental disorder) or global developmental delay. Intellectual disability and autism spectrum disorder frequently co-occur; to make comorbid diagnoses of autism spectrum disorder and intellectual disability, social communication should be below that expected for general developmental level.

Specify if:

With or without accompanying intellectual impairment
With or without accompanying language impairment
Associated with a known medical or genetic condition or environmental factor
Associated with another neurodevelopmental, mental, or behavioral disorder
With catatonia

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

The client:

■ Exhibits no evidence of self-harm
■ Interacts appropriately with at least one staff member
■ Demonstrates trust in at least one staff member
■ Is able to communicate so that he or she can be understood by at least one staff member
■ Demonstrates behaviors that indicate he or she has begun the separation/individuation process

Planning and Implementation

Table 33–3 provides a plan of care for the child with ASD, including selected nursing diagnoses, outcome criteria, and appropriate nursing interventions and rationales.

Evaluation

Evaluation of care for the child with ASD reflects whether the nursing actions have been effective in

---

Table 33–3 | CARE PLAN FOR THE CHILD WITH AUTISM SPECTRUM DISORDER

NURSING DIAGNOSIS: RISK FOR SELF-MUTILATION

RELATED TO: Neurological alterations; history of self-mutilative behaviors; hysterical reactions to changes in the environment

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client demonstrates alternative behavior (e.g., initiating interaction between self and nurse) in response to anxiety within specified time. (Length of time required for this objective will depend on severity and chronicity of the disorder.) **Long-Term Goal** • Client does not harm self.	1. Work with child on a one-to-one basis. 2. Try to determine if the self-mutilative behavior occurs in response to increasing anxiety, and if so, to what the anxiety may be attributed. 3. Try to intervene with diversion or replacement activities and offer self to child as anxiety level starts to rise. 4. Protect child when self-mutilative behaviors occur. Devices such as a helmet, padded hand mitts, or arm covers may provide protection when the risk for self-harm exists.	1. One-to-one interaction facilitates trust. 2. Mutilative behaviors may be averted if the cause can be determined and alleviated. 3. Diversion and replacement activities may provide needed feelings of security and substitute for self-mutilative behaviors. 4. Client safety is a priority nursing intervention.

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Inability to trust; neurological alterations

EVIDENCED BY: Lack of responsiveness to, or interest in, people

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client demonstrates trust in one caregiver (as evidenced by facial responsiveness and eye contract) within specified time (depending on severity and chronicity of disorder). **Long-Term Goal** • Client initiates social interactions (physical, verbal, nonverbal) with caregiver by time of discharge from treatment.	1. Assign a limited number of caregivers to child. Ensure that warmth, acceptance, and availability are conveyed. 2. Provide child with familiar objects, such as familiar toys or a blanket. Support child's attempts to interact with others. 3. Give positive reinforcement for eye contact with something acceptable to child (e.g., food, familiar object). Gradually replace with social reinforcement (e.g., touch, smiling, hugging).	1. Warmth, acceptance, and availability, along with consistency of assignment, enhance the establishment and maintenance of a trusting relationship. 2. Familiar objects and presence of a trusted individual provide security during times of distress. 3. Being able to establish eye contact is essential to child's ability to form satisfactory interpersonal relationships.

Table 33–3 | CARE PLAN FOR THE CHILD WITH AUTISM SPECTRUM DISORDER–cont'd

NURSING DIAGNOSIS: IMPAIRED VERBAL COMMUNICATION

RELATED TO: Withdrawal into the self; neurological alterations

EVIDENCED BY: Inability or unwillingness to speak; lack of nonverbal expression

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client establishes trust with one caregiver (as evidenced by facial responsiveness and eye contact) by specified time (depending on severity and chronicity of disorder). **Long-Term Goal** • Client establishes a means of communicating needs and desires to others.	1. Maintain consistency in assignment of caregivers. 2. Anticipate and fulfill child's needs until communication can be established. 3. Seek clarification and validation. 4. Give positive reinforcement when eye contact is used to convey non-verbal expressions.	1. Consistency facilitates trust and enhances the caregiver's ability to understand child's attempts to communicate. 2. Anticipating needs helps to minimize frustration while child is learning communication skills. 3. Validation ensures that the intended message has been conveyed. 4. Positive reinforcement increases self-esteem and encourages repetition.

NURSING DIAGNOSIS: DISTURBED PERSONAL IDENTITY

RELATED TO: Neurological alterations; delayed developmental stage

EVIDENCED BY: Difficulty separating own physiological and emotional needs and personal boundaries from those of others

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client names own body parts as separate and individual from those of others. **Long-Term Goal** • Client develops ego identity (evidenced by ability to recognize physical and emotional self as separate from others) by time of discharge from treatment.	1. Assist child to recognize separateness during self-care activities, such as dressing and feeding. 2. Assist child in learning to name own body parts. This can be facilitated by the use of mirrors, drawings, and pictures of the child. Encourage appropriate touching of, and being touched by, others.	1. Recognition of body parts during dressing and feeding increases child's awareness of self as separate from others. 2. All of these activities may help increase child's awareness of self as separate from others.

achieving the established goals. The nursing process calls for reassessment of the plan. Questions for gathering reassessment data may include the following:

■ Has the child been able to establish trust with at least *one* caregiver?
■ Have the nursing actions directed toward preventing mutilative behaviors or other injury been effective in protecting the client from self-harm?
■ Has the child attempted to interact with others? Has he or she received positive reinforcement for these efforts?
■ Has eye contact improved?

■ Has the child established a means of communicating his or her needs and desires to others? Have all self-care needs been met?
■ Does the child demonstrate an awareness of self as separate from others? Can he or she name own body parts and body parts of caregiver?
■ Can he or she accept touch from others? Does he or she willingly and appropriately touch others?

Psychopharmacological Intervention for ASD

Pharmacological interventions are directed toward relief of targeted irritability symptoms such as

aggression, hyperactivity self-harm, impulsivity, and temper tantrums. There are no medications that treat the core symptoms of ASD. The U.S. Food and Drug Administration (FDA) has approved two medications for the treatment of irritability associated with ASD: risperidone (Risperdal; in children and adolescents 5 to 16 years) and aripiprazole (Abilify; in children and adolescents 6 to 17 years). When administering risperidone, caution must be maintained concerning uncommon but serious possible side effects, including neuroleptic malignant syndrome, tardive dyskinesia, hyperglycemia, and diabetes.

In clinical studies with aripiprazole, the most frequently reported adverse events included sedation, fatigue, weight gain, vomiting, somnolence, and tremor. The most common reasons for discontinuation of aripiprazole were sedation, drooling, tremor, vomiting, and extrapyramidal disorder.

> ## CORE CONCEPT
> ### Hyperactivity
> Excessive psychomotor activity that may be purposeful or aimless, accompanied by physical movements and verbal utterances that are usually more rapid than normal. Inattention and distractibility are common with hyperactive behavior.

Attention-Deficit/Hyperactivity Disorder
Clinical Findings, Epidemiology, and Course

The essential behavior pattern of a child with ADHD is one of inattention and/or hyperactivity and **impulsivity.** These children are highly distractible and unable to contain stimuli. Motor activity is excessive, and movements are random and impulsive. Onset of the disorder is difficult to diagnose in children younger than age 4 years because their characteristic behavior is much more variable than that of older children. Frequently, the disorder is not recognized until the child enters school. It is more common in boys (14.1%) than girls (6.2%), and the overall prevalence among school-age children is 10.2 percent (CDC, 2016b). In about 60 to 70 percent of the cases, ADHD persists into young adulthood, and about 25 percent will subsequently meet the criteria for antisocial personality disorder as adults (Black & Andreasen, 2014).

In diagnosing ADHD, the *DSM-5* criteria are further specified according to current clinical presentation. These subtypes include a combined presentation (meeting the criteria for both inattention and hyperactivity/impulsivity), a predominantly inattentive presentation, and a predominantly hyperactive/impulsive presentation.

> ## CORE CONCEPT
> ### Impulsiveness
> The trait of acting without reflection and without thought to the consequences of the behavior. An abrupt inclination to act (and the inability to resist acting) on certain behavioral urges.

Predisposing Factors
Biological Influences

Genetics A number of studies have revealed supportive evidence of genetic influences in the etiology of ADHD. Twin studies show an increased risk for monozygotic twins and a risk of two to eight times for siblings and parents of a child with ADHD (Sadock et al., 2015). Adoption studies reveal that biological parents of children with ADHD more often display psychopathology than do the adoptive parents.

Studies of genetic evidence for ADHD have found genetic variants and mutations such as copy number variants on a specific region of chromosome 16 (Acosta et al., 2016; Williams et al., 2010). The researchers also found that copy number variants overlap with chromosomal regions previously linked to ASD and schizophrenia.

Biochemical Theory Although it is believed that certain neurotransmitters—particularly dopamine, norepinephrine, and possibly serotonin—are involved in producing the symptoms associated with ADHD, their involvement is still under investigation. Hypotheses about the impact of neurotransmitters are largely based on benefits associated with taking stimulant medications, which are known to affect dopamine and norepinephrine levels (see Fig. 33–1).

Anatomical Influences Some studies have implicated alterations in specific areas of the brain in individuals with ADHD. Brain imaging studies show decreased volume and activity in the prefrontal cortex, anterior cingulated, globus pallidus, caudate, thalamus, and cerebellum (Sadock et al., 2015).

Prenatal, Perinatal, and Postnatal Factors Maternal smoking during pregnancy has been linked to hyperkinetic-impulsive behavior in offspring (ADHD Institute, 2016; Froehlich et al., 2009). Intrauterine exposure to toxic substances, including alcohol, can produce effects on behavior. Fetal alcohol syndrome includes hyperactivity, impulsivity, and inattention, as well as physical anomalies. Maternal infections during pregnancy have also been associated with higher risks for ADHD.

Perinatal and postnatal influences that may contribute to ADHD are low birth weight, trauma, early infancy infections, or other insults to the brain during
FIGURE 33–1 Neurobiology of Attention-Deficit/Hyperactivity Disorder.

NEUROTRANSMITTERS

The major neurotransmitters implicated in the pathophysiology of ADHD are dopamine, norepinephrine, and possibly serotonin. Dopamine and norepinephrine appear to be depleted in ADHD. Serotonin in ADHD has been studied less extensively, but recent evidence suggests that it also is reduced in children with ADHD.

NEUROTRANSMITTER FUNCTIONS

- Norepinephrine is thought to play a role in the ability to perform executive functions, such as analysis and reasoning, and in the cognitive alertness essential for processing stimuli and sustaining attention and thought.
- Dopamine is thought to play a role in sensory filtering, memory, concentration, controlling emotions, locomotor activity, and reasoning.
- Deficits in norepinephrine and dopamine have both been implicated in the inattention, impulsiveness, and hyperactivity associated with ADHD.
- Serotonin appears to play a role in ADHD, although possibly a less significant role than norepinephrine and dopamine. It has been suggested that alterations in serotonin may be related to the disinhibition and impulsivity observed in children with ADHD. It may play a role in mood disorders, particularly depression, which is a common comorbid disorder associated with ADHD.

FUNCTIONAL AREAS OF THE BRAIN AFFECTED

- **Prefrontal cortex:** Associated with maintaining attention, organization, and executive function. Also serves to modulate behavior inhibition, with serotonin as the predominant central inhibiting neurotransmitter for this function.
- **Basal ganglia** (particularly the caudate nucleus and globus pallidus): Involved in the regulation of high-level movements. In association with its connecting circuits to the prefrontal cortex, may also be important in cognition. Interruptions in these circuits may result in inattention or impulsivity.
- **Hippocampus:** Plays an important role in learning and memory.
- **Limbic System** (composed of the amygdala, hippocampus, mammillary body, hypothalamus, thalamus, fornix, cingulate gyrus, and septum pellucidum): Regulation of emotions. A neurotransmitter deficiency in this area may result in restlessness, inattention, or emotional volatility.
- **Reticular activating system** (composed of the reticular formation [located in the brainstem] and its connections): It is the major relay system among the many pathways that enter and leave the brain. It is thought to be the center of arousal and motivation and is crucial for maintaining a state of consciousness.

MEDICATIONS FOR ADHD

CNS Stimulants

- Amphetamines (dextroamphetamine, lisdexamfetamine, methamphetamine, and mixtures): Cause the release of norepinephrine from central noradrenergic neurons. At higher doses, dopamine may be released in the mesolimbic system.
- Methylphenidate and dexmethylphenidate: Block the reuptake of norepinephrine and dopamine into the presynaptic neuron and increase the release of these monoamines into the extraneuronal space.

Side effects of CNS stimulants include restlessness, insomnia, headache, palpitations, weight loss, suppression of growth in children (with long-term use), increased blood pressure, abdominal pain, anxiety, tolerance, and physical and psychological dependence.

Others

• Atomoxetine: Selectively inhibits the reuptake of norepinephrine by blocking the presynaptic transporter.

Side effects include headache, upper abdominal pain, nausea and vomiting, anorexia, cough, dry mouth, constipation, increase in heart rate and blood pressure, and fatigue.

• Bupropion: Inhibits the reuptake of norepinephrine and dopamine into presynaptic neurons.

Side effects include headache, dizziness, insomnia or sedation, tachycardia, increased blood pressure, dry mouth, nausea and vomiting, weight gain or loss, seizures and (dose dependent).

• Alpha agonists (clonidine, guanfacine): Stimulate central alpha-adrenoreceptors in the brain, resulting in reduced sympathetic outflow from the CNS.

Side effects include palpitations, bradycardia, constipation, dry mouth, and sedation.

---

this period (Sadock et al., 2015). Prematurity was once identified as posing an increased risk for ADHD, but in a large research study (Heinonen et al., 2010) cited by the ADHD Institute (2016), this was not found to be the case.

Environmental Influences

Environmental Lead Studies continue to provide evidence of the adverse effects of elevated body levels of lead on cognitive and behavioral development in children (Froehlich et al., 2009; Rossignol & Frye, 2016). Froehlich and associates' research showed a direct link to ADHD. The government has placed tighter restrictions on the substance in recent years, making exposure to toxic levels less prevalent than it once was. However, reports indicate that at least 4 million households in the United States include children who are being exposed to lead and that approximately 500,000 U.S. children ages 1 to 5 have blood lead levels above 5 micrograms per deciliter, the reference level at which the initiation of public health actions is recommended (CDC, 2016c).

Diet Factors The possible link between food dyes and additives, such as artificial flavorings, preservatives, and sugar, was introduced in the mid-1970s. Studies on these possibilities have failed to confirm a clear link.

Psychosocial Influences

Disorganized or chaotic environments or a disruption in family equilibrium may contribute to ADHD in some individuals. Galéra and associates (2011) identified several psychosocial influences associated with the development of ADHD, including non-intact family, young maternal age at birth of the target child, paternal history of antisocial behavior, and maternal depression.

Application of the Nursing Process to ADHD

Background Assessment Data (Symptomatology)

A major portion of the hyperactive child's problems relate to difficulties in performing age-appropriate tasks. Hyperactive children are highly distractible and have extremely limited attention spans. They often shift from one uncompleted activity to another. Impulsivity, or deficit in inhibitory control, is also common.

Hyperactive children have difficulty forming satisfactory interpersonal relationships. They demonstrate behaviors that inhibit acceptable social interaction. They are disruptive and intrusive in group endeavors. They have difficulty complying with social norms. Some children with ADHD are very aggressive or oppositional, whereas others exhibit more regressive and immature behaviors. Low frustration tolerance and outbursts of temper are common.

Children with ADHD have boundless energy, exhibiting excessive levels of activity, restlessness, and fidgeting. They have been described as "perpetual motion machines," continuously running, jumping, wiggling, or squirming. They experience a greater than average number of accidents, from minor mishaps to more serious incidents that may lead to physical injury or the destruction of property. The *DSM-5* diagnostic criteria for ADHD are presented in Box 33–3.

Comorbidity The prevalence of comorbid psychiatric disorders with ADHD is common, with up to 30 percent demonstrating comorbid depression and 20 percent demonstrating comorbid anxiety (Sherman & Tarnow, 2013). The APA (2013) reports that in children with ADHD who have both symptoms of inattention and hyperactivity/impulsivity, ODD co-occurs about 50 percent of the time. They further identify that most children and adolescents with disruptive mood dysregulation disorder also meet criteria for ADHD. Other comorbidities include conduct disorder, specific learning disorder, and intermittent explosive disorder. Sadock and associates (2015) identify that although bipolar mania and ADHD share many core features, such as distractibility, excessive talking, and hyperactivity, children with

BOX 33–3 Diagnostic Criteria for Attention-Deficit/Hyperactivity Disorder

A. A persistent pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development, as characterized by (1) and/or (2):

1. **Inattention:** Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities. *Note:* The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.

   a. Often fails to give close attention to details or makes careless mistakes in schoolwork, at work, or during other activities (e.g., overlooks or misses details, work is inaccurate).

   b. Often has difficulty sustaining attention in tasks or play activities (e.g., has difficulty remaining focused during lectures, conversations, or reading lengthy reading).

   c. Often does not seem to listen when spoken to directly (e.g., mind seems elsewhere, even in the absence of any obvious distraction).

   d. Often does not follow through on instructions and fails to finish schoolwork, chores, or duties in the workplace (e.g., starts tasks but quickly loses focus and is easily sidetracked).

   e. Often has difficulty organizing tasks and activities (e.g., difficulty managing sequential tasks; difficulty keeping materials and belongings in order; messy, disorganized, work; has poor time management; fails to meet deadlines).

   f. Often avoids, dislikes, or is reluctant to engage in tasks that require sustained mental effort (e.g., schoolwork or homework; for older adolescents and adults, preparing reports, completing forms, reviewing lengthy papers).

   g. Often loses things necessary for tasks or activities (e.g., school materials, pencils, books, tools, wallets, keys, paperwork, eyeglasses, or mobile telephones).

   h. Is often easily distracted by extraneous stimuli (for older adolescents and adults, may include unrelated thoughts).

   i. Is often forgetful in daily activities (e.g., chores, running errands; for older adolescents and adults, returning calls, paying bills, keeping appointments).

2. **Hyperactivity and Impulsivity:** Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities. *Note:* The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or a failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.

   a. Often fidgets with or taps hands or feet or squirms in seat.

   b. Often leaves seat in situations when remaining seated is expected (e.g., leaves his or her place in the classroom, in the office or other workplace, or in other situations that require remaining in place).

   c. Often runs about or climbs in situations where it is inappropriate. (*Note:* In adolescents or adults, may be limited to feeling restless.)

   d. Often unable to play or engage in leisure activities quietly.

   e. Is often "on the go," acting as if "driven by a motor" (e.g., is unable to be or uncomfortable being still for extended time, as in restaurants, meetings; may be experienced by others as being restless and difficult to keep up with).

   f. Often talks excessively.

   g. Often blurts out an answer before a question has been completed (e.g., completes people's sentences; cannot wait for turn in conversation).

   h. Often has difficulty waiting his or her turn (e.g., while waiting in line).

   i. Often interrupts or intrudes on others (e.g., butts into conversations, games, or activities; may start using other people's things without asking or receiving permission; for adolescents or adults, may intrude into or take over what others are doing).

B. Several inattentive or hyperactive-impulsive symptoms were present prior to age 12 years.

C. Several inattentive or hyperactive-impulsive symptoms are present in two or more settings (e.g., at home, school or work; with friends or relatives; in other activities).

D. There is clear evidence that the symptoms interfere with or reduce the quality of social, academic, or occupational functioning.

E. The symptoms do not occur exclusively during the course of schizophrenia or another psychotic disorder and are not better explained by another mental disorder (e.g., mood disorder, anxiety disorder, dissociative disorder, personality disorder, substance intoxication or withdrawal).

Specify whether:

1. **Combined presentation:** If both Criterion A1 (inattention) and Criterion A2 (hyperactivity-impulsivity) are met for the past 6 months.

2. **Predominantly inattentive presentation:** If Criterion A1 (inattention) is met but Criterion A2 (hyperactivity-impulsivity) is not met for the past 6 months.

3. **Predominantly hyperactive/impulsive presentation:** If Criterion A2 (hyperactivity-impulsivity) is met and Criterion A1 (inattention) is not met for the past 6 months.

Specify if: **In partial remission**
Specify current severity: **Mild, Moderate, Severe**

bipolar I disorder exhibit symptoms that wax and wane, whereas children with ADHD have more persistent, continuous symptoms. They note that bipolar disorder and ADHD can coexist and that when certain features of ADHD occur, they appear to predict future mania. Sherman and Tarnow (2013) identify that the prevalence of comorbid bipolar disorder and ADHD is around 20 percent. These authors also note that because ADHD is associated with frontal lobe abnormalities, it is not a surprise that 89.4 percent of children with frontal lobe epilepsy also had comorbid ADHD.

Nursing Diagnosis

Based on the data collected during the nursing assessment, possible nursing diagnoses for the child with ADHD include the following:

■ Risk for injury related to impulsive and accident-prone behavior and the inability to perceive self-harm
■ Impaired social interaction related to intrusive and immature behavior
■ Low self-esteem related to dysfunctional family system and negative feedback
■ Noncompliance with task expectations related to low frustration tolerance and short attention span

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the child with ADHD.

The client:

■ Has experienced no physical harm
■ Interacts with others appropriately
■ Verbalizes positive aspects about self
■ Demonstrates fewer demanding behaviors
■ Cooperatives with staff in an effort to complete assigned tasks

Planning and Implementation

Table 33–4 provides a plan of care for the child with ADHD using nursing diagnoses common to the disorder, outcome criteria, and appropriate nursing interventions and rationales.

Concept Care Mapping

The concept map care plan is an innovative approach to planning and organizing nursing care (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing). It is a diagrammatic teaching and learning strategy that allows visualization of

---

Table 33–4 | CARE PLAN FOR THE CHILD WITH ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

NURSING DIAGNOSIS: RISK FOR INJURY

RELATED TO: Impulsive and accident-prone behavior and the inability to perceive self-harm

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short- and Long-Term Goal • Client is free of injury.	1. Ensure that client has a safe environment. Remove objects from immediate area on which client could injure self as a result of random, hyperactive movements.	1. Objects that are appropriate to the normal living situation can be hazardous to child whose motor activities are out of control.
	2. Identify deliberate behaviors that put child at risk for injury. Institute consequences for repetition of this behavior.	2. Behavior can be modified with aversive reinforcement.
	3. If there is risk of injury associated with specific therapeutic activities, provide adequate supervision and assistance, or limit client's participation if adequate supervision is not possible.	3. Client safety is a nursing priority.

Table 33–4 | CARE PLAN FOR THE CHILD WITH ATTENTION-DEFICIT/HYPERACTIVITY DISORDER–cont'd

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Intrusive and immature behavior

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client interacts in age-appropriate manner with nurse in one-to-one relationship within 1 week. **Long-Term Goal** • Client observes limits set on intrusive behavior and demonstrates ability to interact appropriately with others.	1. Develop a trusting relationship with child. Convey acceptance of child separate from the unacceptable behavior. 2. Discuss with client those behaviors that are and are not acceptable. Describe in a matter-of-fact manner the consequences of unacceptable behavior. Follow through. 3. Provide group situations for client.	1. Unconditional acceptance increases feelings of self-worth. 2. Aversive reinforcement can alter undesirable behaviors. 3. Appropriate social behavior is often learned from the positive and negative feedback of peers.

NURSING DIAGNOSIS: LOW SELF-ESTEEM

RELATED TO: Dysfunctional family system and negative feedback

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client independently directs own care and activities of daily living within 1 week. **Long-Term Goal** • Client demonstrates increased feelings of self-worth by verbalizing positive statements about self and exhibiting fewer demanding behaviors.	1. Ensure that goals are realistic. 2. Plan activities that provide opportunities for success. 3. Convey unconditional acceptance and positive regard. 4. Offer recognition of successful endeavors and positive reinforcement for attempts made. Give immediate positive feedback for acceptable behavior.	1. Unrealistic goals set client up for failure, which diminishes self-esteem. 2. Success enhances self-esteem. 3. Affirmation of client as worthwhile human being may increase self-esteem. 4. Positive reinforcement enhances self-esteem and may increase the desired behaviors.

NURSING DIAGNOSIS: NONCOMPLIANCE (WITH TASK EXPECTATIONS)

RELATED TO: Low frustration tolerance and short attention span

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client participates in and cooperates during therapeutic activities. **Long-Term Goal** • Client is able to complete assigned tasks independently or with a minimum of assistance.	1. Provide an environment for task efforts that is as free of distractions as possible. 2. Provide assistance on a one-to-one basis, beginning with simple, concrete instructions.	1. Client is highly distractible and is unable to perform in the presence of even minimal stimulation. 2. Client lacks the ability to assimilate information that is complicated or has abstract meaning.

Table 33–4	CARE PLAN FOR THE CHILD WITH ATTENTION-DEFICIT/HYPERACTIVITY DISORDER–cont'd		
OUTCOME CRITERIA	**NURSING INTERVENTIONS**	**RATIONALE**
	3. Ask client to repeat instructions to you.	3. Repetition of the instructions helps to determine client's level of comprehension.
	4. Establish goals that allow client to complete a part of the task, rewarding each step-completion with a break for physical activity.	4. Short-term goals are not so overwhelming to one with such a short attention span. The positive reinforcement (physical activity) increases self-esteem and provides incentive for client to pursue the task to completion.
	5. Gradually decrease the amount of assistance given while assuring client that assistance is still available if deemed necessary.	5. This encourages client to perform independently while providing a feeling of security with the presence of a trusted individual.

interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client with ADHD is presented in Figure 33–2.

Evaluation

Evaluation of the care of a client with ADHD involves examining client behaviors following implementation of the nursing actions to determine if the goals of therapy have been achieved. Collecting data by using the following types of questions may provide appropriate information for evaluation.

■ Have the nursing actions directed at client safety been effective in protecting the child from injury?
■ Has the child been able to establish a trusting relationship with the primary caregiver?
■ Is the client responding to limits set on unacceptable behaviors?
■ Is the client able to interact appropriately with others?
■ Is the client able to verbalize positive statements about self?
■ Is the client able to complete tasks independently or with a minimum of assistance? Can he or she follow through after listening to simple instructions?
■ Is the client able to apply self-control to decrease motor activity?

Psychopharmacological Intervention for ADHD

Indications

Pharmacological intervention, particularly stimulants, are considered the first line of treatment for ADHD

(Sadock et al., 2015). For a list of agents used to treat ADHD, see Table 33–5. The mechanism of action is unclear, but since these drugs are known to elevate dopamine and norepinephrine levels, it is hypothesized that their effectiveness is in response to neurotransmitter dysregulation. They have generally mild side effects but are contraindicated in anyone with cardiac problems or risks for cardiac problems.

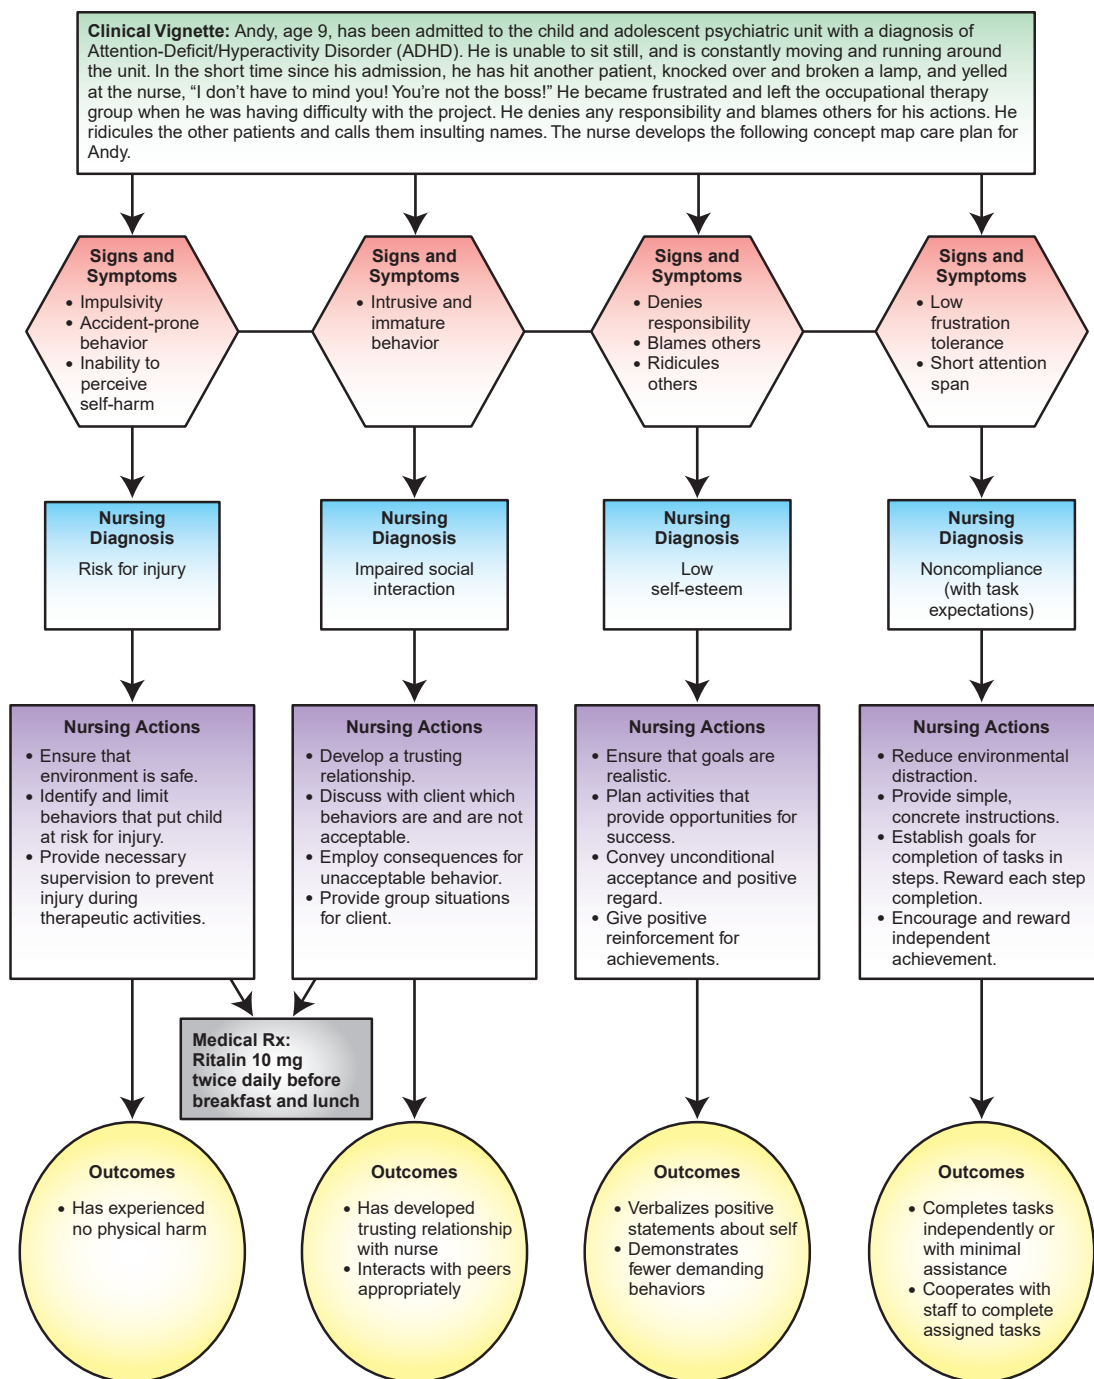
One study (Van Den Ban et al., 2014) explored whether use of stimulants had an impact on reducing injuries and hospital admissions for children with ADHD. This topic is relevant because this population has a high incidence of injury and hospital admissions related to hyperactivity and impulsivity. About 60 percent show suboptimal motor performance, which may also increase their risks for injury. The researchers found that children taking ADHD drugs (mostly stimulants) had a twofold higher risk of injury-related hospital admissions than among those not treated with ADHD drugs. They also found that children who were on ADHD drugs and psychotropic drugs such as antipsychotics and benzodiazepines had five times increased risk for injuries and hospital admissions than those who were on ADHD medication alone. The severity of ADHD in children on medication may, in part, account for these findings, but it is significant that while mediating other core symptoms of ADHD, medication may not reduce risks for injury. Amphetamines have been a common substance of abuse and demonstrate a high risk for dependence, and similar concerns have been identified for clients with ADHD. The recent FDA approval of Adzenys XR-ODT, a


FIGURE 33–2 Concept map care plan for a client with attention deficit/hyperactivity disorder.

flavored, chewable amphetamine mixture tablet, has raised concerns that it might be a recipe for increased medication use in children and become a gateway drug (Grohol, 2016). See Chapter 4, Psychopharmacology, for a complete discussion of the medications used in the treatment of ADHD, including safety and education issues.

Tourette's Disorder

Clinical Findings, Epidemiology, and Course

Tourette's disorder is characterized by the presence of multiple motor tics and one or more vocal tics, which may appear simultaneously or at different periods during the illness (APA, 2013). The disturbance may

TABLE 33–5 Medications for Attention-Deficit/Hyperactivity Disorder

CHEMICAL CLASS	GENERIC (TRADE) NAME	DAILY DOSAGE RANGE (mg)	CONTROLLED CATEGORIES	PREGNANCY CATEGORIES/ HALF-LIFE (hr)
CNS STIMULANTS				
AMPHETAMINES	Dextroamphetamine sulfate (Dexedrine; Dextrostat)	2.5–40	CII	C/ ~12
	Methamphetamine (Desoxyn)	5–25	CII	C/ 4–5
	Lisdexamfetamine (Vyvanse)	20–70	CII	C/ <1
AMPHETAMINE MIXTURES	Dextroamphetamine/ amphetamine (Adderall; Adderall XR)	2.5–40	CII	C/ 9–13

MISCELLANEOUS	Methylphenidate (Ritalin; Ritalin-SR; Ritalin LA; Methylin; Methylin ER; Metadate ER; Metadate CD; Concerta; Daytrana)	10–60	CII	C/ 2–4
	Dexmethylphenidate (Focalin)	5–20	CII	C/ 2.2
ALPHA AGONISTS	Clonidine (Catapres)	0.05–0.3	—	C/ 12–16
	Guanfacine (Tenex; Intuniv)	1–4	—	B/ 10–30
MISCELLANEOUS	Atomoxetine (Strattera)	>70 kg: 40–100; ≤70 kg: 0.5– 1.4 mg/kg (or 100 mg, whichever is less)	—	C/ 5.2 (metabolites 6–8)
	Bupropion (Wellbutrin; Wellbutrin SR; Wellbutrin XL)	3 mg/kg (ADHD); 100–300 (depression)	—	C/ 8–24

cause distress or interfere with social, occupational, or other important areas of functioning. The age at onset of Tourette's disorder can be as early as 2 years, but the disorder occurs most commonly around age 6 to 7 years. Prevalence of the disorder is estimated at from 3 to 8 per 1,000 in school-aged children (APA, 2013). The lifetime prevalence is estimated to be about 1 percent (Sadock et al., 2015). It is two to four times more common in boys than in girls. Although the disorder can be lifelong, most people with this condition experience the worst tic symptoms in their early teens with gradual improvement thereafter (National Institutes of Health [NIH], 2014).

Predisposing Factors

Biological Factors

Genetics Various genetic studies, including twin studies and adoption studies, support a genetic basis for this neurological disorder (Sadock et al., 2015). Although evidence supports that it is an inherited disorder, recent studies suggest that the pattern of inheritance is complex, probably involving several genes influenced by environmental factors (NIH, 2104). In addition, genetic studies suggest that ADHD and obsessive-compulsive disorder (OCD) are genetically related to Tourette's disorder; as many as 50 percent of patients with Tourette's disorder also have ADHD, and up to 40 percent have OCD (NIH, 2014; Sadock et al., 2015).

Biochemical Factors Abnormalities in levels of dopamine, choline, *N*-acetylaspartate, creatine, myoinositol, and norepinephrine have all been demonstrated in neuroimaging studies. The effectiveness of antipsychotic medication (particularly haloperidol and fluphenazine) in suppressing tics also supports neurotransmitter involvement in Tourette's disorder (Sadock et al., 2015). However, Sadock and associates add that there is variability in response to antipsychotic medications, and sometimes Tourette's disorder has emerged in clients being treated with antipsychotics. Based on current evidence, while there appear to be several biochemical

influences in this disorder, these are complex interactions and are not well understood.

Structural Factors Neuroimaging brain studies have been consistent in finding dysfunction in the basal ganglia. The frontal lobes, the cortex, and abnormalities in the circuits that connect these regions have also been implicated in the pathology of this disorder (NIH, 2014). Although many influences have been identified, the direct cause is still unknown. It is probably a complex interaction of genetics, biochemistry, and environmental influences.

Environmental Factors

Some studies have shown that environmental influences such as maternal alcohol use during pregnancy, low birth weight, complications during childbirth, and infection may be associated with the development of Tourette's disorder (CDC, 2016d). Further research is needed to confirm these influences. Sadock and associates (2015) report that studies inferring beta-hemolytic streptococcal infections as a mechanism in Tourette's disorder have been "conflicting and controversial, and this mechanism appears to be unlikely as an etiology of Tourette's disorder in most cases" (p. 1198).

Application of the Nursing Process to Tourette's Disorder

Background Assessment Data (Symptomatology)

The motor tics of Tourette's disorder may involve the head, torso, and upper and lower limbs. Initial symptoms may begin with a single motor tic, most commonly eye blinking, or with multiple symptoms. Tics tend to first occur in the face and neck and progress downward to the torso and lower limbs over time (Sadock et al., 2015). Simple motor tics include movements such as eye blinking, neck jerking, shoulder shrugging, and facial grimacing. The more complex motor tics include squatting, hopping, skipping, tapping, and retracing steps.

Vocal tics include various words or sounds such as squeaks, grunts, barks, sniffs, snorts, coughs, and, in rare instances, a complex vocal tic involving the uttering of obscenities. Vocal tics may include repeating certain words or phrases out of context, repeating one's own sounds or words **(palilalia),** or repeating what others say **(echolalia).**

The movements and vocalizations are experienced as compulsive and irresistible but can be suppressed for varying lengths of time. Many report a buildup of tension as they attempt to suppress tics to the point where they feel the tic must be expressed against their will. Tics are often worse during periods of stress or excitement and better during periods of calm, focused activity (NIH, 2014). In most cases, tics are diminished during sleep. Neurobehavioral disorders that are common in conjunction with Tourette's disorder (and may be more troublesome than the tics themselves) are inattention, hyperactivity and impulsivity as is seen in ADHD, OCD, depression, and anxiety. Many children with Tourette's disorder also manifest difficulty with reading, writing, and arithmetic (NIH, 2014). The *DSM-5* diagnostic criteria for Tourette's disorder are presented in Box 33–4.

Nursing Diagnosis

Based on data collected during the nursing assessment, possible nursing diagnoses for the client with Tourette's disorder include the following:

■ Risk for self-directed or other-directed violence related to low tolerance for frustration
■ Impaired social interaction related to impulsiveness and oppositional and aggressive behavior
■ Low self-esteem related to embarrassment associated with tic behaviors

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with Tourette's disorder.

The client:

■ Has not harmed self or others
■ Interacts with staff and peers in an appropriate manner
■ Demonstrates self-control by managing tic behavior
■ Follows rules of the unit without becoming defensive
■ Verbalizes positive aspects about self

Planning and Implementation

Table 33–6 provides a plan of care for the child or adolescent with Tourette's disorder using selected

---

BOX 33–4 Diagnostic Criteria for Tourette's Disorder

A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.
B. The tics may wax and wane in frequency but have persisted for more than 1 year since first tic onset.
C. Onset is before age 18 years.
D. The disturbance is not attributable to the physiological effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington's disease, postviral encephalitis).

Table 33–6 | CARE PLAN FOR THE CHILD OR ADOLESCENT WITH TOURETTE'S DISORDER

NURSING DIAGNOSIS: RISK FOR SELF-DIRECTED OR OTHER-DIRECTED VIOLENCE

RELATED TO: Low tolerance for frustration

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client seeks out staff or support person at any time if thoughts of harming self or others should occur. **Long-Term Goal** • Client does not harm self or others.	1. Observe client's behavior frequently through routine activities and interactions. Become aware of behaviors that indicate a rise in agitation. 2. Monitor for self-destructive behavior and impulses. A staff member may need to stay with client to prevent self-mutilation. 3. Provide hand coverings and other restraints that prevent client from self-mutilative behaviors. 4. Redirect violent behavior with physical outlets for frustration.	1. Stress commonly increases tic behaviors. Recognition of behaviors that precede the onset of aggression may provide the opportunity to intervene before violence occurs. 2. Client safety is a nursing priority. 3. For client's protection, provide immediate external controls against self-aggressive behaviors. 4. Excess energy is released through physical activities and a feeling of relaxation is induced.

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Impulsiveness; oppositional and aggressive behavior

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client develops a one-to-one relationship with a nurse or support person within 1 week. **Long-Term Goal** • Client is able to interact with staff and peers using age-appropriate, acceptable behaviors.	1. Develop a trusting relationship with client. Convey acceptance of the person separate from the unacceptable behavior. 2. Discuss with client which behaviors are and are not acceptable. Describe in matter-of-fact manner the consequences of unacceptable behavior. Follow through. 3. Provide group situations for client.	1. Unconditional acceptance increases feelings of self-worth. 2. Aversive reinforcement can alter undesirable behaviors. 3. Appropriate social behavior is often learned from the positive and negative feedback of peers.

NURSING DIAGNOSIS: LOW SELF-ESTEEM

RELATED TO: Embarrassment associated with tic behaviors

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client verbalizes positive aspects about self not associated with tic behaviors.	1. Convey unconditional acceptance and positive regard.	1. Communicating a perception of client as a worthwhile human being may increase self-esteem.

Table 33–6 │ CARE PLAN FOR THE CHILD OR ADOLESCENT WITH TOURETTE'S DISORDER—cont'd	

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Long-Term Goal • Client exhibits increased feeling of self-worth as evidenced by verbal expression of positive aspects about self, past accomplishments, and future prospects.	2. Set limits on manipulative behavior. Take caution not to reinforce manipulative behaviors by providing desired attention. Identify the consequences of manipulation. Administer consequences matter-of-factly when manipulation occurs.	2. Aversive consequences may work to decrease unacceptable behaviors.
	3. Help client understand that he or she uses manipulation to try to increase own self-esteem. Interventions should reflect other actions to accomplish this goal.	3. When client feels better about self, the need to manipulate others will diminish.
	4. If client chooses to suppress tics in the presence of others, provide a specified "tic time" during which he or she "vents" tics, feelings, and behaviors (alone or with staff).	4. Allows for release of tics and assists in sense of control and management of symptoms.
	5. Ensure that client has regular one-to-one time with nursing staff.	5. One-to-one time gives the nurse the opportunity to provide client with information about the illness and healthy ways to manage it. Exploring feelings about the illness helps client incorporate the illness into a healthy sense of self.

nursing diagnoses, outcome criteria, and appropriate nursing interventions and rationales.

Evaluation

Evaluation of care for the child with Tourette's disorder reflects whether the nursing actions have been effective in achieving the established goals. The nursing process calls for reassessment of the plan. Questions for gathering reassessment data may include the following:

■ Has the client refrained from causing harm to self or others during times of increased tension?
■ Has the client developed adaptive coping strategies for dealing with frustration to prevent resorting to self-destruction or aggression to others?
■ Is the client able to interact appropriately with staff and peers?
■ Is the client able to suppress tic behaviors when he or she chooses to do so?

■ Does the client set a time for "release" of the suppressed tic behaviors?
■ Does the client verbalize positive aspects about self, particularly as they relate to his or her ability to manage the illness?
■ Does the client comply with treatment in a nondefensive manner?

Psychopharmacological Intervention for Tourette's Disorder

Systematic review of current evidence supports the efficacy of antipsychotic agents, both typical and atypical agents, and the use of alpha$_2$-adrenergic agonist agents (such as clonidine) in treating tics (Weisman et al., 2013). The researchers note that alpha$_2$ agonists are more effective in treating tics among patients with ADHD. Pharmacotherapy is most effective when combined with psychosocial therapy, such as behavioral therapy, individual counseling or psychotherapy,

and/or family therapy. Medications that are used in the treatment of Tourette's disorder include antipsychotics and alpha agonists.

Antipsychotics

The conventional antipsychotics, haloperidol (Haldol) and pimozide (Orap), have been approved by the FDA for control of tics and vocal utterances associated with Tourette's disorder. These drugs have been widely investigated and proven highly effective in alleviating these symptoms. They are often not the first-line choice of therapy, however, because of their propensity for severe adverse effects such as extrapyramidal symptoms, neuroleptic malignant syndrome, tardive dyskinesia, and electrocardiographic changes. Haloperidol is not recommended for children younger than 3 years of age, and pimozide should not be administered to children younger than 12 years.

Although not presently approved by the FDA for use in Tourette's disorder, some clinicians prefer to prescribe the atypical antipsychotics, such as risperidone (Risperdal), olanzapine (Zyprexa), or ziprasidone (Geodon), because of their more favorable side-effect profiles. Sadock and associates (2015) identify risperidone as the most well-studied atypical antipsychotic for the treatment of tics and report that there is considerable evidence for its efficacy. These medications have a lower incidence of neurological side effects than the typical antipsychotics, although extrapyramidal symptoms have been observed with risperidone. Common side effects include weight gain, metabolic side effects, and hyperprolactinemia (Sadock et al., 2015). Ziprasidone has been associated with increased risk of QTc interval prolongation. Hyperglycemia has also been reported in some patients taking atypical antipsychotics.

Alpha Agonists

Clonidine (Catapres) and guanfacine (Tenex, Intuniv) are alpha-adrenergic agonists that are approved for use as antihypertensive agents. The extended-release forms have been approved by the FDA for the treatment of ADHD. These medications may be used for treatment of Tourette's disorder because of their favorable side-effect profile and because they are often effective for comorbid symptoms of ADHD, anxiety, and insomnia. Common side effects include dry mouth, sedation, headaches, fatigue, and dizziness or postural hypotension. Guanfacine is longer lasting and less sedating than clonidine, but its efficacy in reducing tics is controversial (Sadock et al., 2015). Alpha agonists should not be prescribed for children and adolescents with preexisting cardiac or vascular disease. They should not be discontinued abruptly; to do so could result in symptoms of nervousness, agitation, tremor, and a rapid rise in blood pressure.

Disruptive Behavior Disorders

Oppositional Defiant Disorder
Clinical Findings, Epidemiology, and Course

ODD is characterized by a persistent pattern of angry mood and defiant behavior that occurs more frequently than is usually observed in individuals of comparable age and developmental level and interferes with social, educational, occupational, or other important areas of functioning (APA, 2013). It must be understood as distinct, pervasive, and more disruptive than the sometimes negativistic and oppositional behavior that is typical in children and adolescents. The disorder typically begins by 8 years of age and usually not later than early adolescence. Prevalence estimates range from 2 to 16 percent, and common comorbid disorders include ADHD, anxiety, major depressive disorder, conduct disorder, and substance use disorders (APA, 2013). It is more prevalent in boys than in girls before puberty, but the rates are more closely equal after puberty. The *DSM-5* identifies that ODD often precedes conduct disorder, especially in children with onset of conduct disorder prior to 10 years of age (APA, 2013).

Predisposing Factors
Biological Influences

The role, if any, that genetics, temperament, or biochemical alterations play in the etiology of ODD is still unclear. Some studies have identified genetic influences in the establishment of a child's temperament, but there is not clear evidence of this connection in ODD. However, having a temperament in which the child has difficulty regulating emotions and has low frustration tolerance is an identified risk factor for ODD (Mayo Clinic, 2016).

Family Influences

Opposition during various developmental stages is both normal and healthy. Children first exhibit oppositional behaviors at around 10 or 11 months of age, again as toddlers between 18 and 36 months of age, and finally during adolescence. Pathology is considered only when the developmental phase is prolonged or when there is overreaction in the child's environment to his or her behavior.

Some children exhibit these behaviors in a more intense form than others. Sadock and associates (2015) report, "Epidemiological studies of negativistic traits in nonclinical populations found such behavior in 16 to 22 percent of school-age children" (p. 1245).

Some parents interpret average or increased level of developmental oppositional behavior as hostility and a deliberate effort on the part of the child to be in control. If power and control are issues for parents or if they exercise authority for their own needs, a power struggle can be established between the parents and the child that sets the stage for the development of ODD. Lubit (2015) suggests the following pattern of family dynamics:

■ There is the combination of a strong-willed child with a reactive and high-energy temperament and parents who are authoritarian rather than authoritative.

■ The parents become frustrated with the strong-willed child who does not obey and increase their attempts to enforce authority.

■ The child reacts to the excessive parental control with anger and increased self-assertion.

Lubit (2015) states:

These patterns develop when parents inadvertently reinforce disruptive and deviant behaviors in a child by giving those behaviors a significant amount of negative attention. At the same time, the parents, who are often exhausted by the struggle to obtain compliance with simple requests, usually fail to provide positive attention; often, the parents have infrequent positive interactions with their children. The pattern of negative interactions evolves quickly as the result of repeated, ineffective, emotionally expressed commands and comments; ineffective harsh punishments; and insufficient attention and modeling of appropriate behaviors.

Application of the Nursing Process to ODD

Background Assessment Data (Symptomatology)

ODD is characterized by passive-aggressive behaviors such as stubbornness, procrastination, disobedience, carelessness, **negativism,** testing of limits, resistance to directions, deliberately ignoring the communication of others, and unwillingness to compromise. Other symptoms that may be evident are running away, school avoidance, school underachievement, temper tantrums, fighting, and argumentativeness.

Initially, the oppositional attitude is directed toward the parents, but in time, relationships with peers and teachers become affected. These impairments in social interaction often lead to depression, anxiety, and additional problematic behavior (Lubit, 2015).

Usually these children do not see themselves as being oppositional but believe the problem is caused by the unreasonable demands of others. These children are often friendless, perceiving human relationships as negative and unsatisfactory. School performance is usually poor because of their refusal to participate and their resistance to external demands.

The *DSM-5* diagnostic criteria for ODD are presented in Box 33–5.

Nursing Diagnosis

Based on the data collected during the nursing assessment, possible nursing diagnoses for the client with ODD include the following:

■ Noncompliance with therapy related to negative temperament, denial of problems, underlying hostility

■ Defensive coping related to retarded ego development, low self-esteem, unsatisfactory parent/child relationship

■ Low self-esteem related to lack of positive feedback, retarded ego development

■ Impaired social interaction related to negative temperament, underlying hostility, manipulation of others

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with ODD.

The client:

■ Complies with treatment by participating in therapies without negativism

■ Accepts responsibility for his or her part in the problem

■ Takes direction from staff without becoming defensive

■ Does not manipulate other people

■ Verbalizes positive aspects about self

■ Interacts with others in an appropriate manner

Planning and Implementation

Table 33–7 provides a plan of care for the child with ODD using nursing diagnoses common to the disorder, outcome criteria, and appropriate nursing interventions and rationales.

Evaluation

The evaluation step of the nursing process calls for reassessment of the plan of care to determine if the nursing actions have been effective in achieving the goals of therapy. The following questions can be used with the child or adolescent with ODD to gather information for the evaluation.

■ Is the client cooperating with schedule of therapeutic activities? Is level of participation adequate?

■ Is the client's attitude toward therapy less negative?

■ Is the client accepting responsibility for problem behavior?

■ Is the client verbalizing the unacceptability of his or her passive-aggressive behavior?

BOX 33–5 Diagnostic Criteria for Oppositional Defiant Disorder

A. A pattern of angry/irritable mood, argumentative/defiant behavior, or vindictiveness lasting at least 6 months as evidenced by at least four symptoms from any of the following categories, and exhibited during interaction with at least one individual that is not a sibling.

ANGRY/IRRITABLE MOOD
1. Often loses temper.
2. Is often touchy or easily annoyed.
3. Is often angry and resentful.

ARGUMENTATIVE/DEFIANT BEHAVIOR
4. Often argues with authority figures or, for children and adolescents, with adults.
5. Often actively defies or refuses to comply with requests from authority figures or with rules.
6. Often deliberately annoys others.
7. Often blames others for his or her mistakes or misbehavior.

VINDICTIVENESS
8. Has been spiteful or vindictive at least twice within the past 6 months.

   Note: The persistence and frequency of these behaviors should be used to distinguish a behavior that is within normal limits from a behavior that is symptomatic. For children younger than 5 years, the behavior should occur on most days for a period of at least 6 months unless otherwise noted (Criterion A8). For individuals 5 years or older, the behavior should occur at least once per week for at least 6 months, unless otherwise noted (Criterion A8). While these frequency criteria provide guidance on a minimal level of frequency to define symptoms, other factors should also be considered, such as whether the frequency and intensity of the behaviors are outside a range that is normative for the individual's developmental level, gender, and culture.

B. The disturbance in behavior is associated with distress in the individual or others in his or her immediate social context (e.g., family, peer group, work colleagues), or it impacts negatively on social, educational, occupational, or other important areas of functioning.

C. The behaviors do not occur exclusively during the course of a psychotic, substance use, depressive, or bipolar disorder. Also, the criteria are not met for disruptive mood dysregulation disorder.

Specify current severity:

Mild: Symptoms are confined to only one setting (e.g., at home, at school, at work, with peers).

Moderate: Some symptoms are present in at least two settings.

Severe: Some symptoms are present in three or more settings.

Table 33–7 | CARE PLAN FOR THE CHILD/ADOLESCENT WITH OPPOSITIONAL DEFIANT DISORDER

NURSING DIAGNOSIS: NONCOMPLIANCE WITH THERAPY

RELATED TO: Negative temperament; denial of problems; underlying hostility

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client participates in and cooperates during therapeutic activities. Long-Term Goal • Client completes assigned tasks willingly and independently or with a minimum of assistance.	1. Set forth a structured plan of therapeutic activities. Start with minimum expectations and increase as client begins to manifest evidence of compliance.	1. Structure provides security and one or two activities may not seem as overwhelming as the whole schedule of activities presented at one time.
	2. Establish a system of rewards for compliance with therapy and consequences for noncompliance. Ensure that the rewards and consequences are concepts of value to client.	2. Positive, negative, and aversive reinforcements can contribute to desired changes in behavior.
	3. Convey acceptance of client separate from the undesirable behaviors being exhibited. ("It is not *you,* but your *behavior,* that is unacceptable.")	3. Unconditional acceptance enhances self-worth and may contribute to a decrease in the need for passive-aggression toward others.

Table 33–7 | CARE PLAN FOR THE CHILD/ADOLESCENT WITH OPPOSITIONAL DEFIANT DISORDER–cont'd

NURSING DIAGNOSIS: DEFENSIVE COPING

RELATED TO: Retarded ego development; low self-esteem; unsatisfactory parent/child relationship

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client verbalizes personal responsibility for difficulties experienced in interpersonal relationships within (time period reasonable for client). **Long-Term Goal** • Client accepts responsibility for own behaviors and interacts with others without becoming defensive.	1. Help client recognize that feelings of inadequacy provoke defensive behaviors, such as blaming others for problems, and the need to "get even." 2. Provide immediate, nonthreatening feedback for passive-aggressive behavior. 3. Help identify situations that provoke defensiveness, and practice through role-play more appropriate responses. 4. Provide immediate positive feedback for acceptable behaviors.	1. Recognition of the problem is the first step toward initiating change. 2. Because client denies responsibility for problems, he or she is denying the inappropriateness of behavior. 3. Role-playing provides confidence to deal with difficult situations when they actually occur. 4. Positive feedback encourages repetition, and immediacy is significant for these children who respond to immediate gratification.

NURSING DIAGNOSIS: LOW SELF-ESTEEM

RELATED TO: Lack of positive feedback; retarded ego development

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client participates in own self-care and discusses with nurse aspects of self about which he or she feels good. **Long-Term Goal** • Client demonstrates increased feelings of self-worth by verbalizing positive statements about self and exhibiting fewer manipulative behaviors.	1. Ensure that goals are realistic. 2. Plan activities that provide opportunities for success. 3. Convey unconditional acceptance and positive regard. 4. Set limits on manipulative behavior. Take caution not to reinforce manipulative behaviors by providing desired attention. Identify the consequences of manipulation. Administer consequences matter-of-factly when manipulation occurs. 5. Help client understand that he or she uses this behavior to try to increase own self-esteem. Interventions should reflect other actions to accomplish this goal.	1. Unrealistic goals set client up for failure, which diminishes self-esteem. 2. Success enhances self-esteem. 3. Affirmation of client as a worthwhile human being may increase self-esteem. 4. Aversive reinforcement may work to decrease unacceptable behaviors. 5. When client feels better about self, the need to manipulate others will diminish.

Continued

Table 33–7	CARE PLAN FOR THE CHILD/ADOLESCENT WITH OPPOSITIONAL DEFIANT DISORDER–cont'd		

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Negative temperament; underlying hostility; manipulation of others

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client interacts in age-appropriate manner with nurse in one-to-one relationship within 1 week. Long-Term Goal • Client is able to interact with staff and peers using age-appropriate, acceptable behaviors.	1. Develop a trusting relationship with client. Convey acceptance of the person separate from the unacceptable behavior. 2. Explain to client about passive-aggressive behavior. Explain how these behaviors are perceived by others. Describe which behaviors are not acceptable and role-play more adaptive responses. Give positive feedback for acceptable behaviors. 3. Provide peer group situations for client.	1. Unconditional acceptance increases feelings of self-worth and may serve to diminish feelings of rejection that have accumulated over a long period. 2. Role-playing is a way to practice behaviors that do not come readily to client, making it easier when the situation actually occurs. Positive feedback enhances repetition of desirable behaviors. 3. Appropriate social behavior is often learned from the positive and negative feedback of peers. Groups also provide an atmosphere for using the behaviors rehearsed in role-play.

■ Is he or she able to identify which behaviors are unacceptable and substitute more adaptive behaviors?

■ Is the client able to interact with staff and peers without defending behavior in an angry manner?

■ Is the client able to verbalize positive statements about self?

■ Is increased self-worth evident with fewer manifestations of manipulation?

■ Is the client able to make compromises with others when issues of control emerge?

■ Is anger and hostility expressed in an appropriate manner? Can the client verbalize ways of releasing anger adaptively?

■ Is he or she able to verbalize true feelings instead of allowing them to emerge through use of passive-aggressive behaviors?

Conduct Disorder

Clinical Findings, Epidemiology, and Course

With conduct disorder, there is a repetitive and persistent pattern of behavior in which the basic rights of others or major age-appropriate societal norms or rules are violated (APA, 2013). Physical **aggression** is common, and peer relationships are disturbed. Conduct disorder is one of the most frequent reasons that children and adolescents are referred for psychiatric intervention (Sadock et al., 2015). Prevalence estimates range from 2 percent to more than 10 percent, rises from childhood to adolescence, and is more common in males than females (APA, 2013). There is a higher male predominance among those with the childhood-onset subtype. A number of comorbidities are common with conduct disorder, including ADHD, mood disorders, learning disorders, and substance use disorders. When the disorder begins in childhood, there is more likely to be a history of ODD and a greater likelihood of antisocial personality disorder in adulthood than if the disorder is diagnosed in adolescence. Black and Andreasen (2014) report that an estimated 40 percent of boys and 25 percent of girls with conduct disorder will develop adult antisocial personality disorder.

CORE CONCEPT

Temperament

Personality characteristics that define an individual's mood and behavioral tendencies. The sum of physical, emotional, and intellectual components that affect or determine a person's actions and reactions.

Predisposing Factors

Biological Influences

Genetics Family, twin, and adoptive studies have revealed a significantly higher number of individuals with conduct disorder among those who have family members with the disorder (Black & Andreasen, 2014). Although genetic factors appear to be involved in the etiology of conduct disorder, little is yet known about the actual mechanisms involved in genetic transmission. There is some evidence, however, of the distinction between behaviors that appear to be genetic versus environmental risk factors. In a large study of male twins (N = 2,769), researchers attempted to determine the structure of genetic and environmental influences in conduct disorder and found the familial risk to conduct disorder is composed of two discrete dimensions of genetic risk, rule-breaking (such as truancy), and overt aggression (harming other people), and one dimension of shared environmental risk, reflecting covert delinquency (such as stealing and hurting animals) (Kendler, Aggen, & Patrick, 2013). Studies such as these support a complex dynamic of both genetic and environmental factors in the development of conduct disorder.

Temperament The term *temperament* refers to personality traits that become evident very early in life and may be present at birth. Children who show signs of an irritable temperament, poor compliance, inattentiveness, and impulsivity as early as age 2 may show signs of conduct disorder at later ages (Bernstein, 2014). Bernstein adds that children with severe temperamental disturbances, including poor attachment, may develop ODD and conduct disorder despite good parental intervention. More commonly, however, these children come from unstable families, with frequent changes in residence and economic stress. Evidence suggests a genetic influence in temperament and an association between temperament and behavioral problems later in life.

Neurobiological Factors Sadock and associates (2015) identify three neurobiological findings relevant to conduct disorders. First, neuroimaging studies identify decreased gray matter in limbic structures, bilateral insula (an area of the cortex that plays a role connecting emotional responses to pain), and the left amygdala. Second, studies have found high plasma concentration of serotonin and low levels in cerebrospinal fluid, both of which are correlated with aggression and violence. The third finding was that aggressive children had "significantly greater relative right frontal brain activity at rest than healthy controls" (p. 1250).

Psychosocial Influences

Peer Relationships Poor academic performance and social maladaptation often lead to affiliations with a deviant peer group. "Considerable research indicates that the deviant peer group provides training in criminal and delinquent behavior including substance abuse" (Bernstein, 2014). In addition to evidence that engaging in risk-taking behaviors can yield reinforcement on a social level (acceptance within a peer group), Bernstein notes that "studies of neural processing show that risk-taking may be associated with reward-related brain activation."

Family Influences

The following factors related to family dynamics have been implicated as contributors in the predisposition to conduct disorder and typically combine to create a pattern of chaotic disruption in family life (Bernstein, 2014; Mayo Clinic, 2016; Sadock et al., 2015):

- Parental rejection, neglect, or severe physical and verbal aggression
- Inconsistent or harsh, punitive discipline
- Parental sociopathy
- Lack of parental supervision
- Frequent changes in residence
- Economic stressors
- Parents with antisocial personality disorder, severe psychopathology, and/or alcohol/other substance dependence
- Marital conflict and divorce (particularly with persistent hostility)

Application of the Nursing Process to Conduct Disorder

Background Assessment Data (Symptomatology)

The classic characteristic of conduct disorder is the use of physical aggression to violate the rights of others. The behavior pattern manifests itself in virtually all areas of the child's life (home, school, with peers, and in the community). Stealing, lying, and truancy are common problems. The child lacks feelings of guilt or remorse.

The use of tobacco, liquor, or nonprescribed drugs, as well as the participation in sexual activities, occurs earlier than at the expected age for the peer group. Projection is a common defense mechanism.

Low self-esteem is manifested by a "tough guy" image. Characteristics include poor frustration tolerance, irritability, and frequent temper outbursts. Symptoms of anxiety and depression are not uncommon.

Level of academic achievement may be low in relation to age and IQ. Manifestations associated with ADHD (e.g., attention difficulties, impulsiveness, and

hyperactivity) are common in children with conduct disorder.

The *DSM-5* diagnostic criteria for conduct disorder are presented in Box 33–6.

Nursing Diagnosis

Based on the data collected during the nursing assessment, possible nursing diagnoses for the client with conduct disorder include the following:

■ Risk for other-directed violence related to characteristics of temperament, peer rejection, negative parental role models, dysfunctional family dynamics
■ Impaired social interaction related to negative parental role models, impaired peer relations leading to inappropriate social behaviors
■ Defensive coping related to low self-esteem and dysfunctional family system
■ Low self-esteem related to lack of positive feedback and unsatisfactory parent-child relationship

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with conduct disorder.

The client:

■ Has not harmed self or others
■ Interacts with others in a socially appropriate manner
■ Accepts direction without becoming defensive
■ Demonstrates evidence of increased self-esteem by discontinuing exploitative and demanding behaviors toward others

Planning and Implementation

Table 33–8 provides a plan of care for the child with conduct disorder using nursing diagnoses common to the disorder, outcome criteria, and appropriate nursing interventions and rationales.

BOX 33–6 Diagnostic Criteria for Conduct Disorder

A. A repetitive and persistent pattern of behavior in which the basic rights of others or major age-appropriate societal norms or rules are violated, as manifested by the presence of at least three of the following 15 criteria in the past 12 months from any of the categories below, with at least one criterion present in the past 6 months:

AGGRESSION TO PEOPLE AND ANIMALS
1. Often bullies, threatens, or intimidates others.
2. Often initiates physical fights.
3. Has used a weapon that can cause serious physical harm to others (e.g., a bat, brick, broken bottle, knife, gun).
4. Has been physically cruel to people.
5. Has been physically cruel to animals.
6. Has stolen while confronting a victim (e.g., mugging, purse snatching, extortion, armed robbery).
7. Has forced someone into sexual activity.

DESTRUCTION OF PROPERTY
8. Has deliberately engaged in fire setting with the intention of causing serious damage.
9. Has deliberately destroyed others' property (other than by fire setting).

DECEITFULNESS OR THEFT
10. Has broken into someone else's house, building, or car.
11. Often lies to obtain goods or favors or to avoid obligations (i.e., "cons" others).
12. Has stolen items of nontrivial value without confronting a victim (e.g., shoplifting, but without breaking and entering; forgery).

SERIOUS VIOLATIONS OF RULES
13. Often stays out at night despite parental prohibitions, beginning before age 13 years.

14. Has run away from home overnight at least twice while living in parental or parental surrogate home, or once without returning for a lengthy period.
15. Is often truant from school, beginning before age 13 years.

B. The disturbance in behavior causes clinically significant impairment in social, academic, or occupational functioning.
C. If the individual is age 18 years or older, criteria are not met for antisocial personality disorder.

Specify whether:

Childhood-Onset Type: Individuals show at least one symptom characteristic of conduct disorder prior to age 10 years.

Adolescent-Onset Type: Individuals show no symptom characteristic of conduct disorder prior to age 10 years.

Unspecified Onset: Criteria for a diagnosis of conduct disorder are met, but there is not enough information available to determine whether the onset of the first symptom was before or after age 10 years.

Specify if:

With limited prosocial emotions

Specify current severity:

Mild
Moderate
Severe

Table 33–8 | CARE PLAN FOR CHILD/ADOLESCENT WITH CONDUCT DISORDER

NURSING DIAGNOSIS: RISK FOR OTHER-DIRECTED VIOLENCE

RELATED TO: Characteristics of temperament, peer rejection, negative parental role models, dysfunctional family dynamics

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client discusses feelings of anger with nurse or therapist. **Long-Term Goal** • Client does not harm others or others' property.	1. Observe client's behavior frequently through routine activities and interactions. Become aware of behaviors that indicate a rise in agitation. 2. Redirect violent behavior with physical outlets for suppressed anger and frustration. 3. Encourage client to express anger, and act as a role model for appropriate expression of anger. Explore child's perceptions and feelings about contributing factors and triggers for anger and violent behavior. 4. Ensure that a sufficient number of staff is available to indicate a show of strength if necessary. 5. Administer tranquilizing medication, if ordered, or use mechanical restraints or isolation room only if situation cannot be controlled with less restrictive means.	1. Recognition of behaviors that precede the onset of aggression may provide the opportunity to intervene before violence occurs. 2. Excess energy is released through physical activities, inducing a feeling of relaxation. 3. Discussion of situations that create anger may lead to more effective ways of dealing with them. 4. This conveys evidence of control over the situation and provides physical security for staff and others. 5. It is client's right to expect the use of techniques that ensure safety of client and others by the least restrictive means.

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Negative parental role models; impaired peer relations leading to inappropriate social behavior

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client interacts in age-appropriate manner with nurse in one-to-one relationship within 1 week. **Long-Term Goal** • Client is able to interact with staff and peers using age-appropriate, acceptable behaviors.	1. Develop a trusting relationship with client. Convey acceptance of the person separate from the unacceptable behavior. 2. Discuss with client which behaviors are and are not acceptable. Describe in matter-of-fact manner the consequence of unacceptable behavior. Follow through. 3. Provide group situations for client.	1. Unconditional acceptance increases feeling of self-worth. 2. Aversive reinforcement can alter or extinguish undesirable behaviors. 3. Appropriate social behavior is often learned from the positive and negative feedback of peers.

Continued

Table 33–8 | CARE PLAN FOR CHILD/ADOLESCENT WITH CONDUCT DISORDER–cont'd

NURSING DIAGNOSIS: DEFENSIVE COPING

RELATED TO: Low self-esteem and dysfunctional family system

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client verbalizes personal responsibility for difficulties experienced in interpersonal relationships within a time period reasonable for client. Long-Term Goal • Client accepts responsibility for own behaviors and interacts with others without becoming defensive.	1. Explain to client the correlation between feelings of inadequacy and the need for acceptance from others and how these feelings provoke defensive behaviors, such as blaming others for own behaviors. 2. Provide immediate, matter-of-fact, nonthreatening feedback for unacceptable behaviors. 3. Help identify situations that provoke defensiveness, and practice through role-play more appropriate responses. 4. Provide immediate positive feedback for acceptable behaviors.	1. Recognition of the problem is the first step in the change process toward resolution. 2. Client may not realize how these behaviors are being perceived by others. 3. Role-playing provides confidence to deal with difficult situations when they actually occur. 4. Positive feedback encourages repetition, and immediacy is significant for these children, who respond to immediate gratification.

NURSING DIAGNOSIS: LOW SELF-ESTEEM

RELATED TO: Lack of positive feedback and unsatisfactory parent/child relationship

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client participates in own self-care and discusses with nurse aspects of self about which he or she feels good. Long-Term Goal • Client demonstrates increased feelings of self-worth by verbalizing positive statements about self and exhibiting fewer manipulative behaviors.	1. Ensure that goals are realistic. 2. Plan activities that provide opportunities for success. 3. Convey unconditional acceptance and positive regard. 4. Set limits on manipulative behavior. Take caution not to reinforce manipulative behaviors by providing desired attention. Identify the consequences of manipulation. Administer consequences matter-of-factly when manipulation occurs. 5. Help client understand that he or she uses this behavior in order to try to increase own self-esteem. Interventions should reflect other actions to accomplish this goal.	1. Unrealistic goals set client up for failure, which diminishes self-esteem. 2. Success enhances self-esteem. 3. Communicating that client is a worthwhile human being helps to increase self-esteem. 4. Aversive consequences may work to decrease unacceptable behaviors. 5. When client feels better about self, the need to manipulate others will diminish.

Evaluation

Following the planning and implementation of care, evaluation is made of the behavioral changes in the child with conduct disorder. This is accomplished by determining if the goals of therapy have been achieved. Reassessment, the next step in the nursing process, may be initiated by gathering information using the following questions:

■ Have the nursing actions directed toward managing the client's aggressive behavior been effective?
■ Have interventions prevented harm to others or others' property?
■ Is the client able to express anger in an appropriate manner?
■ Has the client developed more adaptive coping strategies to deal with anger and feelings of aggression?
■ Does the client demonstrate the ability to trust others? Is he or she able to interact with staff and peers in an appropriate manner?
■ Is the client able to accept responsibility for his or her own behavior? Is there less blaming of others?
■ Is the client able to accept feedback from others without becoming defensive?
■ Is the client able to verbalize positive statements about self?
■ Is the client able to interact with others without engaging in manipulation?

Anxiety Disorders

Separation Anxiety Disorder

Clinical Findings, Epidemiology, and Course

Separation anxiety disorder is characterized by excessive fear or anxiety concerning separation from those to whom the individual is attached (APA, 2013). The anxiety is beyond that which would be expected for the individual's developmental level and interferes with social, academic, occupational, or others areas of functioning. Onset may occur any time before age 18 years but is most commonly diagnosed around age 5 or 6, when the child goes to school. Diagnosis at this time may be related to the surfacing of symptoms when the child is faced with new stressors and the recognition of symptoms by school counselors and teachers. It is estimated that about 1 percent of children age 2 to 5 already show symptoms of anxiety disorders. In this age group, these signs may be a reflection of anxiety that they are mimicking from their parents. Assessment of the child and the family is important in assuring accurate diagnosis. Prevalence estimates for the disorder average about 4 percent in children and young adults, and it is more common in girls than in boys. Most children grow out of it, but in some instances the symptoms can persist into adulthood. Separation anxiety disorder can be a precursor to adult panic disorder (Black & Andreasen, 2014).

Predisposing Factors

Biological Influences

Genetics A greater number of children with relatives who manifest anxiety problems develop anxiety disorders than do children with no such family patterns. The results are significant enough to speculate that there is a hereditary influence in the development of separation anxiety disorder, but the mode of genetic transmission has not been determined. Sadock and associates (2015) state:

> Current consensus on the genetics of anxiety disorders suggests that what is inherited is a general predisposition toward anxiety, with resulting heightened levels of arousability, emotional reactivity, and increased negative affect, all of which increase the risk for the development of separation anxiety disorder [and other anxiety disorders]. (p. 1255)

Temperament It is well established that children differ in temperament from one another starting at birth or shortly thereafter. "The temperamental traits of shyness and withdrawal in unfamiliar situations, have been shown to be associated with a higher risk of developing separation anxiety disorder [as well as other anxiety disorders]" (Sadock et al., 2015, p. 1255).

Environmental Influences

Stressful Life Events Studies have shown a relationship between life events and the development of anxiety disorders. Significant change or loss often coincides with the development of the disorder (Sadock et al., 2015). Children of mothers who were stressed during pregnancy also appear to be at greater risk for developing separation anxiety disorder (Dryden-Edwards, 2015).

Family Influences

Various theories expound on the idea that anxiety disorders in children are related to an attachment issue with the mother. Three family influences that have demonstrated an increased risk for anxiety disorders in children include parental overprotection, insecure parent-child attachment, and maternal depression (Sadock et al., 2015).

Some parents may also transfer their fears and anxieties to their children through role-modeling. For example, a parent who becomes significantly fearful and apprehensive when confronted with unfamiliar circumstances, such as a job or residence change, teaches the child that this is an appropriate response.

Application of the Nursing Process to Separation Anxiety Disorder

Background Assessment Data (Symptomatology)

Onset of this disorder may occur as early as preschool age; it rarely begins as late as adolescence. In most cases, the child has difficulty separating from the mother. Occasionally, the separation reluctance is directed toward the father, siblings, or other significant individual to whom the child is attached. Anticipation of separation may result in tantrums, crying, screaming, complaints of physical problems, and **clinging** behaviors.

Reluctance or refusal to attend school occurs in the majority of these children. Up to 80 percent of children with school refusal meet criteria for separation anxiety disorder (Dryden-Edwards, 2015). Younger children may "shadow" or follow around the person from whom they are afraid to be separated. During middle childhood or adolescence, they may refuse to sleep away from home (e.g., at a friend's house or at camp). Interpersonal peer relationships are usually not a problem with these children. They are generally well liked by their peers and are reasonably socially skilled.

Worrying is common and relates to the possibility of harm coming to self or to the attachment figure. Younger children may even have nightmares to this effect. Specific phobias are not uncommon (e.g., fear of the dark, ghosts, animals). Depressed mood is frequently present and often precedes the onset of the anxiety symptoms, which commonly occur following a major stressor. The *DSM-5* diagnostic criteria for separation anxiety disorder are presented in Box 33–7.

Nursing Diagnosis

Based on the data collected during the nursing assessment, possible nursing diagnoses for the client with separation anxiety disorder include the following:

■ Anxiety (severe) related to family history, temperament, overattachment to parent, negative role modeling
■ Ineffective coping related to unresolved separation conflicts and inadequate coping skills evidenced by numerous somatic complaints
■ Impaired social interaction related to reluctance to be away from attachment figure

Outcome Identification

Outcome criteria include short- and long-term goals. Time lines are individually determined. The following criteria may be used for measurement of outcomes in the care of the client with separation anxiety disorder.

The client:

■ Is able to maintain anxiety at manageable level
■ Demonstrates adaptive coping strategies for dealing with anxiety when separation from attachment figure is anticipated

---

BOX 33–7 Diagnostic Criteria for Separation Anxiety Disorder

A. Developmentally inappropriate and excessive fear or anxiety concerning separation from those to whom the individual is attached, as evidenced by at least three of the following:
  1. Recurrent excessive distress when anticipating or experiencing separation from home or major attachment figures.
  2. Persistent and excessive worry about losing major attachment figures or about possible harm to them, such as illness, injury, disasters, or death.
  3. Persistent and excessive worry about experiencing an untoward event (e.g., getting lost, being kidnapped, having an accident, becoming ill) that causes separation from a major attachment figure.
  4. Persistent reluctance or refusal to go out, away from home, to school, to work, or elsewhere because of fear of separation.
  5. Persistent and excessive fear of or reluctance about being alone or without major attachment figures at home or in other settings.
  6. Persistent reluctance or refusal to sleep away from home or to go to sleep without being near a major attachment figure.

  7. Repeated nightmares involving the theme of separation.
  8. Repeated complaints of physical symptoms (e.g., headaches, stomachaches, nausea, vomiting) when separation from major attachment figures occurs or is anticipated.
B. The fear, anxiety, or avoidance is persistent, lasting at least 4 weeks in children and adolescents and typically 6 months or more in adults.
C. The disturbance causes clinically significant distress or impairment in social, academic, occupational, or other important areas of functioning.
D. The disturbance is not better accounted for by another mental disorder, such as refusing to leave home because of excessive resistance to change in autism spectrum disorder; delusions or hallucinations concerning separation in psychotic disorders; refusal to go outside without a trusted companion in agoraphobia; worries about ill health or other harm befalling significant others in generalized anxiety disorder; or concerns about having an illness in illness anxiety disorder.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition *(Copyright 2013). American Psychiatric Association.*

■ Interacts appropriately with others and spends time away from attachment figure to do so

Planning and Implementation

Table 33–9 provides a plan of care for the child or adolescent with separation anxiety, using nursing diagnoses common to this disorder, outcome criteria, and appropriate nursing interventions and rationales.

Evaluation

Evaluation of the child or adolescent with separation anxiety disorder requires reassessment of the behaviors for which the family sought treatment. Both the client and the family members will have to change their behavior. The following types of questions may provide assistance in gathering data required for evaluating whether the nursing interventions have been effective in achieving the goals of therapy.

■ Is the client able to maintain anxiety at a manageable level (i.e., without temper tantrums, screaming, or clinging)?

■ Have complaints of physical symptoms diminished?
■ Has the client demonstrated the ability to cope in more adaptive ways in the face of escalating anxiety?
■ Have the parents identified their role in the separation conflict? Are they able to discuss more adaptive coping strategies?
■ Does the client verbalize an intention to return to school?
■ Have nightmares and fears of the dark subsided?
■ Is the client able to interact with others away from the attachment figure?
■ Has the precipitating stressor been identified? Have strategies for coping more adaptively to similar stressors in the future been established?

Quality and Safety Education for Nurses (QSEN)

The Institute of Medicine (now the National Academy of Medicine), in its 2003 report *Health Professions Education: A Bridge to Quality,* challenged faculties of

Table 33–9 | CARE PLAN FOR THE CLIENT WITH SEPARATION ANXIETY DISORDER

NURSING DIAGNOSIS: ANXIETY (SEVERE)
RELATED TO: Family history; temperament; overattachment to parent; negative role modeling

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client discusses fears of separation with trusted individual. **Long-Term Goal** • Client maintains anxiety at no higher than moderate level in the face of events that formerly have precipitated panic.	1. Establish an atmosphere of calmness, trust, and genuine positive regard.	1. Trust and unconditional acceptance are necessary for satisfactory nurse-client relationship. Calmness is important because anxiety is easily transmitted from one person to another.
	2. Assure client of his or her safety and security.	2. Symptoms of panic anxiety are very frightening.
	3. Explore child's or adolescent's fears of separating from the parents. Explore with parents possible fears they may have of separation from child.	3. Some parents may have an underlying fear of separation from the child, of which they are unaware and which they are unconsciously transferring to child.
	4. Help parents and child initiate realistic goals (e.g., child to stay with sitter for 2 hours with minimal anxiety; or, child to stay at friend's house without parents until 9 p.m. without experiencing panic anxiety).	4. Parents may be so frustrated with child's clinging and demanding behaviors that assistance with problem-solving may be required.
	5. Give, and encourage parents to give, positive reinforcement for desired behaviors.	5. Positive reinforcement encourages repetition of desirable behaviors.

Continued

Table 33–9 | CARE PLAN FOR THE CLIENT WITH SEPARATION ANXIETY DISORDER–cont'd

NURSING DIAGNOSIS: INEFFECTIVE COPING

RELATED TO: Unresolved separation conflicts and inadequate coping skills

EVIDENCED BY: Numerous somatic complaints

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client verbalizes correlation of somatic symptoms to fear of separation. **Long-Term Goal** • Client demonstrates use of more adaptive coping strategies (rather than physical symptoms) in response to stressful situations.	1. Encourage child or adolescent to discuss specific situations in life that produce the most distress and describe his or her response to these situations. Include parents in the discussion. 2. Help child or adolescent who is perfectionistic to recognize that self-expectations may be unrealistic. Connect times of unmet self-expectations to the exacerbation of physical symptoms. 3. Encourage parents and child to identify more adaptive coping strategies that child could use in the face of anxiety that feels overwhelming. Practice through role-play.	1. Client and family may be unaware of the correlation between stressful situations and the exacerbation of physical symptoms. 2. Recognition of maladaptive patterns is the first step in the change process. 3. Practice facilitates the use of the desired behavior when the individual is actually faced with the stressful situation.

NURSING DIAGNOSIS: IMPAIRED SOCIAL INTERACTION

RELATED TO: Reluctance to be away from attachment figure

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal • Client spends time with staff or other support person, without presence of attachment figure, without excessive anxiety. **Long-Term Goal** • Client is able to spend time with others (without presence of attachment figure) without excessive anxiety.	1. Develop a trusting relationship with client. 2. Attend groups with child and support efforts to interact with others. Give positive feedback. 3. Convey to child the acceptability of his or her not participating in group in the beginning. Gradually encourage small contributions until client is able to participate more fully. 4. Help client set small personal goals (e.g., "Today I will speak to one person I don't know").	1. This is the first step in helping client learn to interact with others. 2. Presence of a trusted individual provides security during times of distress. Positive feedback encourages repetition. 3. Small successes will gradually increase self-confidence and decrease self-consciousness, so that client will feel less anxious in the group situation. 4. Simple, realistic goals provide opportunities for success that increase self-confidence and may encourage client to attempt more difficult objectives in the future.

medicine, nursing, and other health professions to ensure that their graduates have achieved a core set of competencies in order to meet the needs of the 21st-century health-care system. These competencies include *providing patient-centered care, working in interdisciplinary teams, maintaining safety, employing evidence-based practice, applying quality improvement,* and *utilizing informatics.* A QSEN teaching strategy is presented in Box 33–8. The use of this type of activity is intended to arm the instructor and student with guidelines for attaining the knowledge, skills, and attitudes necessary for achievement of quality and safety competencies in nursing.

General Therapeutic Approaches

Treatment for neurodevelopmental disorders, disruptive behavior disorders, and anxiety disorders poses many challenges and requires a comprehensive treatment plan that may include individual, group, and family therapies; family education; pharmacotherapy; and psychotherapeutic interventions specifically designed for the unique clinical issues presented in each disorder. General therapeutic approaches are described in the next sections.

Behavior Therapy

Behavior therapy is based on the concepts of classical conditioning and operant conditioning and is a common and effective treatment with disruptive behavior disorders such as ADHD, ODD, and conduct disorder. With this approach, rewards are given for appropriate behaviors and withheld when behaviors are disruptive or otherwise inappropriate. The principle behind behavior therapy is that positive reinforcements encourage repetition of desirable behaviors and aversive reinforcements (punishments) discourage repetition of undesirable behaviors. Behavior modification techniques—the system of rewards and consequences—can be taught to parents to be used in the home environment. Consistency is an essential component.

In the treatment setting, individualized behavior modification programs are designed for each client.

Family Therapy

Children cannot be separated from their family. Therapy for children and adolescents must involve the entire family if problems are to be resolved. Parents should be involved in designing and implementing the treatment plan for the child and all other aspects of the treatment process.

The genogram can be used to identify problem areas between family members. It provides an overall picture of the family life over several generations, including roles that various family members play and emotional distance between specific individuals. Areas for change can be easily identified.

The impact of family dynamics on disruptive behavior disorders has been identified. The impact of disruptive behavior on family dynamics cannot be ignored. Family coping can become severely compromised by the chronic stress of dealing with a child with a behavior disorder. It is therefore imperative that the treatment plan for the identified client be instituted within the context of family-centered care.

BOX 33–8 QSEN TEACHING STRATEGY

Assignment: Patient-Centered Care: Kleinman's Mini-Ethnography
Interviewing Families of Children With Psychiatric Disorders

Competency Domain: Patient-Centered Care

Learning Objectives: Student will:
- Demonstrate skills in hearing patients' and family members' stories of living with the disorder.
- Identify his or her own explanatory models of the disorder.
- Demonstrate attitudes that reflect a desire to cultivate cultural humility and cultural competence in nursing practice.

Strategy Overview:
1. Read "Anthropology in the Clinic: The Problem of Cultural Competency and How to Fix It," by A. Kleinman and P. Benson. The article is available online at www.plosmedicine.org/article/info:doi/10.1371/journal.pmed.0030294
2. Based on the mini-ethnography described by Kleinman and Benson, interview a family member of a child with a psychiatric disorder and elicit a narrative of his or her experience in living with the disorder.
3. Drawing on notes from the interview, write one paper that is the narrative of the illness from the perspective of the interviewee and another paper that describes the student's own explanatory model.

Source: Adapted from teaching strategy submitted by Lisa Day, Assistant Clinical Professor, UCSF, School of Nursing, San Francisco, CA. © 2009 QSEN; http://qsen.org. With permission.

Group Therapy

Group therapy provides children and adolescents with the opportunity to interact within an association of their peers. This experience can be both gratifying and overwhelming, depending on the child.

Group therapy provides a number of benefits. Appropriate social behavior often is learned from the positive and negative feedback of peers. Opportunity is provided to learn to tolerate and accept differences in others, learn that it is acceptable to disagree, offer and receive support from others, and practice these new skills in a safe environment. It is also a way to learn from the experiences of others.

Group therapy with children and adolescents can take several forms. Music therapy groups allow clients to express feelings through music, often when they are unable to express themselves in any other way. Art and activity/craft therapy groups allow individual expression through artistic means.

Group play therapy is the treatment of choice for many children between the ages of 3 and 9 years, and evidence supports its effectiveness for many different childhood problems. The Association for Play Therapy (2016) states:

> Play therapy builds on the natural way that children learn about themselves and their relationships in the world around them. Through play therapy, children learn to communicate with others, express feelings, modify behavior, develop problem-solving skills, and learn a variety of ways of relating to others. Play provides a safe psychological distance from their problems and allows expression of thoughts and feelings appropriate to their development.

Psychoeducational groups are very beneficial for adolescents. The only drawback to this type of group is that it works best when the group is closed-ended; that is, once the group has been formed, no one is allowed to join until the group has reached its preestablished closure. Members are allowed to propose topics for discussion. The leader serves as teacher much of the time and facilitates discussion of the proposed topic. Members may from time to time be presenters and serve as discussion leaders. Sometimes, psychoeducation groups evolve into traditional therapy discussion groups.

Psychopharmacology

Several of the disorders presented in this chapter are treated with medications. The appropriate pharmacology was presented in the section in which the disorder was discussed. Medication should never be the sole method of treatment. It is undeniable that medication can and does improve quality of life for families of children and adolescents with these disorders.

However, research has indicated that medication alone is not as effective as a combination of medication and psychosocial therapy. It is important for families to understand that there is no way to "give him a pill and make him well." The importance of the psychosocial therapies cannot be overstressed. Some clinicians will not prescribe medications for a client unless he or she also participates in concomitant psychotherapy sessions. The beneficial effects of the medications promote improved coping ability, which in turn enhances the intent of the psychosocial therapy.

Summary and Key Points

- Intellectual disability is defined by deficits in general intellectual functioning and adaptive functioning.
- Four levels of intellectual disability—mild, moderate, severe, and profound—are associated with various behavioral manifestations and abilities.
- ASD is characterized by a withdrawal of the child into the self and into a fantasy world of his or her own creation.
- It is generally accepted that ASD is caused by abnormalities in brain structures or functions. Genetic factors are also thought to play a significant role in ASD.
- Children with ADHD may exhibit symptoms of inattention or hyperactivity and impulsiveness or a combination of the two.
- Genetics plays a role in the etiology of ADHD. Neurotransmitters that have been implicated include dopamine, norepinephrine, and serotonin. Maternal smoking during pregnancy has been linked to hyperactive behavior in offspring.
- CNS stimulants, alpha agonists, atomoxetine, and bupropion are commonly used to treat ADHD.
- The essential feature of Tourette's disorder is the presence of multiple motor tics and one or more vocal tics.
- Common medications used with Tourette's disorder include haloperidol, pimozide, clonidine, guanfacine, and atypical antipsychotics such as risperidone, olanzapine, and ziprasidone.
- Oppositional defiant disorder is characterized by a pattern of negativistic, defiant, disobedient, and hostile behavior toward authority figures that occurs more frequently than is usually observed in individuals of comparable age and developmental level.
- With conduct disorder, there is a repetitive and persistent pattern of behavior in which the basic rights of others or major age-appropriate societal norms or rules are violated.
- The essential feature of separation anxiety disorder is excessive anxiety concerning separation from the

home or from those to whom the person is attached.

■ Children with separation anxiety disorder may have temperamental characteristics present at birth that predispose them to the disorder.

■ General therapeutic approaches for child and adolescent psychiatric disorders include behavior therapy, family therapy, group therapies (including music, art, crafts, play, and psychoeducation), and psychopharmacology.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. In an effort to help the child with mild to moderate intellectual developmental disorder develop satisfying relationships with others, which of the following nursing interventions is most appropriate?
   a. Interpret the child's behavior for others.
   b. Set limits on behavior that is socially inappropriate.
   c. Allow the child to behave spontaneously, for he or she has no concept of right or wrong.
   d. This child is not capable of forming social relationships.

2. The child with autism spectrum disorder has difficulty with trust. With this in mind, which of the following nursing actions would be most appropriate?
   a. Encourage all staff to hold the child as often as possible, conveying trust through touch.
   b. Assign a different staff member each day so the child will learn that everyone can be trusted.
   c. Assign the same staff person as often as possible to promote feelings of security and trust.
   d. Avoid eye contact because it is extremely uncomfortable for the child and may even discourage trust.

3. Which of the following nursing diagnoses would be considered the *priority* in planning care for the child with severe autism spectrum disorder?
   a. Risk for self-mutilation evidenced by banging head against wall
   b. Impaired social interaction evidenced by unresponsiveness to people
   c. Impaired verbal communication evidenced by absence of verbal expression
   d. Disturbed personal identity evidenced by inability to differentiate self from others

4. Which of the following activities would be most appropriate for the child with attention-deficit/hyperactivity disorder?
   a. Monopoly
   b. Volleyball
   c. Pool
   d. Checkers

5. Which of the following groups is most commonly used for drug management of the child with attention-deficit/hyperactivity disorder?
   a. CNS depressants (e.g., diazepam [Valium])
   b. CNS stimulants (e.g., methylphenidate [Ritalin])
   c. Anticonvulsants (e.g., phenytoin [Dilantin])
   d. Major tranquilizers (e.g., haloperidol [Haldol])

6. The child with attention-deficit/hyperactivity disorder has a nursing diagnosis of impaired social interaction. Which of the following nursing interventions are appropriate for this child? (Select all that apply.)
   a. Socially isolate the child when interactions with others are inappropriate.
   b. Set limits with consequences on inappropriate behaviors.
   c. Provide rewards for appropriate behaviors.
   d. Provide group situations for the child.

Review Questions—cont'd
Self-Examination/Learning Exercise

7. The nursing history and assessment of an adolescent with a conduct disorder might reveal all of the following behaviors *except:*
   a. Manipulation of others for fulfillment of own desires.
   b. Chronic violation of rules.
   c. Feelings of guilt associated with the exploitation of others.
   d. Inability to form close peer relationships.

8. Certain family dynamics often predispose adolescents to the development of conduct disorder. Which of the following patterns is thought to be a contributing factor?
   a. Parents who are overprotective
   b. Parents who have high expectations for their children
   c. Parents who consistently set limits on their children's behavior
   d. Parents who are alcohol dependent

9. Which of the following is *least* likely to predispose a child to Tourette's disorder?
   a. Absence of parental bonding
   b. Family history of the disorder
   c. Abnormalities of brain neurotransmitters
   d. Structural abnormalities of the brain

10. Which of the following medications is used to treat Tourette's disorder?
   a. Methylphenidate (Ritalin)
   b. Haloperidol (Haldol)
   c. Imipramine (Tofranil)
   d. Phenytoin (Dilantin)

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

DESCRIPTION OF THE STUDY: This study evaluated the reports of 120 parents of preschool children with ADHD, ODD, or anxiety disorders to identify whether their reports of child temperament and character accurately predicted their child's diagnostic picture using a specific assessment inventory (the Preschool Temperament and Character Inventory).

RESULTS OF THE STUDY: The researchers found that three dimensions of temperament (harm avoidance, novelty seeking, and persistence) enabled correct identification of ADHD, ODD, or anxiety disorders 75 percent of the time.

Specifically, children with ADHD showed high scores on novelty-seeking and low scores on reward dependence and persistence; children with anxiety disorders showed high scores on harm avoidance; and children with ODD had higher scores on novelty-seeking, persistence, and harm avoidance.

IMPLICATIONS FOR NURSING PRACTICE: This study has implications for nurses who work with children, and particularly those who work in schools. Early identification of these childhood disorders enables intensive and comprehensive intervention to be initiated at the earliest signs of a developing disorder. If temperament profiles can accurately differentiate among these disorders, then screening as early as preschool is justified and may help to mediate longer-term consequences of these disorders by enabling targeted intervention.

TEST YOUR CRITICAL THINKING SKILLS

Jimmy, age 9, has been admitted to the child psychiatric unit with a diagnosis of attention-deficit/hyperactivity disorder. He has been unmanageable at school and at home and has had several suspensions from school for continuous disruption of his class. He refuses to sit in his chair or do his work. He yells out in class, interrupts the teacher and the other students, and lately has become physically aggressive when he cannot have his way. Most recently, he was suspended after hitting his teacher when she asked him to return to his seat.

Jimmy's mother describes him as a restless and demanding baby who grew into a restless and demanding toddler. He has never gotten along well with his peers. Even as a small child, he would take his friends' toys away from them or bite them if they tried to hold their own with him. His 5-year-old sister is afraid of him and refuses to be alone with him.

During the nurse's intake assessment, Jimmy paced the room or rocked in his chair. He talked incessantly on a superficial level and jumped from topic to topic. He told the nurse that he did not know why he was there. He acknowledged that he had some problems at school but said that it was only because the other kids picked on him and the teacher did not like him. He said he got into trouble at home sometimes but that it was because his parents liked his little sister better than they liked him.

The physician has ordered methylphenidate 5 mg twice a day for Jimmy. His response to this order is, "I'm not going to take drugs. I'm not sick!"

Answer the following questions related to Jimmy:

1. What are the pertinent assessment data to be noted by the nurse?
2. What is the primary nursing diagnosis for Jimmy?
3. Aside from client safety, to what problems would the nurse want to direct intervention with Jimmy?

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss societal perspectives on aging.
2. Describe an epidemiological profile of aging in the United States.
3. Discuss various theories of aging.
4. Describe biological, psychological, sociocultural, and sexual aspects of the normal aging process.
5. Discuss retirement as a special concern to the aging individual.
6. Explain personal and sociological perspectives of long-term care of the aging individual.
7. Describe the problem of elder abuse as it exists in today's society.
8. Discuss the implications of the increasing number of suicides among the elderly population.
9. Apply the steps of the nursing process to the care of aging individuals.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Which theory of aging postulates that life span and longevity changes are predetermined?
2. How is the ability to learn affected by aging?
3. What is the most common cause of psychopathology in the elderly?
4. What are some factors that are thought to contribute to elder abuse?

What is it like to grow old? It is not likely that many people in the American culture would state that it is something they want to do. Most would agree, however, that it is "better than the alternative."

Roberts (1991) recounts the tale of Supreme Court Justice Oliver Wendell Holmes Jr. In the year before he retired at age 91 as the oldest justice ever to sit on the Supreme Court of the United States, Holmes and his close friend Justice Louis Brandeis, then a mere 74 years old, were out for one of their frequent walks on Washington's Capitol Hill. On this particular day, the justices spotted a very attractive young woman approaching them. As she passed, Holmes paused, sighed, and said to Brandeis, "Oh, to be 70 again!" Obviously, being old is relative to the individual experiencing it.

Growing old has not historically been desirable among the youth-oriented American culture. However, with 66 million baby boomers reaching their 65th birthdays by the year 2030, greater emphasis is being placed on the needs of an aging population. The disciplines of **gerontology** (the study of the aging process), **geriatrics** (the branch of clinical medicine specializing in problems of the elderly), and **geropsychiatry** (the branch of clinical medicine specializing in psychopathology of the elderly population) are expanding rapidly in response to this demand.

Growing old in a society that has been obsessed with youth may have a critical impact on the mental health of many people. This situation has serious implications for psychiatric nursing.

What is it like to grow old? More and more people will be able to answer this question as the 21st century progresses. Perhaps they will also be asking the question that Roberts (1991) asks: "How did I get here so fast?"

This chapter focuses on physical and psychological changes associated with the aging process, as well as special concerns of the elderly population, such as retirement, long-term care, elder abuse, and high suicide rates. The nursing process is presented as the vehicle for delivery of nursing care to elderly individuals.

How Old Is *Old*?

The concept of "old" has changed drastically over the years. Our prehistoric ancestors probably had a life span of 40 years, with the average individual living around 18 years. As civilization developed, mortality rates remained high as a result of periodic famine and frequent malnutrition. An improvement in the standard of living was not truly evident until about the middle of the 17th century. Since that time, assured food supply, changes in food production, better housing conditions, and more progressive medical and sanitation facilities have contributed to population growth, declining mortality rates, and substantial increases in longevity.

In 1900, the average life expectancy in the United States was 47 years, and only 4 percent of the population was age 65 or older. By 2014, the average life expectancy at birth was 78.8 years (76.4 years for men and 81.2 years for women) (National Center for Health Statistics, 2016).

The U.S. Census Bureau has created a system for classification of older Americans:

- Older: 55 through 64 years
- Elderly: 65 through 74 years
- Aged: 75 through 84 years
- Very old: 85 years and older

Some gerontologists have elected to use a simpler classification system:

- Young old: 60 through 74 years
- Middle old: 75 through 84 years
- Old old: 85 years and older

So how old is *old*? Obviously, the term cannot be defined by a number. Myths and stereotypes of aging have long obscured our understanding of the aged and the process of aging. Ideas that all elderly individuals are sick, depressed, obsessed with death, senile, and incapable of change affect the way elderly people are treated. They even shape the pattern of aging for people who believe them by becoming self-fulfilling prophecies—people start to believe they should behave in certain ways and therefore act according to those beliefs. Generalized assumptions can be demeaning and can interfere with the quality of life for older individuals.

Just as there are many differences in individual adaptation at earlier stages of development, so it is in the elderly population. Erikson (1963) has suggested that the mentally healthy older person possesses a sense of ego integrity and self-acceptance that will help in adapting to the ambiguities of the future with a sense of security and optimism.

Murray, Zentner, and Yakimo (2009) stated:

> [Having accomplished the earlier developmental tasks], the person accepts life as his or her own and as the only life for the self. He or she would wish for none other and would defend the meaning and the dignity of the lifestyle. The person has further refined the characteristics of maturity described for the middle-aged adult, achieving both wisdom and an enriched perspective about life and people. (p. 662)

Everyone, particularly health-care workers, should see aging people as individuals, each with specific needs and abilities, rather than as a stereotypical

group. Some individuals may seem "old" at 40, whereas others may not seem "old" at 70. Variables such as attitude, mental health, physical health, and degree of independence strongly influence how an individual perceives himself or herself. Surely, in the final analysis, whether one is considered "old" must be self-determined.

Epidemiological Statistics

The Population

In 1980, Americans 65 years of age and older numbered 25.5 million. By 2014, this number increased to 46.2 million and is expected to double by 2060 to 98 million (Administration on Aging [AoA], 2016). In 2015, that number represented 14.5 percent of the population, and it is projected that by 2040 the number of Americans older than age 65 will represent 21.7 percent of the population. The population of those 85 years of age and older is expected to triple by the year 2040. As of 2014, 0.2 percent of the population was older than 100 (AoA, 2016).

Marital Status

In 2015, of individuals age 65 and older, 70 percent of men and 45 percent of women were married (AoA, 2016). Thirty-four percent of all women in this age group were widowed. There were three times as many widows as widowers, which is consistent with the longer life expectancy for women.

Living Arrangements

The majority of individuals age 65 or older live alone, with a spouse, or with relatives. In 2014, 2.2 million adults older than 65 were living in a household with a grandchild present, and 554,579 of these grandparents had primary responsibility for the grandchild living with them (AoA, 2016). This trend continues to grow and has significant implications for the changing complexion of older adult life. At any one time, fewer than 5 percent of people in this age group live in institutions. This percentage increases dramatically with age, ranging from 1 percent for persons 65 to 74 years, to 3 percent for persons 75 to 84 years, to 10 percent for persons 85 and older. See Figure 34–1 for a distribution of living arrangements for persons age 65 and older.

Economic Status

More than 4.5 million (10%) individuals aged 65 or older were below the poverty level in 2014. When the U.S Census Bureau figures adjusted for regional variations in cost of housing, other benefits, and out-of-pocket expenses such as for medical care, the
FIGURE 34–1 Living arrangements of noninstitutionalized persons aged 65 and older (Source: Administration on Aging, Aging statistics, 2016, retrieved from https://www.giaging.org/documents/A_Profile_of_Older_Americans__2016.pdf

percentage of those living below the poverty level rose to 14.4 percent (AoA, 2016). These statistics are higher than those from 2012 and 2013, suggesting a trend toward increasing numbers of older adults living below the poverty level. Older women had a higher poverty rate than older men, and older Hispanic women living alone had the highest poverty rate. Poor people who have worked all their lives can expect to become poorer in old age, and others will become poor only after becoming old. However, there is a substantial number of affluent and middle-income older persons.

Of individuals in this age group, 81 percent owned their own homes in 2013 (AoA, 2016). However, the housing of this population of Americans is usually older and less adequate than that of the younger population; therefore, a higher percentage

of income must be spent on maintenance and repairs. The AoA reports that in 2013, 45 percent of older adults living in houses spent more than 25 percent of their income on housing costs.

Employment

With the passage of the Age Discrimination in Employment Act in 1967, forced retirement has been virtually eliminated in the workplace. It is well accepted that involvement in purposeful activity is vital to successful adaptation and perhaps even to survival at any age. Increasing numbers of adults over 65 are remaining active in employment environments. In 2015, 8.8 million Americans (18.8 %) aged 65 and older were in the labor force (working or actively seeking work), and that number represents a steady increase for both men and women since around the year 2000 (AoA, 2016). This increase is particularly apparent in the 65- to 69-year-old age group. The data does not clarify whether this tendency to remain in the workforce during older adulthood is related to the desire to remain active and productive through the labor force or is based in necessity for income.

Health Status

The number of days in which usual activities are restricted because of illness or injury increases with age. The Centers for Disease Control and Prevention (CDC, 2015) reports that approximately 80 percent of older adults have at least one chronic condition, and 50 percent have two or more chronic conditions. The most commonly occurring conditions among the elderly population are hypertension (71%), arthritis (49%), heart disease (30%), cancer (24%), and diabetes (21%) (AoA, 2016).

Emotional and mental illnesses increase over the life cycle. Depression is particularly prevalent, and suicide is a serious problem among elderly Americans. Prevalence of major depression is estimated at between 1 and 5 percent for the general population of older adults but may rise to as high as 13.5 percent for older adults requiring hospitalization or home health care (CDC, 2015). The CDC adds that depression in this age group is particularly underdiagnosed and undertreated by both health-care providers and older adults themselves, perhaps related to a misperception that this is a normal part of aging or a natural reaction to illnesses. Neurocognitive disorders increase dramatically in old age.

Theories of Aging

A number of theories related to the aging process have been described. These theories are grouped into two broad categories: biological and psychosocial.

Biological Theories

Biological theories attempt to explain the physical process of aging, including molecular and cellular changes in the major organ systems and the body's ability to function adequately and resist disease. They also attempt to explain why people age differently and what factors affect longevity and the body's ability to resist disease.

Genetic Theory

According to one genetic theory, aging is an involuntarily inherited process that operates over time to alter cellular or tissue structures. This theory suggests that life-span and longevity changes are predetermined. This is supported by the finding that identical twins have similar life spans and children of parents with a long life span tend to live for a long time as well (Guarente, 2016).

A second genetic theory identifies aging as a process of genetic mutations that essentially create errors in transmission of information, causing molecules to become dysfunctional. Epigenetics, which involves the study of changes in the way genes are expressed in the absence of changes in the sequence of nucleic acids (Venes, 2014), has confirmed fascinating findings that have implications for aging and illness. First, it was discovered that DNA methylation (the addition of a methyl group to a DNA base) is a mechanism responsible for gene regulation. Genome studies of aging cells and tissues have shown a variable "DNA methylation drift," which creates changes in aging stem cells that culminates in reduced stem cell plasticity, stem cell exhaustion, and focal defects that can lead to illnesses such as cancer (Issa, 2014). Issa describes that "aging pathologies in turn accelerate methylation drift by promoting chronic inflammation and uncontrolled proliferation which creates a vicious cycle that may explain why some illnesses increase . . . exponentially . . . with age" (p.28).

With ongoing research, we may discover what aging will look like for an individual and what his or her disease risks are. If epigenetic drift can be prevented, it may be possible to prevent diseases associated with aging.

Wear-and-Tear Theory

Proponents of this theory believe that the body wears out on a scheduled basis. Since animals have some ability to repair themselves, this theory does not seem to fit what we know about biological systems (Guarente, 2016). A related theory suggests that free radicals, the waste products of metabolism, accumulate and cause damage to important biological structures. Free radicals are molecules with unpaired electrons that exist normally in the body; they

also are produced by ionizing radiation, ozone, and chemical toxins. According to this theory, these free radicals cause DNA damage, cross-linkage of collagen, and the accumulation of age pigments.

Environmental Theory

According to this theory, factors in the environment (e.g., industrial carcinogens, sunlight, trauma, and infection) bring about changes in the aging process. Although these factors are known to accelerate aging, the impact of the environment is a secondary rather than a primary factor in aging. Science is only beginning to uncover the many environmental factors that affect aging.

Autoimmune Theory

The autoimmune theory describes an age-related decline in the immune system. As people age, their ability to defend against foreign organisms decreases, resulting in susceptibility to infection and diseases such as cancer. A rise in the body's autoimmune response occurs in which aging cells can no longer distinguish foreign bodies and instead begin to attack themselves. This leads to the development of autoimmune diseases such as rheumatoid arthritis and allergies to food and environmental agents. However, this theory is based on clinical rather than experimental evidence (Guarente, 2016).

Neuroendocrine Theory

The neuroendocrine theory was first developed in 1954 by Vladimir Dilman, MD, who subsequently worked with another physician, Ward Dean, to update this theory in the early 1990s. The theory suggests that as humans age, the hypothalamus declines in its ability to regulate hormones and becomes less sensitive to their effects. Consequently, hormone secretion and effectiveness declines. Dilman identified several hypotheses about why this decrease in sensitivity occurs, including reduced neurotransmitter levels (serotonin in particular), decline in the secretion of pineal gland hormones, reduced glucose utilization and fat accumulation, neuronal lesions caused by chronically elevated cortisol levels secondary to stress, and accumulation of cholesterol in plasma membranes of neurons (Ward, 2015). Some believe that hormone replacements impacted by the hypothalamus may be a future treatment to counter the effects of aging, but more research is needed.

Psychosocial Theories

Psychosocial theories focus on social and psychological changes that accompany advancing age, as opposed to the biological implications of anatomic deterioration. Several theories have attempted to describe how attitudes and behavior in the early phases of life affect people's reactions during the late phase. This work is called the process of "successful aging."

Personality Theory

Personality theories address aspects of psychological growth without delineating specific tasks or expectations for older adults. Some evidence suggests that personality characteristics in old age are highly correlated with early life characteristics. Murray and associates (2009) state:

> No specific personality changes occur as a result of aging. The older person becomes more of what he or she was. The older person continues to develop emotionally and in personality and adds on characteristics instead of making drastic changes. (p. 663)

However, people in extreme old age show greater similarity with one another in certain characteristics, possibly related to similar changes in physical functioning and social roles.

In one study of personality traits, Srivastava and associates (2003) examined the Big Five personality trait dimensions in a large sample to determine how personality changes over the life span, including conscientiousness, agreeableness, neuroticism, openness, and extraversion. The participants ranged in age from 21 to 60. The researchers found that conscientiousness (being organized and disciplined) increased throughout the age range studied, with the biggest increases during the 20s. Agreeableness (being warm, generous, and helpful) increased most during a person's 30s. Neuroticism (being anxious and emotionally labile) declined with age for women but did not decline for men. Openness (being accepting of new experiences) showed small declines with age for both men and women. Extroversion (being outwardly expressive and interested in the environment) declined for women but did not show changes in men. This study contradicts the view that personality traits tend to stop changing in early adulthood. These researchers suggest that personality traits change gradually but systematically throughout the life span. Their research was foundational in understanding the adult population, though the elderly were not evaluated in that study.

In a review of the research on personality and aging that studied people between 60 and 80 years of age, Srivastava and Das (2013) identify support for the premise that personality traits are relatively stable but change somewhat over the long term with age and possibly in response to intervention. The personality trait of conscientiousness, for example, was found to be relatively stable when viewed over the course of a lifetime.

As the population of older adults continues to grow, research has focused not only on what constitutes

aging but more specifically what constitutes successful aging. Srivastava and Das stress that personality is undeniably influential in successful aging (they note that the term "successful aging" is often used but is controversial to some). Rowe and Kahn (1997) provide the classic paradigm for successful aging, identifying three criteria that must be met: (a) absence of disease, disability, and risk factors; (b) maintaining physical and mental functioning, and; (c) active engagement in life.

So what role do personality factors play in these aspects of successful aging? The research of Kern and Friedman (2008) has identified the personality trait of conscientiousness as most linked to health-promoting behaviors. Even more recent research (Terracciano et al., 2010) studied the genetic underpinnings of each of the Big Five personality traits and, among other findings, identified a gene associated with the trait of conscientiousness. They found that this personality trait gene was associated with the same gene that has been linked to some neurodegenerative diseases, including Alzheimer's disease. Could personality traits unravel the mysteries of aging and age-related illnesses? What all of this means for intervening upon and possibly improving the aging process is still unknown. Future research may begin to unfold the intricate interaction between genetic and environmental influences such that personality traits might become alterable to promote healthier, more successful aging.

Developmental Task Theory

In contrast to the personality theories of aging, which discuss a largely stable process that continues into old age, developmental task theory holds that there are activities and challenges that one must accomplish at predictable, changing stages in life to achieve successful aging. Erikson (1963) described the primary task of old age as being able to see one's life as having been lived with integrity. In the absence of achieving that sense of having lived well, the older adult is at risk for becoming preoccupied with feelings of regret or despair. As noted previously, the life span was significantly shorter when Erikson's developmental tasks and stages were first identified. In the late 1990s, Erikson expanded the concept of **transcendence** as an additional stage that occurs after the stage of integrity versus despair (Erikson & Erikson, 1997). McCarthy, Ling, and Carini (2013) identify transcendence as a concept within the spiritual domain, and they cite McCarthy and Bockweg's (2012) definition:

> Transcendence [is] an inherent developmental process, resulting in a shift from a rational, materialistic view to a wider world view characterized by broadened personal boundaries, within interpersonal, intrapersonal, transpersonal, and temporal dimensions resulting in an increased sense of meaning in life, well-being, and life satisfaction. (p. 180)

McCarthy and associates' research on transcendence supported that this concept is a significant contributor to successful aging.

Disengagement Theory

Disengagement theory describes the process of withdrawal by older adults from societal roles and responsibilities. According to the theory, this withdrawal process is predictable, systematic, inevitable, and necessary for the proper functioning of a growing society. Older adults were believed to be happy when social contacts diminished and responsibilities were assumed by a younger generation, providing time for reflecting on life's accomplishments and coming to terms with unfulfilled expectations. For society, the benefit is an orderly transfer of power from old to young.

There have been many critics of this theory, and the postulates have been challenged. For many healthy and productive older individuals, the prospect of a slower pace and fewer responsibilities is undesirable.

Activity Theory

In direct opposition to the disengagement theory is the activity theory of aging, which holds that the way to age successfully is to stay active. Sadock, Sadock, and Ruiz (2015) report that growing evidence supports the importance of remaining socially active for both physical and emotional well-being. Cultural expectations are influential, and as older Americans increasingly reap the benefits of physical and social activity, cultural expectations begin to shift. Many fitness classes, for example, are now finding a membership of people in their 80s and beyond.

Continuity Theory

This theory, also known as the *developmental theory,* is a follow-up to the disengagement and activity theories. It emphasizes the individual's previously established coping abilities and personal character traits as a basis for predicting how the person will adjust to the changes of aging. Basic lifestyle characteristics are likely to remain stable in old age, barring physical or other types of complications that necessitate change. A person who has enjoyed the company of others and an active social life will continue to enjoy this lifestyle into old age. One who has preferred solitude and a limited number of activities will probably find satisfaction in a continuation of this lifestyle.

Maintenance of internal continuity is motivated by the need for preservation of self-esteem, ego integrity, cognitive function, and social support. As they age, individuals maintain self-concept by reinterpreting current experiences so that old values can take on new meanings in keeping with present circumstances. Internal self-concepts and beliefs are not readily vulnerable to environmental change, and external continuity in skills, activities, roles, and relationship styles can remain remarkably stable into the 70s and beyond.

The Normal Aging Process

Biological Aspects of Aging

Individuals are unique in their physical and psychological aging processes, as influenced by their predisposition or resistance to illness; the effects of their external environment and behaviors; their exposure to trauma, infections, and past diseases; and the health and illness practices they have adopted during their life spans. As the individual ages, a quantitative loss of cells and changes in many of the enzymatic activities within cells results in a diminished responsiveness to biological demands made on the body. Age-related changes occur at different rates for different individuals, although in actuality, when growth stops, aging begins. This section presents a brief overview of the normal biological changes that occur with the aging process.

Skin

One of the most dramatic changes that occurs in aging is the loss of elastin in the skin. This effect, along with changes in collagen, causes aged skin to wrinkle and sag. Excessive exposure to sunlight compounds these changes and increases the risk of developing skin cancer.

Fat redistribution results in a loss of the subcutaneous cushion of adipose tissue. Thus, older people lose "insulation," the skin appears thinner, and they are more sensitive to extremes of ambient temperature than are younger people. A diminished supply of blood vessels to the skin results in a slower rate of healing.

Cardiovascular System

The age-related decline in the cardiovascular system is thought to be the major determinant of decreased tolerance for exercise, loss of conditioning, and the overall decline in energy reserve. The aging heart is characterized by modest hypertrophy and loss of pacemaker cells, resulting in a decrease in maximal heart rate and diminished cardiac output (Blair, 2012). This results in a decrease in response to work

demands and some diminishment of blood flow to the brain, kidneys, liver, and muscles. Heart rate also slows with time. If arteriosclerosis is present, cardiac function is further compromised.

Respiratory System

Thoracic expansion is diminished by an increase in fibrous tissue and loss of elastin. Pulmonary vital capacity decreases and the amount of residual air increases. Scattered areas of fibrosis in the alveolar septa interfere with exchange of oxygen and carbon dioxide. These changes are accelerated by the use of cigarettes or other inhaled substances. Cough and laryngeal reflexes are reduced, causing decreased ability to defend the airway. Decreased pulmonary blood flow and diffusion ability result in reduced efficiency in responding to sudden respiratory demands.

Musculoskeletal System

Skeletal aging involving the bones, muscles, ligaments, and tendons probably generates the most frequent limitations on activities of daily living for aging individuals. Loss of muscle mass is significant, although this occurs more slowly in men than in women. Demineralization of the bones occurs at a rate of about 1 percent per year throughout the life span in both men and women. However, this increases to approximately 10 percent in women around **menopause,** making them particularly vulnerable to **osteoporosis.**

Individual muscle fibers become thinner and less elastic with age. Muscles become less flexible following disuse. Diminished storage of muscle glycogen results in loss of energy reserve for increased activity. These changes are accelerated by nutritional deficiencies and inactivity.

Gastrointestinal System

In the oral cavity, the teeth show a reduction in dentine production, shrinkage and fibrosis of root pulp, gingival retraction, and loss of bone density in the alveolar ridges. There is some loss of peristalsis in the stomach and intestines, and gastric acid production decreases. Levels of intrinsic factor may also decrease, resulting in vitamin B_{12} malabsorption in some aging individuals. A significant decrease in absorptive surface area of the small intestine may be associated with some decline in nutrient absorption. Motility slowdown of the large intestine, combined with poor dietary habits, dehydration, lack of exercise, and some medications, may give rise to problems with constipation.

A modest decrease in size and weight of the liver results in losses in enzyme activity required to deactivate certain medications by the liver. These age-related

changes can influence the metabolism and excretion of these medications. These changes, along with the pharmacokinetics of the drug, must be considered when giving medications to aging individuals.

Endocrine System

A decreased level of thyroid hormones causes a lowered basal metabolic rate. Decreased amounts of adrenocorticotropic hormone may result in less efficient stress response.

Impairments in glucose tolerance are evident in aging individuals. Studies of glucose challenges show that insulin levels are equivalent to or slightly higher than those from younger challenged individuals, although peripheral insulin resistance appears to play a significant role in carbohydrate intolerance. The observed glucose clearance abnormalities and insulin resistance in older people may be related to many factors other than biological aging (e.g., obesity, family history of diabetes) and may be influenced substantially by diet or exercise.

Genitourinary System

Age-related declines in renal function occur because of a steady attrition of nephrons and sclerosis within the glomeruli over time. Vascular changes affect blood flow to the kidneys, which results in reduced glomerular filtration and tubular function. Elderly people are prone to develop inappropriate antidiuretic hormone secretion, causing slight elevation in levels of blood urea nitrogen and creatinine. The overall decline in renal function has serious implications for physicians who prescribe medications for elderly individuals.

In men, enlargement of the prostate gland is common as aging occurs. Prostatic hypertrophy is associated with an increased risk for urinary retention and may also be a cause of urinary incontinence (Johnston, Harper, & Landefeld, 2013). Loss of muscle and sphincter control, as well as the use of some medications, may cause urinary incontinence in women. Not only is this problem a cause of social stigma, but it increases the risk of urinary tract infection and local skin irritation if left untreated. Normal changes in the genitalia are discussed in the section "Sexual Aspects of Aging."

Immune System

Aging results in changes in both cell-mediated and antibody-mediated immune responses. The size of the thymus gland declines continuously beginning just after puberty, reaching about 15 percent of its original size at age 50. The consequences of these changes include a greater susceptibility to infections and a diminished inflammatory response that results in delayed healing. There is also evidence of an increase in various autoantibodies as a person ages, increasing the risk of autoimmune disorders such as rheumatoid arthritis (National Institutes of Health, 2014). Because of the overall decrease in efficiency of the immune system, the proliferation of abnormal cells is facilitated in the elderly individual. Cancer is the best example of aberrant cells allowed to proliferate due to the ineffectiveness of the immune system.

Nervous System

With aging, an absolute loss of neurons correlates with decrease in brain weight of about 10 percent by age 90 (Murray et al., 2009). Gross morphological examination reveals gyral atrophy in the frontal, temporal, and parietal lobes; widening of the sulci; and ventricular enlargement. These changes have been identified in careful study of adults with normal intellectual function.

The brain has enormous reserve, and little cerebral function is lost over time, although greater functional decline is noted in the periphery. There appears to be a disproportionately greater loss of cells in the cerebellum, the locus ceruleus, the substantia nigra, and olfactory bulbs, accounting for some of the more characteristic aging behaviors such as mild gait disturbances, sleep disruptions, and decreased smell and taste perception.

Some of the age-related changes within the nervous system may be caused by alterations in neurotransmitter release, uptake, turnover, catabolism, or receptor functions (Beers & Jones, 2006; Blair, 2012). A great deal of attention is being given to brain biochemistry and in particular to the neurotransmitters acetylcholine, dopamine, norepinephrine, and epinephrine. These biochemical changes may be responsible for the altered responses of many older persons to stressful events and some biological treatments.

Sensory Systems
Vision

Visual acuity begins to decrease in midlife. Presbyopia (blurred near vision) is the standard marker of aging of the eye. It is caused by a loss of elasticity of the crystalline lens and results in compromised accommodation.

Cataract development is inevitable if the individual lives long enough for vision changes to occur. Cataracts occur when the lens of the eye becomes less resilient due to compression of fibers and increasingly opaque as proteins lump together, ultimately resulting in a loss of visual acuity.

The color in the iris may fade, and the pupil may become irregular in shape. A decrease in production

of secretions by the lacrimal glands may cause dryness and result in increased irritation and infection. The pupil may become constricted, requiring an increase in the amount of light needed for reading.

Hearing

Hearing changes significantly with the aging process. Gradually, the ear loses its sensitivity to discriminate sounds because of damage to the hair cells of the cochlea. The most dramatic decline appears to be in perception of high-frequency sounds.

Age-related hearing loss, called *presbycusis,* is common and affects more than half of all adults by age 75 years (Blevins, 2015). It occurs more frequently in men than in women, a fact that may be related to differences in levels of lifetime noise exposure.

Taste and Smell

Beyond 70 years of age, taste sensitivity begins to decline related to atrophy and loss of taste buds (Shock, 2015). Taste discrimination decreases, and bitter taste sensations predominate. Sensitivity to sweet and salty tastes is diminished.

The deterioration of the olfactory bulbs is accompanied by loss of smell acuity. The effect of aging on sense of smell has not been precisely identified and is difficult to evaluate because so many environmental factors influence sensitivity to smell (Shock, 2015). However, some decreased sensitivity may be related to loss of nerve endings in the nose and decreased mucus production (MedlinePlus, 2014).

Touch and Pain

Although the primary sensory changes related to aging are in hearing and vision, sensitivity to touch and pain may also decline or change because of decreased blood flow to nerve endings, in the spinal cord, or to the brain (MedlinePlus, 2014). These changes have critical implications for the elderly in their potential inability to use sensory warnings to escape serious injury.

Psychological Aspects of Aging

Memory Functioning

Age-related memory deficiencies and slower response times have been extensively reported in the literature. Although **short-term memory** seems to deteriorate with age, perhaps because of poorer sorting strategies, **long-term memory** does not show similar changes. However, in nearly every instance, well-educated, mentally active people do not exhibit the same decline in memory functioning as their peers who lack similar opportunities to flex their minds. Nevertheless, with few exceptions, the time required for memory scanning is longer for both recent and remote recall among older people. This can sometimes be attributed to social or health factors (e.g., stress, fatigue, illness), but it can also occur because of certain normal physical changes associated with aging (e.g., decreased blood flow to the brain).

Intellectual Functioning

There appears to be a high degree of regularity in intellectual functioning across the adult age span. Crystallized abilities, or knowledge acquired in the course of the socialization process, tend to remain stable over the adult life span. Fluid abilities, or abilities involved in solving novel problems, tend to decline gradually from youth to old age. In other words, intellectual abilities of older people do not decline but do become obsolete. The age of their formal educational experiences is reflected in their intelligence scoring.

Learning Ability

The ability to learn is not diminished by age. Studies, however, have shown that some aspects of learning do change with age. The ordinary slowing of reaction time with age for nearly all tasks or the overarousal of the central nervous system may account for lower performance levels on tests requiring rapid responses. Under conditions that allow for self-pacing by the participant, differences in accuracy of performance diminish. Ability to learn continues throughout life, although it is strongly influenced by interests, activity, motivation, health, and experience. Adjustments need to be made in teaching methodology and time allowed for learning.

Adaptation to the Tasks of Aging

Loss and Grief

Individuals experience losses from the very beginning of life. By the time individuals reach their 60s and 70s, they have experienced numerous losses, and mourning has become a lifelong process. Unfortunately, with the aging process comes a convergence of losses, the timing of which makes it impossible for the aging individual to complete the grief process in response to one loss before another occurs. Because grief is cumulative, this can result in **bereavement overload,** which has been implicated in the predisposition to depression in the elderly.

Attachment to Others

Many studies have confirmed the importance of interpersonal relationships at all stages in the life cycle. Murray and associates (2009) state:

> [Social networks] contribute to well-being of the elder by (a) promoting socialization and companionship, (b) elevating morale and life satisfaction, (c) buffering the effects of stressful events, (d) providing a confidant, and (e) facilitating coping skills and mastery. (p. 620)

This need for **attachment** is consistent with the activity theory of aging that correlates the importance of social integration with successful adaptation in later life. Evidence supports that in addition to the psychosocial benefits, social engagement is also correlated with physical and cognitive health in older adulthood (Thomas, 2011).

Maintenance of Self-Identity

Maintaining a positive self-concept and identity is important in successful aging. Individuals who tend toward a rigid self-identity and a negative self-concept will no doubt struggle with any changes and adaptations faced in the aging process. For example, someone whose identity centers entirely around his job may struggle more with identity in retirement than someone whose identity includes job, family, travel, and hobbies. Researchers in one study found that maintaining a youthful age identity and positive perceptions and experiences related to aging had a self-enhancing function for self-esteem and identity (Westerhof, Whitbourne, & Freeman, 2012). The authors compared citizens in the United States with those in the Netherlands and found that for the former, this self-enhancing function was stronger than for those from the latter. They concluded that factors influencing self-identity and self-concept in older age need to be considered within the cultural context.

Dealing With Death

Death anxiety is a universal phenomenon, and attitudes about death are a result of cumulative life experiences (Lehto & Stein, 2009). As average life span has increased, there has been a resurgence of interest in research about death anxiety. Lehto and Stein conducted an extensive review of the research to lay a foundation for an emerging understanding of this concept. Kübler-Ross's (1969) pioneering research on attitudes about death and the experience of dying paved the way for discussions of this issue, but as Lehto and Stein identify in their review, death anxiety is largely denied or repressed. They cite several studies confirming that religious beliefs reduced death anxiety and suggest that such beliefs are beneficial because they provide a context for meaning about life and death. Positive self-esteem mediates death anxiety or at least "assists in preventing overt manifestations of death anxiety" (Lehto & Stein, p. 27). Other researchers similarly found that fear of the dying process among elderly individuals in care institutions was correlated with low self-esteem, feelings of purposelessness, and poor mental health (Missler et al., 2012). These authors also found that death anxiety was more strongly correlated with fears for significant others than fear of the unknown.

Interestingly, death anxiety seems to be the highest during middle age and stabilizes by later adulthood. But as Lehto and Stein (2009) identified, maladaptive consequences of death anxiety include mental illnesses such as depression and anxiety disorders, so assessing and intervening with regard to death anxiety may be beneficial in preventing longer-term consequences. Self-esteem interventions, for example, may be beneficial in preventing older adult depression secondary to death anxiety. Some research has shown that death education is beneficial in reducing anxiety associated with fear of death (McClatchey & King, 2015). Addressing these issues with middle-aged clients may be in the interest of primary or secondary prevention in the aging process.

Psychiatric Disorders in Later Life

Cognitive disorders, depressive disorders, phobias, and alcohol use disorders are among the most common psychiatric illnesses in later life (Sadock et al., 2015). Recent attention is focused on the growing opiate addiction problem in the older adult population. Many factors influence symptomatology, including medical conditions and medications. One should never assume that psychiatric symptoms are a usual part of aging. For example, as Sadock and colleagues identify, "Age itself is not a risk factor for depression but being widowed and having a chronic medical illness are associated with vulnerability to depressive disorders" (p. 1346). A thorough assessment is essential to distinguish the multiple factors that may be concurrently influencing symptomatology.

Neurocognitive Disorder

Neurocognitive disorders (NCDs) are the most common causes of psychopathology in the elderly. About half of these disorders are of the Alzheimer's type, characterized by an insidious onset and a gradually progressive course of cognitive impairment. No curative treatment is currently available. Symptomatic treatments, including pharmacological interventions, attention to the environment, and family support, can help to maximize the client's level of functioning.

Delirium

Delirium is one of the most common and critical forms of psychopathology in later life. A number of factors have been identified that predispose elderly people to delirium, including structural brain disease, reduced capacity for homeostatic regulation, impaired vision and hearing, a high prevalence of chronic disease, reduced resistance to acute stress, and age-related changes in the pharmacokinetic and pharmacodynamics of drugs. Delirium needs to be recognized and the underlying condition treated as soon as possible. A high mortality rate is associated with this condition.

Depression

Depressive disorders are the most common affective illnesses occurring after the middle years. The incidence of increased depression among elderly people is influenced by the variables of physical illness, functional disability, cognitive impairment, and loss of a spouse (Lang, 2012). Somatic symptoms are common in the depressed elderly. Symptomatology often mimics that of NCD, a condition called *pseudodementia*. (See Chapter 22, Neurocognitive Disorders, Table 22-1 for a comparison of the symptoms of NCD and pseudodementia.) Suicide is prevalent in the elderly, with declining health and decreased economic status considered important influencing factors. Treatment of depression in the elderly individual may include psychotropic medications or electroconvulsive therapy. Tricyclic antidepressants pose a risk for orthostatic hypotension and other anticholinergic effects, and selective serotonin reuptake inhibitors pose a higher risk for hyponatremia in the elderly, so risks and benefits of medication use should be carefully reviewed.

Schizophrenia

Schizophrenia typically begins in young adulthood. In most instances, individuals who manifest psychotic disorders early in life show a decline in psychopathology as they age. Late-onset schizophrenia (after age 60) is rare, and when it does occur, it is more common in women and is often characterized by paranoid delusions or hallucinations. Antipsychotic agents may be beneficial but should be used judiciously and at lower than usual doses (Sadock et al., 2015).

Anxiety Disorders

Most anxiety disorders begin in early to middle adulthood, but some appear for the first time after age 60. Because the autonomic nervous system is more fragile in older persons, the response to a major stressor is often quite intense. The presence of physical disability frequently compounds the situation, resulting in a more severe posttraumatic stress response than is commonly observed in younger persons. In older adults, symptoms of anxiety and depression often accompany each other, making it difficult to determine which disorder is dominant.

Personality Disorders

Personality disorders are uncommon in the elderly population. The incidence of personality disorders among individuals older than age 65 is less than 5 percent. Most elderly people with personality disorder have likely manifested the symptomatology for many years.

Sleep Disorders

Sleep disorders are very common in the aging individual. Roughly 50 percent of older adults report difficulty initiating or maintaining sleep (Crowley, 2011), and these disorders may contribute to cognitive changes. Contributing factors include medical conditions, medications, age-related changes in circadian rhythms, sleep-disordered breathing, and restless leg syndrome (Crowley, 2011; Roepke & Ancoli-Israel, 2010). Sedative-hypnotics, along with nonpharmacological approaches, are often used as sleep aids for the elderly. Changes associated with metabolism and elimination must be considered when maintenance medications are administered for chronic insomnia in the aging client.

Sociocultural Aspects of Aging

Old age brings many important socially induced changes, some of which have the potential for negative effects on both the physical and mental well-being of older persons. In American society, old age is defined arbitrarily as 65 years or older because that is when most people are able to retire with full Social Security and other pension benefits. Recent legislation has increased the age beyond 65 years for full Social Security benefits. Currently, the age increases yearly (based on year of birth) until 2027, when the age for full benefits will be 67 for all individuals.

Elderly people in virtually all cultures share some basic needs and interests. There is little doubt that most individuals choose to live the most satisfying life possible for as long as possible. They want protection from hazards and release from the weariness of everyday tasks. They want to be treated with the respect and dignity that individuals who have reached this pinnacle in life deserve, and they want to die with the same respect and dignity.

Historically, the aged have had special status in society. Even today, in some cultures the aged are the most powerful, the most engaged, and the most respected members. This has not been the case in modern industrial societies, although trends in the status of the aged differ widely between one industrialized country and another. For example, the status and integration of the aged in Japan have remained relatively high when compared with other industrialized nations, including the United States. There are subcultures in the United States, including Latino American, African American, and Asian American, in which the elderly have a higher degree of status than they receive in the mainstream population. The aged are awarded a position of honor in cultures that place emphasis on family cohesiveness. In these cultures, the aged are revered for their knowledge and wisdom gained through their years of life experiences (Purnell, 2013).

Many negative stereotypes color the perspective on aging in the United States. Views of elderly individuals as always tired or sick, slow and forgetful, isolated and

lonely, unproductive, and angry determine the way younger individuals relate to the elderly in this society. Increasing disregard for the elderly has resulted in a type of segregation as aging individuals voluntarily seek out or are involuntarily placed in special residences for older adults.

Assisted living centers, retirement apartment complexes, and even entire retirement communities intended solely for individuals over age 50 are becoming increasingly common. In 2014, 63 percent of persons age 65 and older lived in 14 states, with the largest numbers in California, Florida, Texas, New York, and Pennsylvania (AoA, 2016). It is important for elderly individuals to feel part of an integrated group, and they are migrating to these areas in an effort to achieve this integration. This phenomenon provides additional corroboration for the activity theory of aging and the importance of attachment to others.

Employment is another area in which the elderly experience discrimination. Although compulsory retirement has been virtually eliminated, discrimination still exists in hiring and promotion practices. Many employers are reluctant to retain or hire older workers. It is difficult to determine how much of the failure to hire and promote results from discrimination based on age alone and how much of it is related to a realistic and fair appraisal of the aged employee's ability and efficiency. It is true that some elderly individuals may perform at lower levels than younger workers do, but there are many who likely can do a *better* job than their younger counterparts if given the opportunity. Nevertheless, surveys have shown that some employers accept the negative stereotypes about elderly individuals and believe that older workers are hard to please, set in their ways, less productive, frequently absent, and involved in more accidents.

The status of the elderly may improve with time and as their numbers increase with the aging of the baby boomers. As older individuals gain political power, the benefits and privileges designed for the elderly will increase. There is power in numbers, and the 21st century promises power for people age 65 and older.

Sexual Aspects of Aging

Sexuality and the sexual needs of elderly people are frequently misunderstood, condemned, stereotyped, ridiculed, repressed, and ignored. Americans have grown up in a society that has liberated sexual expression for all other age groups but still retains certain Victorian standards regarding sexual expression by the elderly. Negative stereotyped notions concerning sexual interest and activity among the elderly are common. Some of these include ideas that older people have no sexual interests or desires, that they are sexually undesirable, or that they are too fragile or too ill to engage in sexual activity. Some people even believe it is disgusting or comical to consider elderly individuals as sexual beings.

These cultural stereotypes undoubtedly play a large part in the misperception many people hold regarding sexuality of the aged, and they may be reinforced by the common tendency of the young to deny the inevitability of aging. With reasonably good health and an interesting and interested partner, there is no inherent reason why individuals should not enjoy an active sexual life well into late adulthood (King & Regan, 2013).

Physical Changes Associated With Sexuality

Many of the changes in sexuality that occur in later years are related to the physical changes that take place at that time of life.

Changes in Women

Menopause may begin anytime during the 40s or early 50s. During this time, there is a gradual decline in ovary function and the subsequent production of estrogen, which results in a number of changes. The walls of the vagina become thin and inelastic, the vagina itself shrinks in both width and length, and the amount of vaginal lubrication noticeably decreases. Orgastic uterine contractions may become spastic. All of these changes can result in painful penetration, vaginal burning, pelvic aching, or irritation on urination. In some women, the discomfort may be severe enough to result in avoidance of intercourse. Paradoxically, these symptoms are more likely to occur with infrequent intercourse (once a month or less). Regular and more frequent sexual activity results in a greater capacity for sexual performance (King & Regan, 2013). Other symptoms associated with menopause in some women include hot flashes, night sweats, sleeplessness, irritability, mood swings, migraine headaches, urinary incontinence, and weight gain.

Some menopausal women elect to take hormone replacement therapy (HRT) for relief of these symptoms. With estrogen therapy, the symptoms of menopause are minimized or eliminated, but this treatment is associated with increased risk for breast and endometrial cancer. To combat this latter effect, many women also take a second hormone, progesterone. Taken for 7 to 10 days during the month, progesterone decreases the risk of estrogen-induced endometrial cancer. Some physicians prescribe a low

dose of progesterone that is taken along with estrogen for the entire month. A combination pill taken in this manner is also available.

Results of the Women's Health Initiative reported in the *Journal of the American Medical Association* indicated that the combination pill is associated with an increased risk of cardiovascular disease and breast cancer. Benefits related to colon cancer and osteoporosis were reported; however, investigators stopped this arm of the study and suggested discontinuation of this treatment. In a 3-year follow-up study of the participants, the results showed that the increased risk for cardiovascular disease dissipated with discontinuation of the hormone therapy (Heiss et al., 2008).

Other studies have indicated that HRT may have a *cardioprotective* effect, but Yang and Reckelhoff's review of the literature (2011) did not substantiate that finding. Their review cites other studies that suggest the cardiovascular risks versus benefits may be associated with the age at which HRT is initiated. A more recent Women's Health Initiative study reported that their findings do not support use of HRT for chronic disease prevention but indicate that it may be beneficial in some management of menopause symptoms (Manson et al., 2013). Controversies about HRT and conflicting study findings continue to highlight the need for ongoing research on this topic.

Changes in Men

Testosterone production declines gradually over the years, beginning between ages 40 and 60. A major change resulting from this hormone reduction is that erections occur more slowly and require more direct genital stimulation to achieve. There may also be a modest decrease in the firmness of the erection in men older than age 60. Erectile dysfunction is more common as men grow older but it can often be managed and sometimes reversed (National Institute on Aging, 2016). The refractory period lengthens with age, increasing the amount of time following orgasm before the man may achieve another erection. The volume of ejaculate gradually decreases, and the force of ejaculation lessens. The testes become somewhat smaller, but most men continue to produce viable sperm well into old age. Prolonged control over ejaculation in middle-aged and elderly men may bring increased sexual satisfaction for both partners.

Sexual Behavior in the Elderly

Coital frequency in early marriage and the overall quantity of sexual activity between ages 20 and 40 correlate significantly with frequency patterns of sexual activity during aging (Masters, Johnson, & Kolodny,

1995). Although sexual interest and behavior do appear to decline somewhat with age, studies show that significant numbers of elderly men and women have active and satisfying sex lives well into their 80s. A survey commissioned by the American Association of Retired Persons provided some revealing information regarding the sexual attitudes and behavior of senior citizens. Some statistics from the survey are summarized in Table 34–1. The information from this survey clearly indicates that sexual activity can and does continue well past the 70s for healthy, active individuals who have regular opportunities for sexual expression. King and Regan (2013) identify that if an individual has healthy attitudes about sexuality and healthy sexual relationships in younger adulthood, those will probably continue into older adulthood.

Special Concerns of the Elderly Population

Retirement

Statistics reflect that a larger percentage of Americans are living longer and many of them are retiring earlier. Reasons often given for the increasing pattern of early retirement include health problems, Social Security and other pension benefits, attractive "early-out" packages offered by companies, and long-held plans (e.g., turning a hobby into a money-making situation). The Bureau of Labor Statistics' Current Population Surveys indicated a gradual increase, between 2004 and 2014, in the percentage of adults aged 65 and older who have delayed retirement (Hipple, 2015). Although many choose early retirement, the overall trend appears to be that more older adults keep working.

Studies show that 10 to 20 percent of individuals reenter the workforce following retirement (Cahill, Giandrea, & Quinn, 2011). Reentry is more common among men than women and among individuals who are younger and in good health at the time of retirement. Reasons people give for returning to work include negative reactions to being retired, feelings of being unproductive, economic hardship, and loneliness. Recent downturns in economic conditions have forced many retired people to seek employment to augment dwindling retirement resources.

Retirement has both social and economic implications for elderly individuals. The role is fraught with ambiguity and requires many adaptations on the part of those involved.

Social Implications

Retirement is often anticipated as an achievement, in principle, but is met with many mixed feelings when it actually occurs. Our society places a great deal of importance on productivity, making as much money

TABLE 34–1 **Sexuality at Midlife and Beyond**			
	AGES	MEN (%)	WOMEN (%)
Have sex at least once a week	45–49 50–59 60–69 70+	50 41 24 15	26 32 24 5
Report very satisfied with physical relationship	45–49 50–59 60–69 70+	60 50 52 26	48 40 41 27
Report very satisfied with emotional relationship	45–49 50–59 60–69 70+	26 32 28 20	37 23 29 24
Report sexual activity is important to their overall quality of life	45–49 50–59 60–69 70+	69 65 55 46	33 28 33 12
Believe nonmarital sex is okay	45–49 50–59 60–69 70+	88 91 80 68	86 75 71 61
Describe their partners as physically attractive	45–49 50–59 60–69 70+	50 53 58 51	60 48 58 48
Report always or usually having an orgasm with sexual intercourse	45–49 50–59 60–69 70+	95 88 91 82	70 64 59 61
Report being impotent	45–49 50–59 60–69 70+	6 16 29 48	
Report having used medicine, hormones, or other treatments to improve sexual functioning	45–49 50–59 60–69 70+	7 12 14 13	9 16 14 13
What would most improve your sex life?	All	Better health for self; partner initiates sex more often; less stress	Less stress; better health for self and partner; finding a partner

Adapted from the 2010 May AARP Research Survey on Sex, Romance, and Relationships: AARP Survey of Midlife and Older Adults by Linda Fisher with the Assistance of Gretchen Anderson, Matrika Chapagain, Xenia Montenegro, James Smoot, Amishi Takalkar. Copyright 2010 AARP. All rights reserved.

as possible, and doing it at as young an age as possible. These types of values contribute to the ambiguity associated with retirement. Although leisure has been acknowledged as a legitimate reward for workers, leisure during retirement historically has lacked the same social value. Adjustment to this life-cycle event becomes more difficult in the face of societal values that are in direct conflict with the new lifestyle.

Historically, many women have derived substantial self-esteem from their families—birthing them, rearing them, and being a "good mother." Likewise, many men have achieved self-esteem through work-related

activities—creativity, productivity, and earning money. With the termination of these activities may come a loss of self-worth, resulting in depression in some individuals who are unable to adapt satisfactorily. Well-being in retirement is linked to factors such as stable health status and access to health-care services, adequate income, the ability to pursue new goals or activities, extended social network of family and friends, and satisfaction with current living arrangements (Murray et al., 2009).

American society often identifies an individual by his or her occupation. This is reflected in the conversations of people meeting each other for the first time. Undoubtedly, most everyone has either asked or been asked at some point in time, "What do you do?" or "Where do you work?" Occupation determines status, and retirement represents a significant change in status. The basic ambiguity of retirement occurs in an individual's or society's definition of this change. Is it undertaken voluntarily or involuntarily? Is it desirable or undesirable? Is one's status made better or worse by the change? With the population of older adults growing, retirement versus remaining in the workforce will continue to be an important issue for this age group. Clearly, this is a major life event that requires planning and realistic expectations of life changes.

Economic Implications

Because retirement is generally associated with a 20 to 40 percent reduction in personal income, the standard of living after retirement may be adversely affected. Most older adults derive postretirement income from a combination of Social Security benefits, public and private pensions, and income from savings or investments.

The Social Security Act of 1935 promised assistance with financial security for the elderly. Since then, the original legislation has been modified, yet the basic philosophy remains intact. Its effectiveness, however, is now in question. Faced with deficits, the program is forced to pay benefits to the currently retired from both the reserve funds and monies being collected at present. There is genuine concern about future generations, when there may be no reserve funds from which to draw. Because many of the programs that benefit older adults depend on contributions from the younger population, the growing ratio of older Americans to younger people may affect society's ability to supply the goods and services necessary to meet this expanding demand.

Medicare and **Medicaid** were established by the government to provide medical care benefits for elderly and indigent Americans. The Medicaid program is jointly funded by state and federal governments, and coverage varies significantly from state to state. Medicare covers only a percentage of health-care costs; therefore, to reduce risk related to out-of-pocket expenditures, many older adults purchase private "medigap" policies designed to cover charges in excess of those approved by Medicare.

The magnitude of retirement earnings depends almost entirely on preretirement income. The poor will remain poor and the wealthy are unlikely to lower their status during retirement; however, for many in the middle classes, the relatively fixed income sources may be inadequate, possibly forcing them to face financial hardship for the first time in their lives.

Long-Term Care

Long-term care facilities are defined by the level of care they provide. They may be skilled nursing facilities, intermediate care facilities, or a combination of the two. Some institutions provide convalescent care for individuals recovering from acute illness or injury, some provide long-term care for individuals with chronic illness or disabilities, and still others provide both types of assistance.

Most elderly individuals prefer to remain in their own homes or in the homes of family members for as long as this is possible without deterioration of family or social patterns. Many elderly individuals are placed in institutions as a last resort only after heroic efforts have been made to keep them in their own or a relative's home. The increasing emphasis on home health care has extended the period of independence for aging individuals.

Fewer than 4 percent of the population ages 65 and older live in nursing homes. The percentage increases dramatically with age, ranging from 1 percent for persons aged 65 to 74 and 3 percent for persons aged 75 to 84 to 10 percent for persons aged 85 and older (AoA, 2016). A profile of the "typical" elderly nursing home resident is about 80 years of age, white, female, and widowed, with multiple chronic health conditions.

Risk Factors for Institutionalization

In determining who in our society will need long-term care, several factors have been identified that appear to place people at risk. The following risk factors are taken into consideration to predict potential need for services and to estimate future costs.

Age

Because people grow older in very different ways and the range of differences becomes greater with the passage of time, age is becoming a less relevant characteristic than it once was. However, because of the high prevalence of chronic health conditions and disabilities

and the greater chance of diminishing social supports associated with advancing age, the 65-and-older population is often viewed as an important long-term care target group.

Health

Level of functioning, as determined by ability to perform various behaviors or activities—such as bathing, eating, mobility, meal preparation, handling finances, judgment, and memory—is a measurable risk factor. The need for ongoing assistance from another person is critical in determining the need for long-term care.

Mental Health Status

Mental health problems are risk factors in assessing need for long-term care. Many symptoms associated with certain mental disorders (especially neurocognitive disorders), such as memory loss, impaired judgment, impaired intellect, and disorientation, would render the individual incapable of meeting the demands of daily living independently.

Socioeconomic and Demographic Factors

Low income generally is associated with greater physical and mental health problems among the elderly. Because many elderly individuals have limited finances, they are less able to purchase care resources available outside of institutions (e.g., home health care), although Medicare and Medicaid now contribute a limited amount to this type of noninstitutionalized care.

Women are at greater risk of being institutionalized than men, not because they are less healthy but because they tend to live longer and thus reach the age at which more functional and cognitive impairments occur. They are also more likely to be widowed. Whites have a higher rate of institutionalization than nonwhites. This may be related to cultural and financial influences.

Marital Status, Living Arrangement, and the Informal Support Network

Individuals who are married and live with a spouse are the least likely of all disabled people to be institutionalized. Those who live alone without resources for home care and with few or no relatives living nearby to provide informal care are at higher risk for institutionalization.

Attitudinal Factors

Many people dread the thought of even visiting a nursing home, let alone moving to one or placing a relative in one. Negative perceptions exist of nursing homes as "places to go to die." The media picture and subsequent reputation of nursing homes has not been positive. Stories of substandard care and patient abuse have scarred the industry, making it difficult for those facilities that are clean, well managed, and provide innovative, quality care to their residents to rise above the stigma.

State and national licensing boards perform periodic inspections to ensure that standards set forth by the federal government are met. These standards address quality of patient care as well as adequacy of the nursing home facility. Yet many elderly individuals and their families still perceive nursing homes as a place to go to die, and the fact that many of these institutions are poorly equipped, understaffed, and disorganized keeps this societal perception alive. There are, however, many excellent nursing homes that strive to go beyond the minimum federal regulations for Medicaid and Medicare reimbursement. In addition to medical, nursing, rehabilitation, and dental services, social and recreational services are provided to increase the quality of life for elderly people living in nursing homes. These activities include playing cards, bingo, and other games; parties; church activities; books; television; movies; and arts, crafts, and other classes. Some nursing homes provide occupational and professional counseling. These facilities strive to enhance opportunities for improving quality of life and for becoming "places to live" rather than "places to die."

Elder Abuse

Abuse of elderly individuals is a serious form of family violence. Statistics regarding the prevalence of elder abuse are difficult to determine. It is estimated that annually up to 2 million older adults in the United States are victims of abuse (Stark, 2012). However, the data suggest that only about 84 percent of these cases are reported to authorities. The abuser is often a relative who lives with the elderly person and may be the assigned caregiver. Typical caregivers who are likely to be abusers of the elderly were described by Murray and associates (2009) as those under economic stress, substance abusers, those who themselves have been victims of previous family violence, and those who are exhausted and frustrated by the caregiver role. Identified risk factors for victims of abuse include being a white female aged 70 or older, mental or physical impairment, inability to meet daily self-care needs, and having care needs that exceed the caretaker's ability.

Abuse of elderly individuals may be psychological, physical, or financial. Neglect may be intentional or unintentional. Psychological abuse includes yelling, insulting, harsh commands, threats, silence, and social isolation. Physical abuse is described as striking, shoving, beating, or restraint. Financial abuse refers to misuse or theft of finances, property, or material possessions. Neglect implies failure to fulfill the physical needs of an individual who cannot do so

independently. Unintentional neglect is inadvertent, whereas intentional neglect is deliberate. In addition, elderly individuals may be the victims of sexual abuse, which is sexual intimacy between two persons that occurs without the consent of one of the persons involved. Another type of abuse, called **granny-dumping** by the media, involves abandoning elderly individuals at emergency departments, nursing homes, or other facilities—literally leaving them in the hands of others when the strain of caregiving becomes intolerable. Types of elder abuse are summarized in Box 34–1.

Elder victims often minimize the abuse or deny that it has occurred. The elderly person may be unwilling to disclose information because of fear of retaliation, embarrassment about the existence of abuse in the family, protectiveness toward a family member, or unwillingness to institute legal action. Adding to this unwillingness to report is that infirm elders are often isolated, so their mistreatment is less likely to be noticed by those who might be alert to symptoms of abuse. For these reasons, detection of abuse in the elderly is difficult at best.

Factors That Contribute to Abuse

A number of contributing factors have been implicated in the abuse of elderly individuals.

Longer Life

The 65-and-older age group has become the fastest growing segment of the population. Within this segment, the number of elderly older than age 75 has increased most rapidly. This trend is expected to continue well into the 21st century. The 75-and-older age group is the one most likely to be physically or mentally impaired, requiring assistance and care from family members. This group also is the most vulnerable to abuse from caregivers.

Dependency

Dependency appears to be the most common precondition in domestic abuse. Changes associated with normal aging or induced by chronic illness often result in loss of self-sufficiency in the elderly person, requiring that he or she become dependent on another for assistance with daily functioning. Long life may also consume finances to the point that the elderly individual becomes financially dependent on another. This type of dependency also increases the elderly person's vulnerability to abuse.

Stress

The stress inherent in the caregiver role is a factor in most abuse cases. Some clinicians believe that elder abuse results from individual or family psychopathology. Others suggest that even psychologically healthy family members can become abusive as a result of the exhaustion and acute stress caused by overwhelming caregiving responsibilities. This is compounded in an age group that has been dubbed the "sandwich generation"—those individuals who

---

BOX 34–1 Examples of Elder Abuse

PHYSICAL ABUSE
Striking, hitting, beating
Shoving
Bruising
Cutting
Restraining

PSYCHOLOGICAL ABUSE
Yelling
Insulting, name-calling
Harsh commands
Threats
Ignoring, silence, social isolation
Withholding of affection

NEGLECT (INTENTIONAL OR UNINTENTIONAL)
Withholding food and water
Inadequate heating

Unclean clothes and bedding
Lack of needed medication
Lack of eyeglasses, hearing aids, false teeth

FINANCIAL ABUSE OR EXPLOITATION
Misuse of the elderly person's income by the caregiver
Forcing the elderly person to sign over financial affairs to another person against his or her will or without sufficient knowledge about the transaction

SEXUAL ABUSE
Sexual molestation; rape
Any type of sexual intimacy against the elderly person's will

(2015). Synopsis of psychiatry: Behavioral sciences/clinical psychiatry *(11th ed.). Philadelphia: Lippincott Williams & Wilkins.*

elected to delay childbearing so that they are now at a point in their lives when they are "sandwiched" between providing care for their children and providing care for their aging parents.

Learned Violence

Children who have been abused or have witnessed abusive and violent parents are more likely to evolve into abusive adults. In some families, abusive behavior is the normal response to tension or conflict, and this type of behavior can be transmitted from one generation to another. There may be unresolved family conflicts or retaliation for previous maltreatment that foster and promote abuse of the elderly person.

Identifying Elder Abuse

Because so many elderly individuals are reluctant to report personal abuse, health-care workers must be able to detect signs of mistreatment when they are in a position to do so. Box 34–1 listed a number of *types* of elder abuse. The following *manifestations* of the various categories of abuse have been identified (Koop, 2012; Murray et al., 2009):

- Indicators of psychological abuse include a broad range of behaviors such as the symptoms associated with depression, withdrawal, anxiety, sleep disorders, and increased confusion or agitation.
- Indicators of physical abuse may include bruises, welts, lacerations, burns, punctures, evidence of hair pulling, and skeletal dislocations and fractures.
- Neglect may be manifested as consistent hunger, poor hygiene, inappropriate dress, consistent lack of supervision, consistent fatigue or listlessness, unattended physical problems or medical needs, or abandonment.
- Sexual abuse may be suspected when the elderly person is presented with pain or itching in the genital area; bruising or bleeding in external genitalia, vaginal, or anal areas; or unexplained sexually transmitted disease.
- Financial abuse may be occurring when there is an obvious disparity between assets and satisfactory living conditions or when the elderly person complains of a sudden lack of sufficient funds for daily living expenses.

Health-care workers often feel intimidated when confronted with cases of elder abuse. In these instances, referral to an individual experienced in management of victims of such abuse may be the most effective approach to evaluation and intervention. Health-care workers are responsible for reporting suspicions of elder abuse. An investigation is then conducted by regulatory agencies, whose job it is to determine if the suspicions are corroborated. Every effort must be made to ensure the client's safety, but it is important to remember that a competent elderly person has the right to choose his or her health-care options. As inappropriate as it may seem, some elderly individuals choose to return to the abusive situation. In this instance, he or she should be provided with names and phone numbers to call for assistance if needed. A follow-up visit by an adult protective services representative should be conducted.

Increased efforts need to be made to ensure that health-care providers have comprehensive training in the detection of and intervention in elder abuse. More research is needed to increase knowledge and understanding of the phenomenon of elder abuse and ultimately to effect more sophisticated strategies for prevention, intervention, and treatment.

Suicide

Although persons aged 65 and older comprise only 14.1 percent of the population, they represent a disproportionately high percentage of individuals who die by suicide. The highest number of suicides (19.3%) occurred among those 85 years of age and older (American Foundation for Suicide Prevention, 2016). The group especially at risk appears to be white men older than age 65, who are at five times greater risk for suicide than the general population (Sadock et al., 2015). Predisposing factors include loneliness, financial problems, physical illness, loss, and depression.

Increased social isolation may be a contributing factor to suicide among the elderly. The number of elderly individuals who are divorced, widowed, or otherwise living alone has increased, and being a widow is associated with higher risk for depression and suicide (Sadock et al., 2015).

Many elderly individuals express symptoms associated with depression that are never recognized as such, particularly somatic symptoms. Any sign of helplessness or hopelessness should prompt an assessment for suicide risk using clear and often closed-ended questions to elicit a specific response. These include:

- Have you thought of hurting yourself or taking your own life?
- Do you have a plan for hurting yourself?
- Have you ever acted on that plan?
- Have you ever attempted suicide?

Components of intervention with a suicidal elderly person should include demonstrations of genuine concern, interest, and caring; indications of empathy for his or her fears and concerns; and help in identifying, clarifying, and formulating a plan of action to deal with the unresolved issue. If the elderly person's behavior seems particularly lethal, additional family or staff coverage and contact should be arranged to prevent isolation.

Application of the Nursing Process

Assessment

Assessment of the elderly individual may follow the same framework used for all adults, but with consideration of the possible biological, psychological, sociocultural, and sexual changes that occur in the normal aging process described previously in this chapter. In no other area of nursing is it more important to practice holistic nursing than with the elderly. Older adults are likely to have multiple physical problems that contribute to problems in other areas of their lives. Obviously, these components cannot be addressed as separate entities. Nursing the elderly is a multifaceted, challenging process because of the multiple changes occurring at this time in the life cycle and the way in which each change affects every aspect of the individual.

Several considerations are unique to assessment of the elderly. Assessment of the older person's thought processes is a primary responsibility. Knowledge about the presence and extent of disorientation or confusion will influence the way in which the nurse approaches elder care.

Information about sensory capabilities is also extremely important. Because hearing loss is common, the nurse should lower the pitch and loudness of his or her voice when addressing the older person. Looking directly into the face of the older person when talking facilitates communication. Questions that require a declarative sentence in response should be asked; in this way, the nurse is able to assess the client's ability to use words correctly. Visual acuity can be determined by assessing adaptation to the dark, color matching, and the perception of color contrast. Knowledge about these aspects of sensory functioning is essential in the development of an effective care plan.

The nurse should be familiar with the normal physical changes associated with the aging process. Following are examples of some of these changes:

■ Less effective response to changes in environmental temperature, resulting in hypothermia
■ Decreases in oxygen use and the amount of blood pumped by the heart, resulting in cerebral anoxia or hypoxia
■ Skeletal muscle wasting and weakness, resulting in difficulty in physical mobility
■ Limited cough and laryngeal reflexes, resulting in risk of aspiration
■ Demineralization of bones, resulting in spontaneous fracturing
■ Decrease in gastrointestinal motility, resulting in constipation
■ Decrease in the ability to interpret painful stimuli, resulting in risk of injury

Common psychosocial changes associated with aging include the following:

■ Prolonged and exaggerated grief, resulting in depression
■ Physical changes, resulting in disturbed body image
■ Changes in status, resulting in loss of self-worth

This list is by no means exhaustive. The nurse should consider many other alterations in his or her assessment of the client. Knowledge of the client's functional capabilities is essential for determining the physiological, psychological, and sociological needs of the elderly individual. Age alone does not preclude the occurrence of all these changes. The aging process progresses at a wide range of variance, and each client must be assessed as a unique individual.

Diagnosis and Outcome Identification

Virtually any nursing diagnosis may be applicable to the aging client, depending on individual needs for assistance. Based on normal changes that occur in the elderly, the following nursing diagnoses may be considered:

Physiologically related diagnoses

■ Risk for trauma related to confusion, disorientation, muscular weakness, spontaneous fractures, and falls
■ Hypothermia related to loss of adipose tissue under the skin, evidenced by increased sensitivity to cold and body temperature below 98.6°F
■ Decreased cardiac output related to decreased myocardial efficiency secondary to age-related changes, evidenced by decreased tolerance for activity and decline in energy reserve
■ Ineffective breathing pattern related to increase in fibrous tissue and loss of elasticity in lung tissue, evidenced by dyspnea and activity intolerance
■ Risk for aspiration related to diminished cough and laryngeal reflexes
■ Impaired physical mobility related to muscular wasting and weakness, evidenced by need for assistance in ambulation
■ Imbalanced nutrition less than body requirements, related to inefficient absorption from gastrointestinal tract, difficulty chewing and swallowing, anorexia, and difficulty in feeding self, evidenced by wasting syndrome, anemia, and weight loss
■ Constipation related to decreased motility; inadequate diet; insufficient activity or exercise, evidenced by decreased bowel sounds; hard, formed stools; or straining at stool
■ Stress urinary incontinence related to degenerative changes in pelvic muscles and structural supports associated with increased age, evidenced by

reported or observed dribbling with increased abdominal pressure or urinary frequency

■ Urinary retention related to prostatic enlargement, evidenced by bladder distention, frequent voiding of small amounts, dribbling, or overflow incontinence

■ Disturbed sensory perception related to age-related alterations in sensory transmission, evidenced by decreased visual acuity, hearing loss, diminished sensitivity to taste and smell, or increased touch threshold (This diagnosis has been retired by NANDA-I but retained in this text because of its appropriateness to the specific behaviors described.)

■ Insomnia related to age-related cognitive decline, decrease in ability to sleep ("sleep decay"), or medications, evidenced by interrupted sleep, early awakening, or falling asleep during the day

■ Chronic pain related to degenerative changes in joints, evidenced by verbalization of pain or hesitation to use weight-bearing joints

■ Self-care deficit (specify) related to weakness, confusion, or disorientation, evidenced by inability to feed self, maintain hygiene, dress or groom self, or use the toilet without assistance

■ Risk for impaired skin integrity related to alterations in nutritional state, circulation, sensation, or mobility

Psychosocially related diagnoses

■ Disturbed thought processes related to age-related changes that result in cerebral anoxia, evidenced by short-term memory loss, confusion, or disorientation (This diagnosis has been retired by NANDA-I but retained in this text because of its appropriateness to the specific behaviors described.)

■ Complicated grieving related to bereavement overload, evidenced by symptoms of depression

■ Risk for suicide related to depressed mood and feelings of low self-worth

■ Powerlessness related to lifestyle of helplessness and dependency on others, evidenced by depressed mood, apathy, or verbal expressions of having no control or influence over life situation

■ Low self-esteem related to loss of preretirement status, evidenced by verbalization of negative feelings about self and life

■ Fear related to nursing home placement, evidenced by symptoms of severe anxiety and statements such as, "Nursing homes are places to go to die"

■ Disturbed body image related to age-related changes in skin, hair, and fat distribution, evidenced by verbalization of negative feelings about body

■ Ineffective sexuality pattern related to pain associated with vaginal dryness, evidenced by reported dissatisfaction with decrease in frequency of sexual intercourse

■ Sexual dysfunction related to medications (e.g., antihypertensives) evidenced by inability to achieve an erection

■ Social isolation related to total dependence on others, evidenced by expression of inadequacy in or absence of significant purpose in life

■ Risk for trauma (elder abuse) related to caregiver role strain

■ Caregiver role strain related to severity and duration of the care receiver's illness; lack of respite and recreation for the caregiver, evidenced by feelings of stress in relationship with care receiver; feelings of depression and anger; or family conflict around issues of providing care

Outcome Criteria

The following criteria may be used for measurement of outcomes in the care of the elderly client.

The client:

■ Has not experienced injury

■ Maintains reality orientation consistent with cognitive level of functioning

■ Manages own self-care with assistance

■ Expresses positive feelings about self, past accomplishments, and hope for the future

■ Compensates adaptively for diminished sensory perception

Caregivers:

■ Can problem-solve effectively regarding care of the elderly client

■ Demonstrate adaptive coping strategies for dealing with stress of caregiver role

■ Openly express feelings

■ Express desire to join a support group of other caregivers

Planning and Implementation

In Table 34–2, selected nursing diagnoses are presented for the elderly client. Outcome criteria are included, along with appropriate nursing interventions and rationale for each.

Reminiscence therapy is especially helpful with elderly clients. This therapeutic intervention is highlighted in Box 34–2.

Evaluation

Reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of nursing actions for the elderly client may be facilitated by gathering information using the following types of questions:

■ Has the client escaped injury from falls, burns, or other means to which he or she is vulnerable because of age?

Table 34–2 | CARE PLAN FOR THE ELDERLY CLIENT

NURSING DIAGNOSIS: RISK FOR TRAUMA

RELATED TO: Confusion, disorientation, muscular weakness, spontaneous fractures, falls

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE

Short-Term Goals:
• Client calls for assistance when ambulating or carrying out other activities.
• Client does not experience injury.
Long-Term Goal:
• Client does not experience injury.
	1. The following measures may be instituted:
	  a. Arrange furniture and other items in the room to accommodate client's disabilities.
	  b. Store frequently used items within easy access.
	  c. Keep bed in unelevated position. Pad side rails and headboard if client has history of seizures. Keep bedrails up when client is in bed (if permitted by institutional policy).
	  d. Assign room near nurses' station; observe frequently.
	  e. Assist client with ambulation.
	  f. Keep a dim light on at night.
	  g. If client is a smoker, cigarettes and lighter or matches should be kept at the nurses' station and dispensed only when someone is available to stay with client while he or she is smoking.
	  h. Frequently orient client to place, time, and situation.
	  i. Soft restraints may be required if client is very disoriented and hyperactive.
		1. To ensure client safety.

NURSING DIAGNOSIS: DISTURBED THOUGHT PROCESSES

RELATED TO: Age-related changes that result in cerebral anoxia

EVIDENCED BY: Short-term memory loss, confusion, or disorientation

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client accepts explanations of inaccurate interpretations of the environment within (time to be determined based on client condition). Long-Term Goal: • Client interprets the environment accurately and maintains reality orientation to the best of his or her cognitive ability.	1. Frequently orient client to reality. Use clocks and calendars with large numbers that are easy to read. Notes and large, bold signs may be useful as reminders. Allow client to have personal belongings. 2. Keep explanations simple. Use face-to-face interaction. Speak slowly and do not shout. 3. Discourage rumination on delusional thoughts. Talk about real events and real people.	1. To help maintain orientation and aid in memory and recognition. 2. To facilitate comprehension. Shouting may create discomfort and, in some instances, may provoke anger. 3. Rumination promotes disorientation. Reality orientation increases sense of self-worth and personal dignity.

Table 34–2 | CARE PLAN FOR THE ELDERLY CLIENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	4. Monitor for medication side effects.	4. Physiological changes in the elderly can alter the body's response to certain medications. Toxic effects may intensify altered thought processes.

NURSING DIAGNOSIS: SELF-CARE DEFICIT (SPECIFY)
RELATED TO: Weakness, disorientation, confusion, or memory deficits
EVIDENCED BY: Inability to fulfill activities of daily living (ADLs)

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client participates in ADLs with assistance from caregiver. Long-Term Goals: • Client accomplishes ADLs to the best of his or her ability. • Unfulfilled needs are met by caregivers.	1. Provide a simple, structured environment: a. Identify self-care deficits and provide assistance as required. Promote independent actions as able. b. Allow plenty of time for client to perform tasks. c. Provide guidance and support for independent actions by talking client through the task one step at a time. d. Provide a structured schedule of activities that does not change from day to day. e. ADLs should follow home routine as closely as possible. f. Allow consistency in assignment of daily caregivers.	1. To minimize confusion.

NRSING DIAGNOSIS: CAREGIVER ROLE STRAIN
RELATED TO: Severity and duration of the care receiver's illness; lack of respite and recreation for the caregiver
EVIDENCED BY: Feelings of stress in relationship with care receiver; feelings of depression and anger; family conflict around issues of providing care

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Caregivers verbalize understanding of ways to facilitate the caregiver role. Long-Term Goal: • Caregivers achieve effective problem-solving skills and develop adaptive coping mechanisms to regain equilibrium.	1. Assess prospective caregivers' ability to anticipate and fulfill client's unmet needs. Provide information to assist caregivers with this responsibility. Ensure that caregivers are aware of available community support systems from which they can seek assistance when required. Examples include adult day-care centers, housekeeping and homemaker services, respite care services, or a local	1. Caregivers require relief from the pressures and strain of providing 24-hour care for their loved one. Studies have shown that elder abuse arises out of caregiving situations that place overwhelming stress on the caregivers.

Table 34–2 | CARE PLAN FOR THE ELDERLY CLIENT–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	chapter of the Alzheimer's Association. This organization sponsors a nationwide 24-hour hotline to provide information and link families who need assistance with nearby chapters and affiliates: 800-272-3900.	
	2. Encourage caregivers to express feelings, particularly anger.	2. Release of these emotions can serve to prevent psychopathology, such as depression or psychophysiological disorders, from occurring.
	3. Encourage participation in support groups composed of members with similar life situations.	3. Hearing others who are experiencing the same problems discuss ways in which they have coped may help caregiver adopt more adaptive strategies. Individuals with similar life experiences provide empathy and support for each other.

NURSING DIAGNOSIS: LOW SELF-ESTEEM

RELATED TO: Loss of preretirement status; early stages of cognitive decline

EVIDENCED BY: Verbalization of negative feelings about self and life

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client verbalizes positive aspects of self and past accomplishments. Long-Term Goal: • Client participates in group activities in which he or she can experience a feeling of enjoyment and accomplishment (to the best of his or her ability).	1. Encourage client to express honest feelings in relation to loss of prior status. Acknowledge pain of loss. Support client through process of grieving. Assess for depression and warning signs of risk for suicide.	1. Client may be fixed in anger stage of grieving process, which is turned inward on the self, resulting in diminished self-esteem.
	2. If lapses in memory are occurring, devise methods for assisting client with memory deficit. Examples: a. Name sign on door identifying client's room b. Identifying sign on outside of dining room door c. Identifying sign on outside of restroom door d. Large clock, with oversized numbers and hands, appropriately placed e. Large calendar, indicating one day at a time, with month, day, and year in bold print f. Printed, structured daily schedule, with one copy for client and one posted on unit wall g. "News board" on unit wall where current news of national and local interest may be posted	2. These aids may assist client to function more independently, thereby increasing self-esteem.

Table 34–2 | CARE PLAN FOR THE ELDERLY CLIENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	3. Encourage client's attempts to communicate. If verbalizations are not understandable, express to client what you think he or she intended to say. It may be necessary to reorient client frequently.	3. The ability to communicate effectively with others may enhance self-esteem.
	4. Encourage reminiscence and discussion of life review (see Box 34–2). Sharing picture albums, if possible, is especially good. Also discuss present-day events.	4. Reminiscence and life review help client resume progression through the grief process associated with disappointing life events and increase self-esteem as successes are reviewed.
	5. Encourage participation in group activities. May need to accompany client at first until he or she feels secure that the group members will be accepting, regardless of limitations in verbal communication.	5. Positive feedback from group members increases self-esteem.
	6. Encourage client to be as independent as possible in self-care activities. Provide written schedule of tasks to be performed. Intervene in areas where client requires assistance.	6. The ability to perform independently preserves self-esteem.

NURSING DIAGNOSIS: DISTURBED SENSORY PERCEPTION

RELATED TO: Age-related alterations in sensory transmission

EVIDENCED BY: Decreased visual acuity, hearing loss, diminished sensitivity to taste and smell, and increased touch threshold

OUTCOME CRITERIA	NURSING INTERVENTIONS*	RATIONALE

Short-Term Goal:
• Client does not experience injury due to diminished sensory perception.
 	
Long-Term Goals:
• Client attains optimal level of sensory stimulation.
• Client does not experience injury due to diminished sensory perception.
	1. The following nursing strategies are indicated:
	  a. Provide meaningful sensory stimulation to all special senses through conversation, touch, music, or pleasant smells.
	  b. Encourage wearing of glasses, hearing aids, prostheses, and other adaptive devices.
	  c. Use bright, contrasting colors in the environment.
	  d. Provide large-print reading materials, such as books, clocks, calendars, and educational materials.
	  e. Maintain room lighting that distinguishes day from night and that is free of shadows and glare.
		1. To assist client with diminished sensory perception and because client safety is a nursing priority.

Table 34–2 | CARE PLAN FOR THE ELDERLY CLIENT—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	f. Teach client to scan the environment to locate objects.	
	g. Help client to locate food on plate using "clock" system, and describe food if client is unable to visualize; assist with feeding as needed.	
	h. Arrange physical environment to maximize functional vision.	
	i. Place personal items and call light within client's field of vision.	
	j. Teach client to watch the person who is speaking.	
	k. Reinforce wearing of hearing aid; if client does not have an aid, may consider a communication device (e.g., amplifier).	
	l. Communicate clearly, distinctly, and slowly, using a low-pitched voice and facing client; avoid overarticulation.	
	m. Remove as much unnecessary background noise as possible.	
	n. Do not use slang or extraneous words.	
	o. As speaker, position self at eye level and no farther than 6 feet away.	
	p. Get the client's attention before speaking.	
	q. Avoid speaking directly into the client's ear.	
	r. If the client does not understand what is being said, rephrase the statement rather than simply repeating it.	
	s. Help client select foods from the menu that will ensure discrimination between various tastes and smells.	
	t. Ensure that food has been properly cooled so that client with diminished pain threshold is not burned.	
	u. Ensure that bath or shower water is appropriate temperature.	
	v. Use backrubs and massage as therapeutic touch to stimulate sensory receptors.	

*The interventions for this nursing diagnosis were adapted from Rogers-Seidl, F.F. (1997). *Geriatric nursing care plans* (2nd ed.). St. Louis: Mosby Year Book.

BOX 34–2 Reminiscence Therapy and Life Review With the Elderly

Studies have indicated that *reminiscence,* or thinking about the past and reflecting on it, may promote better mental health in old age. *Life review* is related to reminiscence but differs in that it is a more guided or directed cognitive process that constructs a history or story in an autobiographical way (Murray et al., 2009).

Elderly individuals who spend time thinking about the past experience an increase in self-esteem and are less likely to suffer depression. Some psychologists believe that life review may help some people adjust to memories of an unhappy past. Others view reminiscence and life review as ways to bolster feelings of well-being, particularly in older people who can no longer remain active.

Reminiscence therapy can take place on a one-to-one basis or in a group setting. In reminiscence groups, elderly individuals share significant past events with peers. The nurse leader facilitates the discussion of topics that deal with specific life transitions, such as childhood, adolescence, marriage, childbearing, grandparenthood, and retirement. Members share both positive and negative aspects, including personal feelings, about these life cycle events.

Reminiscence on a one-to-one basis can provide a way for elderly individuals to work through unresolved issues from the past. Painful issues may be too difficult to discuss in the group setting. As the individual reviews his or her life process, the nurse can validate feelings and help the elderly client come to terms with painful issues that may have been long suppressed. This process is necessary if the elderly individual is to maintain (or attain) a sense of positive identity and self-esteem and ultimately achieve the goal of ego integrity as described by Erikson (1963).

A number of creative measures can be used to facilitate life review with the elderly individual. Having the client keep a journal for sharing may be a way to stimulate discussion (as well as providing a permanent record of past events for significant others). Pets, music, and special foods have a way of provoking memories from the client's past. Photographs of family members and past significant events are an excellent way of guiding the elderly client through his or her autobiographical review.

Care must be taken in the life review to assist clients to work through unresolved issues. Anxiety, guilt, depression, and despair may result if the individual is unable to work through the problems and accept them. Life review can work in a negative way if the individual comes to believe that his or her life was meaningless. However, it can be a very positive experience for the person who can take pride in past accomplishments and feel satisfied with his or her life, resulting in a sense of serenity and inner peace in the older adult.

- Can caregivers verbalize means of providing a safe environment for the client?
- Does the client maintain reality orientation at an optimum for his or her cognitive functioning?
- Can the client distinguish between reality-based and non-reality-based thinking?
- Can caregivers verbalize ways in which to orient client to reality as needed?
- Is the client able to accomplish self-care activities independently to his or her optimum level of functioning?
- Does the client seek assistance for aspects of self-care that he or she is unable to perform independently?
- Does the client express positive feelings about himself or herself?
- Does the client reminisce about accomplishments that have occurred in his or her life?
- Does the client express some hope for the future?
- Does the client wear eyeglasses or a hearing aid if needed to compensate for sensory deficits?
- Does the client consistently look others in the face to facilitate hearing when they are talking to him or her?
- Does the client use helpful aids, such as signs identifying various rooms, to help maintain orientation?

- Can the caregivers work through problems and make decisions regarding care of the elderly client?
- Do the caregivers include the elderly client in the decision-making process, if appropriate?
- Can the caregivers demonstrate adaptive coping strategies for dealing with the strain of long-term caregiving?
- Are the caregivers open and honest in expression of feelings?
- Can the caregivers verbalize community resources to which they can go for assistance with their caregiving responsibilities?
- Have the caregivers joined a support group?

Summary and Key Points

- Care of the aging individual presents one of the greatest challenges for nursing.
- The growing population of individuals aged 65 and older suggests that the trend will progress well into the 21st century.
- America is a youth-oriented society. It is not desirable to be old in mainstream American culture.
- In some cultures, the elderly are revered and hold a special place of honor within the society, but in highly industrialized countries such as the

United States, status declines with the decrease in productivity and participation in the mainstream of society.

■ Individuals experience many changes as they age. Physical changes occur in virtually every body system.

■ Psychologically, there may be age-related memory deficiencies, particularly for recent events.

■ Intellectual functioning does not decline with age, but length of time required for learning increases.

■ Aging individuals experience many losses, potentially leading to bereavement overload. They are vulnerable to depression and to feelings of low self-worth.

■ The elderly population represents a disproportionately high percentage of individuals who die by suicide.

■ Neurocognitive disorders are the most frequent causes of psychopathology in the elderly. Sleep disorders are very common.

■ The need for sexual expression by the elderly is often misunderstood within our society. Although many physical changes occur at this time of life that alter an individual's sexuality, if he or she has reasonably good health and a willing partner, sexual activity can continue well past the 70s for most people.

■ Retirement has both social and economic implications for elderly individuals. Society often equates an individual's status with occupation, and loss of employment may result in the need for adjustment in the standard of living because retirement income may be reduced by 20 to 40 percent of preretirement earnings.

■ Less than 4 percent of the population aged 65 and older live in nursing homes. A profile of the typical elderly nursing home resident is a white woman about 80 years old, widowed, with multiple chronic health conditions. Much stigma is attached to what some still call "rest homes" or "old age homes," and many elderly people still equate them with a "place to go to die."

■ The strain of the caregiver role has become a major dilemma in our society. Elder abuse is sometimes inflicted by caregivers for whom the role has become overwhelming and intolerable. There is an intense need to find assistance for these people, who must provide care for their loved ones on a 24-hour basis. Home health care, respite care, support groups, and financial assistance are needed to ease the burden of this role strain.

■ Caring for elderly individuals requires a special kind of inner strength and compassion. The poem that follows conveys a vital message for nurses.

DavisPlus | Additional info available at www.davisplus.com

What Do You See, Nurse?

What do you see, nurse, what do you see?
    What are you thinking when you look at me?
A crabbed old woman, not very wise.
    Uncertain of habit, with faraway eyes.
Who dribbles her food and makes no reply
    When you say in a loud voice, "I do wish you'd try."
Who seems not to notice the things that you do
    And forever is losing a stocking or shoe.
Who unresisting or not, lets you do as you will
    With bathing and feeding, the long day to fill.
Is that what you're thinking, is that what you see?
    Then open your eyes, you're not looking at me.
I'll tell you who I am as I sit there so still.
    As I move at your bidding, as I eat at your will.
I'm a small child of ten with a father and a mother,
    Brothers and sisters who love one another.

A young girl at sixteen with wings on her feet
    Dreaming that soon now a lover she'll meet.
A bride soon at twenty—my heart gives a leap
    Remembering the vows that I promised to keep.
At twenty-five, now, I have young of my own
    Who need me to build a secure happy home.
A woman of thirty, my young now grow fast
    Bound to each other with ties that should last.

At forty my young will now soon be gone,
    But my man stays beside me to see I don't mourn.
At fifty once more babies play round my knee.
    Again we know children, my loved one and me.

Dark days are upon me, my husband is dead.
    I look at the future, I shudder with dread.
For my young are all busy rearing young of their own.
    And I think of the years and the love I have known.

I'm an old woman now and nature is cruel.
    Tis her jest to make old age look like a fool.
The body it crumbles, grace and vigor depart.
    There is now just a stone where I once had a heart.
But inside this old carcass a young girl still dwells.
    And now and again my battered heart swells.

I remember the joys, I remember the pain.
    And I'm loving and living life all over again.
I think of the years all too few—gone so fast.
    And accept the stark fact that nothing can last.
So open your eyes, nurse, open and see.
    Not a crabbed old woman—look closer—SEE ME.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Stanley, age 72, is admitted to the hospital for depression. His son reports that he has periods of confusion and forgetfulness. In her admission assessment, the nurse notices an open sore on Stanley's arm. When she questions him about it, he says, "I scraped it on the fence two weeks ago. It's smaller than it was." How might the nurse analyze these data?
   a. Consider that Stanley may have been attempting self-harm.
   b. The delay in healing may indicate that Stanley has developed skin cancer.
   c. A diminished inflammatory response in the elderly increases healing time.
   d. Age-related skin changes and distribution of adipose tissue delay healing in the elderly.

2. What is the most appropriate way to communicate with an elderly person who is deaf in his right ear?
   a. Speak loudly into his left ear.
   b. Speak to him from a position on his left side.
   c. Speak face-to-face in a high-pitched voice.
   d. Speak face-to-face in a low-pitched voice.

3. Why is it important for the nurse to check the temperature of the water before an elderly individual gets into the shower?
   a. The client may catch a cold if the water temperature is too low.
   b. The client may burn himself because of a higher pain threshold.
   c. Elderly clients have difficulty discriminating between hot and cold.
   d. The water must be exactly 98.6°F.

4. Mr. B., age 79, is admitted to the psychiatric unit for depression. He has lost weight and become socially isolated. His wife died 5 years ago, and his son tells the nurse, "He did very well when Mom died. He didn't even cry." Which would be the priority nursing diagnosis for Mr. B.?
   a. Complicated grieving
   b. Imbalanced nutrition: less than body requirements
   c. Social isolation
   d. Risk for injury

5. Mr. B., age 79, is admitted to the psychiatric unit for depression. He has lost weight and has become socially isolated. His wife died 5 years ago, and he lives alone. A suicide assessment is conducted. Why is Mr. B. at high risk for suicide?
   a. All depressed people are at high risk for suicide.
   b. Mr. B. is in the age group in which the highest percentage of suicides occur.
   c. Mr. B. is a white man, recently bereaved, living alone.
   d. His son reports that Mr. B. owns a gun.

6. Mr. B., age 79, is admitted to the psychiatric unit for depression. He has lost weight and has become socially isolated. His wife died 5 years ago, and his son tells the nurse, "He did very well when Mom died. He didn't even cry." Which would be the priority nursing intervention for Mr. B.?
   a. Take blood pressure once each shift.
   b. Ensure that Mr. B. attends group activities.
   c. Encourage Mr. B. to eat all of the food on his food tray.
   d. Encourage Mr. B. to talk about his wife's death.

7. In group exercise, Mr. B., a 79-year-old man with major depression, becomes tired and short of breath very quickly. This is most likely due to:
   a. Age-related changes in the cardiovascular system.
   b. A sedentary lifestyle.
   c. The effects of pathological depression.
   d. Medication the physician has prescribed for depression.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. Clara, an 80-year-old woman, says to the nurse, "I'm all alone now. My husband is gone. My best friend is gone. My daughter is busy with her work and family. I might as well just go, too." Which is the best response by the nurse?
   a. "Are you thinking that you want to die, Clara?"
   b. "You have lots to live for, Clara."
   c. "Cheer up, Clara. You have so much to be thankful for."
   d. "Tell me about your family, Clara."

9. An elderly client says to the nurse, "I don't want to go to that crafts class. I'm too old to learn anything." Based on knowledge of the aging process, which of the following is a true statement?
   a. Memory functioning in the elderly most likely reflects loss of long-term memories of remote events.
   b. Intellectual functioning declines with advancing age.
   c. Learning ability remains intact, but time required for learning increases with age.
   d. Cognitive functioning is rarely affected in aging individuals.

10. According to the literature, which of the following is most important for individuals to maintain a healthy, adaptive old age?
   a. To remain socially interactive
   b. To disengage slowly in preparation of the last stage of life
   c. To move in with family
   d. To maintain total independence and accept no help from anyone

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Turvey, C.L., Conwell, Y., Jones, M.P., Phillips, C., Simonsick, E., Pearson, J.L., & Wallace, R. (2002). Risk factors for late-life suicide: A prospective, community-based study. *American Journal of Geriatric Psychiatry, 10*(4), 398-406. doi:10.1097/00019442-200207000-00006

DESCRIPTION OF THE STUDY: Studies have suggested that a negative or depressive mental outlook, being widowed or divorced, sleeping more than 9 hours per day, and drinking more than three alcoholic beverages per day are risk factors for late-life suicide. The primary aim of this study was to examine the relationship between completed suicide in late life and physical health, disability, and social support. The participants were 14,456 individuals selected from a general population of elderly subjects age 65 and older. Control subjects were a group of 420 individuals who were matched by age and sex. This 10-year longitudinal study began in 1981. Variables were assessed at baseline, year 3, and year 6, with a 10-year mortality follow-up. Baseline variables included sleep quality, social support, alcohol use, medical illness, physical impairment, cognitive impairment, and depressive symptoms.

RESULTS OF THE STUDY: The 10-year mortality follow-up indicated that 75 percent of the control subjects had died, but none had died from suicide. Twenty-one of the 14,456 participants died by suicide within the follow-up period. Twenty of the 21 suicide victims were male. Average age was 78.6 years, with a range from 67 to 90 years. The most common means was gunshot. Other means included hanging, cutting, overdose, drowning, and carbon monoxide inhalation, and one participant jumped to his death. In this study, presence of friends or relatives to confide in was negatively associated with suicide. Likewise, regular church attendance was more common in control subjects than in the participant sample, indicating an even wider range of community support. Those who died by suicide had reported more depressive symptoms than those who did not, but they did not consume more alcohol (inconsistent with previous studies). Poor sleep quality was positively correlated with suicide in this study, but no specific physical illness was identified as a predisposition. The authors identify the small suicide sample as a limitation of this study.

IMPLICATIONS FOR NURSING PRACTICE: This study identified depression, poor sleep quality, and limited social support as important variables in the potential for elderly suicide. Sleep disturbance may be an important indicator of depression, whereas limited social support may be a contributing factor. The study provides reinforcement for the U.S. Department of Health and Human Services (USDHHS) recommendation

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE—cont'd

in *National Strategy for Suicide Prevention: Goals and Objectives for Action* (2001). The USDHHS recommends detection and treatment of depression as a strategy to prevent late-life suicide. The authors stated, "Because both depression and social support are amenable to intervention, this study provides further evidence for the possible

effectiveness of such strategies to reduce suicides among older adults." Nurses can become actively involved in assessing for these risk factors, as well as planning, implementing, and evaluating the effectiveness of strategies for preventing suicide in the elderly population.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Jeste, D.V., Savla, G.N., Thompson, W.K., Vahia, I.V., Glorioso, D.K., Martin, A.S., . . . Kraemer, H.C. (2013). Association between older age and successful aging: Critical role of resilience and depression. *American Journal of Psychiatry, 170*(2), 188-196. doi:10.1176/appi.ajp.2012. 12030386

DESCRIPTION OF THE STUDY: This study was a Successful AGing Evaluation (SAGE) study of 1,006 community-dwelling adults between 55 and 99 years of age. The mean age of respondents was 77.3 years of age. Telephone interviews were conducted for 25 minutes followed by a comprehensive mail-in survey in which physical, cognitive, and psychological domains were assessed. In addition, participants completed a self-reported rating of successful aging.

RESULTS OF THE STUDY: Contrary to the researchers' hypothesis, older age was associated with higher reported ratings of successful aging in spite of worsening physical and cognitive functions. The two factors contributing most to successful aging were higher scores on resilience and lower scores on depression. These were similar in strength to physical disability as an influential factor in successful aging. The authors identify, therefore, that interventions

focused on increasing resilience and decreasing depression might be factors as strong as decreasing physical disability in contributing to successful aging. They add that the study highlighted the benefits of self-measurement tools. This is supported by the fact that when people were asked about their own perceptions, information was revealed that was contrary to what was expected.

IMPLICATIONS FOR NURSING PRACTICE: First, this study underscores the importance of thorough assessment to rule out depression in the elderly and to initiate intervention as soon as possible when it is identified. Historically, depression has been underrecognized and undertreated in this population, and we are learning that reducing depression may have a significant impact on successful aging. Second, nurses can play an active role in assessing, educating, and initiating other interventions to promote resilience in the elderly. Finally, as the authors suggest, using self-reporting measures provides a valuable tool for identifying the abilities and needs of this population. Stated more simply, when health-care providers listen to what the client has to say, there is much to be learned and it lays the foundation for patient-centered care.

TEST YOUR CRITICAL THINKING SKILLS

Mrs. M., age 76, is seeing her primary physician for her regular 6-month physical examination. Mrs. M.'s husband died 2 years ago, at which time she sold her home in Kansas and came to live in California with her only child, a daughter. The daughter is married and has three children (one in college and two teenagers at home). The daughter reports that her mother is becoming increasingly withdrawn, stays in her room, and eats very little. She has lost 13 pounds since her last 6-month visit. The primary physician refers Mrs. M. to a psychiatrist, who hospitalizes her for evaluation. He diagnoses Mrs. M. with major depressive disorder.

Mrs. M. tells the nurse, "I didn't want to leave my home, but my daughter insisted. I would have been all right. I miss my friends and my church. Back home I drove my car everywhere. But there's too

much traffic out here. They sold my car and I have to depend on my daughter or grandkids to take me places. I hate being so dependent! I miss my husband so much. I just sit and think about him and our past life all the time. I don't have any interest in meeting new people. I want to go home!"

Mrs. M. admits to having some thoughts of dying, although she denies feeling suicidal. She denies having a plan or means for taking her life. "I really don't want to die, but I just can't see much reason for living. My daughter and her family are so busy with their own lives. They don't need me—or even have time for me!"

Answer the following questions about Mrs. M.:

1. What would be the *primary* nursing diagnosis for Mrs. M.?
2. Formulate a short-term goal for Mrs. M.
3. From the assessment data, identify the major problem that may be a long-term focus of care for Mrs. M.

Survivors of Abuse or Neglect

CHAPTER OUTLINE

KEY TERMS

acquaintance rape

child sexual abuse

compounded rape reaction

controlled response pattern

cycle of battering

date rape

emotional abuse

emotional neglect

expressed response pattern

intimate partner violence

marital rape

physical neglect

rape trauma syndrome

safe house or shelter

sexual exploitation of a child

silent rape reaction

statutory rape

OBJECTIVES
After reading this chapter, the student will be able to:

1. Describe epidemiological statistics associated with intimate partner violence, child abuse, and sexual assault.
2. Discuss characteristics of victims and victimizers.
3. Identify predisposing factors to abusive behaviors.
4. Describe physical and psychological effects on the survivors of intimate partner violence, child abuse, and sexual assault.
5. Identify nursing diagnoses, goals of care, and appropriate nursing interventions for care of survivors of intimate partner violence, child abuse, and sexual assault.
6. Evaluate nursing care of survivors of intimate partner violence, child abuse, and sexual assault.
7. Discuss modalities relevant to treatment of survivors of abuse.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What neurotransmitters have been implicated in the etiology of aggression and violence?
2. What is the most common reason that women give for staying in an abusive relationship?
3. Describe a compounded rape reaction.
4. What are some adult manifestations of childhood sexual abuse?

Abuse is a significant and frightening public health problem. Books, newspapers, movies, and television inundate their readers and viewers with stories of "man's inhumanity to man" (no gender bias intended).

More than 1 in 3 women (35.6%) and more than 1 in 4 men (28%) experience rape, physical violence, and/or stalking by an intimate partner during their lives (Centers for Disease Control and Prevention [CDC], 2016a).

Rape is vastly underreported in the United States. Because many of these attacks go unreported and unrecognized, sexual assault is often considered a silent, violent epidemic. In the United States, 1 in 5 women and 1 in 71 men report having been raped at some time in their lives (CDC, 2016b). The CDC also reports that rape often occurs before 25 years of age; 42 percent of reported rapes occurred before 18 years of age. This crime is often committed by someone known to the victim.

Child abuse and related fatalities continue to be a significant health concern, although most recent statistics identify an overall decline for the period from 2009 to 2013 (U.S. Department of Health and Human Services [USDHHS], 2015). During the same time period, the number of children seen by child protective services agencies has increased. Public awareness, better screening tools with differential response systems, and funding for prevention programs have all been identified as possible contributing factors for changes in these current trends. Based on the 2013 statistics (USDHHS, 2015), 9.1 in 1,000 children (679,000) were victimized; 79.5 percent of those were neglected, 18 percent were physically abused, 9 percent were sexually abused, and 8.7 percent were victims of psychological maltreatment. Human trafficking, which includes sex trafficking, is defined by federal law as "a commercial sex act [that] is induced by force, fraud, or coercion, or in which the person induced to perform such act has not attained 18 years of age" (U.S. Department of Education, 2013). Prevalence statistics are difficult to compile, but sex trafficking of children has been reported in all 50 U.S. states, and traffickers have been known to prey on children as young as 9 years of age. An estimated 1,520 children died from causes related to abuse or neglect in 2013.

Elder abuse and neglect is also a significant problem. The CDC (2016c) estimates that 1 in 10 people older than age 60 and living at home are victims of abuse, neglect, and/or financial exploitation. There is general agreement that these statistics underestimate the scope of the problem. Despite mandatory reporting laws in most states and the recent trend toward more reporting of abuse, adult protective services vary markedly among states. One study found that for every case that came to the attention of these agencies, 24 had not been reported (National Center on Elder Abuse, 2015).

Abuse affects all populations equally. It occurs among all races, religions, economic classes, ages, and educational backgrounds. The phenomenon is cyclical in that many abusers were themselves victims of abuse as children.

Family violence is not a new problem; in fact, it is probably as old as humankind and has been documented as far back as biblical times. Child abuse became a mandatory reportable occurrence in the United States in 1968. Responsibility for the protection of elders from abuse rests primarily with the states. In 1987, Congress passed amendments to the Older Americans Act of 1965 that provide for state Area Agencies on Aging to assess the need for elder abuse prevention services. These laws have made it possible for individuals who once felt powerless to stop the abuse against them to come forward and seek advice, support, and protection.

This chapter discusses intimate partner violence, child abuse (including neglect), and sexual violence. Elder abuse is discussed in more detail in Chapter 34, The Aging Individual. Factors that predispose individuals to commit acts of abuse against others, as well as the physical and psychological effects on the survivors, are examined.

Nursing of individuals who have experienced abusive behavior from others is presented within the context of the nursing process. Various treatment modalities are described.

Predisposing Factors

What predisposes individuals to be abusive? Although no one really knows for sure, several theories have been espoused. As researchers have sought to better understand aggression and violence, two distinct forms of aggression have been identified: reactive aggression, which is associated with impulsivity and is more common among people who have a history of being abused, and proactive aggression, which is initiated rather than provoked and is more common in psychopathy (Rosell & Siever, 2015). Most research is associated with reactive aggression. The following is a brief discussion of current evidence associated with biological, psychological, and sociocultural influences.

Biological Theories

Neurophysiological Influences

Research demonstrates consistently that lower amygdala volume plays a role in aggression (Rosell & Siever, 2015). The amygdala, which is responsible for impulse control and affective processing, appears to be less well modulated in people with aggression, and responses to fear are reduced. The limbic prefrontal cortex also has a primary role in aggression; smaller volumes of left-sided gray matter and greater right-sided volume have been noted in people with aggressive traits. Evidence has also demonstrated lowered connectivity between the amygdala and the prefrontal cortex as associated with increased aggression. The striatum, an area of the brain that plays a critical role in selection and inhibition of affective, cognitive, and motor responses, has been identified as dysfunctional in aggression (Rosell & Siever, 2015).

Biochemical Influences

Studies have associated increased dopamine release with aggression, and low levels of striatal serotonin have been associated with increases in impulsivity and aggression (Rosell & Siever, 2015). Evidence supports that high plasma (and low cerebrospinal fluid) concentrations of 5-hydroxyindoleacetic acid (5-HIAA) serotonin are associated with aggression (Sadock, Sadock, & Ruiz, 2015). Finally, research shows that a complex interaction between testosterone and cortisol levels is associated with aggression (Batrinos, 2012). Research is ongoing to explore these mechanisms, their interactions in the brain, and the influence of environmental factors. An explanation of these biochemical influences on violent behavior is presented in Figure 35–1.

Genetic Influences

Various genetic components related to aggressive behavior have been investigated. Studies have found a potential role for the X-linked monoamine oxidase A gene in the etiology of antisocial behaviors (Sadock et al., 2015). This gene may have implications for impulsivity and aggression, but further research is needed. Human and animal genetics studies show a strong role for 5-hydroxytryptamine (5-HT) transporter genes in aggression.

Disorders of the Brain

Organic brain syndromes associated with various cerebral disorders have been implicated in the predisposition to aggressive and violent behavior (Sadock et al., 2015). Brain tumors, particularly in the areas of the limbic system and the temporal lobes; trauma to the brain, resulting in cerebral changes; and diseases, such as encephalitis (or medications that may affect this syndrome) and epilepsy, particularly temporal lobe epilepsy, have all been implicated.

Psychological Theories

Psychodynamic Theory

The psychodynamic theorists imply that unmet needs for satisfaction and security result in an underdeveloped ego and a weak superego. It is thought that when frustration occurs, aggression and violence supply this individual with a dose of power and prestige that boosts self-image and validates a significance to his or her life that is lacking. The immature ego cannot prevent dominant id behaviors from occurring, and the weak superego is unable to produce feelings of guilt.

Learning Theory

Children learn to behave by imitating their role models, usually their parents. Models are more likely to be imitated when they are perceived as prestigious or influential or when the behavior is followed by positive reinforcement. Children may have an idealistic perception of their parents during the very early developmental stages, but as they mature, they often begin to imitate the behavior patterns of their teachers, friends, and others. Individuals who were abused as children or who witnessed domestic violence as a child are more likely to manifest reactive aggression as adults (Rosell & Siever, 2015).

Adults and children alike model many behaviors after individuals they observe on television and in movies. Unfortunately, modeling can result in maladaptive as well as adaptive behavior, particularly when children view heroes triumphing over villains by using violence. Individuals who have a biological predisposition toward aggressive behavior may be more susceptible to negative role modeling.

Sociocultural Theories

Societal Influences

Although they agree that biological and psychological aspects are influential, social scientists believe that aggressive behavior is primarily a product of one's culture and social structure.

American society essentially was founded on a general acceptance of violence as a means of solving problems. The concept of relative deprivation (lack of necessities for life in comparison to another individual or group) has been shown to have a profound effect on collective violence within a society. Poverty, prolonged unemployment, family breakdown, and exposure to violence in the community and in the family have all been linked to increases in aggression (American Psychological Association, 2016; Sullivan, 2009).

One's culture also influences the manner in which violence and aggression is expressed; in American culture, violence is more often expressed in physical aggression, and in Japanese culture,
FIGURE 35–1 Neurobiology of violence.

NEUROTRANSMITTERS

Neurotransmitters that have been implicated in the etiology of aggression and violence include decreases in striatal serotonin and increases in norepinephrine and dopamine.

ASSOCIATED AREAS OF THE BRAIN

- Limbic structures: Emotional alterations
- Prefrontal and frontal cortices: Modulation of social judgment
- Amygdala: Anxiety, rage, fear
- Hypothalamus: Stimulates sympathetic nervous system in fight-or-flight response
- Hippocampus: Learning and memory

MEDICATIONS USED TO MODULATE AGGRESSION

1. Studies have suggested that selective serotonin reuptake inhibitors (SSRIs) may reduce irritability and aggression consistent with the hypothesis of reduced serotonergic activity in aggression.
2. Mood stabilizers that dampen limbic irritability may be important in reducing the susceptibility to react to provocation or threatening stimuli by overactivation of limbic system structures such as the amygdala (Rosell & Siever, 2015). Carbamazepine (Tegretol), phenytoin (Dilantin), and divalproex sodium (Depakote) have yielded positive results. Lithium has also been used effectively in violent individuals (Schatzberg, Cole, & DeBattista, 2015).
3. Antiadrenergic agents such as beta blockers (e.g., propranolol) have been shown to reduce aggression in some individuals, presumably by dampening excessive noradrenergic activity (Schatzberg et al., 2015).
4. In their ability to modulate excessive dopaminergic activity, antipsychotics–both typical and atypical–have been helpful in the control of aggression and violence, particularly in individuals with comorbid psychosis.

aggression is expressed more often by verbal means (Sullivan, 2009).

Application of the Nursing Process

Background Assessment Data

Data related to **intimate partner violence,** child abuse and neglect, and sexual assault are presented in this section. Characteristics of both victim and abuser are addressed. This information may be used as background knowledge in designing plans of care for these clients.

Intimate Partner Violence

Various terms are used to describe the pattern of violence between intimate partners, including intimate partner violence (IPV), domestic violence, and battering.

CORE CONCEPT

Battering
A pattern of coercive control founded on and supported by physical and/or sexual violence or threat of violence toward an intimate partner.

Tracy (2016) adds to the definition of *battering* as follows:

> Battering is also known by the term "domestic violence" and refers to acts of violence between two parties in an intimate relationship. Battering happens in heterosexual and homosexual relationships and either a male or a female can be the batterer or victim. Battering may occur in a marriage or in any other form of relationship.

The CDC (2015) defines *intimate partner violence* as follows:

> Intimate partner violence includes physical violence, sexual violence, stalking and psychological aggression (including coercive tactics) by a current or former intimate partner (i.e., spouse, boyfriend/girlfriend, dating partner, or ongoing sexual partner). An intimate partner is a person with whom one has a close personal relationship that may be characterized by the partners' emotional connectedness, regular contact, ongoing physical contact and sexual behavior, identity as a couple, and familiarity and knowledge about each other's lives. The relationship need not involve all of these dimensions.

The U.S. Department of Justice (2012) defines *intimate partner violence* as:

> A pattern of abusive behavior that is used by an intimate partner to gain or maintain power and control over the other intimate partner. [Intimate partner] violence can be physical, sexual, emotional, economic, or psychological actions or threats of actions that influence another person. This includes any behaviors that intimidate, manipulate, humiliate, isolate, frighten, terrorize, coerce, threaten, blame, hurt, injure, or wound someone.

Physical abuse between domestic partners may be known as spousal abuse, domestic or family violence, wife or husband battering, or IPV. Data from the U.S. Bureau of Justice Statistics (2012) reflect that over the period from 1993 to 2010, 82 percent of victims of intimate partner violence were women, women aged 25 to 34 experienced the highest per capita rates of intimate violence, and intimate partners committed 2 percent of the nonfatal violence against men. Two-thirds of IPV events for both men and women involved physical attack, 8 percent of IPV events for women involved sexual violence, and between 4 percent and 8 percent (for women and men

respectively) of the events involved the victim being shot at, stabbed, or hit with a weapon (U.S. Bureau of Justice Statistics, 2014a). Many of the victimizations were not reported to the police, and the main reason given for not reporting is that it was "considered a personal matter."

It is difficult to completely understand the prevalence and extent of IPV because multiple patterns of IPV may be used to threaten, intimidate, or harm an intimate partner, and victims who do not perceive that nonphysical coercive strategies are considered IPV may never report it.

Profile of the Victim

For the purposes of this chapter, women are identified as the victim (and men as the victimizer) because the largest percentage of victims are women and most of the available data speaks specifically about female victims. It should be noted that men may also be victims and victimized in similar ways. Battered women represent all age, racial, religious, cultural, educational, and socioeconomic groups. They may be married or single, housewives or business executives. Many who are battered have low self-esteem, commonly adhere to feminine sex-role stereotypes, and often accept the blame for the batterer's actions. Feelings of guilt, anger, fear, and shame are common. They may be isolated from family and support systems.

Some women in violent relationships grew up in abusive homes and may have left those homes, even gotten married, at a very young age in order to escape the abuse. The battered woman views her relationship as male dominant, and as the battering continues, her ability to see the options available and make decisions concerning her life (and possibly those of her children) decreases. The phenomenon of *learned helplessness* may be applied to the woman's progressing inability to act on her own behalf. Learned helplessness occurs when an individual comes to understand that regardless of his or her behavior, the outcome is unpredictable and usually undesirable.

Profile of the Victimizer

Men who batter usually are characterized as persons with low self-esteem. Pathologically jealous, they present a "dual personality," one to the partner and one to the rest of the world (Meskill & Conner, 2013). They are often under a great deal of stress with which they have a limited ability to cope. The typical abuser is very possessive and perceives his spouse as a possession. He becomes threatened when she shows any sign of independence or attempts to share herself and her time with others. Small children are often ignored by the abuser; however, they may also become the targets of abuse as they grow older, particularly if they attempt to protect their mother from abuse. The abuser also

may use threats of taking the children away as a tactic of emotional abuse.

The abusing man typically wages a continuous campaign of degradation against his female partner. He insults and humiliates her and everything she does at every opportunity. He strives to keep her isolated from others and totally dependent on him. He demands to know where she is at every moment, and when she tells him, he challenges her honesty. He achieves power and control through intimidation.

The Cycle of Battering

In her classic studies of battered women and their relationships, Walker (1979) identified a cycle of predictable behaviors that are repeated over time. The behaviors can be divided into three distinct phases that vary in time and intensity both within the same relationship and among different couples. Figure 35–2 depicts a graphic representation of the **cycle of battering.**

Phase I. The Tension-Building Phase During this phase, the woman senses that the man's tolerance for frustration is declining. He becomes angry with little provocation, but after lashing out at her may be quick to apologize. The woman may become very nurturing and compliant, anticipating his every whim in an effort to prevent his anger from escalating. She may just try to stay out of his way.

Minor battering incidents may occur during this phase, and in a desperate effort to avoid more serious confrontations, the woman accepts the abuse as legitimately directed toward her. She denies her anger and rationalizes his behavior (e.g., "I need to do better," "He's under so much stress at work," "It's the alcohol. If only he didn't drink"). She assumes the guilt for the abuse, even reasoning that perhaps she *did* deserve the abuse, just as her aggressor suggests.
FIGURE 35–2 The cycle of battering.

The minor battering incidents continue, and the tension mounts as the woman waits for the impending explosion. The abuser begins to fear that his partner will leave him. His jealousy and possessiveness increase, and he uses threats and brutality to keep her in his captivity. Battering incidents become more intense, after which the woman becomes less and less psychologically capable of restoring equilibrium. She withdraws from him, which he misinterprets as rejection, further escalating his anger toward her. Phase I may last from a few weeks to many months or even years.

Phase II. The Acute Battering Incident This phase is the most violent and the shortest, usually lasting up to 24 hours. It most often begins with the batterer justifying his behavior to himself. By the end of the incident, however, he cannot understand what has happened, only that in his rage he has lost control over his behavior.

This incident may begin with the batterer wanting to "just teach her a lesson." In some instances, the woman may intentionally provoke the behavior. Having come to a point in phase I in which the tension is unbearable, long-term battered women know that once the acute phase is behind them, things will be better.

During phase II, women feel their only option is to find a safe place to hide from the batterer. The beating is severe, and many women can describe the violence in great detail, almost as if dissociation from their bodies had occurred. The batterer generally minimizes the severity of the abuse. Help is usually sought only in the event of severe injury or if the woman fears for her life or those of her children.

Phase III. Calm, Loving, Respite ("Honeymoon") Phase In this phase, the batterer becomes extremely loving, kind, and contrite. He promises that the abuse will never recur and begs her forgiveness. He is afraid she will leave him and uses every bit of charm he can muster to ensure this does not happen. He believes he can now control his behavior, and because he has "taught her a lesson," he believes she will not "act up" again.

He plays on her feelings of guilt, and she desperately wants to believe him. She wants to believe that he *can* change and that she will no longer have to suffer abuse. During this phase, the woman relives her original dream of ideal love and chooses to believe that *this* is what her partner is *really* like.

This loving phase becomes the focus of the woman's perception of the relationship. She bases her reason for remaining in the relationship on this "magical" ideal phase and hopes against hope that the previous phases will not be repeated. This hope is evident even in those women who have lived through a number of horrendous cycles.

Although phase III usually lasts somewhere between the lengths of time associated with phases I and II, it can be so short as to almost pass undetected. In most instances, the cycle soon begins again with renewed tensions and minor battering incidents. In an effort to "steal" a few precious moments of the phase III kind of love, the battered woman becomes a collaborator in her own abusive lifestyle. Victim and batterer become locked together in an intense, symbiotic relationship.

Why Do They Stay?

Probably the most common response that battered women give for staying is that they fear for their life and/or the lives of their children. As the battering progresses, the man gains power and control through intimidation and fear, with threats such as, "I'll kill you and the kids if you try to leave." Challenged by these threats and compounded by her low self-esteem and sense of powerlessness, the woman sees no way out. In fact, she may try to leave only to return when confronted by her partner and the psychological power he holds over her.

Victims have been known to stay in an abusive relationship for many reasons, some of which include the following (Dockterman, 2014; Malkin, 2013; Meskill & Conner, 2013):

- **Fear of retaliation:** A woman may have been threatened with murder of herself and her children. Other acts Dockterman (2014) describes as psychological terrorism, such as sleep deprivation, blackmail, and murdering pets, may be used to increase fear of retaliation. In the lesbian, gay, bisexual, and transgender community, fear of being outed is sometimes used to manipulate the victim.
- **Fear of losing custody of children:** Women are sometimes threatened by the spouse that he or she will take away the children. There may have been attempts to convince the woman that she is an unfit mother.
- **Physical or financial dependence:** Victims may fear they are unable to care for themselves without the victimizer. Victims with disabilities may also be physically dependent on the victimizer for caregiving and physical support.
- **Lack of a support network:** The victim may be under pressure from family members to stay in the marriage and try to work things out. In addition, the victimizer may have isolated the victim from family and friends.
- **Cultural/religious reasons:** Cultural or religious convictions against divorce may dictate trying to save the marriage at all costs.

- **Hopefulness:** The victim remembers good times and love in the relationship and has hope that her partner will change his behavior and they can have good times again.
- **Lack of attention to the danger:** Malkin (2013) describes the dissociation that accompanies post-traumatic stress disorder (PTSD), which may contribute to the victim's numbness or lack of awareness of the reality of the situation. Or, as Leslie Morgan Steiner poignantly states in a Ted talk (cited by Dockterman, 2014):

> Why did I stay? I didn't know he was abusing me. Even though he held those loaded guns to my head, pushed me down stairs, threatened to kill our dog, pulled the key out of the car ignition as I drove down the highway, poured coffee grinds on my head as I dressed for a job interview, I never once thought of myself as a battered wife. Instead I was a very strong woman in love with a deeply troubled man, and I was the only person on earth who could help [him] face his demons.

It is important to recognize that when a victim leaves an abusive relationship, he or she is at a 75 percent greater risk of being killed by the partner, and the abuse often does not stop once a person has left (Colorado Bar Association, 2016). Clients should be empowered to make that decision and provided with resources and referrals to maximize their safety if they choose to leave, but, nonetheless, the decision must be theirs to make.

Child Abuse

Erik Erikson (1963) stated, "The worst sin is the mutilation of a child's spirit." Children are vulnerable and relatively powerless, and the effects of maltreatment are infinitely deep and long-lasting. Child maltreatment typically includes physical or emotional injury, physical or emotional neglect, or sexual acts inflicted upon a child by a caregiver. The Child Abuse Prevention and Treatment Act (CAPTA), as amended and reauthorized in 2010, identifies a minimum set of acts or behaviors that characterize maltreatment (Child Welfare Information Gateway [CWIG], 2013). States may use these as foundations on which to establish state legislation.

Physical Abuse

Physical abuse of a child includes "any nonaccidental physical injury (ranging from minor bruises to severe fractures or death) as a result of punching, beating, kicking, biting, shaking, throwing, stabbing, choking, hitting (with a hand, stick, strap, or other object), burning, or otherwise harming a child, that is inflicted by a parent, caregiver, or other person who has responsibility for the child" (CWIG, 2013). Maltreatment is considered whether

or not the caretaker intended to cause harm or even if the injury resulted from overdiscipline or physical punishment. The most obvious way to detect this type of abuse is by outward physical signs. However, behavioral indicators also may be evident.

Signs of Physical Abuse Indicators of physical abuse may include any of the following (CWIG, 2013). The child:

- Has unexplained burns, bites, bruises, broken bones, or black eyes
- Has fading bruises or other marks noticeable after an absence from school
- Seems frightened of the parents and protests or cries when it is time to go home
- Shrinks at the approach of adults
- Reports injury by a parent or another adult caregiver
- Abuses animals or pets

Physical abuse may be suspected when the parent or other adult caregiver (CWIG, 2013):

- Offers conflicting, unconvincing, or no explanation for the child's injury
- Describes the child as "evil" or in some other very negative way
- Uses harsh physical discipline with the child
- Has a history of abuse as a child
- Has a history of abusing animals or pets

Emotional Abuse

Emotional abuse involves a pattern of behavior on the part of the parent or caretaker that results in serious impairment of the child's social, emotional, or intellectual functioning. Examples of emotional injury include belittling or rejecting the child, ignoring the child, blaming the child for things over which he or she has no control, isolating the child from normal social experiences, and using harsh and inconsistent discipline. Behavioral indicators of emotional maltreatment may include (CWIG, 2013):

- Extremes in behavior, such as overly compliant or demanding behavior, extreme passivity, or aggression
- Inappropriately adult (e.g., parenting other children) or inappropriately infantile (e.g., frequently rocking or head-banging) behavior
- Delays in physical or emotional development
- Suicide attempts
- Lack of attachment to the parent

Emotional abuse may be suspected when the parent or other adult caregiver (CWIG, 2013):

- Constantly blames, belittles, or berates the child
- Is unconcerned about the child and refuses to consider offers of help for the child's problems
- Overtly rejects the child

Physical and Emotional Neglect

CORE CONCEPT

Neglect

Physical neglect of a child includes refusal of or delay in seeking health care, abandonment, expulsion from the home or refusal to allow a runaway to return home, and inadequate supervision.

Emotional neglect refers to a chronic failure by the parent or caretaker to provide the child with the hope, love, and support necessary for the development of a sound, healthy personality.

Indicators of Neglect The possibility of neglect may be considered when the child (CWIG, 2013):

- Is frequently absent from school
- Begs or steals food or money
- Lacks needed medical or dental care, immunizations, or glasses
- Is consistently dirty and has severe body odor
- Lacks sufficient clothing for the weather
- Abuses alcohol or other drugs
- States that there is no one at home to provide care

The possibility of neglect may be considered when the parent or other adult caregiver (CWIG, 2013):

- Appears to be indifferent to the child
- Seems apathetic or depressed
- Behaves irrationally or in a bizarre manner
- Is abusing alcohol or other drugs

Sexual Abuse of a Child

Various definitions of **child sexual abuse** are available in the literature. CAPTA defines *sexual abuse* as:

> Employment, use, persuasion, inducement, enticement, or coercion of any child to engage in, or assist any other person to engage in, any sexually explicit conduct or simulation of such conduct for the purpose of producing any visual depiction of such conduct; or the rape, and in cases of caretaker or inter-familial relationships, statutory rape, molestation, prostitution, or other form of sexual exploitation of children, or incest with children. (CWIG, 2013)

Included in the definition is **sexual exploitation of a child,** in which a child is induced or coerced into engaging in sexually explicit conduct for the purpose of promoting any performance, and child sexual abuse, in which a child is being used for the sexual pleasure of an adult (parent or caretaker) or any other person.

CORE CONCEPT
Incest
The occurrence of sexual contacts or interaction between, or sexual exploitation of, close relatives, or between participants who are related to each other by a kinship bond that is regarded as a prohibition to sexual relations (e.g., caretakers, stepparents, stepsiblings) (Sadock et al., 2015).

Indicators of Sexual Abuse Child abuse may be considered a possibility when the child (CWIG, 2013):

■ Has difficulty walking or sitting
■ Suddenly refuses to change for gym or to participate in physical activities
■ Reports nightmares or bedwetting
■ Experiences a sudden change in appetite
■ Demonstrates bizarre, sophisticated, or unusual sexual knowledge or behavior
■ Becomes pregnant or contracts a venereal disease, particularly if younger than age 14
■ Runs away
■ Reports sexual abuse by a parent or another adult caregiver
■ Attaches very quickly to strangers or new adults in their environment

Sexual abuse may be considered a possibility when the parent or other adult caregiver (CWIG, 2013):

■ Is unduly protective of the child or severely limits the child's contact with other children, especially of the opposite sex
■ Is secretive and isolated
■ Is jealous or controlling with family members

Characteristics of the Abuser

A number of factors have been associated with adults who abuse or neglect their children. Sadock and associates (2015) report that parents who abuse their children were often victims of abuse in their own early lives and have impaired attachment with their child. Substance use disorders increase the risk of child abuse and neglect. Hosier (2015) identifies additional characteristics that may be associated with an abusive parent:

■ Isolated with little support from family and friends
■ Expects that the child should fulfill their emotional needs
■ Prone to depression
■ Frequent outbursts, anger and rage
■ Low frustration tolerance

Flaherty and Stirling (2010) identify a number of factors that place a child at risk for maltreatment. They cite certain characteristics of the child, the parent, and the environment. These characteristics are presented in Box 35–1. When multiple factors coexist, the risk of child abuse increases.

The Incestuous Relationship

A great deal of attention has been given to the study of father-daughter incest. In these cases, there is usually an impaired sexual relationship between the parents. Communication between the parents is ineffective, which prevents them from correcting their problems. Typically, the father is domineering, impulsive, and physically abusive, while the mother is passive and submissive and denigrates her role as wife and mother. She is often aware of, or at least strongly

---

BOX 35–1 Factors and Characteristics That Place a Child at Risk for Maltreatment

Child	Parent	Environment (Community and Society)
Emotional/behavioral difficulties	Low self-esteem	Social isolation
Chronic illness	Poor impulse control	Poverty
Physical disabilities	Substance abuse/alcohol abuse	Unemployment
Developmental disabilities	Young maternal or paternal age	Low educational achievement
Preterm birth	Abused as a child	Single-parent home
Unwanted	Depression or other mental illness	Non-biologically related male living in the home
Unplanned	Poor knowledge of child development or unrealistic expectations of the child	Family or intimate partner violence
	Negative perception of normal child behavior

suspects, the incestuous behavior between the father and daughter but may believe in or fear her husband's absolute authority over the family. She may deny that her daughter is being harmed and may actually be grateful that her husband's sexual demands are being met by someone other than herself.

Onset of the incestuous relationship typically occurs when the daughter is 8 to 10 years of age and commonly begins with genital touching and fondling. In the beginning, the child may accept the sexual advances from her father as signs of affection. As the incestuous behavior continues and progresses, the daughter usually becomes more bewildered, confused, and frightened, never knowing whether her father will be paternal or sexual in his interactions with her.

The relationship may become a love-hate situation on the part of the daughter. She continues to strive for the ideal father-daughter relationship but is fearful and hateful of the sexual demands he places on her. The mother may be alternately caring and competitive as she witnesses her husband's possessiveness and affections directed toward her daughter. Out of fear that his daughter may expose their relationship, the father may attempt to interfere with her normal peer relationships (Sadock et al., 2015).

Although the oldest daughter in a family is most vulnerable to becoming a participant in father-daughter incest, some fathers form sequential relationships with several daughters. If incest has been reported with one daughter, it should be suspected with all of the other daughters.

The Adult Survivor of Incest

Several common characteristics have been identified in adults who have experienced childhood incest, most notably a fundamental lack of trust resulting from an unsatisfactory parent-child relationship. This causes low self-esteem and a poor sense of identity. Children of incest often feel trapped, for they have been admonished not to talk about the experience and may even fear for their lives if they are exposed. If they do muster the courage to report the incest, often to the mother, they sometimes are not believed. This is confusing to the child, who is left with a sense of self-doubt and the inability to trust his or her own feelings. The child develops feelings of guilt with the realization over the years that the parents are using him or her in an attempt to solve their own problems.

Childhood sexual abuse commonly disrupts the development of a normal association of pleasure with sexual activity. Peer relationships are often delayed, altered, inhibited, or perverted. In some instances, individuals who were sexually abused as children completely retreat from sexual activity and avoid all close

interpersonal relationships throughout life, while others engage in high-risk and frequent sexual activity. Other adult manifestations of childhood sexual abuse in women include diminished libido, pain/penetration disorder, nymphomania, and promiscuity. In male survivors of childhood sexual abuse, erectile disorder, premature ejaculation, exhibitionistic disorder, and compulsive sexual conquests may occur. Sadock and associates (2015) report that child maltreatment, including repeated sexual abuse, causes changes in a child's brain that are evident on magnetic resonance imaging in adult survivors. They add that a robust finding from 20 studies indicates that childhood maltreatment culminates in future increased levels of C-reactive protein, fibrinogen, and pro-inflammatory cytokines. These inflammatory markers increase the adult survivor's risk for multiple physical illnesses. Depression, anxiety, substance use, eating disorders, suicidal behaviors, and a pattern of unstable relationships are also identified as increased risks from a history of child maltreatment (Sadock et al., 2015).

The conflicts associated with pain (either physical or emotional) and sexual pleasure experienced by children who are sexually abused are commonly manifested symbolically in adult relationships. Women who were abused as children often enter into relationships with men who abuse them physically, sexually, or emotionally. Berman (2013) describes this pattern as "repetition compulsion," a reliving of trauma in adult relationships rooted in subconscious efforts to "fix" situations they were unable to fix in childhood. The outcome is a repetitive cycle of unhealthy and often dangerous relationships. Berman adds that about a third of children who were abused or neglected in childhood become perpetrators of the same kinds of abuse as parents.

Adult survivors of incest who come forward with their stories usually are estranged from nuclear family members, blamed for disclosing the "family secret," and often accused of overreacting to the incest. Frequently, the estrangement becomes permanent when family members continue to deny the behavior and the individual is accused of lying. Many survivors choose to make the disclosure only after the death of their parents. Revelation of these past activities can be one way of contributing to the healing process for which incest survivors so desperately strive.

Sexual Violence

Sexual violence is often equated with rape, but that is only one type of sexual assault. It is important for nurses and other health-care providers to be aware that sexual violence includes any act of sexual coercion, including penetration, unwanted sexual contact,

and noncontact unwanted sexual experiences (CDC, 2016a). All of these experiences can result in trauma, and assessment for history of these events is foundational to providing trauma-informed care. Read about Bridget's experiences in this chapter's "Real People, Real Stories" feature.

CORE CONCEPT

Rape

The expression of power and dominance by means of sexual violence, most commonly by men over women, although men may also be rape victims.

Sexual assault is any type of sexual act in which an individual is threatened or coerced, or forced, to submit against his or her will. Rape, a type of sexual assault, occurs over a broad spectrum of experiences ranging from the surprise attack by a stranger to insistence on sexual intercourse by an acquaintance or spouse. Regardless of the defining source, one common theme always emerges: rape is an act of aggression, not one of passion.

Acquaintance rape (called **date rape** if the encounter occurs during a social engagement agreed to by the victim) is a term applied to situations in which the rapist is acquainted with the victim. They may be

Real People, Real Stories: Bridget's Journey

This individual wished to remain anonymous. Bridget is not her real name. Her story is a poignant lesson in the various ways that one can be victimized, the long-term impact of such experiences on one's sense of self-esteem and personal safety, and the importance of nurses' understanding of trauma-informed care.

Karyn: I appreciate your willingness to talk about your experiences. If at any time you become uncomfortable discussing these events we don't need to continue. All right?

Bridget: I've had a lot of therapy, and I feel like it's important to tell and keep on telling so that, hopefully, something good will come out of it. When I was 6 years old, I had a crush on my best friend's brother. He was 12 years old, and when he started giving me attention, I thought he liked me; until he took me into a room, took my clothes off, and was touching me. He wanted me to take his clothes off, and I said no. I told my mom, and she intervened with his parents, but when a second incident occurred, my mother stopped me from going to my friend's house. I felt a lot of shame and embarrassment, but I never really talked about my feelings. For a long time, I carried around the belief that it was somehow my fault because I had a crush on him. I found out later that there were several other children who he molested and that his mom had implied they were "making it up."

When I was around 8 years old, I was in a toy store and a man came up from behind me and rubbed my rear end under my dress. I ran to get my father, but the perpetrator ran out of the store, and my parents decided not to call the police. They felt like I'd been scared enough. As an adult, I can understand that. But as a child, I felt like someone did a bad thing to me, and I wished that someone had defended me. As a middle schooler, one of the neighborhood girls wanted to play Truth or Dare. I think she did this with a lot of girls. The dare was to take off my clothes after which she put her hands on me. I said no but felt paralyzed with fear when she touched me anyway. She

was a year older, and again, I remember feeling powerless and thinking I didn't know what to do.

In another incident in middle school, one of the boys jumped out in front of me in the school hallway and grabbed my breasts. A teacher saw him do it and was going to send him to the principal's office, but the boy looked scared and I somehow thought it must be my job to protect him . . . or maybe I was trying to act like it was no big deal, so I told the teacher to just let him go. I didn't want to get the boy in trouble, and I was so embarrassed and humiliated, I just wanted it to go away. Part of me wishes the teacher hadn't listened to me, though. I don't think that boy had any idea how much he hurt me and how awful it was.

Karyn: I think that may be a common reaction by girls or women; even though someone has offended against us, we don't want to hurt them in return. And it minimizes the fact that *we* have been hurt.

Bridget: Yes, and my parents were knee deep in the Catholic training that if someone hurts you, you should just walk away or turn the other cheek. That influenced my own thinking, that you don't defend yourself—you should just walk away and avoid conflict. But that's a misunderstanding of the "turn the other cheek" teaching, which is really about showing forgiveness when people demonstrate remorse. It doesn't mean letting people hurt you without consequences. Around this time, I started putting on a lot of weight. I've always felt it was, in part, a reaction meant to keep people at a distance, so they couldn't hurt me.

Karyn: I've heard other people share a similar coping or defense mechanism; doing something simply to keep people away. Was that effective?

Bridget: It only added to my self-esteem issues. I struggled with the question of why these things were happening to me. I felt like *I* must be doing *something* wrong. As a teenager, I struggled with anxiety and depression, and I was sent to a psychiatrist, but it wasn't helpful. Then when I moved to New York City for college, there were a couple of incidents on the subway. One was a frail-looking elderly

Real People, Real Stories: Bridget's Journey—cont'd

man who stuck his hand between my legs, and when I turned around to confront him, he was laughing at me. I felt very powerless. I thought about kicking him, but, again, I didn't want to injure this shriveled-up old man, and I also didn't know if he had a knife, a gun. . . . So there's the fear, the powerlessness, and the anger that someone was touching me and *laughing* at me, and I could do nothing. I wondered if I was sending out some vibe—i.e., it must be my fault. My friend told me I needed to learn how to put on an angry face and carry an umbrella to better defend myself. I knew I had anxiety and self-esteem issues, and that's when I decided I needed therapy.

Karyn: That took a lot of courage to identify what you needed to do to take some control back. What has been most helpful about that process?

Bridget: I explored the underpinnings of my self-esteem issues and identified coping skills, but nonetheless, as an adult many things can trigger the feelings of vulnerability, anxiety, and low self-esteem: news stories about rape or abuse, or times when women or children are demeaned in the media, especially from people manipulating their power or authority. That brings up a lot of "stuff" for me. When my counselor challenged me to identify what was in the way of being able to set all this stuff aside—that's when I had the insight that I just wanted to know something good could come out of all this pain.

Karyn: One of the things you've told me is that you've been able to teach your daughters how to respond in such situations.

Bridget: Yes, that was important and felt like a victory. I'm better able to identify potentially harmful situations. I've taught them to listen to that inner voice, where you get that "bad feeling" you can get that warns you when you're in a situation that may require defending or protecting yourself, and I taught my daughters how to be prepared. I've told them that if someone tries to touch them, it's okay to fight back. It's okay to tell me, school officials, tell *any-one,* and to keep telling until someone believes them and responds. I want them to know that it's safe to talk to me about their feelings and that they are not powerless.

Karyn: I think that's an important message for health-care professionals as well: to listen, to not brush off someone's experiences but rather to explore the events, thoughts, and feelings and identify coping strategies.

Bridget: Yes, I think sometimes adults who thought it was less traumatizing for me to walk away or try to forget about it thought they were helping, but that's not the answer. Even now, after all these years, I wasn't sure if you would think my story was important enough to tell, I mean, to some people, it might not seem so bad. I wasn't raped, it wasn't a family member—but it still left me feeling awful.

Karyn: I think your story is very important to tell. You are taking the opportunity to teach others that victimization can occur in a variety of ways, that it can have long-term effects on self-esteem, and that it is important to find ways to regain a sense of control and self-worth. I really appreciate your sharing this. What do you think are the most important things that nurses need to know about your and others' experience with victimization and trauma?

Bridget: First of all, that 40 years later, those incidents still affect me. I saw a picture of the boy who molested me on a friend's Facebook page, and I felt sick and afraid all over again. And I beat myself up for still letting it get to me. Nurses need to know that even events that happened years ago can influence one's emotional responses in the present.

Second, the idea of "getting closure," even so many years later, is a misnomer. Certain things can trigger those memories and anxieties, and when they come back, all you can do is drag them out and talk about them again and again and again. It's another version of "you tell and you tell and you don't stop telling" until you remember that you survived it, that it wasn't your fault, and that you don't need to feel ashamed or embarrassed or humiliated (even if part of you still does).

Third, I want nurses to know that they are the front lines, and no matter what clinical area they practice in, a history of sexual trauma or abuse can affect how their patients experience and receive health care. I had a lot of trouble as an adult fertility patient, having to dress and undress so many times and deal with so many invasive procedures. It was important to tell my health-care providers why my heart was pounding, why I seemed so nervous, why I hated mammographies and regular GYN exams a little bit more than the average woman. . . . That, as always, a nurse's ability to care and offer compassion can make the biggest difference, and it all begins with trust and helping your patient to "tell." And I wanted to say thank you for the times those nurses held my hand, and squeezed tight, and told me that I would be okay.

out on a first date, have been dating for a number of months, or merely be acquaintances or schoolmates. College campuses are the location for a staggering number of these types of rapes, a great many of which go unreported. An increasing number of colleges and universities are establishing programs for rape prevention and counseling for survivors of rape.

Marital rape, which has been recognized only in recent years as a legal category, occurs when a spouse is liable for sexual abuse directed at a marital partner against that person's will. Historically, with societal acceptance of the concept of women as marital property, the legal definition of rape held an exemption within the marriage relationship. In 1993, marital

rape became a crime in all 50 states, under at least one section of the sexual offenses code. In 17 states and the District of Columbia, there are no exemptions from rape prosecution granted to husbands. However, in 33 states, there are still some exemptions given to husbands from rape prosecution, and in all states where husbands can be prosecuted, the criteria for proving marital rape are very stringent.

Statutory rape is unlawful intercourse between a person who is over the age of consent and a person who is under the age of consent. The legal age of consent varies from state to state, ranging from age 14 to 18 (King & Regan, 2014). An adult who has intercourse with a person who is younger than the age of consent can be arrested for statutory rape, even if the interaction occurred between consenting individuals.

Profile of the Victimizer

It is difficult to profile a rapist because rapists comprise a heterogenous group and are not distinguished by looks or intelligence. They tend to score normally on psychological tests with the exception of higher scores on expressing anger (St. Petersburg College, 2016). Sadock and associates (2015) identify that the underlying motives of rape perpetrators can be classified into four groups: sexual sadists who are aroused by inflicting pain, exploitative predators who are using the victim to gratify needs such as dominance and power, inadequate men who are obsessed with fantasies of sex they believe cannot be achieved without force, and those who are displacing anger and rage. They add that victims of childhood abuse show increased likelihood of perpetrating violence of all kinds in adulthood.

The majority of rapes are premeditated. Behavioral characteristics that have been associated with premeditation include seeking out a victim who appears to be vulnerable (capable of being overpowered or isolated from others), violating or ignoring others' rights (sometimes in a way that informs whether a potential victim is passive or tolerant of those behaviors), or generally lacking skills of empathy. But again, while these behaviors might be observed more commonly, they do not define the complete profile of these perpetrators. A feminist view suggests that rape is most common in societies that encourage aggressiveness in males, that have distinct gender roles, and in which men regard women's roles as inferior (King & Regan, 2014). Male aggressiveness as a cultural norm, however, does not explain why some men become perpetrators of criminal aggression and violence while others do not.

Statistics show that most rapists are between the ages of 25 and 44. Fifty-four percent are white, 32 percent are African American, and the remainder are of other races, mixed race, or unknown race (U.S. Bureau of Justice Statistics, 2011). In 80 percent of rape and sexual assault cases, the offender was known to the victim, and 1 in 10 rapes involved the use of a weapon (U.S. Bureau of Justice Statistics, 2014b). Statistics such as these help describe aspects of the problem, but understanding the essence of the perpetrator of aggression and violence is the subject of ongoing research.

The Victim

Rape can occur at any age, but the most recent statistics suggest that the highest-risk age group is females younger than age 34, those with lower income, and those living in rural areas (U.S. Bureau of Justice Statistics, 2014b). Most sexual assault victims are single women, and the attack frequently occurs in or close to the victim's own neighborhood.

Although women are at highest risk for rape perpetrated by males, males may also be victimized by women or other men. Sadock and associates (2015) describe the dynamics as identical and state that in all cases:

> the crime enables the rapist to discharge aggression and aggrandize himself [or herself]. The victim is usually smaller than the rapist, perceived as passive . . . and is used as an object. (p. 826)

Rape survivors who present themselves for care shortly after the crime has occurred likely are experiencing an overwhelming sense of violation and helplessness that began with the powerlessness and intimidation experienced during the rape. Burgess (1974), who has classically defined what has been described as **rape trauma syndrome,** identified two emotional patterns of response that may occur within hours after a rape and with which health-care workers may be confronted in the emergency department or rape crisis center. In the **expressed response pattern,** the survivor expresses feelings of fear, anger, and anxiety through such behaviors as crying, sobbing, restlessness, and tension. In the **controlled response pattern,** the feelings are masked or hidden, and a calm, composed, or subdued affect is seen.

The following manifestations may be evident in the days and weeks after the attack (Burgess, 2010):

- Contusions and abrasions about various parts of the body
- Headaches, fatigue, sleep pattern disturbances
- Stomach pains, nausea and vomiting
- Vaginal discharge and itching, burning upon urination, rectal bleeding and pain
- Rage, humiliation, embarrassment, desire for revenge, and self-blame
- Fear of physical violence and death

The long-term effects of sexual assault depend largely on the individual's ego strength, social support system, and the way he or she was treated as a victim (Burgess, 2010). Various long-term effects include increased restlessness, dreams and nightmares, and phobias (particularly those having to do with sexual interaction). Some women report that it takes years to get over the experience; they describe a sense of vulnerability and a loss of control over their own lives during this period. They feel defiled and unable to wash themselves clean, and some women are unable to remain living alone in their home or apartment.

Some survivors develop a **compounded rape reaction,** in which additional symptoms such as depression and suicide, substance abuse, and even psychotic behaviors may be noted (Burgess, 2010). Another variation has been called the **silent rape reaction,** in which the survivor tells no one about the assault. Anxiety is suppressed and the emotional burden may become overwhelming. The unresolved sexual trauma may not be revealed until the woman is forced to face another sexual crisis in her life that reactivates the previously unresolved feelings.

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the situation. Some common nursing diagnoses for survivors of abuse include:

- Rape-trauma syndrome related to sexual assault evidenced by verbalizations of the attack; bruises and lacerations over areas of body; severe anxiety
- Powerlessness related to cycle of battering evidenced by verbalizations of abuse; bruises and lacerations over areas of body; fear for her safety and that of her children; verbalizations of no way to get out of the relationship
- Risk for delayed development related to abusive family situation

Outcome Criteria

The following criteria may be used to measure outcomes in the care of abuse survivors:

The client who has been sexually assaulted:

- Is no longer experiencing panic anxiety
- Demonstrates a degree of trust in the primary nurse
- Has received immediate attention to physical injuries
- Has initiated behaviors consistent with the grief response

The client who has been physically battered:

- Has received immediate attention to physical injuries

- Verbalizes assurance of his or her immediate safety
- Discusses life situation with primary nurse
- Can verbalize choices from which he or she may receive assistance

The child who has been abused:

- Has received immediate attention to physical injuries
- Demonstrates trust in primary nurse by discussing abuse through the use of play therapy
- Is demonstrating a decrease in regressive behaviors

Planning and Implementation

Table 35–1 provides a plan of care for the client who is a survivor of abuse. Nursing diagnoses are presented, along with outcome criteria, appropriate nursing interventions, and rationales for each.

Concept Care Mapping

The concept map care plan (see Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing) is a diagrammatic teaching and learning strategy that allows visualization of interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. An example of a concept map care plan for a client who is a survivor of abuse is presented in Figure 35–3.

Evaluation

Evaluation of nursing actions to assist survivors of abuse must be considered on both a short- and a long-term basis.

Short-term evaluation may be facilitated by gathering information using the following types of questions:

- Has the individual been reassured of his or her safety?
- Is this evidenced by a decrease in panic anxiety?
- Have wounds been properly cared for and provision made for follow-up care?
- Have emotional needs been attended to?
- Has trust been established with at least one person to whom the client feels comfortable relating the abusive incident?
- Have available support systems been identified and notified?
- Have options for immediate circumstances been presented?

Long-term evaluation may be conducted by healthcare workers who have contact with the individual long after the immediate crisis has passed.

- Is the individual able to conduct activities of daily living satisfactorily?
- Have physical wounds healed properly?

Table 35–1 | CARE PLAN FOR SURVIVORS OF ABUSE

NURSING DIAGNOSIS: RAPE-TRAUMA SYNDROME
RELATED TO: Sexual assault
EVIDENCED BY: Verbalizations of the attack; bruises and lacerations over areas of body; severe anxiety

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client's physical wounds heal without complication. Long-Term Goal: • Client begins a healthy grief resolution, initiating the process of physical and psychological healing (time to be individually determined).	1. It is important to communicate the following to the individual who has been sexually assaulted: • You are safe here. • I'm sorry that it happened. • I'm glad you survived. • It's not your fault. No one deserves to be treated this way. • You did the best that you could.	1. The woman who has been sexually assaulted fears for her life and must be reassured of her safety. She may also be overwhelmed with self-doubt and self-blame, and these statements instill trust and validate self-worth.
	2. Explain every assessment procedure that will be conducted and why it is being conducted. Ensure that data collection is conducted in a caring, nonjudgmental manner. Engage the services of a sexual assault nurse examiner, where available, to facilitate evidence collection and client advocacy (See bonus chapter, Forensic Nursing, for further discussion; available on-line at DavisPlus.com)	2. This may serve to decrease fear/anxiety and increase trust.
	3. Ensure that client has adequate privacy for all immediate postcrisis interventions. Try to have as few people as possible providing the immediate care or collecting immediate evidence.	3. The posttrauma client is extremely vulnerable. Additional people in the environment increase this feeling of vulnerability and serve to escalate anxiety.
	4. Encourage client to give an account of the assault. Listen, but do not probe.	4. Nonjudgmental listening provides an avenue for catharsis that client needs to begin healing. A detailed account may be required for legal follow-up, and a caring nurse, as client advocate, may help to lessen the trauma of evidence collection.
	5. Discuss with client whom to call for support or assistance. Provide information about referrals for aftercare.	5. Because of severe anxiety and fear, the client may need assistance from others during immediate postcrisis period. Provide referral information in writing for later reference (e.g., psychotherapist, mental health clinic, community advocacy group).

Table 35–1 | CARE PLAN FOR SURVIVORS OF ABUSE–cont'd

NURSING DIAGNOSIS: POWERLESSNESS

RELATED TO: Cycle of battering

EVIDENCED BY: Verbalizations of abuse; bruises and lacerations over areas of body; fear for own safety and that of children; verbalizations of no way to get out of the relationship

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client recognizes and verbalizes choices available, thereby perceiving some control over life situation. Long-Term Goal: • Client exhibits control over life situation by making decision about what to do regarding living with cycle of abuse.	1. In collaboration with physician, ensure that all physical wounds, fractures, and burns receive immediate attention. Take photographs if client permits.	1. Client safety is a nursing priority. Photographs may be called as evidence if charges are filed.
	2. Take client to a private area to do the interview.	2. If client is accompanied by the person who did the battering, she is not likely to be truthful about the injuries.
	3. If she has come alone or with her children, assure her of her safety. Encourage her to discuss the battering incident. Ask questions about whether this has happened before, whether the abuser takes drugs, whether the woman has a safe place to go, and whether she is interested in pressing charges.	3. Some women will attempt to keep secret how their injuries occurred in an effort to protect the partner or because they are fearful that the partner will kill them if they tell.
	4. Ensure that "rescue" efforts are not attempted by the nurse. Offer support, but remember that the final decision must be made by client.	4. Making her own decision gives client a sense of control over her life situation. Imposing judgments and giving advice are nontherapeutic.
	5. Stress to client the importance of safety. She must be made aware of the variety of resources that are available to her. These may include crisis hot lines, community groups for women who have been abused, shelters, counseling services, and information regarding the victim's rights in the civil and criminal justice system. Following a discussion of these available resources, the woman may choose for herself. If her decision is to return to the marriage and home, this choice also must be respected.	5. Knowledge of available choices decreases the individual's sense of powerlessness, but true empowerment comes only when she chooses to use that knowledge for her own benefit.

Continued

Table 35–1 | CARE PLAN FOR SURVIVORS OF ABUSE–cont'd

NURSING DIAGNOSIS: RISK FOR DELAYED DEVELOPMENT

RELATED TO: Child abuse

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client develops trusting relationship with nurse and reports how evident injuries were sustained. Long-Term Goal: • Client demonstrates behaviors consistent with age-appropriate growth and development.	1. Perform complete physical assessment of the child. Take particular note of bruises (in various stages of healing), lacerations, and client complaints of pain in specific areas. Do not overlook or discount the possibility of sexual abuse. Assess for nonverbal signs of abuse: aggressive conduct, excessive fears, extreme hyperactivity, apathy, withdrawal, age-inappropriate behaviors.	1. An accurate and thorough physical assessment is required to provide appropriate care for client.
	2. Conduct an in-depth interview with the parent or adult who accompanies the child. Consider: If the injury is being reported as an accident, is the explanation reasonable? Is the injury consistent with the explanation? Is the injury consistent with the child's developmental capabilities?	2. Fear of imprisonment or loss of child custody may place the abusive parent on the defensive. Discrepancies may be evident in the description of the incident, and lying to cover up involvement is a common defense that may be detectable in an in-depth interview.
	3. Use games or play therapy to gain child's trust. Use these techniques to assist in describing his or her side of the story.	3. Establishing a trusting relationship with an abused child is extremely difficult. He or she may not even want to be touched. These types of play activities can provide a nonthreatening environment that may enhance the child's attempt to discuss these painful issues.

- Is the client appropriately progressing through the behaviors of grieving?
- Is the client free of sleep disturbances (nightmares, insomnia), psychosomatic symptoms (headaches, stomach pains, nausea/vomiting), regressive behaviors (enuresis, thumb sucking, phobias), and psychosexual disturbances?
- Is the individual free from problems with interpersonal relationships?
- Has the individual considered the alternatives for change in his or her personal life?
- Has a decision been made relative to the choices available?
- Is he or she satisfied with the decision that has been made?

Treatment Modalities

Crisis Intervention

The focus of the initial interview and follow-up with the client who has been sexually assaulted is on the rape incident alone. Problems not associated with the rape are not dealt with at this time. The goal of crisis intervention is to help survivors return to their previous lifestyle as quickly as possible.

The client should be involved in the intervention from the beginning. This promotes a sense of competency, control, and decision-making. Because an overwhelming sense of powerlessness accompanies the rape experience, active involvement by the survivor is both a validation of personal worth and the beginning

Clinical Vignette: Annette and Charles, both 21, have been dating for 2 years. Charles has always been jealous and gets very angry when Annette even talks to another man. He has hit her several times, hard enough to produce bruises, but never on her face, and she is able to hide the abuse from others. Tonight at a party, Annette danced with another man, and Charles became violent. He punched the man in the face and dragged Annette out to the parking lot. She yelled at him, "This is it! We are through! I don't ever want to see you again!" He started beating her around the face and upper body, and yelled, "You can't break up with me! I won't allow it! You belong to me, and no one else!" He left her lying in the parking lot. She felt powerless and, in her despondency, opened her purse and swallowed half a bottle of acetaminophen. When she told her girlfriend, Dana, what had happened, Dana called 911, and Annette was taken to the hospital. She was treated for the overdose, and her wounds were cleaned and dressed. Following physical stability, she was transferred to the psychiatric unit. She tells the nurse, "I can't live like this. He won't let me go! I don't know what to do!" The nurse develops the following concept map care plan for Annette.

Signs and Symptoms
Risk factors:
• Suicidal attempt
• Suicidal ideations
• Verbalizations of hopelessness

Signs and Symptoms
• Verbalizations of abuse
• Bruises and lacerations
• Fear for safety
• Verbalizations of powerlessness

Nursing Diagnosis
Risk for suicide

Nursing Diagnosis
Powerlessness

Nursing Actions
• Inquire about suicidal thoughts, plan, means.
• Make environment safe.
• Collaborate with the patient to identify a plan for ongoing safety.
• Observe closely.
• Make frequent rounds at irregular intervals.
• Encourage open, honest expression of feelings.

Nursing Actions
• Give attention to injuries.
• Encourage discussion of the incident.
• Stress importance of personal safety.
• Discuss available options and alternatives.
• Set realistic goals and help with problem-solving.
• Provide positive feedback for decisions made.

Outcomes
• Client verbalizes no thoughts of suicide
• Client commits no acts of self-harm
• Client verbalizes names of resources outside the hospital that may provide help

Outcomes
• Physical wounds are healing
• Client verbalizes assurance of immediate safety
• Client discusses life situation with nurse
• Client verbalizes available choices and plan of action

FIGURE 35–3 Concept map care plan for a client with physical abuse.

of the recovery process. Crisis intervention is time limited, usually 6 to 8 weeks. If problems resurface beyond this time, the individual is referred for assistance from other agencies (e.g., long-term psychotherapy from a psychiatrist or mental health clinic).

During the crisis period, attention is given to coping strategies for dealing with the symptoms common to the posttrauma client. Initially, the individual undergoes a period of disorganization during which there is difficulty making decisions, extreme or irrational fears, and general mistrust. Observable manifestations may range from stark hysteria to expression of anger and rage to silence and withdrawal. Guilt and feelings of responsibility for the rape, as well as numerous physical manifestations, are common. The crisis counselor attempts to help the individual draw upon previous successful coping strategies to regain control over his or her life.

If the client is a victim of domestic violence, the counselor ensures that various resources and options are made known to the individual so that she may make a personal decision about moving forward with her life. Discussing strategies for minimizing the dangers of leaving (sometimes called an escape plan) may be helpful if the client is considering leaving the relationship. Support groups provide a valuable forum for reducing isolation and learning new strategies for coping with the aftermath of physical or sexual abuse. Particularly for the survivor of rape, the peer support group provides a therapeutic forum for reducing the sense of isolation she may feel in the aftermath of predictable social and interpersonal responses to her experience.

The Safe House or Shelter

Most major cities in the United States now have **safe houses** or **shelters** where women can be assured of protection for them and their children. These shelters provide a variety of services, and the women receive emotional support from staff and each other. Most shelters provide individual and group counseling; help with bureaucratic institutions such as the police, legal representation, and social services; child care and children's programs; and aid for the woman in making future plans, such as employment counseling and linkages with housing authorities.

The shelters are usually run by a combination of professional and volunteer staff, including nurses, psychologists, lawyers, and others. Women who themselves have been previously abused are often among the volunteer staff members.

Group work is an important part of the service of shelters. Women in residence range from those in the immediate crisis phase to those who have progressed through a variety of phases of the grief process. Newer members can learn a great deal from the women who have successfully resolved similar problems. Length of stay varies a great deal among individuals, depending on a number of factors such as outside support network, financial situation, and personal resources.

The shelter provides a haven of physical safety for the battered woman and promotes expression of the intense emotions she may be experiencing regarding her situation. A woman often exhibits depression, extreme fear, or even violent expressions of anger and rage. In the shelter, she learns that these feelings are normal and that others have experienced these same emotions in similar situations. She is allowed to grieve for what has been lost and for what was expected but not achieved. Help is provided in overcoming the tremendous guilt associated with self-blame. This is a difficult step for someone who has accepted responsibility for another's behavior over a long period.

New arrivals at the shelter are given time to experience the relief from the safety and security provided. Making decisions is discouraged during the period of immediate crisis and disorganization. Once the woman's emotions have become more stable, planning for the future begins. Through information from staff and peers, she learns about available community resources. Feedback is provided, but the woman makes her own decision about "where she wants to go from here." She is accepted and supported in whatever she chooses to do.

Family Therapy

Therapy with families who use violence focuses on helping them develop democratic ways of solving problems. Studies show that the more a family uses the democratic means of conflict resolution, the less likely they are to engage in physical violence. Families must learn to deal with problems in ways that can produce mutual benefits for all concerned rather than engage in power struggles among family members.

Parents also need to learn effective methods of disciplining children aside from physical punishment. Time-out techniques and methods that emphasize the importance of positive reinforcement for acceptable behavior can be very effective. Family members must be committed to consistent use of this behavior modification technique for it to be successful.

Teaching parents about expectations for various developmental levels may alleviate some of the stress that accompanies these changes. Anticipatory guidance is needed to deal with the crises commonly associated with these stages.

Therapy sessions with all family members together may focus on problems with family communication. Members are encouraged to express honest feelings in a manner that is nonthreatening to other family members. Active listening, assertiveness techniques, and respecting the rights of others are taught and encouraged. Barriers to effective communication are identified and resolved.

Referrals to agencies that promote effective parenting skills (e.g., parent effectiveness training) may be made. Alternative agencies that may relieve the stress of parenting (e.g., Mom's Day Out programs, sitter-sharing organizations, and day-care institutions) also may be considered. Support groups for abusive parents may also be helpful, and assistance in locating or initiating such a group may be provided.

Summary and Key Points

- Abuse is the maltreatment of one person by another.
- Intimate partner violence, child abuse, and sexual assault are widespread, and all populations are equally affected.

■ Various factors have been theorized as influential in the predisposition to violent behavior. Physiological and biochemical influences within the brain have been suggested, as has the possibility of a direct genetic link.

■ Organic brain syndromes associated with various cerebral disorders and traumatic brain injury have been implicated in the predisposition to aggressive and violent behavior.

■ Psychoanalytical theorists relate the predisposition to violent behavior to underdeveloped ego and a poor self-concept.

■ Learning theorists suggest that children imitate the abusive behavior of their parents. This theory has been substantiated by studies that show that individuals who were abused as children or whose parents disciplined them with physical punishment are more likely to be abusive as adults.

■ Societal influences, such as acceptance of violence as a means of solving problems, also have been implicated.

■ Women who are battered often take blame for their situations. They may have been reared in abusive families and thus expect this type of behavior.

■ Battered women commonly see no way out of their present situation and may be encouraged by their social support network to remain in the abusive relationship.

■ Child abuse includes physical and emotional abuse, physical and emotional neglect, and sexual abuse of a child.

■ A child may experience many years of abuse without reporting it because of fear of retaliation by the abuser.

■ Some children report incest experiences to their mothers, only to be rebuffed by her and told to remain secretive about the abuse.

■ Adult survivors of incest often experience physical and emotional manifestations as a result of the incestuous relationship.

■ Sexual assault is identified as an act of aggression, not passion.

■ A history of abuse and neglect in childhood increase one's risk of perpetrating abuse and neglect upon others in adulthood. Rape is a traumatic experience, and many women experience flashbacks, nightmares, rage, physical symptoms, depression, and thoughts of suicide for many years after the occurrence.

■ Treatment modalities for survivors of abuse include crisis intervention with the sexual assault victim, safe shelter for battered women, and therapy for families who use violence.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Sharon, a woman with multiple cuts and abrasions, arrives at the emergency department with her three small children. She tells the nurse her husband inflicted the wounds. She says, "I didn't want to come. I'm really okay. He only does this when he has too much to drink. I just shouldn't have yelled at him." The best response by the nurse is:
   a. "How often does he drink too much?"
   b. "It is not your fault. You did the right thing by coming here."
   c. "How many times has he done this to you?"
   d. "He is not a good husband. You have to leave him before he kills you."

2. Sharon, a woman with multiple cuts and abrasions, arrives at the emergency department with her three small children. She tells the nurse her husband inflicted the wounds. In the interview, Sharon tells the nurse, "He's been getting more and more violent lately. He's been under a lot of stress at work the last few weeks, so he drinks a lot when he gets home. He always gets mean when he drinks. I was getting scared. So I just finally told him I was going to take the kids and leave. He got furious when I said that and began beating me with his fists." With knowledge about the cycle of battering, what does this situation represent?
   a. Phase I. Sharon was desperately trying to stay out of his way and keep everything calm.
   b. Phase I. A minor battering incident for which Sharon assumes all the blame.
   c. Phase II. The acute battering incident that Sharon provoked with her threat to leave.
   d. Phase III. The honeymoon phase where the husband believes that he has "taught her a lesson and she won't act up again."

3. A battered woman presents to the emergency department with multiple cuts and abrasions. Her right eye is swollen shut. She says that her husband did this to her. What is the *priority* nursing intervention?
   a. Tending to the immediate care of her wounds
   b. Providing her with information about a safe place to stay
   c. Administering the prn tranquilizer ordered by the physician
   d. Explaining how she may go about bringing charges against her husband

4. A woman who has a long history of being battered by her husband is staying at the woman's shelter. She has received emotional support from staff and peers and has been made aware of the alternatives open to her. Nevertheless, she decides to return to her home and marriage. The best response by the nurse to the woman's decision is:
   a. "I just can't believe you have decided to go back to that horrible man."
   b. "I'm just afraid he will kill you or the children when you go back."
   c. "What makes you think things have changed with him?"
   d. "I hope you have made the right decision. Call this number if you need help."

5. Jana, age 5, is sent to the school nurse's office with an upset stomach. She has vomited and soiled her blouse. When the nurse removes her blouse, she notices that Jana has numerous bruises on her arms and torso in various stages of healing. She also notices some small scars. Jana's abdomen protrudes on her small, thin frame. From the objective physical assessment, the nurse suspects that:
   a. Jana is experiencing physical and sexual abuse.
   b. Jana is experiencing physical abuse and neglect.
   c. Jana is experiencing emotional neglect.
   d. Jana is experiencing sexual and emotional abuse.

6. A school nurse notices bruises and scars on a child's body, but the child refuses to say how she received them. Another way in which the nurse can get information from the child is to:
   a. Have her evaluated by the school psychologist.
   b. Tell her she may select a "treat" from the treat box (e.g., sucker, balloon, junk jewelry) if she answers the nurse's questions.
   c. Explain to her that if she answers the questions, she may stay in the nurse's office and not have to go back to class.
   d. Use a "family" of dolls to role-play the child's family with her.

7. A school nurse notices bruises and scars on a child's body. The nurse suspects that the child is being physically abused. How should the nurse proceed with this information?
   a. As a health-care worker, report the suspicion to child protective services.
   b. Check the child again in a week and see if there are any new bruises.
   c. Meet with the child's parents and ask them how she got the bruises.
   d. Initiate paperwork to have the child placed in foster care.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. Kate is an 18-year-old freshman at the state university. She was extremely flattered when Don, a senior star football player, invited her to a party. On the way home, he parked the car in a secluded area by the lake. He became angry when she refused his sexual advances. He began to beat her and finally raped her. She tried to fight him, but his physical strength overpowered her. He dumped her in the dorm parking lot and left. The dorm supervisor rushed Kate to the emergency department. Kate says to the nurse, "It's all my fault. I shouldn't have allowed him to stop at the lake." The nurse's best response is:
   a. "Yes, you're right. You put yourself in a very vulnerable position when you allowed him to stop at the lake."
   b. "You are not to blame for his behavior. You obviously made some right decisions, because you survived the attack."
   c. "There's no sense looking back now. Just look forward, and make sure you don't put yourself in the same situation again."
   d. "You'll just have to see that he is arrested so he won't do this to anyone else."

9. A young woman who has just undergone a sexual assault is brought into the emergency department by a friend. What is the *priority* nursing intervention?
   a. Help her to bathe and clean herself up.
   b. Provide physical and emotional support during evidence collection.
   c. Provide her with a written list of community resources for survivors of rape.
   d. Discuss the importance of a follow-up visit to evaluate for sexually transmitted diseases.

10. A woman who was sexually assaulted 6 months ago by a male acquaintance has been attending a support group for survivors of rape. From this group, she has learned that the most likely reason the man raped her was that:
    a. Because he had been drinking, he was not in control of his actions.
    b. He had not had sexual relations with a girl in many months.
    c. He was predisposed to become a rapist by virtue of the poverty conditions under which he was reared.
    d. He was expressing power and dominance by means of sexual aggression and violence.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Bowland, S., Edmond, T., & Fallot, R.D. (2012). Evaluation of a spiritually focused intervention with older trauma survivors. *Social Work, 57*(1), 73-82.

DESCRIPTION OF THE STUDY: The purpose of this study was to evaluate a spiritually focused group intervention for a sample of women trauma survivors older than age 55 years (*n* = 21, control group *n* = 22). The authors cite research supporting that older women value spirituality more than men or younger adults, and often this was correlated to personal growth, well-being, and involvement in creative activities. They also cited research linking personal violation (trauma) to spiritual crisis. Inclusion criteria sought a homogenous group of participants who all had a background in Christian tradition. They randomly assigned participants into treatment and control groups, and they chose a treatment intervention that was a "manualized, psychoeducational, cognitive restructuring and skill building approach to addressing spiritual struggles in recovery." They evaluated for changes in symptoms of depression, anxiety, PTSD, and physical symptoms.

RESULTS OF THE STUDY: The treatment group in this study was found to have fewer symptoms of depression, anxiety, and PTSD and fewer physical symptoms than the control group at the completion of the intervention. These gains were still evident at 3-month follow-up.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE—cont'd

IMPLICATIONS FOR NURSING PRACTICE: Holistic nursing practice includes addressing the spiritual needs of clients in recovery, particularly since spiritual crisis has been identified as a risk for trauma survivors. This study supported that interventions focused on spiritual needs can have an impact on symptom reduction for several disorders common to this population. Use of structured interventions, consideration for homogeneity of belief traditions, and individual assessment of the client's interest in such interventions are important variables to consider.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

McClean, C.P., Morris, S.H., Conklin, P., Jayawickreme, N., & Foa, E.B. (2014). Trauma characteristics and posttraumatic stress disorder among adolescent survivors of childhood sexual abuse. *Journal of Family Violence, 29*(5), 559-566. doi:10.1007/s10896-014-9613-6

DESCRIPTION OF THE STUDY: This study examined the relationship between specific characteristics of childhood sexual abuse and the severity of consequent PTSD, depression, suicide ideation, and substance use symptoms. The risk for illness subsequent to trauma is well documented in the literature, but these researchers wanted to know if specific characteristics such as the relationship of the perpetrator to the victim, the duration or frequency of abuse, and the type of abuse could predict the severity of future PTSD or other symptoms. The participants ($N = 83$) were a culturally diverse sample of female adolescents who were already seeking treatment. The researchers note that there have been conflicting findings in existing research about these relationships in previous studies of adolescents.

RESULTS OF THE STUDY: One significant finding in this study was that the frequency of sexual abuse victimization was correlated with an increase in suicide ideation. Contrary to what the researchers expected to find, the type of trauma, the relationship of the perpetrator, and the duration of victimization did not predict severity of other future illness symptoms, including depression, PTSD, and substance use. They acknowledge that two influential variables are that (1) all participants in their sample had already identified themselves as having moderate to high PTSD, and (2) the severity of symptoms may be more distinctive in adulthood, so the relationships that are not clear in a study of adolescents may become clearer as the adolescent moves through adulthood.

IMPLICATIONS FOR NURSING PRACTICE: The finding that frequency of victimization was linked to increased suicide ideation suggests that nurses who conduct victim assessment should assess for suicide ideation and evaluate risks for suicide attempts, especially in adolescents who have sustained frequent sexual abuse victimization.

The other findings of this research (including their review of studies with conflicting results) highlight that it is important for nurses to explore the bulk of available research on any issue to increase confidence in their clinical judgments.

TEST YOUR CRITICAL THINKING SKILLS

Sandy is a psychiatric registered nurse who works at a safe house for battered women. Lisa has just been admitted with her two small children after she was treated in the emergency department. She was beaten severely by her husband while he was intoxicated last night. She escaped with her children after he passed out in their bedroom.

In her initial assessment, Sandy learns from Lisa that she has been battered by her husband for 5 years, beginning shortly after their marriage. She explained that she "knew he drank quite a lot before we were married, but thought he would stop after we had kids." Instead, the drinking has increased. Sometimes he does not even get home from work until midnight, after stopping to drink at the bar with his buddies.

Lately, he has begun to express jealousy and a lack of trust in Lisa, accusing her of numerous infidelities and indiscretions, none of which are true. Lisa says, "If only he wasn't under so much stress on his job, then maybe he wouldn't drink so much. Maybe if I tried harder to make everything perfect for him at home—I don't know. What do you think I should do to keep him from acting this way?"

Answer the following questions related to Lisa:

1. What is an appropriate response to Lisa's question?
2. Identify the priority psychosocial nursing diagnosis for Lisa.
3. What must the nurse do to ensure that Lisa learns from this experience?

💬 Communication Exercises

1. Sarah is being treated in the emergency department for wounds inflicted by her husband. She says to the nurse, "He's really not a bad person. He's just under so much stress right now. His company is laying people off, and he thinks he will be next. He drinks a lot when he comes home from work. I just need to make things easier for him at home. I shouldn't have asked him to mow the lawn."
   - How would the nurse respond appropriately to this statement by Sarah?
2. "I don't know what to do. I'm afraid he will hurt the kids."
   - How would the nurse respond appropriately to this statement by Sarah?
3. "I don't want to press charges. I just want to go home!"
   - How would the nurse respond appropriately to this statement by Sarah?

Community Mental Health Nursing

36

CORE CONCEPTS

Community
Primary Prevention
Secondary Prevention
Tertiary Prevention

KEY TERMS

case management
case manager
deinstitutionalization

diagnosis-related groups
 (DRGs)
mobile outreach units

prospective payment
shelters
storefront clinics

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss the changing focus of care in the field of mental health.
2. Define the concepts of care associated with the public health model.
3. Discuss primary prevention of mental illness within the community.
4. Identify populations at risk for mental illness within the community.
5. Discuss nursing intervention in primary prevention of mental illness within the community.
6. Discuss secondary prevention of mental illness within the community.
7. Describe treatment alternatives related to secondary prevention within the community.
8. Discuss tertiary prevention of mental illness within the community as it relates to the seriously mentally ill and homeless mentally ill.
9. Relate historical and epidemiological factors associated with caring for the seriously mentally ill and homeless mentally ill within the community.
10. Identify treatment alternatives for care of the seriously mentally ill and homeless mentally ill within the community.
11. Apply steps of the nursing process to care of the seriously mentally ill and homeless mentally ill within the community.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What are *diagnosis-related groups* (DRGs)?
2. Describe and differentiate how interventions at the primary, secondary, and tertiary prevention levels are implemented.
3. Name three common client populations that benefit from psychiatric home health nursing.
4. What is the most common psychiatric diagnosis among homeless people with mental illness?

831

This chapter explores the concepts of primary and secondary prevention of mental illness within communities. Additional focus is placed on tertiary prevention of mental illness: treatment with community resources of those who suffer from severe and persistent mental illness, including homeless persons with mental illness. Emphasis is given to the role of the psychiatric nurse in the various treatment alternatives within the community setting.

The Changing Focus of Care

Before 1840, there was no known treatment for individuals with mental illness. Because mental illness was perceived as incurable, the only "reasonable" intervention was thought to be removing these individuals from the community to a place where they would do no harm to themselves or others.

In 1841, Dorothea Dix, a former schoolteacher, began a personal crusade on behalf of institutionalized individuals with mental illness. Her efforts resulted in more humane treatment of these clients and the establishment of a number of psychiatric hospitals across the country.

After the movement initiated by Dix, the number of hospitals for persons with mental illness increased, although unfortunately not as rapidly as did the population with mental illness. Hospitals became overcrowded and understaffed, with conditions that would have sorely distressed Dix.

The community mental health movement had its impetus in the 1940s. With establishment of the National Mental Health Act of 1946, the U.S. government awarded grants to the states to develop mental health programs outside of state hospitals. Outpatient clinics and psychiatric units in general hospitals were inaugurated. Then, in 1949, as an outgrowth of the National Mental Health Act, the National Institute of Mental Health (NIMH) was established. The U.S. government has charged this agency with the responsibility for mental health in the United States.

In 1955, the Joint Commission on Mental Health and Illness was established by Congress to identify the nation's mental health needs and make recommendations for improvement in psychiatric care. In 1961, the Joint Commission published the report *Action for Mental Health* in which recommendations were made for treatment of clients with mental illness, training for caregivers, and improvements in education and research on mental illness. With consideration given to these recommendations, Congress passed the Mental Retardation Facilities and Community Mental Health Centers Construction Act (often called the *Community Mental Health Centers Act*) of 1963. This act called for the construction of comprehensive community mental health centers, the cost of which would be shared by federal and state governments. The **deinstitutionalization** movement (the closing of state mental hospitals and discharging of individuals with mental illness) had begun.

Unfortunately, many state governments did not have the capability to match the federal funds required for the establishment of these mental health centers. Some communities found it difficult to follow the rigid requirements for services required by the legislation that provided the grant.

In 1980, the Community Mental Health Systems Act, which would have a major role in renovation of mental health care, was established. Funding was authorized for community mental health centers, services to high-risk populations, and rape research and services. Approval was also granted for the appointment of an associate director for minority concerns at NIMH. However, before this plan could be enacted, the newly inaugurated administration set forth its intention to diminish federal involvement. Budget cuts reduced the number of mandated services, and federal funding for community mental health centers was terminated in 1984.

Meanwhile, costs of care for hospitalized psychiatric clients continued to rise. The problem of the "revolving door" began to intensify. Individuals with severe and persistent mental illness had no place to go when their symptoms exacerbated except back to the hospital. Individuals without support systems remained in the hospital for extended periods because of lack of appropriate community services. Hospital services were paid for by cost-based, retrospective reimbursement: Medicaid, Medicare, and private health insurance. Retrospective reimbursement encouraged hospital expenditure; the more services provided, the more payment received.

This system of health-care delivery was interrupted in 1983 with the advent of **prospective payment**—the Reagan administration's proposal of cost containment. It was directed at control of Medicare costs by setting forth preestablished amounts that would be reimbursed for specific diagnoses, or **diagnosis-related groups (DRGs).** Since that time, prospective payment has also been integrated by the states (Medicaid) and by some private insurance companies, drastically affecting the amount of reimbursement for health-care services.

Under prospective payment, general hospital services to psychiatric clients have been severely restricted. Clients who present with acute symptoms, such as acute psychosis, suicidal ideations or attempts, or manic exacerbations, constitute the largest segment of the psychiatric hospital census. Clients with less serious illnesses (e.g., moderate depression or adjustment disorders) may be hospitalized, but length of stay has been shortened considerably by the reimbursement guidelines. Clients are being discharged from the hospital with a greater need for aftercare than in the

past, when hospital stays were longer. A positive outgrowth of these struggles with costly hospital stays and restricted reimbursement has been the development of a broader continuum of outpatient treatment options than what has been available historically. In the past, individuals who needed psychiatric treatment saw an outpatient therapist or were hospitalized, but today there are partial hospitalization programs, intensive outpatient programs, aftercare programs, and a host of other community-based services available to clients with mental health disorders.

Deinstitutionalization continues to impact mental health care in the United States. Care for the client in the hospital has become cost prohibitive, whereas care for the client in the community is considered cost effective. However, the community mental health movement has also been criticized for being a continuation of an "overly narrow biomedical model" (Vanderplasschen et al., 2013). Ironically, the prison populations of homeless and mentally ill persons has risen dramatically during this same time period, one of the problems that Dorothea Dix fought so adamantly against in the first place. The reality of the provision of health-care services today is often more of a political and funding issue than providers would care to admit. Decisions about how to treat are rarely made without consideration of cost and method of payment.

The recovery model (see Chapter 21, The Recovery Model) promises the hope of integrating the support of community mental health services, peer support, and client empowerment to improve interventions and outcomes as we look to the future. We must serve the consumer by working collaboratively to provide the essential services for health promotion, for early intervention, and to promote improvement in quality of life for this population.

The Public Health Model

The premise of the model of public health is based largely on the concepts set forth by Gerald Caplan (1964) during the initial community mental health movement. They include primary prevention, secondary prevention, and tertiary prevention. These concepts have expanded beyond mental health treatment and are now widely accepted as guiding principles in clinical and community settings over a wide range of medical and nursing specialties.

CORE CONCEPT
Primary Prevention
Services aimed at reducing the incidence of mental disorders within the population.

Primary prevention targets both individuals and the environment. Emphasis is twofold:

1. Assisting individuals to increase their ability to cope effectively with stress
2. Targeting and diminishing harmful forces (stressors) within the environment

Nursing in primary prevention is focused on the targeting of groups at risk and the provision of educational programs. Examples include:

■ Teaching parenting skills and child development to prospective new parents
■ Teaching physical and psychosocial effects of alcohol/drugs to elementary school students
■ Teaching techniques of stress management to virtually anyone who desires to learn
■ Teaching groups of individuals ways to cope with the changes associated with various maturational stages
■ Teaching concepts of mental health to various groups within the community
■ Providing education and support to unemployed or homeless individuals
■ Providing education and support to other individuals in various transitional periods (e.g., widows and widowers, new retirees, and women entering the work force in middle life)

These are only a few examples of the types of services nurses provide in primary prevention. Such services can be offered in a variety of convenient public settings (e.g., churches, schools, colleges, community centers, YMCAs and YWCAs, workplaces of employee organizations, meetings of women's groups, or civic or social organizations such as parent-teacher associations, health fairs, and community shelters).

CORE CONCEPT
Secondary Prevention
Interventions aimed at minimizing early symptoms of psychiatric illness and directed toward reducing the prevalence and duration of the illness.

Secondary prevention is accomplished through early identification of problems and prompt initiation of effective treatment. Nursing in secondary prevention focuses on recognition of symptoms and provision of or referral for treatment. Examples include:

■ Ongoing assessment of individuals at high risk for illness exacerbation (e.g., during home visits, day care, community health centers, or in any setting where screening of high-risk individuals might occur)

- Provision of care for individuals in whom illness symptoms have been assessed (e.g., individual or group counseling, medication administration, education and support during period of increased stress [crisis intervention], staffing rape crisis centers, suicide hotlines, homeless shelters, shelters for abused persons, or mobile mental health units)
- Referral for treatment of individuals in whom illness symptoms have been assessed. Referrals may come from support groups, community mental health centers, emergency services, psychiatrists or psychologists, and day or partial hospitalization. Inpatient therapy on a psychiatric unit of a general hospital or in a private psychiatric hospital may be necessary. Psychopharmacology and various adjunct therapies may be initiated as part of the treatment.

Secondary prevention is addressed extensively in Unit 4, Nursing Care of Clients With Alterations in Psychosocial Adaptation, of this text. Nursing assessment, diagnosis and outcome identification, planning and implementation, and evaluation are discussed for many of the mental illnesses identified in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) (American Psychiatric Association [APA], 2013). These concepts may be applied in any setting where nursing is practiced.

> ## CORE CONCEPT
> **Tertiary Prevention**
> Services aimed at reducing the residual defects that are associated with severe and persistent mental illness.

Tertiary prevention is accomplished in two ways:

1. Preventing complications of the illness
2. Promoting rehabilitation directed toward achievement of each individual's maximum level of functioning

Historically, individuals with severe and persistent mental illness often experienced long hospitalizations that resulted in loss of social skills and increased dependency. With deinstitutionalization, many of these individuals may never have experienced hospitalization, but they still do not possess adequate skills to live productive lives within the community.

Nursing in tertiary prevention focuses on helping clients learn or relearn socially appropriate behaviors so that they may achieve a satisfying role within the community. Examples include:

- Consideration of the rehabilitation process at the time of initial diagnosis and treatment planning

- Teaching the client daily living skills and encouraging independence to his or her maximum ability
- Referring clients for various aftercare services (e.g., support groups, day treatment programs, partial hospitalization programs, psychosocial rehabilitation programs, group home, or other transitional housing)
- Monitoring effectiveness of aftercare services (e.g., through home health visits or follow-up appointments in community mental health centers)
- Making referrals for support services when required (e.g., some communities have programs linking individuals with serious mental disorders to volunteers who develop friendships with the individuals and may assist with household chores, shopping, and other activities of daily living with which the individual is having difficulty, in addition to participating in social activities with the individual)

Nursing care at the tertiary level of prevention can be administered on an individual or group basis and in a variety of settings, such as inpatient hospitalization, day or partial hospitalization, group home or halfway house, shelters, home health care, nursing homes, and community mental health centers.

The Community as Client

Primary Prevention

> ## CORE CONCEPT
> **Community**
> A group, population, or cluster of people with at least one common characteristic, such as geographic location, occupation, ethnicity, or health concern.

Primary prevention within communities encompasses the twofold emphasis defined earlier in this chapter:

1. Identifying stressful life events that precipitate crises and targeting the relevant populations at high risk
2. Intervening with these high-risk populations to prevent or minimize harmful consequences

Populations at Risk

One way to view populations at risk is to focus on types of crises that individuals experience in their lives. Two broad categories are maturational crises and situational crises.

Maturational Crises

Maturational crises are crucial experiences associated with various stages of growth and development. Erikson

(1963) described eight stages of the life cycle during which individuals struggle with developmental "tasks." Crises can occur during any of these stages, although several developmental periods and life-cycle events have been recognized as having increased crisis potential: adolescence, marriage, parenthood, midlife, and retirement.

Adolescence The task for adolescence according to Erikson (1963) is *identity versus role confusion*. This is the time in life when individuals ask questions such as "Who am I?," "Where am I going?," and "What is life all about?"

Adolescence is a transition into young adulthood. It is a very volatile time in most families. Commonly, conflict arises over issues of control. Parents sometimes have difficulty relinquishing even a minimal amount of the control they have had throughout their child's infancy, toddlerhood, and school-aged years at this time when the adolescent is seeking increased independence. It may seem that the adolescent is 25 years old one day and 5 years old the next. An often-quoted definition of an adolescent, by an anonymous author, is: "A toddler with hormones and wheels."

At this time, adolescents are "trying out their wings," although they possess an essential need to know that the parents (or surrogate parents) are available if support is required. In fact, it is believed that the most frequent immediate precipitant to adolescent suicide is loss of or threat of loss or abandonment by parents or closest peer relationship.

Adolescents have many issues to deal with and many choices to make. Some of these include issues that relate to self-esteem and body image (in a body that is undergoing rapid changes), peer relationships (with both genders), education and career selection, establishing a set of values and ideals, sexuality and sexual experimentation (including issues of birth control and prevention of sexually transmitted infections), drug and alcohol use, and physical appearance.

Nursing interventions with adolescents at the primary level of prevention focus on providing support and accurate information to ease the difficult transition they are undergoing. Educational offerings can be presented in schools, churches, youth centers, or any location in which groups of teenagers gather. Types of programs may include, but are not limited to, the following:

■ Alateen groups for adolescents with alcoholic parent(s)
■ Other support groups for teenagers who are in need of assistance to cope with stressful situations (e.g., children dealing with divorce of their parents, pregnant teenagers, teenagers coping with abortion, adolescents coping with the death of a parent)

■ Educational programs that inform about and validate bodily changes and emotions about which there may be some concerns
■ Educational programs that inform about positive self-esteem and resilience
■ Educational programs that inform about sexuality, pregnancy, contraception, and sexually transmitted infections
■ Educational programs that inform about the use of alcohol and other drugs

Marriage The "American dream" of the 1950s—especially that of the American woman—was to marry, have two or three children, buy a house in the suburbs, and drive a station wagon. To not be at least betrothed by their mid-20s caused many women to fear becoming an "old maid." Living together without the benefit of marriage was unacceptable and rarely considered an option.

Times have changed considerably since the middle of the 20th century. Today's young women are choosing to pursue careers before entering into marriage, to continue their careers after marriage, or to not marry at all. Many couples are deciding to live together without being married, and, as with most trends, the practice now receives more widespread societal acceptance than it once did. Although there are far more culturally accepted relationship and living arrangement choices in today's society, crises may develop related to conflicting values between generations within a family and related to the many factors influencing those choices, including economic concerns. Cultural changes such as the growth in individualism and self-realization have decreased interest in long-term commitments and childbearing, but economics and the reality of gender inequalities in the workplace have accentuated conflicts around choosing how to move forward at this stage of life (Kaakinen et al., 2015).

When young adults do decide to enter into marriage, crisis may develop associated with unrealistic or uninformed expectations about this institution. It is well understood that children raised in abusive, dysfunctional families are at higher risk for subconsciously choosing partners who perpetuate the experiences they had while growing up. Both of these circumstances can increase the risk for crisis within a marriage.

Nursing interventions at the primary level of prevention with individuals in this stage of development involve education about what to expect at various stages in the marriage. Many high schools offer courses in marriage and family living in which students role-play anticipatory marriage and family situations. Nurses could offer these kinds of classes within the community to individuals considering marriage. Educating young adults about factors to consider when

choosing a spouse, particularly the risks associated with choosing a partner who perpetuates a cycle of violence, may provide the opportunity to provide primary prevention at the level of basic survival. Too many people enter marriage with the notion that, as sure as the depth of their love, their soon-to-be husband or wife will discontinue his or her "undesirable" traits and change into the perceived ideal spouse. Primary prevention with these individuals involves:

■ Encouraging honest communication
■ Determining what each person expects from the relationship
■ Discerning whether each individual can accept compromise

This type of intervention can be effective in individual or couple's therapy and in support or educational groups of couples experiencing similar circumstances.

Parenthood There is perhaps no developmental stage that creates an upheaval equal to that of the arrival of a child. Even when the child is desperately wanted and pleasurably anticipated, his or her arrival usually results in some degree of chaos within the family.

Because the family operates as a system, the addition of a new member influences all parts of the system as a whole. If it is a first child, the relationship between spouses is likely to be affected by the demands of caring for the infant on a 24-hour basis. If there are older children, they may resent the attention showered on the new arrival and show their resentment in a variety of creative ways.

The concept of having a child (particularly the first one) is often romanticized, with little or no consideration given to the realities and responsibilities that accompany this "bundle of joy." Many young parents are shocked to realize that such a tiny human can create so many changes in so many lives. It is unfortunate that although parenting is one of the most important positions an individual will hold in life, it is one for which he or she is often least prepared.

Nursing intervention at the primary level of prevention with those in the developmental stage of parenthood must begin long before the child is even born. How do we prepare individuals for parenthood? *Anticipatory guidance* is the term used to describe the interventions used to help new parents know what they might expect. Volumes have been written on the subject, but it is also important for expectant parents to have a support person or network with whom they can talk honestly and express feelings, excitement, and fears. Nurses can provide the following type of information to help ease the transition into parenthood (Kaakinen et al., 2015; Spock, 2012).

■ **Prepared childbirth classes:** These classes present what most couples can expect along with information about possible deviations from what is expected.

■ **Information about what to expect after the baby arrives:**
  ■ *Parent-infant bonding:* Expectant parents should know that it is common for parent-infant bonding not to occur immediately. The strong attachment will occur as parent and infant get to know each other.
  ■ *Changing communication patterns and relationship styles:* The couple should be encouraged to engage in open, honest communication with each other. Education should be offered about expected changes in communication patterns and the challenges of establishing communication with an infant as well as resources for referral if communication patterns are creating significant role strain. Frustrated attempts to adapt to these challenges can have consequences for the infant as well. In some cases, an infant's need may be neglected if the parents lack skills or resources to navigate communication challenges. "The most extreme example of an inability to adapt to communication patterns with an infant is shaken baby syndrome" (Kaakinen et al., 2015, p.363). Discuss strategies family members may use to maintain motivation and morale as well as provide for comfort, rest, and self-care for each member.
  ■ *Clothing and equipment:* Expectant parents need to know what is required to care for a newborn child. Financing childbearing and child rearing, arranging space for a child, and lifestyle should be considered.
  ■ *Feeding:* Advantages and disadvantages of breastfeeding and formula feeding should be presented. The couple should be supported in whatever method is chosen. Anticipatory guidance related to technique should be provided for one or both methods as the expectant parents request.
  ■ *Other expectations:* It is important for expectant parents to receive anticipatory guidance about the infant's sleeping and crying patterns, bathing the infant, care of the circumcision and cord, toys that provide stimulation of the newborn's senses, aspects of providing a safe environment, and when to call the physician.
■ **Stages of growth and development:** It is very important for parents to understand what behaviors should be expected at what stage of development. It is also important to know that their child may not necessarily follow the age guidelines associated with these stages. However, a substantial deviation from these guidelines should be reported to the pediatrician.

Midlife What is middle age? A colleague once remarked that upon turning 50 years of age, she stated, "'Now I can say I am officially middle aged' . . . until I began thinking about how few individuals I really knew who were 100!"

Midlife crises are not defined by a specific number. Various sources in the literature identify these conflicts as occurring anytime between ages 35 and 65.

What is a midlife crisis? It is very individual, but a number of patterns have been identified within three broad categories:

1. **An alteration in perception of the self:** One's perception of self may change slowly, or a person may suddenly become aware of being "old" or "middle aged." Other biological changes that occur naturally with the aging process may also affect the crises that occur at this time. In women, a gradual decrease in estrogen production initiates menopause, which results in a variety of physical and emotional symptoms. Some physical symptoms include hot flashes, vaginal dryness, cessation of menstruation, loss of reproductive ability, night sweats, insomnia, headaches, and minor memory disturbances. Emotional symptoms include anxiety, depression, crying for no reason, and temper outbursts.

   Some men experience hot flashes, sweating, chills, dizziness, and heart palpitations, while others may experience severe depression and an overall decline in physical vigor (Sadock, Sadock, & Ruiz, 2015). An alteration in sexual functioning is not uncommon.

2. **An alteration in perception of others:** A change in relationship with adult children requires a sensitive shift in caring. Wright and Leahey (2013) state:

   The family of origin must relinquish the primary roles of parent and child. They must adapt to the new roles of parent and adult child. This involves renegotiation of emotional and financial commitments. The key emotional process during this stage is for family members to deal with a multitude of exits from and entries into the family system. (p. 107)

   These experiences are particularly difficult when parents' values conflict with the relationships and types of lifestyles their children choose. An alteration in perception of one's parents also begins to occur during this time. Having always looked to parents for support and comfort, the middle-aged individual may suddenly find that the roles are beginning to reverse. Aging parents may look to their children for assistance with decisions regarding their everyday lives and chores they have previously accomplished independently. When parents die, middle-aged individuals must come to terms with their own mortality. The process of recognition and resolution of one's own finitude begins in earnest at this time.

3. **An alteration in perception of time:** Middle age has been defined as the end of youth and the beginning of old age. Individuals often experience a sense that time is running out: "I haven't done all I want to do or accomplished all I intended to accomplish!" Depression and a sense of loss may occur as individuals realize that some of the goals established in their youth may go unmet.

The term *empty nest syndrome* has been used to describe the adjustment period parents experience when the last child leaves home to establish an independent residence. The crisis is often more profound for the mother who has devoted her life to nurturing her family. As the last child leaves, she may perceive her future as uncertain and meaningless.

Some women who have devoted their lives to rearing their children decide to develop personal interests and pursue personal goals once the children are grown. This occurs at a time when many husbands have begun to decrease what may have been a compulsive drive for occupational security during the earlier years of their lives. This disparity in common goals may create conflict between husband and wife. At a time when she is experiencing more value in herself and her own life, he may begin to feel less valued. This may also relate to a decrease in the amount of time and support from the wife to which the husband has become accustomed. This type of role change will require numerous adaptations on the part of both spouses.

Finally, an alteration in one's perception of time may be related to the societal striving for eternal youth. The individual may try to delay the external changes that come with aging by the use of cosmetics, hormone creams, or even surgery. This yearning for youth may take the form of sexual promiscuity or extramarital affairs with much younger individuals, in an effort to prove that one "still has what it takes." Some individuals reach for the trappings of youth with regressive-type behaviors, such as the middle-aged man who buys a motorcycle and joins a motorcycle club, and the 50-year-old woman who wears miniskirts and flirts with her daughter's boyfriends. These individuals may be denying their own past and experience. With a negative view of self, they strongly desire to relive their youth.

Nursing intervention at the primary level of prevention with those in the developmental stage of midlife involves providing accurate information regarding changes that occur during this time of life and support for adapting to these changes effectively. These interventions might include:

■ Nutrition classes to inform individuals in this age group about the essentials of diet and exercise. Educational materials on how to avoid obesity and the importance of good nutrition can be included.

■ Assistance with ways to improve health (e.g., quit smoking, cease or reduce alcohol consumption, reduce fat intake).

- Discussions of the importance of having regular physical examinations, including Pap and breast examinations for women and prostate examinations for men. Monthly breast self-examinations should be taught and yearly mammograms encouraged.
- Classes on menopause should be given. Provide information about what to expect. Myths that abound regarding this topic should be expelled. Support groups for women (and men) undergoing the menopausal experience could be formed.
- Support and information related to physical changes occurring in the body during this time of life. Assist with the grief response that some individuals will experience in relation to loss of youth, empty nest, and sense of identity.
- Support and information related to care of aging parents should be given. Individuals should be referred to community resources for respite and assistance before strain of the caregiver role threatens to disrupt the family system.

Retirement   Retirement, which is often anticipated as an achievement in principle, may be met with ambivalence when it actually occurs. Our society places profound importance on productivity and earning as much money as possible at as young an age as possible. These types of values contribute to the ambivalence associated with retirement. Although leisure has been acknowledged as a legitimate reward for workers, leisure during retirement has never been accorded the same social value. Adjustment to this life-cycle event becomes more difficult in the face of societal values that are in direct conflict with the new lifestyle.

Historically, many women have derived much of their self-esteem from having children, rearing children, and being "good mothers." Likewise, many men have achieved self-esteem through work-related activities—creativity, productivity, and earning money. Termination of these activities can result in a loss of self-worth, and individuals who are unable to adapt satisfactorily may become depressed.

It would appear that retirement is becoming, and will continue to become, more accepted by societal standards. With more and more individuals living longer, a growing number of aging persons will spend more time in retirement. At present, retirement has become more of an institutionalized expectation, with increasing acceptance as a social status.

Nursing intervention at the primary level of prevention with the developmental task of retirement involves providing information and support to individuals who have retired or are considering retirement. Support can be provided on a one-to-one basis to assist these individuals to sort out their feelings regarding retirement. Well-being in retirement is linked to factors such as stable health status, adequate income, the ability to pursue new goals or activities, extended social network of family and friends, and satisfaction with current living arrangements.

One hallmark of change for many older adults is the increasing numbers of grandparents who are caring for grandchildren and, in many cases, assuming primary responsibility for their care (Kaakinen et al., 2015). Nurses can promote primary prevention of crisis through education about resources for caregiving assistance and evidence-based information about this new role. In fact, evidence shows that in spite of grief and burdens associated with caregiving, many grandparents identify that this role revealed their inner strength and gave them a sense of accomplishment (Kaakinen et al., 2015).

Support can also be provided in a group environment. Support groups of individuals undergoing the same types of experiences can be extremely helpful. Nurses can form and lead groups to assist retiring individuals through this critical period. These groups can also serve to provide information about available resources that offer assistance to individuals in or nearing retirement, such as information concerning Medicare, Social Security, and Medicaid; information related to organizations that specialize in hiring retirees; and information regarding ways to use newly acquired free time constructively.

Situational Crises

Situational crises are acute responses that occur as a result of an external stressor. The number and types of situational stressors are limitless and may be real or exist only in the perception of the individual. Some types of situational crises that put individuals at risk for mental illness are discussed next.

Poverty   A number of studies have identified poverty as a direct correlation to emotional illness. This may have to do with the direct consequences of poverty, such as inadequate and crowded living conditions, nutritional deficiencies, medical neglect, unemployment, and homelessness.

High Rate of Life-Change Events   Many studies have found that changes in life patterns when a large number of significant events occur in close proximity tend to decrease a person's ability to deal with stress, sometimes resulting in physical or emotional illness (McLeod, 2010). These include events such as death of a loved one, divorce, being fired from a job, a change in living conditions, a change in place of employment or residence, physical illness, or a change in body image caused by the loss of a body part or function.

Environmental Conditions   Environmental conditions can create situational crises. Tornados, floods, hurricanes, and earthquakes have wreaked devastation on thousands of individuals and families in recent years.

Trauma Individuals who have encountered traumatic experiences must be considered at risk for emotional illness. These include those considered outside the range of typical human experience, such as rape, war, physical attack, torture, or natural or manmade disaster.

Nursing intervention at the primary level of prevention with individuals experiencing situational crises is aimed at helping them maintain the highest possible level of functioning while offering support and assistance with problem-solving during the crisis period. Interventions for nursing of clients in crisis include the following:

■ Use a reality-oriented approach. The focus of the problem is on the here and now.

■ Remain with the individual who is experiencing panic anxiety.

■ Establish a rapid working relationship by showing unconditional acceptance, actively listening, and attending to immediate needs.

■ Discourage lengthy explanations or rationalizations of the situation; promote an atmosphere for verbalization of true feelings.

■ Set firm limits on aggressive, destructive behaviors. At high levels of anxiety, behavior is likely to be impulsive and regressive. Establish at the outset what is acceptable and what is not, and maintain consistency.

■ Clarify the problem the individual is facing. The nurse does this by describing his or her perception of the problem and comparing it with the individual's perception of the problem.

■ Help the individual determine what he or she believes precipitated the crisis.

■ Acknowledge feelings of anger, guilt, helplessness, and powerlessness, while taking care not to provide positive feedback for these feelings.

■ Guide the individual through a problem-solving process by which he or she may move in the direction of positive life change:

  ▪ Help the individual confront the source of the problem that is creating the crisis response.

  ▪ Encourage the individual to discuss changes he or she would like to make. Jointly determine whether desired changes are realistic.

  ▪ Encourage exploration of feelings about aspects that cannot be changed, and explore alternative ways of coping more adaptively in these situations.

  ▪ Discuss alternative strategies for creating change in situations that can realistically be changed.

  ▪ Weigh benefits and consequences of each alternative.

  ▪ Assist the individual to select alternative coping strategies that will help alleviate future crises.

■ Identify external support systems and new social networks from which the individual may seek assistance in times of stress.

Nursing at the level of primary prevention focuses largely on education of the consumer to prevent initiation or exacerbation of mental illness. An example of content that may be included in one type of primary prevention teaching plan is presented in Table 36-1.

Secondary Prevention

Populations at Risk

Secondary prevention within communities relates to early detection of and prompt intervention with individuals experiencing mental illness symptoms. The same maturational and situational crises presented in the previous section on primary prevention are used to discuss intervention at the secondary level of prevention.

Maturational Crises

Adolescence The need for intervention at the secondary level of prevention in adolescence occurs when disruptive and age-inappropriate behaviors become the norm, and the family can no longer cope adaptively with the situation. All levels of dysfunction are considered— from dysfunctional family coping to the need for hospitalization of the adolescent.

Nursing intervention with the adolescent at this level may occur in the community setting at community mental health centers, physician's offices, schools, public health departments, and crisis intervention centers. Nurses may work with families to problemsolve and improve coping and communication skills, or they may work on a one-to-one basis with the adolescent in an attempt to modify behavior patterns.

Adolescents may be hospitalized for a variety of problems, including (but not limited to) conduct disorders, adjustment disorders, eating disorders, substance-related disorders, depression, and anxiety disorders. Inpatient care is determined by severity of symptomatology. Nursing care of adolescents in the hospital setting focuses on problem identification and stabilizing a crisis situation. Once stability has been achieved, clients are commonly discharged to outpatient care. If an adolescent's home situation has been deemed unsatisfactory, the state may take custody and the child is then discharged to a group or foster home.

Marriage Problems that commonly disrupt a marriage relationship include substance abuse on the part of one or both partners and disagreements on issues of sex, money, children, gender roles, and infidelity, among others.

Nursing intervention at the secondary level of prevention with individuals encountering marriage problems may include one or more of the following:

■ Counseling with the couple or with one of the spouses on a one-to-one basis

TABLE 36–1 Client Education for Primary Prevention: Drugs of Abuse

CLASS OF DRUGS	EFFECTS	SYMPTOMS OF OVERDOSE	TRADE NAMES	COMMON NAMES	EFFECTS ON THE BODY (CHRONIC OR HIGH-DOSE USE)
CNS DEPRESSANTS Alcohol	Relaxation, loss of inhibitions, lack of concentration, drowsiness, slurred speech, sleep	Nausea, vomiting; shallow respirations; cold, clammy skin; weak, rapid pulse; coma; possible death	Ethyl alcohol, beer, gin, rum, vodka, bourbon, whiskey, liqueurs, wine, brandy, sherry, champagne	Booze, alcohol, liquor, drinks, cocktails, high-balls, nightcaps, moonshine, white lightning, firewater	Peripheral nerve damage, skeletal muscle wasting, encephalopathy, psychosis, cardiomyopathy, gastritis, esophagitis, pancreatitis, hepatitis, cirrhosis of the liver, leukopenia, thrombocytopenia, sexual dysfunction
Other (barbiturates and nonbarbiturates)	Same as alcohol	Anxiety, fever, agitation, hallucinations, disorientation, tremors, delirium, convulsions, possible death	Seconal Nembutal Amytal Valium Librium Chloral hydrate Miltown	Red birds Yellow birds Blue birds Blues/yellows Green & whites Mickies Downers	Decreased REM sleep, respiratory depression, hypotension, possible kidney or liver damage, sexual dysfunction
CNS STIMULANTS Amphetamines and related drugs	Hyperactivity, agitation, euphoria, insomnia, loss of appetite	Cardiac arrhythmias, headache, convulsions, hypertension, rapid heart rate, coma, possible death	Dexedine, Didrex, Tenuate, Bontril, Ritalin, Focalin, Provigil	Uppers, pep pills, wakeups, bennies, eyeopeners, speed, black beauties, sweet A's	Aggressive, compulsive behavior; paranoia; hallucinations; hypertension
Cocaine	Euphoria, hyperactivity, restlessness, talkativeness, increased pulse, dilated pupils	Hallucinations, convulsions, pulmonary edema, respiratory failure, coma, cardiac arrest, possible death	Cocaine hydrochloride	Coke, flake, snow, dust, happy dust, gold dust, girl, Cecil, C, toot, blow, crack	Pulmonary hemorrhage, myocardial infarction, ventricular fibrillation
Synthetic stimulants	Agitation, insomnia, irritability, dizziness, decreased ability to think clearly, increased heart rate, chest pains	Depression, paranoia, delusions, suicidal thoughts, seizures, panic attacks, nausea, vomiting, heart attack, stroke	Mephedrone, MDPV (3-4 methylenedioxypyrovalerone)	Bath salts, bliss, vanilla sky, ivory wave, purple wave	Increased heart rate, increased blood pressure, nosebleeds, hallucinations, aggressive behavior

Category					
OPIOIDS	Euphoria, lethargy, drowsiness, lack of motivation, constricted pupils	Shallow breathing, slowed pulse, clammy skin, pulmonary edema, respiratory arrest, convulsions, coma, possible death	Heroin Morphine Codeine Dilaudid Demerol Dolophine Percodan Talwin Opium	Snow, stuff, H, Harry, horse M, morph, Miss Emma Schoolboy Lords Doctors Dollies Perkies T's Big O, black stuff U47700 (synthetic)	Respiratory depression, constipation, fecal impaction, hypotension, decreased libido, retarded ejaculation, impotence, orgasm failure
HALLUCINOGENS	Visual hallucinations, disorientation, confusion, paranoid delusions, euphoria, anxiety, panic, increased pulse	Agitation, extreme hyperactivity, violence, hallucinations, psychosis, convulsions, possible death	LSD PCP Mescaline DMT STP, DOM MDMA Ketamine	Acid, cube, big D Angel dust, hog, peace pill Mesc Businessman's trip Serenity and peace Ecstasy, XTC Special K, vitamin K, Kit Kat	Panic reaction, acute psychosis, flashbacks
CANNABINOLS	Relaxation, talkativeness, lowered inhibitions, euphoria, mood swings	Fatigue, paranoia, delusions, hallucinations, possible psychosis	Cannabis Hashish	Marijuana, pot, grass, joint, Mary Jane, MJ Hash, rope, sweet Lucy	Tachycardia, orthostatic hypotension, chronic bronchitis, problems with infertility, amotivational syndrome

- Referral to a couples' support group
- Identification of the problem and possible solutions; support and guidance as changes are undertaken
- Referral to a sex therapist
- Referral to a financial advisor
- Referral to parental effectiveness training

When a marriage fails, individuals often experience a spectrum of troubling emotions including anger, mistrust, depression, and grief (even among individuals who initiate divorce). In community health settings, nurses can lead support groups for newly divorced individuals. They can also provide one-to-one counseling for individuals experiencing the emotional chaos engendered by the dissolution of a marriage relationship.

Divorce also has an impact on the children involved. Nurses can intervene with the children of divorce in an effort to prevent dysfunctional behaviors associated with the break-up of a marriage.

Parenthood Intervention at the secondary level of prevention with parents can be required for a number of reasons. A few of these include:

- Physical, emotional, or sexual abuse of a child
- Physical or emotional neglect of a child
- Birth of a child with special needs
- Diagnosis of a terminal illness in a child
- Death of a child

Nursing intervention at the secondary level of prevention includes recognition of the physical and behavioral signs that indicate possible abuse of a child. The child may be cared for in the emergency department or as an inpatient on the pediatric unit or child psychiatric unit of a general hospital.

Nursing intervention with parents may include teaching effective methods of disciplining children aside from physical punishment. Methods that emphasize the importance of positive reinforcement for acceptable behavior can be very effective. Family members must be committed to consistent use of this behavior modification technique for it to be successful.

Parents should also be informed about behavioral expectations at the various levels of development. Knowledge of what to expect from children at these various stages may provide needed anticipatory guidance to deal with the crises commonly associated with each stage.

Therapy sessions with all family members may focus on communication problems. Members are encouraged to express honest feelings in a manner that is nonthreatening to other family members. Active listening, assertiveness techniques, and respect for the rights of others are taught and encouraged. Barriers to effective communication are identified and resolved.

Referrals to agencies that promote effective parenting skills may be made (e.g., parent effectiveness training). Alternative agencies that may provide relief from the stress of parenting may also be considered (e.g., Mom's Day Out programs, sitter-sharing organizations, and day-care institutions). Support groups for abusive parents may also be helpful and assistance in locating or initiating such a group may be provided.

The nurse can assist parents who are grieving the loss of a child or the birth of a child with special needs by helping them express their true feelings associated with the loss. Feelings such as shock, denial, anger, guilt, powerlessness, and hopelessness must be expressed for the parents to progress through the grief response.

Home health-care assistance can be provided for the family of a child with special needs by making referrals to other professionals, such as speech, physical, and occupational therapists; medical social workers; psychologists; and nutritionists. If the child with special needs is hospitalized, the home health nurse can provide specific information to hospital staff that may be helpful in providing continuity of care for the client and in the transition for the family.

Nursing intervention also includes providing assistance in the location of and referral to support groups that deal with loss of a child or birth of a child with special needs. Some nurses may serve as leaders of these types of groups in the community.

Midlife Nursing care at the secondary level of prevention during midlife becomes necessary when the individual is unable to integrate all of the changes that are occurring during this period. An inability to accept the physical and biological changes, the changes in relationships between themselves and their adult children and aging parents, and the loss of the perception of youth may result in depression that help may be needed to resolve.

Retirement Retirement can also result in depression for individuals who are unable to satisfactorily grieve for the loss of this aspect of their lives. This is more likely to occur if the individuals have not planned for retirement or if they have derived most of their self-esteem from their employment.

Nursing intervention at the secondary level of prevention with depressed individuals takes place in both inpatient and outpatient settings. Severely depressed clients with suicidal ideations will need close observation in the hospital setting, whereas those with mild to moderate depression may be treated in the community. A plan of care for the client with depression is found in Chapter 25, Depressive Disorders. These concepts apply to the secondary level of prevention and may be used in all nursing care settings.

The physician may elect to use pharmacotherapy with antidepressants. Nurses may intervene by providing information to the client about what to expect

from the medication, possible side effects, adverse effects, and how to self-administer the medication.

Situational Crises

Nursing care at the secondary level of prevention with clients undergoing situational crises occurs only if crisis intervention at the primary level failed and the individual is unable to function socially or occupationally. Exacerbation of mental illness symptoms requires intervention at the secondary level of prevention. These disorders were addressed extensively in Unit 4. Nursing assessment, diagnosis and outcome identification, planning, implementation, and evaluation were discussed for many of the mental illnesses identified in the *DSM-5* (APA, 2013). These skills may be applied in any setting where nursing is practiced.

A case study situation of nursing care at the secondary level of prevention in a community setting is presented in Box 36–1.

Tertiary Prevention

Individuals With Severe and Persistent Mental Illness

Severe and persistent mental illness is characterized by complex symptoms that reflect a biological phenomenon "causing marked changes in a person's ability to make choices based on consequences, to socialize, to access community supports, to identify what is real, and to organize thoughts (UNC Center of Excellence for Community Mental Health, 2015). Other definitions stress that severe mental illness is marked by severe functional impairment, substantially

---

BOX 36–1 Secondary Prevention Case Study: Parenthood

The identified patient was a petite, doll-like 4-year-old girl named Tanya. She was the older of two children. The other child was a boy named Joseph, aged 2. The mother was 5 months pregnant with their third child. The family had been referred to the nurse after Tanya was placed in foster care following a report to child protective services by her nursery school teacher that the child had marks on her body suspicious of child abuse.

The parents, Paulo and Annette, were in their mid-20s. Paulo had lost his job at an aircraft plant 3 months ago and had been unable to find work since. Annette brought in a few dollars from cleaning houses for other people, but the family was struggling to survive.

Paulo and Annette were angry at having to see the nurse. After all, "Parents have the right to discipline their children." The nurse did not focus on the *intent* of the behavior but instead looked at factors in the family's life that could be viewed as stressors. This family had multiple stressors: poverty, the father's unemployment, the age and spacing of the children, the mother's chronic fatigue from work at home and in other people's homes, and finally, having a child removed from the home against the parents' wishes.

During therapy with this family, the nurse discussed the behaviors associated with various developmental levels. She also discussed possible deviations from these norms and when they should be reported to the physician. The nurse and the family discussed Tanya's behavior and how it compared with the norms.

The parents also discussed their own childhoods. They were able to relate some of the same types of behaviors that they observed in Tanya, but they both admitted that they came from families whose main method of discipline was physical punishment. Annette had been the oldest child in her large family and had been expected to "keep the younger ones in line." When she had not done so, she was punished with her father's belt. She expressed anger toward her father, although she had never been allowed to express it at the time.

Paulo's father had died when he was a small boy, and Paulo had been expected to be the "man of the family." From the time he was very young, he worked at odd jobs to bring money into the home. Consequently, he had little time for the usual activities of childhood and adolescence. He held much resentment toward the young men who "had everything and never had to work for it."

Paulo and Annette had high expectations for Tanya. In effect, they expected her to behave in a manner well beyond her developmental level. These expectations were based on the reflections of their own childhoods. They were uncomfortable with the spontaneity and playfulness of childhood because they had had little personal experience with these behaviors. When Tanya balked and expressed the verbal assertions common to early childhood, Paulo and Annette interpreted these behaviors as defiance toward them and retaliated with anger in the manner in which they had been parented.

With the parents, the nurse explored feelings and behaviors from their past so that they were able to understand the correlation to their current behaviors. They learned to negotiate ways to deal with Tanya's age-appropriate behaviors. In combined therapy with Tanya, they learned how to relate to her childishness and even how to enjoy playing with both of their children.

The parents ceased blaming each other for the family's problems. Annette had spent a good deal of her time deprecating Paulo for his lack of support of his family, and Paulo blamed Annette for being "unable to control her daughter." Communication patterns were clarified, and life in the family became more peaceful.

Without a need to "prove himself" to his wife, Paulo's efforts to find employment met with success because he no longer felt the need to turn down jobs that he believed his wife would perceive to be beneath his capabilities. Annette no longer works outside the home, and both she and Paulo participate in the parenting chores. Tanya and her siblings continue to demonstrate age-appropriate developmental progression.

interfering with major life activities (National Institute of Mental Health [NIMH], 2015). These disorders are identified by criteria listed in the *DSM-5*. Diagnoses may include schizophrenia and related disorders, bipolar disorder, autism spectrum disorders, major depressive disorder, panic disorder, obsessive-compulsive disorder, posttraumatic stress disorder, borderline personality disorder, and attention-deficit/hyperactivity disorder. Based on 2014 statistics, severe mental illness affects about 4.2 percent of the population residing in communities in the United States (NIMH, 2015). The actual number may be significantly higher, since this research did not attempt to include the homeless or those who were in correctional facilities for the entire year.

Historical and Epidemiological Aspects

In 1955, more than half a million individuals resided in public mental hospitals, compared to fewer than 100,000 based on today's estimates.

Deinstitutionalization of persons with serious mental illness began in the 1960s as national policy change based on a strong belief in the individual's right to freedom. Other considerations included the deplorable conditions of some of the state asylums, the introduction of psychotropic medications, and the cost-effectiveness of caring for these individuals in the community setting.

Deinstitutionalization began to occur rapidly and without sufficient planning for the needs of these individuals as they reentered the community. Those who were fortunate enough to have support systems to provide assistance with living arrangements and sheltered employment experiences most often received the outpatient treatment they required. Those without adequate support, however, either managed to survive on a meager income or were forced to join the ranks of the homeless. Some ended up in nursing homes meant to provide care for individuals with physical disabilities.

Certain segments of our population with severe and persistent mental illness have been left untreated: the elderly, the working poor, the homeless, and those individuals previously covered by funds cut by various social reforms. These circumstances have promoted a greater number of crisis-oriented emergency department visits and hospital admissions for individuals with severe and persistent mental illness, as well as frequent confrontations with law enforcement officials.

In 2002, President George W. Bush established the New Freedom Commission on Mental Health, charged with conducting a comprehensive study of the United States mental health service delivery system. They were to identify unmet needs and barriers to services and recommend steps for improvement in services and support for individuals with serious mental illness. In July 2003, the commission presented its final report to the President (President's New Freedom Commission on Mental Health, 2003). The Commission identified the following five barriers:

1. **Fragmentation and gaps in care for children:** About 7 to 9 percent of all children (aged 9 to 17) have a serious emotional disturbance (SED). The Commission found that services for children are even more fragmented than those for adults, with more uncoordinated funding and differing eligibility requirements. Only a fraction of children with SED appear to have access to school-based or school-linked mental health services. Children with SED who are identified for special education services have higher levels of absenteeism, higher drop-out rates, and lower levels of academic achievement than students with other disabilities.

2. **Fragmentation and gaps in care for adults with serious mental illness:** The commission expressed concern that so many adults with serious mental illness are homeless, dependent on alcohol or drugs, unemployed, and untreated. According to the World Health Organization (WHO), mental and behavioral disorders account for 13.6 percent of the total Disability Adjusted Life Years (DALYs) lost due to all disease and injuries in the United States, with the majority of those being associated with major depressive disorder (US Burden of Disease Collaborators, 2013). The Commission identified public attitudes and the stigma associated with mental illness as major barriers to treatment. Stigma is often internalized by individuals with mental illness, leading to hopelessness, lower self-esteem, and isolation. Stigma deprives these individuals of the support they need to recover.

3. **High unemployment and disability for people with serious mental illness:** Undetected, untreated, and poorly treated mental disorders interrupt careers, leading many individuals into lives of disability, poverty, and long-term dependence. The Commission found a 90 percent unemployment rate among adults with serious mental illness—the worst level of employment of any group of people with disabilities. Some surveys have shown that many individuals with serious mental illness *want* to work and could do so with modest assistance. However, the largest "program" of assistance the United States has for people with mental illness is disability payments. Sadly, societal stigma is also reflected in employment discrimination against people with mental illness.

4. **Older adults with mental illnesses are not receiving care:** The Commission reported that about 5 to

10 percent of older adults have major depression, yet most cases are not properly recognized and treated. The report stated:

Older people are reluctant to get care from specialists. They feel more comfortable going to their primary care physician. Still, they are often more sensitive to the stigma of mental illness, and do not readily bring up their sadness and despair. If they acknowledge problems, they are more likely than young people to describe physical symptoms. Primary care doctors may see their suffering as "natural" aging, or treat their reported physical distress instead of the underlying mental disorder. What is often missed is the deep impact of depression on older people's capacity to function in ways that are seemingly effortless for others.

5. **Mental health and suicide prevention are not yet national priorities:** The failure of the United States to prioritize mental health puts many lives at stake. Families struggle to maintain equilibrium while communities strain (and often fail) to provide needed assistance for adults and children who suffer from mental illness. Over 30,000 lives are lost annually to suicide. About 90 percent of those who take their life have a mental disorder. Many individuals who die by suicide have not had care that would help them to affirm life in the months before their deaths. Both the American Psychiatric Association and the National Mental Health Association called on the U.S. Congress to pass parity legislation. In 2008, a federal law known as the Paul Wellstone and Pete Domenici Mental Health Parity and Addiction Equity Act was enacted that generally prevents group health plans and health insurance issuers that provide mental health or substance use disorder benefits from imposing less favorable benefit limitations on those benefits than on medical/surgical benefits. In 2010, the Affordable Care Act amended this legislation to include individual insurance plans, and in 2014, a final regulation clarified and expanded the parity law (Centers for Medicare and Medicaid Services [CMS], 2015a). Many recent national initiatives since the Commission's report have attempted to bridge the gaps, particularly with efforts to address the national suicide rates and the opiate overdose epidemic.

The Commission outlined the following goals and recommendations for mental health reform:

Goal 1. Americans will understand that mental health is essential to overall health.

Commission recommendations:

■ Advance and implement a national campaign to reduce the stigma of seeking care and a national strategy for suicide prevention.

■ Address mental health with the same urgency as physical health.

Goal 2. Mental health care will be consumer and family driven.

Commission recommendations:

■ Develop an individualized plan of care for every adult with a serious mental illness and child with a serious emotional disturbance.

■ Involve consumers and families fully in orienting the mental health system toward recovery.

■ Align relevant federal programs to improve access and accountability for mental health services.

■ Create a comprehensive state mental health plan.

■ Protect and enhance the rights of people with mental illness.

Goal 3. Disparities in mental health services will be eliminated.

Commission recommendations:

■ Improve access to quality care that is culturally competent.

■ Improve access to quality care in rural and geographically remote areas.

Goal 4. Early mental health screening, assessment, and referral to services will be common practice.

Commission recommendations:

■ Promote the mental health of young children.

■ Improve and expand school mental health programs.

■ Screen for co-occurring mental and substance use disorders and link with integrated treatment strategies.

■ Screen for mental disorders in primary health care across the life span and connect to treatment and supports.

Goal 5. Excellent mental health care will be delivered and research will be accelerated.

Commission recommendations:

■ Accelerate research to promote recovery and resilience, and ultimately to cure and prevent mental illnesses.

■ Advance evidence-based practices using dissemination and demonstration projects, and create a public-private partnership to guide their implementation.

■ Improve and expand the workforce providing evidence-based mental health services and supports.

■ Develop the knowledge base in four understudied areas: mental health disparities, long-term effects of medications, trauma, and acute care.

Goal 6. Technology will be used to access mental health care and information.

Commission recommendations:

■ Use health technology and telehealth to improve access and coordination of mental health care, especially for Americans in remote areas or in underserved populations.
■ Develop and implement integrated electronic health record and personal health information systems.

The Substance Abuse and Mental Health Services Administration (SAMHSA), in collaboration with a number of other federal agencies, currently identifies about 390 federal action agenda initiatives to address mental health issues for specific, underserved populations, suicide prevention, and a host of other community and public health concerns (SAMHSA, 2017). Most recently, the surgeon general released a landmark report in 2016 identifying substance abuse as a national health priority in response to the rising death toll from opiate overdoses.

Many nurse leaders see this period of health-care reform as an opportunity for nurses to expand their roles and assume key positions in education, prevention, assessment, and referral. Nurses are, and will continue to be, in key positions to help individuals with severe and persistent mental illness remain as independent as possible, manage their illnesses within the community setting, and minimize the number of hospitalizations required.

Treatment Alternatives

In the current *Scope and Standards of Practice: Psychiatric Mental Health Nursing* (American Nurses Association, American Psychiatric Nurses Association, & International Society of Psychiatric-Mental Health Nurses, 2014), community-based care is identified as within the scope of practice for psychiatric-mental health registered nurses. It defines community-based care as potentially including "care delivered in partnership with health care consumers in their homes, worksites, mental health clinics and programs, health maintenance organizations, shelters and clinics for the homeless, crisis centers, senior centers, group homes, and other community settings" (p. 24). It is clear that psychiatric nurses can and should play an active role in mental health care in the community.

Community Mental Health Centers   The goal of community mental health centers in caring for individuals with severe and persistent mental illness is to improve coping ability and prevent exacerbation of acute symptoms. A major obstacle in meeting this goal has been the lack of advocacy or sponsorship for clients who require services from a variety of sources. This has placed responsibility for health care on individuals with mental illness who are often unable to cope with everyday life.

Case management (which was discussed in Chapter 9, The Nursing Process in Psychiatric-Mental Health Nursing, of this text) has become a recommended method of treatment for individuals with severe and persistent mental illness. Ling and Ruscin (2013) state:

> Nurses may be uniquely qualified to be case managers because of their holistic and broad-based background, understanding of health care, and role in patient education and referrals. Case management is an area of practice that offers nurses an opportunity to build on their clinical knowledge, communication, and nursing process skills to function in an expanded patient care role.

Ling and Ruscin (2013) identify six essential activities and nursing role functions that blend with the steps of the nursing process to form a framework for nursing case management:

1. **Assessment:** During the assessment process, the nurse gathers pertinent information about a client's situation and ability to function. Information may be obtained through physical examination, client interview, medical records, and reports from significant others. Ling and Ruscin state, "The case manager's goal is to obtain accurate information about the patient's status and identify factors that may significantly affect the patient's recovery and care."
2. **Planning:** A service care plan is devised with client participation. The plan should include mutually agreed-on goals, specific actions directed toward goal achievement, and selection of essential resources and services through collaboration among health-care professionals, the client, and the family or significant others.
3. **Implementation:** In this phase, the client receives the needed services from the appropriate providers. In some instances, the nursing **case manager** is also a provider of care, while in others, he or she is only the coordinator of care.
4. **Coordination:** The case manager organizes, secures, integrates, and modifies the resources necessary to accomplish the case management goals (Case Management Society of America [CMSA], 2016). This coordination effort involves the client, the physician, any other pertinent health-care providers, and family members or significant others concerned with the client's care. The case manager ensures that all tests and treatments are conducted according to schedule and maintains close communication with all health-care providers to ensure that client care is proceeding according to the plan.
5. **Monitoring:** The case manager monitors the effectiveness of the care plan by gathering pertinent information from various sources at regular intervals to determine the client's response and progress (CMSA, 2016). If problems are identified, immediate adjustments are made.

6. **Evaluation:** The case manager evaluates the client's responses to interventions and progress toward preestablished goals. Regular contact is maintained with client, family or significant others, and direct service providers. Ongoing coordination of care continues until outcomes have been achieved. If the expected outcomes are not achieved, the case manager reevaluates the plan to determine the reason and takes steps to intervene and modify the existing plan.

A case study of nursing case management within a community mental health center is presented in Box 36–2.

Assertive Community Treatment (ACT) The National Alliance on Mental Illness (NAMI, 2016) defines ACT as:

> a team-based treatment model that provides multidisciplinary, flexible treatment and support to people with mental illness 24/7. ACT is based around the idea that people receive better care when their mental health care providers work together. ACT team members help the person address every aspect of their life, whether it be medication, therapy, social support, employment or housing.

This approach includes members from psychiatry, social work, nursing, and substance abuse and vocational rehabilitation. The ACT team provides these services 24 hours a day, 7 days a week, 365 days a year.

The ACT team provides treatment, rehabilitation, and support services to individuals with severe and persistent mental illness who are unable to receive treatment from a traditional model of case management. The team is usually able to provide most services with minimal referrals to other mental health programs or providers. Services are provided within community settings, such as a person's home, local restaurants, parks, nearby stores, and anywhere else the individual requires assistance with living skills. NAMI (2016) reports, "Studies have shown that ACT is more effective than traditional treatment for people experiencing mental illnesses such as schizophrenia and schizoaffective disorder and can reduce hospitalizations by 20%."

BOX 36–2 Nursing Case Management in the Community Mental Health Center: A Case Study

William is a 63-year-old man with chronic schizophrenia who came into the community mental health center upon the recommendation of a local church where he sometimes attends their meal program. The nurse begins a comprehensive assessment and assures William that she wants to collaborate with him to identify how to best meet his needs. She assesses his basic physical health, management of daily living, family involvement, work history, involvement with any other social agencies, finances, medications, and other concerns identified by William.

She determines that William has not been taking antipsychotic medication for at least 3 months. Prior to that, he had been living in a house with several other individuals, most of whom were abusing substances. They were helping him access medications from a community medication program but were often taking or reselling most of his prescription. When the house was raided by police, William became homeless. He is currently disorganized in his thinking and actively hallucinating.

He expresses desire to take medication but feels that finding a place to live is his most important priority. There is no family involvement, and William is unable to identify any support systems.

The nurse contacts the social worker for assistance with housing options and social resources such as food stamps, and contacts the physician to schedule an appointment for medication evaluation.

The nurse recommends that William attend the partial hospitalization program offered at the community mental health center, and he agrees but says he does not have transportation. The local church has offered to help William in any way they can, so the nurse contacts them and asks about their availability to provide transportation. The church informs her that they can provide transportation on Tuesdays and Thursdays.

During the assessment, William identified that sometimes the "people start fighting" in his mind and when he starts to scream back someone nearby always calls the police because they "don't get that I'm just trying to defend myself."

The nurse then engages a peer support specialist who introduces William to Alfonzo, a 65-year-old man with chronic schizophrenia who is willing to provide support to William regarding symptom management. Alfonzo is also willing to provide transportation to the partial hospitalization program on the days when the church resources are not available.

The nurse notices that William has some open sores on his feet. She cleans and bandages his feet, orders bloodwork to assess for infection, and accesses socks and footwear from the clothes bank offered through the Salvation Army.

She continues to meet regularly with William once a month on a day that he attends PHP and administers the Prolixin injection ordered by the physician. During her reassessment, William identifies that he has been "hanging out" with Alfonzo and states "he really understands me." He expresses still hearing people fight sometimes in his head but is not as bothered by them. The social worker has facilitated group home placement, which is not available for another 3 months, but in the meantime the local homeless shelter has arranged for William to stay there. The local church has offered William a small stipend to help with stuffing envelopes, and when the nurse asks him how that job is going, William says, "They are nice people at the church, and they say I really help them, too."

Partial Hospitalization Programs Partial hospitalization programs, also called day or evening treatment programs, are designed to prevent institutionalization or to ease the transition from inpatient hospitalization to community living. Various types of treatment are offered. Many include therapeutic community (milieu) activities; individual, group, and family therapies; psychoeducation; alcohol and drug education; crisis intervention; therapeutic recreational activities; and occupational therapy. Many programs offer medication administration and monitoring as part of their care. Some programs have established medication clinics for individuals on long-term psychopharmacological therapy. These clinics may include educational classes and support groups for individuals with similar conditions and treatments.

Partial hospitalization programs generally offer a comprehensive treatment plan formulated by an interdisciplinary team of psychiatrists, psychologists, nurses, occupational and recreational therapists, and social workers. Nurses take a leading role in the administration of partial hospitalization programs. They lead groups, provide crisis intervention, conduct individual counseling, act as role models, and make necessary referrals for specialized treatment. Use of the nursing process provides continual evaluation of the program, and modifications can be made as necessary.

Partial hospitalization programs are an effective method of preventing hospitalization for many individuals with severe and persistent mental illness. They are a way of transitioning these individuals from the acute care setting back into the mainstream community. For some individuals who have been deinstitutionalized, they provide structure, support, opportunities for socialization, and an improvement in their overall quality of life.

Community Residential Facilities Community residential facilities for persons with severe and persistent mental illness are known by many names: group homes, halfway houses, foster homes, boarding homes, sheltered care facilities, transitional housing, independent living programs, social rehabilitation residences, and others. These facilities differ by the purpose for which they exist and the activities that they offer.

Some of these facilities provide food, shelter, housekeeping, and minimal supervision and assistance with activities of daily living. Others may also include a variety of therapies and serve as a transition between hospital and independent living. In addition to the basics, services might include individual and group counseling, medical care, job training or employment assistance, and leisure-time activities.

The concept of transitional housing for individuals with serious mental illness is sound and has often been a successful means of therapeutic support and intervention for maintaining them within the community. However, without guidance and planning, transition to the community can be futile. These individuals may be ridiculed and rejected by the community or be targets of unscrupulous individuals who take advantage of their inability to care for themselves. These occurrences may increase maladaptive responses to the demands of community living and exacerbate the mental illness. Some facilities have live-in professionals who are available at all times, some have professional staff who are on call for intervention during crisis situations, and some are staffed by volunteers and individuals with little knowledge or background for understanding and treating persons with severe and persistent mental illness. A period of structured reorientation to the community in a supervised living situation monitored by professionals is more likely to result in a successful transition for the individual with severe and persistent mental illness.

Psychiatric Home Health Care For the individual with serious mental illness who no longer lives in a structured, supervised setting, home health care may help him or her maintain independent living. To receive home health care, individuals must validate their homebound status for the prospective payer (Medicare, Medicaid, most insurance companies, and Department of Veterans Affairs [VA] benefits). An acute psychiatric diagnosis is not sufficient to qualify for the service. The client must show that he or she is unable to leave the home without considerable difficulty or the assistance of another person. The plan of treatment and subsequent charting must explain why the client's psychiatric disorder keeps him or her at home and justify the need for home services.

Homebound clients most often have a diagnosis of depressive disorder, neurocognitive disorder, anxiety disorder, bipolar disorder, or schizophrenia. Many elderly clients are homebound because of medical conditions that impair mobility and necessitate home care.

Nurses who provide psychiatric home care must have an in-depth knowledge of psychopathology, psychopharmacology, and how medical and physical problems can be influenced by psychiatric impairments. These nurses must be highly adept at performing biopsychosocial assessments. They must be sensitive to changes in behavior that signal that the client is decompensating psychiatrically or medically so that early intervention may be implemented.

Another important job of the psychiatric home health nurse is monitoring the client's adherence to the regimen of psychotropic medications. Some clients receiving injectable medications remain on home health care only until they can be placed on

oral medications. Those clients receiving oral medications require close monitoring for adherence and assistance with the uncomfortable side effects of some of these drugs. Lack of adherence to the medication regimen is responsible for approximately two-thirds of psychiatric hospital readmissions. Home health nurses can assist clients with this problem by helping them see the relationship between control of their psychiatric symptoms and adherence to their medication regimen.

Client populations that benefit from psychiatric home health nursing include:

■ **Elderly clients:** These individuals do not necessarily have a psychiatric diagnosis but may be experiencing emotional difficulties caused by medical, sociocultural, or developmental factors. Depressed mood and social isolation are common.

■ **Persons with severe and persistent mental illness:** These individuals have a history of psychiatric illness and hospitalization. They require long-term medications and continual supportive care. Common diagnoses include recurrent major depressive disorder, schizophrenia, and bipolar disorder.

■ **Individuals in acute crisis situations:** These individuals are in need of crisis intervention and/or short-term psychotherapy.

Medicare requires that psychiatric home nursing care be provided by "psychiatrically trained nurses," which CMS defines as "nurses who have special training and/or experience beyond the standard curriculum required for a registered nurse" (CMS, 2015b). The guidelines that cover psychiatric nursing services are not well defined by the CMS. This has presented reimbursement problems for psychiatric nurses in the past. The CMS statement regarding psychiatric nursing services is presented in Box 36–3.

BOX 36–3 CMS Guidelines for Psychiatric Home Nursing Care

PSYCHIATRIC EVALUATION, THERAPY, AND TEACHING

The evaluation, psychotherapy, and teaching needed by a patient suffering from a diagnosed psychiatric disorder that requires active treatment by a psychiatrically trained nurse and the costs of the psychiatric nurse's services may be covered as a skilled nursing service. Psychiatrically trained nurses are nurses who have special training and/or experience beyond the standard curriculum required for a registered nurse. The services of the psychiatric nurse are to be provided under a plan of care established and reviewed by a physician.

From Centers for Medicare & Medicaid Services. (2015b). Medicare Benefit Policy Manual. *Baltimore, MD: Author.*

Preparation for psychiatric home health nursing, in addition to the registered nurse licensure, should include several years of psychiatric inpatient treatment experience. It is also recommended that the nurse have medical-surgical nursing experience, because of common client physical comorbidity and the holistic nursing perspective. Additional training and experience in psychotherapy is viewed as an asset. However, psychotherapy is not the primary focus of psychiatric home nursing care. In fact, most reimbursement sources do not pay for exclusively insight-oriented therapy. Crisis intervention, client education, and hands-on care are common interventions in psychiatric home nursing care.

The psychiatric home health nurse provides comprehensive nursing care, incorporating interventions for physical and psychosocial problems into the treatment plan. The interventions are based on the client's mental and physical health status, cultural influences, and available resources. The nurse is accountable to the client at all times during the therapeutic relationship. Nursing interventions are carried out with appropriate knowledge and skill, and referrals are made when the need is outside the scope of nursing practice. Continued collaboration with other members of the health-care team (e.g., psychiatrist, social worker, psychologist, occupational therapist, and/or physical therapist) is essential for maintaining continuity of care.

A case study of psychiatric home health care and the nursing process is presented in Box 36–4. A plan of care for Mrs. C. (the client in the case study) is presented in Table 36–2. Nursing diagnoses are presented, along with outcome criteria, appropriate nursing interventions, and rationale for each.

Care for the Caregivers Psychiatric home health care also provides support and assistance to primary caregivers. When family is the provider of care on a 24/7 schedule for a loved one with a severe and persistent mental disorder, it can be very exhausting and very frustrating. A care plan for primary caregivers is presented in Table 36–3.

The Homeless Population

Historical and Epidemiological Aspects

In 1993, Dr. Richard Lamb, a recognized expert in the field of severe and persistent mental illness, wrote:

Alec Guinness, in his memorable role as a British Army colonel in *Bridge on the River Kwai,* exclaims at the end of the film when he finally realizes he has been working to help the enemy, "What have I done?" As a vocal advocate and spokesman for deinstitutionalization and community treatment of severely mentally ill patients for well over two decades, I often find myself asking that same question. (p. 1209)

BOX 36–4 Psychiatric Home Health Care and the Nursing Process: A Case Study

ASSESSMENT

Mrs. C., age 76, has been living alone in her small apartment for 6 months since the death of her husband, to whom she had been married for 51 years. Mrs. C. was an elementary school teacher for 40 years, retiring at age 65 with an adequate pension. She and her husband had no children. A niece looks in on Mrs. C. regularly. It was she who contacted Mrs. C.'s physician when she observed that Mrs. C. was not eating properly, was losing weight, and seemed to be isolating herself more and more. She had not left her apartment in weeks. Her physician referred her to psychiatric home health care.

On her initial visit, Carol, the psychiatric home health nurse, conducted a preliminary assessment revealing the following information about Mrs. C.:

1. Blood pressure 90/60 mm Hg
2. Height 5'5"; weight 102 lb
3. Poor skin turgor; dehydration
4. Subjective report of occasional dizziness
5. Subjective report of loss of 20 pounds since the death of her husband
6. Oriented to time, place, person, and situation
7. Memory (remote and recent) intact
8. Flat affect
9. Mood is dysphoric and tearful at times, but client is cooperative
10. Denies thoughts to harm self, but states, "I feel so alone; so useless"
11. Subjective report of difficulty sleeping
12. Subjective report of constipation

DIAGNOSIS AND OUTCOME IDENTIFICATION

The following nursing diagnoses were formulated for Mrs. C.:

1. Complicated grieving related to death of husband evidenced by symptoms of depression such as withdrawal, anorexia, weight loss, difficulty sleeping, dysphoric/tearful mood
2. Risk for injury related to dizziness and weakness from lack of activity, low blood pressure, and poor nutritional status
3. Social isolation related to depressed mood and feelings of worthlessness, evidenced by staying home alone, refusing to leave her apartment

OUTCOME CRITERIA

The following criteria were selected as measurement of outcomes in the care of Mrs. C.:

1. Experiences no physical harm/injury
2. Is able to discuss feelings about husband's death with nurse

3. Sets realistic goals for self
4. Is able to participate in problem solving regarding her future
5. Eats a well-balanced diet with snacks to restore nutritional status and gain weight
6. Drinks adequate fluid daily
7. Sleeps at least 6 hours per night and verbalizes feeling well rested
8. Shows interest in personal appearance and hygiene, and is able to accomplish self-care independently
9. Seeks to renew contact with previous friends and acquaintances
10. Verbalizes interest in participating in social activities

PLANNING AND IMPLEMENTATION

A plan of care for Mrs. C. is presented in Table 36–2.

Evaluation

Mrs. C. started the second week taking trazodone (Desyrel) 150 mg at bedtime. Her sleep was enhanced, and within 2 weeks she showed a noticeable improvement in mood. She began to discuss how angry she felt about being all alone in the world. She admitted that she had felt anger toward her husband but experienced guilt and tried to suppress that anger. As she was assured that these feelings were normal, they became easier for her to express.

The nurse arranged for a local teenager to do some weekly grocery shopping for Mrs. C. and contacted the local Meals on Wheels program, which delivered her noon meal to her every day. Mrs. C. began to eat more and slowly gained a few pounds. She still has an occasional problem with constipation but verbalizes improvement with the addition of vegetables, fruit, and a daily stool softener prescribed by her physician.

Mrs. C. used her walker until she felt she was able to ambulate without assistance. She reports that she no longer experiences dizziness, and her blood pressure has stabilized at around 100/70 mm Hg.

Mrs. C. has joined a senior citizens group and attends activities weekly. She has renewed previous friendships and formed new acquaintances. She sees her physician monthly for medication management and visits a local adult day health center for regular blood pressure and weight checks. Her niece still visits regularly, but her favorite relationship is the one she has formed with her constant canine companion, Molly, whom Mrs. C. rescued from the local animal shelter and who continually demonstrates her unconditional love and gratitude.

The number of homeless individuals in the United States has been estimated at over 3.5 million (National Coalition for the Homeless [NCH], 2014). It is difficult to determine the true scope of the problem because even the statisticians who collect the data have difficulty defining homeless persons. They have sometimes been identified as "those people who sleep in shelters or public spaces." This approach results in underestimates because available shelter services are insufficient to meet the numbers of homeless people (U.S. Conference of Mayors [USCM], 2014).

According to the Stewart B. McKinney Act, a person is considered homeless who:

lacks a fixed, regular, and adequate night-time residence; and . . . has a primary night-time residency that is: (A) a supervised publicly or privately operated

Table 36–2 | CARE PLAN FOR PSYCHIATRIC HOME HEALTH CARE OF DEPRESSED ELDERLY (MRS. C.)

NURSING DIAGNOSIS: COMPLICATED GRIEVING

RELATED TO: Death of husband

EVIDENCED BY: Symptoms of depression such as withdrawal, anorexia, weight loss, difficulty sleeping, and dysphoric/tearful mood

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Mrs. C. discusses any angry feelings she has about the loss of her husband. **Long-Term Goal:** • Mrs. C. demonstrates adaptive grieving behaviors and evidence of progression toward resolution.	1. Assess Mrs. C.'s position in the grief process. 2. Develop a trusting relationship by showing empathy and caring. Be honest and keep all promises. Show genuine positive regard. 3. Explore feelings of anger and help Mrs. C. direct them toward the source. Help her understand it is appropriate and acceptable to have feelings of anger and guilt about her husband's death. 4. Encourage Mrs. C. to review honestly the relationship she had with her husband. With support and sensitivity, point out reality of the situation in areas where misrepresentations may be expressed. 5. Determine if Mrs. C. has spiritual needs that are going unfulfilled. If so, contact spiritual leader for intervention with Mrs. C. 6. Refer Mrs. C. to physician for medication evaluation.	1. Accurate baseline data are required to plan accurate care for Mrs. C. 2. These interventions provide the basis for a therapeutic relationship. 3. Knowledge of acceptability of the feelings associated with normal grieving may help to relieve some of the guilt that these responses generate. 4. Mrs. C. must give up an idealized perception of her husband. Only when she is able to see both positive and negative aspects about the relationship will the grieving process be complete. 5. Recovery may be blocked if spiritual distress is present and care is not provided. 6. Antidepressant therapy may help Mrs. C. to function while confronting the dynamics of her depression.

NURSING DIAGNOSIS: RISK FOR INJURY

RELATED TO: Dizziness and weakness from lack of activity, low blood pressure, and poor nutritional status

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals: • Mrs. C. uses walker when ambulating. • Mrs. C. does not experience physical harm or injury. **Long-Term Goal:** • Mrs. C. does not experience physical harm or injury.	1. Assess vital signs at every visit. Report to physician should they fall below baseline. 2. Encourage Mrs. C. to use walker until strength has returned. 3. Visit Mrs. C. during mealtimes and sit with her while she eats. Encourage her niece to do the same. Ensure that easy to prepare, nutritious foods for meals and snacks are available in the house and that they are items that Mrs. C. likes.	1. Client safety is a nursing priority. 2. The walker will help prevent Mrs. C. from falling. 3. She is more likely to eat what is convenient and what she enjoys.

Table 36–2 | CARE PLAN FOR PSYCHIATRIC HOME HEALTH CARE OF DEPRESSED ELDERLY (MRS. C.)–cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	4. Contact local meal delivery service (e.g., Meals on Wheels) to deliver some of Mrs. C.'s meals.	4. This ensures that she receives at least one complete and nutritious meal each day.
	5. Weigh Mrs. C. each week.	5. Weight gain is a measurable, objective means of assessing whether Mrs. C. is eating.
	6. Ensure that diet contains sufficient fluid and fiber.	6. Adequate dietary fluid and fiber will help to alleviate constipation. She may also benefit from a daily stool softener.

NURSING DIAGNOSIS: SOCIAL ISOLATION

RELATED TO: Depressed mood and feelings of worthlessness

EVIDENCED BY: Staying home alone, refusing to leave apartment

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Mrs. C. discusses with nurse feelings about past social relationships and those she may like to renew. Long-Term Goal: • Mrs. C. renews contact with friends and participates in social activities.	1. As nutritional status is improving and strength is gained, encourage Mrs. C. to become more active. Take walks with her; help her perform simple tasks around her house.	1. Increased activity enhances both physical and mental status.
	2. Assess lifelong patterns of relationships.	2. Basic personality characteristics will not change. Mrs. C. will very likely keep the same style of relationship development that she had in the past.
	3. Help her identify present relationships that are satisfying and activities that she considers interesting.	3. She is the person who truly knows what she likes, and these personal preferences will facilitate success in reversing social isolation.
	4. Consider the feasibility of a pet.	4. There are many documented studies of the benefits to elderly individuals of companion pets.
	5. Suggest possible alternatives that Mrs. C. may consider as she seeks to participate in social activities. These may include foster grandparent programs, senior citizens centers, church activities, craft groups, and volunteer activities. Help her to locate individuals with whom she may attend some of these activities.	5. She is more likely to attend and participate if she does not have to do so alone.

Table 36–3 | CARE PLAN FOR PRIMARY CAREGIVER OF CLIENT WITH SEVERE AND PERSISTENT MENTAL ILLNESS

NURSING DIAGNOSIS: CAREGIVER ROLE STRAIN

RELATED TO: Severity and duration of the care receiver's illness and lack of respite and recreation for the caregiver

EVIDENCED BY: Feelings of stress in relationship with care receiver, feelings of depression and anger, family conflict around issues of providing care

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Caregivers verbalize understanding of ways to facilitate the caregiver role. Long-Term Goal: • Caregivers demonstrate effective problem-solving skills and develop adaptive coping mechanisms to regain equilibrium.	1. Assess caregivers' abilities to anticipate and fulfill client's unmet needs. Provide information to assist caregivers with this responsibility. Ensure that caregivers encourage client to be as independent as possible.	1. Caregivers may be unaware of what the client can realistically accomplish. They may be unaware of the nature of the illness.
	2. Ensure that caregivers are aware of available community support systems from which they may seek assistance when required. Examples include respite care services, day treatment centers, and adult day-care centers.	2. Caregivers require relief from the pressures and strain of providing 24-hour care for their loved one. Studies have shown that abuse arises out of caregiving situations that place overwhelming stress on the caregivers.
	3. Encourage caregivers to express feelings, particularly anger.	3. Release of these emotions can serve to prevent psychopathology, such as depression or psychophysiological disorders, from occurring.
	4. Encourage participation in support groups comprised of members with similar life situations. Provide information about support groups that may be helpful: a. National Alliance on Mental Illness (NAMI) (800) 950-NAMI b. American Association on Intellectual and Developmental Disabilities (AAIDD) (800) 424-3688 c. Alzheimer's Association (800) 272-3900	4. Hearing others who are experiencing the same problems discuss ways in which they have coped may help caregiver adopt more adaptive strategies. Individuals who are experiencing similar life situations provide empathy and support for each other.

shelter designed to provide temporary living accommodations, (B) an institution that provides a temporary residence for individuals intended to be institutionalized, or (C) a public or private place not designed for, or ordinarily used as, a regular sleeping accommodation for human beings. (NCH, 2009)

The National Alliance to End Homelessness (2015) reports that in ongoing recovery from the recession, the homeless population decreased in 2014 by 2.3 percent. However, statistics are not reported for the subpopulation of those with severe mental illness. Federal and state assistance programs may be responsible for some of this decrease. Efforts to meet the needs of this population continue. In October 2016, amendments to the McKinney-Vento Act went into effect that include provisions for homeless children

and young adults to receive adequate and accessible education.

Mental Illness and Homelessness

The prevalence of severe mental illness among the homeless population is difficult to clarify. SAMHSA (2016) provides the following demographics through statistics gathered from Projects for Assistance in Transition from Homelessness, (PATH), which is specifically established for funding services to people with severe mental illness (SMI). Thus, these statistics are based on the makeup of PATH clients:

Age Thirty-nine percent of clients with SMI are younger than age 30; individuals between the ages of 31 and 61 make up the bulk of this population at 70 percent; about 5 percent are older than age 61.

Gender Fifty-nine percent of homeless individuals are male, and 41 percent are female.

Ethnicity The homeless SMI population is estimated to be 57 percent Caucasian, 34 percent African American, 13 percent Hispanic, 3 percent of other single races/ethnic groups, and 5 percent of multiple races (SAMHSA, 2016). The ethnic makeup of homeless populations varies according to geographic location.

The USCM (2014) survey revealed that approximately 28 percent of the homeless population suffers from some form of mental illness. Who are these individuals, and why are they homeless? Some blame the deinstitutionalization movement. Persons with mental illness who were released from state and county mental hospitals and did not have families with whom they could reside sought residence in board-and-care homes of varying quality. Halfway houses and supportive group living arrangements were helpful but scarce. Many of those with families returned to their homes, but because families received little if any instruction or support, the environment was frequently turbulent, and individuals with mental illness often went on to leave these homes.

Types of Mental Illness Among the Homeless A number of studies have been conducted, primarily in large urban areas, that have addressed the most common types of mental illness among homeless individuals. Schizophrenia is frequently described as the most common diagnosis. Other prevalent disorders include bipolar disorder, substance addiction, depression, personality disorders, and neurocognitive disorders. Many exhibit psychotic symptoms, many are former residents of long-term care institutions for the mentally ill, and many have such a strong desire for independence that they isolate themselves in an effort to avoid identification by the mental health system. Many are clearly a danger to themselves or others, yet they often do not even see themselves as ill. SAMHSA (2016) identifies that in 2015, 53 percent of clients receiving PATH services had a co-occurring substance use disorder.

Contributing Factors to Homelessness Among Individuals With Mental Illness

Deinstitutionalization As previously stated, deinstitutionalization is frequently implicated as a contributing factor to homelessness among individuals with mental illness. Deinstitutionalization began out of expressed concern by mental health professionals and others who described the "deplorable conditions" under which mentally ill individuals were housed.

The advent of psychotropic medications and the community mental health movement began a growing philosophical view that individuals with mental illness receive better and more humanitarian treatment in the community than in state hospitals far removed from their homes. It was believed that commitment and institutionalization in many ways deprived these individuals of their civil rights. Not the least of the motivating factors for deinstitutionalization was the financial burden these clients placed on state governments.

While the deinstitutionalization movement has prompted an expansion of community mental health resources, the number of people with mental illness incarcerated in correctional facilities has skyrocketed and is now estimated to be two to four times that of the general population (National Institute of Corrections, 2016). Supporters of the community mental health movement have argued that ongoing problems for those with severe mental illness are related to lack of compliance with medications, but critics have argued that the community mental health model is too narrowly focused on a biomedical approach and needs to revise and expand its services to meet the complex needs of this population going forward.

Deinstitutionalization has been criticized for contributing to both homelessness rates and criminalization of people with mental illnesses, but several other factors have been implicated as well.

Poverty Cuts in various government entitlement programs have depleted the allotments available for individuals with severe and persistent mental illness living in the community. The job market is prohibitive for individuals whose behavior is incomprehensible or even frightening to many. The stigma and discrimination associated with mental illness may be diminishing slowly but remains highly visible to those who suffer from its effects.

Scarcity of Affordable Housing Not only is there a scarcity of affordable housing but the number of single-room-occupancy (SRO) hotels has diminished drastically. SRO hotels provided a means of relatively inexpensive housing, and although some people believe that these facilities nurtured isolation, they provided adequate

shelter from the elements for their occupants. So many individuals currently frequent the shelters of our cities that there is concern they are becoming mini-institutions for individuals with serious mental illness.

Other Factors Several other factors that may contribute to homelessness have been identified:

- **Lack of affordable health care:** For families barely able to scrape together enough money to pay for day-to-day living, a catastrophic illness can create the level of poverty that starts the downward spiral to homelessness.
- **Domestic violence:** The NCH (2014) reports that domestic violence is a primary cause of homelessness, with approximately 63 percent of homeless women having experienced domestic violence in their adult lives. Battered women are often forced to choose between an abusive relationship and homelessness.
- **Addiction disorders:** Individuals with untreated alcohol or drug addictions are at increased risk for homelessness. The following have been cited as obstacles to addiction treatment for homeless persons: lack of health insurance, lack of documentation, waiting lists, scheduling difficulties, daily contact requirements, lack of transportation, ineffective treatment methods, lack of supportive services, and cultural insensitivity.

Community Resources for the Homeless

Interfering Factors Among the many issues that complicate service planning for homeless individuals with mental illness is this population's penchant for mobility. Frequent relocation confounds service delivery and interferes with providers' efforts to ensure appropriate care. Some individuals with serious mental illness may be affected by homelessness only temporarily or intermittently. These individuals are sometimes called the "episodically homeless." Others move around within neighborhoods or cities as needs and availability of services change. A large number of the homeless mentally ill population exhibits continuous unbounded movement over wide geographical areas.

Not all homeless individuals with mental illness are mobile. Some studies have indicated that a large percentage remain in the same location over a number of years. Health-care workers must identify movement patterns of homeless people in their area to at least try to bring the best care possible to this unique population. This may indeed mean delivering services to those individuals who do not seek out services on their own.

Health Issues Life as a homeless person can have severe consequences in terms of health. Exposure to the elements, poor diet, sleep deprivation, risk of violence, injuries, and lack of health care lead to a precarious state of health and exacerbate preexisting illnesses. It has been estimated that about 40 percent of homeless individuals abuse alcohol. Compared to other homeless individuals, those who abuse alcohol are at greater risk for neurological impairment, heart disease and hypertension, chronic lung disease, gastrointestinal disorders, hepatic dysfunction, and trauma.

Thermoregulation is a health problem for all homeless individuals because of their exposure to all kinds of weather. It is a compounded problem for the homeless alcoholic who spends much time in an altered level of consciousness.

It is difficult to determine whether mental illness is a cause or effect of homelessness. Some behaviors that seem deviant may in actuality be adaptations to life on the street. Homeless individuals may even seek hospitalization in psychiatric institutions in an attempt to get off the streets for a while.

Outbreaks of tuberculosis among homeless persons continue to challenge public control efforts (CDC, 2013). Crowded **shelters** provide ideal conditions for spread of respiratory infections among inhabitants. The risk of acquiring tuberculosis is also increased by the prevalence of alcoholism, drug addiction, HIV infection, and poor nutrition among homeless individuals.

Dietary deficiencies are a continuing problem for homeless individuals. Not only is the homeless person commonly in a poor nutritional state, but the condition itself exacerbates a number of other health problems. Homeless people suffer from higher mortality rates and a greater number of serious disorders than their counterparts in the general population.

Sexually transmitted infections (STIs), such as gonorrhea and syphilis, are a serious problem for the homeless. One of the most serious STIs prevalent among homeless individuals is HIV infection. Street life is precarious for individuals whose systems are immunosuppressed by HIV. Rummaged food scraps are often spoiled, and exposure to the elements is a continuous threat. Individuals with HIV who stay in shelters often are exposed to the infectious diseases of others, which can be life-threatening in this vulnerable condition.

Homeless children have special health needs. Children without a home are prone to higher rates of asthma, ear infections, stomach problems, and speech problems than their counterparts who are not homeless. They are also more likely to experience mental health problems, such as anxiety, depression, and withdrawal.

A growing problem that has captured national attention is the increasing number of hate crimes perpetrated against the homeless. These attacks do not appear to be specifically directed toward the mentally ill but rather reflect a primary bias against homeless

people. Based on a report by NCH (2012), most of the victims (88%) are male, 72 percent are 40 years of age or older, 21 percent of the attacks are fatal, and at least 50 percent of the perpetrators are under the age of 20. The NCH highlights the problem more dramatically in the statement, "While this report provides alarming numbers, it is important to note that homeless people are so poorly treated by society that their attacks are often forgotten or unreported" (p. 10). Community mental health nurses have an opportunity and a responsibility to assess and intervene for homeless people who are a vulnerable population on so many levels.

Types of Resources Available

Homeless Shelters Shelters for the homeless in the United States vary from converted warehouses that provide cots or floor space for overnight stays to significant operations that provide a multitude of social and health-care services. They are run by volunteers and paid professionals and sponsored by churches, community governments, and various social agencies.

It is impossible, then, to describe a "typical" shelter. One description is the provision of lodging, food, and clothing to individuals who are in need of these services. Some shelters also provide medical and psychiatric evaluations, first aid and other health-care services, and referral for case management services by nurses or social workers.

Individuals who seek services from the shelter are generally assigned a bed or cot, issued a set of clean linen, provided a place to shower, shown laundry facilities, and offered a meal in the shelter kitchen or dining hall. Most shelters attempt to separate dormitory areas for men and women, with various consequences for those who violate the rules.

Shelters cover expenses through private and corporate donations, church sponsorships, and government grants. From the outset, shelters were conceptualized as "temporary" accommodations for individuals who needed a place to spend the night. Realistically, they have become permanent lodging for homeless individuals with little hope for improving their situations. Some individuals even use their shelters' mailing address.

Shelters provide a safe and supportive environment for homeless individuals who have no other place to go. Some homeless people who inhabit shelters use the resources offered to improve their lot in life, whereas others become hopelessly dependent on the shelter's provisions. To a few, the availability of a shelter may mean the difference between life and death.

Health-Care Centers and Storefront Clinics Some communities have established "street clinics" to serve the homeless population. Many are operated by nurse practitioners who work in consultation with physicians in the area. In recent years, some of these clinics have provided clinical sites for nursing students in community health rotations. Some have been staffed by nursing school faculties that have established group practices in the community setting.

A wide variety of services are offered at these clinics, including administering medications, assessing vital signs, screening for tuberculosis and other communicable diseases, giving immunizations and flu shots, changing dressings, and administering first aid. Physical and psychosocial assessments, health education, and supportive counseling are also frequent interventions.

Nursing in **storefront clinics** for the homeless provides many special challenges, not the least of which is poor working conditions. These clinics often operate under severe budgetary constraints with inadequate staffing, supplies, and equipment, in rundown facilities located in high-crime neighborhoods. Frustration is often high among nurses who work in these clinics, as they are seldom able to see measurable progress in their homeless clients. Maintenance of health management is virtually impossible for individuals who have no resources outside the health-care setting. If return appointments for preventive care are made, they are often missed.

Mobile Outreach Units Outreach programs literally reach out to the homeless in their own environments in an effort to provide health care. Volunteers and paid professionals form teams to seek out homeless individuals who are in need of assistance. They offer coffee, sandwiches, and blankets in an effort to show concern and establish trust. Assistance can be provided at the site if possible. If not, every effort is made to ensure that the individual is linked with a source that can provide the necessary services.

Mobile outreach units provide assistance to homeless individuals who are in need of physical or psychological care. The emphasis of outreach programs is to accommodate the homeless who refuse to seek treatment elsewhere. Most target the mentally ill segment of the population. When trust has been established and the individual agrees to come to the team's office, medical and psychiatric treatment is initiated. Involuntary hospitalization is initiated when an individual is deemed harmful to self or others, or otherwise meets the criteria to be considered "gravely disabled."

The Homeless Client and the Nursing Process

A case study demonstrating nursing process with a homeless client is presented in Box 36–5.

BOX 36–5 Case Study: Nursing Process With a Homeless Client

ASSESSMENT

Joe, age 68, is brought to the Community Health Clinic by two of his peers, who report, "He just had a fit. He needs a drink bad!" Joe is dirty and unkempt, has visible tremors of the upper extremities, and is weak enough to require assistance when ambulating. He is cooperative as the nurse completes the intake assessment. He is coherent, although thought processes are slow. He is disoriented to time and place. He appears somewhat frightened as he scans the unfamiliar surroundings. He is unable to tell the nurse when he had his last drink. He reports no physical injury, and none is observable.

Joe carries a small bag with a few personal items inside, including a Department of Veterans Affairs (VA) benefit card, identifying him as a veteran of the Vietnam War. The nurse finds a cot for Joe, ensures that his vital signs are stable, and telephones the number on the VA card. The clinic nurse discovers that Joe is well known to the admissions personnel at the VA. He has a 35-year history of schizophrenia with numerous hospitalizations. At the time of his last discharge, he was taking fluphenazine (Prolixin) 10 mg twice a day. He told the clinic nurse that he took the medication for a few months after he got out of the hospital but then did not have the prescription refilled. He could not remember when he had last taken fluphenazine.

Joe also has a long history of alcohol-related disorders and has participated in the VA substance rehabilitation program three times. He has no home address and receives his VA disability benefit checks at a shelter address. He reports that he has no family. The nurse makes arrangements for VA personnel to drive Joe from the clinic to the VA hospital, where he is admitted for detoxification. She sets up a case management file for Joe and arranges with the hospital to have Joe return to the clinic after discharge.

DIAGNOSIS AND OUTCOME IDENTIFICATION

The following nursing diagnosis was formulated for Joe:

- Ineffective health maintenance related to ineffective coping skills evidenced by abuse of alcohol, lack of follow-through with antipsychotic medication, and lack of personal hygiene

Ongoing criteria were selected as outcomes for Joe:

- Follows the rules of the group home and maintains his residency status
- Attends weekly sessions of group therapy at the VA day treatment program
- Attends weekly sessions of Alcoholics Anonymous and maintains sobriety
- Reports regularly to the health clinic for injections of fluphenazine
- Volunteers at the VA hospital 3 days a week
- Secures and retains permanent employment

PLANNING AND IMPLEMENTATION

During Joe's hospitalization, the clinic nurse remained in contact with his case. Joe received complete physical and dental examinations and treatment during his hospital stay. The clinic nurse attended the treatment team meeting for Joe as his outpatient case manager. It was decided at the meeting to try giving Joe injections of fluphenazine decanoate because of his history of lack of adherence to his daily oral medication regimen. The clinic nurse would administer the injection every 4 weeks.

At Joe's follow-up clinic visit, the nurse explains to Joe that she has found a group home where he may live with others who have personal circumstances similar to his. At the group home, meals will be provided and the group home manager will ensure that Joe's basic needs are fulfilled. A criterion for remaining at the residence is for Joe to remain alcohol free. Joe is agreeable to these living arrangements.

With Joe's concurrence, the clinic nurse also performs the following interventions:

- Goes shopping with Joe to purchase some new clothing, allowing Joe to make decisions as independently as possible
- Helps Joe move into the group home and introduces him to the manager and residents
- Helps Joe change his address from the shelter to the group home so that he may continue to receive his VA benefits
- Enrolls Joe in the weekly group therapy sessions of the day treatment facility connected with the VA hospital
- Helps Joe locate the nearest Alcoholics Anonymous group and identifies a sponsor who will ensure that Joe gets to the meetings
- Sets up a clinic appointment for Joe to return in 4 weeks for his fluphenazine injection; telephones Joe 1 day in advance to remind him of his appointment
- Instructs Joe to return to or call the clinic if any of the following symptoms occur: sore throat, fever, nausea and vomiting, severe headache, difficulty urinating, tremors, skin rash, or yellow skin or eyes
- Assists Joe in securing transportation to and from appointments
- Encourages Joe to set realistic goals for his life and offers recognition for follow-through
- When Joe is ready, discusses employment alternatives with him; suggests the possibility of starting with a volunteer job (perhaps as a VA hospital volunteer)

EVALUATION

Evaluation of the nursing process with homeless individuals who have mental illness must be highly individualized. Statistics show that chances for relapse with this population are high. Therefore, it is extremely important that outcome criteria be realistic so as not to set the client up for failure.

Summary and Key Points

■ The focus of psychiatric care is shifting from inpatient hospitalization to outpatient care within the community. This trend is largely due to the need for greater cost effectiveness in providing medical care to the masses.

■ The community mental health movement began in the 1960s with the closing of state hospitals and the deinstitutionalization of many individuals with severe and persistent mental illness.

■ Mental health care within the community targets primary prevention (reducing the incidence of mental disorders within the population), secondary prevention (reducing the prevalence of psychiatric illness by shortening the course of the illness), and tertiary prevention (reducing the residual defects that are associated with severe and persistent mental illness).

■ Primary prevention focuses on identification of populations at risk for mental illness, increasing their ability to cope with stress, and targeting and diminishing harmful forces within the environment.

■ The focus of secondary prevention is accomplished through early identification of problems and prompt initiation of effective treatment.

■ Tertiary prevention focuses on preventing complications of the illness and promoting rehabilitation directed toward achievement of the individual's maximum level of functioning.

■ Registered nurses serve as providers of psychiatric-mental health care in the community setting.

■ Nurses provide outpatient care for individuals with severe and persistent mental illness in community mental health centers, in day and evening treatment programs, in partial hospitalization programs, in community residential facilities, and with psychiatric home health care.

■ Homeless persons with mental illness provide a special challenge for the community mental health nurse. Care is provided within homeless shelters, at health-care centers or storefront clinics, and through mobile outreach programs.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Which of the following represents a nursing intervention at the primary level of prevention?
   a. Teaching a class in parent effectiveness training
   b. Leading a group of adolescents in drug rehabilitation
   c. Referring a married couple for sex therapy
   d. Leading a support group for battered women

2. Which of the following represents a nursing intervention at the secondary level of prevention?
   a. Teaching a class about menopause to middle-aged women
   b. Providing support in the emergency room to a rape victim
   c. Leading a support group for women in transition
   d. Making monthly visits to the home of a client with schizophrenia to ensure medication compliance

3. Which of the following represents a nursing intervention at the tertiary level of prevention?
   a. Serving as case manager for a mentally ill homeless client
   b. Leading a support group for newly retired men
   c. Teaching prepared childbirth classes
   d. Caring for a depressed widow in the hospital

4. John, a homeless person, has just come to live in the shelter. The shelter nurse is assigned to his care. Which of the following is a *priority* intervention on the part of the nurse?
   a. Referring John to a social worker
   b. Developing a plan of care for John
   c. Conducting a behavioral and needs assessment on John
   d. Helping John apply for Social Security benefits

Review Questions—cont'd
Self-Examination/Learning Exercise

5. John, a homeless person, has a history of schizophrenia and nonadherence to his medication regimen. Which of the following medications might be the best choice for John?
   a. Haldol
   b. Navane
   c. Lithium carbonate
   d. Prolixin decanoate

6. Ann is a psychiatric home health nurse. She has just received an order to begin regular visits to Mrs. W., a 78-year-old widow who lives alone. Mrs. W.'s primary care physician has diagnosed her as depressed. Which of the following criteria would qualify Mrs. W. for home health visits?
   a. Mrs. W. never learned to drive and has to depend on others for her transportation.
   b. Mrs. W. is physically too weak to travel without risk of injury.
   c. Mrs. W. refuses to seek assistance as suggested by her physician, "because I don't have a psychiatric problem."
   d. Mrs. W. says she would rather have home visits than go to the physician's office.

7. Ann is a psychiatric home health nurse. She has just received an order to begin regular visits to Mrs. W., a 78-year-old widow who lives alone. Mrs. W.'s primary care physician has diagnosed her as depressed. Which of these potential problems is a priority to evaluate for during the first home visit?
   a. Complicated grieving
   b. Social isolation
   c. Risk for injury
   d. Sleep pattern disturbance

8. Mrs. W., a 78-year-old depressed widow, says to her home health nurse, "What's the use? I don't have anything to live for anymore." Which is the best response on the part of the nurse?
   a. "Of course you do, Mrs. W. Why would you say such a thing?"
   b. "You seem so sad. I'm going to do my best to cheer you up."
   c. "Let's talk about why you are feeling this way."
   d. "Are you having thoughts about harming yourself in any way?"

9. The physician orders trazadone (Desyrel), 150 mg to be taken at bedtime, for Mrs. W., a 78-year-old widow with depression. Which of the following statements about this medication would be appropriate for the home health nurse to make in teaching Mrs. W. about trazadone?
   a. "You may feel dizzy when you stand up, so go slowly when you get up from sitting or lying down."
   b. "You must not eat chocolate while you are taking this medicine."
   c. "We will need to draw a sample of blood to send to the lab every month while you are on this medication."
   d. "If you don't feel better right away with this medicine, the doctor can order a different kind for you."

10. Which of the following issues have been identified as contributing to the rise in the population of those who are homeless? (Select all that apply.)
   a. Poverty
   b. Lack of affordable health care
   c. Substance abuse
   d. Severe and persistent mental illness
   e. Growth in the number of family members living together

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Ng, P., Chun, W.K., & Tsun, A. (2012). Recovering from hallucinations: A qualitative study of coping with voices hearing of people with schizophrenia in Hong Kong. *The Scientific World Journal, 2012*(5), 1-8. doi:10.1100/2012/232619

DESCRIPTION OF THE STUDY: This study involved in-depth interviews with 20 people who had schizophrenia and were hearing voices to learn more about their coping strategies. All of the participants were living in halfway houses, receiving Social Security assistance, and taking psychotropic medications. Most had been living with schizophrenia for 20 years or more. The authors note literature supporting that those who had coping strategies were better able to manage, whereas "non-copers" had more difficulty managing and perceived the voices as negative and aggressive. The most common coping strategies were social engagement (by talking with others, the voices were less pronounced) and manipulating the level of sensory stimulation (including selectively listening to the voices). They also cite the significance of exploring coping strategies, since auditory hallucinations often persisted in spite of psychotropic medication.

RESULTS OF THE STUDY: Several effective coping strategies were identified:

1. Changing social contacts through ignoring or justifying the voices

2. Manipulating and regulating the voices
3. Changing their perceptions about the meaning of the voices

IMPLICATIONS FOR NURSING PRACTICE: In a strictly biomedical approach, auditory hallucinations are a phenomenon that is to be treated and hopefully eliminated. Studies such as this encourage nurses to expand their understanding of this phenomenon and options for intervention. The authors summarize implications for practice that are relevant for nurses and other health-care providers:

1. We need to develop a respectful attitude toward voice-hearing experiences.
2. We need to understand voice hearing and coping strategies in a cultural context; some cultures prefer alternative strategies over medication for coping.
3. Specialized programs for coping with voice hearing will promote adjustment to community living.
4. Specialized training for professionals about how discussing hallucinations can be informative, particularly with regard for their propensity toward self-harm or violence.
5. Family education about auditory hallucinations and how some people cope may provide a foundation that allows for open discussion about hearing voices within a supportive context.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Corbiere, M., Samson, E., Villotti, P., & Pelletier, J.F. (2012). Strategies to fight stigma toward people with mental disorders: Perspectives from different stakeholders. *The Scientific World Journal, 2012*(3), 1-10. doi:10.1100/2012/516358

DESCRIPTION OF THE STUDY: The purpose of this survey was to identify perspectives of mental health professionals, clients with mental illness, family members, and other mental health care providers to identify a broad range of activities being used to combat stigma toward people with mental illness. The participants ($N = 253$) were delegates to a Canadian conference and were asked to identify specific practices used to reduce prejudice and stigma in this population.

RESULTS OF THE STUDY: Fifteen categories of activities were identified that fell under six main themes:

Education: Stigma may be reduced by providing factual knowledge about mental illnesses.

Contact: Direct interaction with affected persons may decrease negative attitudes.

Protestation: Protesting against bias and promoting advocacy may support culture change through personal protestation.

Person-centered: Incorporating an attitude of normalizing in interaction with clients and modifying elements that

contribute to the client being identifiable in the general population may promote social integration.

Working on recovery and social inclusion: Supporting, assisting, and encouraging clients to capitalize on their strengths promotes working on integration in the community.

Reflexive consciousness: Encouraging others to reflect on their attitudes about mental illness promotes insight and creates a foundation for change in attitudes.

IMPLICATIONS FOR NURSING PRACTICE: As the authors cite, the literature reports more than 40 negative consequences of stigma, the effects of which extend beyond the individual to family, friends, and health-care workers. Successful community mental health and recovery models must address reduction of the stigma associated with mental illness. Student nurses, as they begin to learn about this vulnerable and often disenfranchised population, are often confronted with their own attitudes and ask ,"What can I do?" A study such as this informs about central themes and activities for nurses to support patients with mental illness in any practice or community setting. The authors note that knowledge is helpful but does not necessarily translate to behavior change, so perhaps the more important question is, "What *will* you do?"

The Bereaved Individual

CHAPTER OUTLINE

KEY TERMS

advance directive

anticipatory grieving

bereavement

bereavement overload

delayed grief

hospice

luto

mourning

shiva

velorio

OBJECTIVES
After reading this chapter, the student will be able to:

1. Describe various types of loss that trigger the grief response in individuals.
2. Discuss theoretical perspectives of grieving as proposed by Elisabeth Kübler-Ross, John Bowlby, George Engel, and J. William Worden.
3. Differentiate between normal and maladaptive responses to loss.
4. Discuss grieving behaviors common to individuals at various stages across the life span.
5. Describe customs associated with grief in individuals of various cultures.
6. Formulate nursing diagnoses and goals of care for individuals experiencing the grief response.
7. Describe appropriate nursing interventions for individuals experiencing the grief response.
8. Identify relevant criteria for evaluating nursing care of individuals experiencing the grief response.
9. Describe the concept of hospice care for people who are dying and their families.
10. Discuss the use of advance directives for individuals to provide directions about their future medical care.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. What type of maladaptive response to loss occurs when an individual becomes fixed in the anger stage of grief? What clinical disorder is associated with this occurrence?
2. Describe the phenomenon of bereavement overload.
3. With what types of behaviors is grief manifested in school-aged children?
4. According to Engel, when is the grief response thought to be resolved?

Loss is anything that is perceived as such by the individual. The separation from loved ones or the giving up of treasured possessions, for whatever reason; the experience of failure, either real or perceived; or life events that create change in a familiar pattern of existence—all can be experienced as loss, and all can trigger behaviors associated with the grieving process. Loss and bereavement are universal events encountered by all beings that experience emotions. Following are examples of some notable forms of loss:

- A significant other (person or pet), through death, divorce, or separation for any reason.
- Illness or debilitating conditions. Examples include (but are not limited to) diabetes, stroke, cancer, rheumatoid arthritis, multiple sclerosis, Alzheimer's disease, hearing or vision loss, and spinal cord or head injuries. Some of these conditions not only incur a loss of physical and/or emotional wellness but may also result in the loss of personal independence.
- Developmental/maturational changes or situations, such as menopause, andropause, infertility, "empty nest," aging, impotence, or hysterectomy.
- Real or perceived loss of hopes, dreams, and potential for specific accomplishments.
- Personal possessions that symbolize familiarity and security in a person's life. Separation from these familiar and personally valued external objects represents a loss of material extensions of the self.

Some texts differentiate the terms **mourning** and grief by describing mourning as the psychological process (or stages) through which the individual passes on the way to successful adaptation to the loss of a valued object. Grief may be viewed as the subjective states that accompany mourning or the emotional work involved in the mourning process. Similarly, **bereavement** is described as the period of grief and sadness that is the normal process of reacting to a loss and may include mental, physical, social, and emotional reactions (MedlinePlus, 2015). For purposes of this text, grief work, bereavement, and the process of mourning are collectively referred to as the *grief response.*

This chapter examines human responses to the experience of loss. Care of bereaved individuals is presented in the context of the nursing process.

Theoretical Perspectives on Loss and Bereavement

Stages of Grief

Behavior patterns associated with the grief response include many individual variations. However, sufficient similarities have been observed to warrant characterization of the grief response as a syndrome that has a predictable course with an expected resolution. Early theorists, including Kübler-Ross (1969), Bowlby (1961), and Engel (1964), described behavioral stages through which individuals advance in their progression toward resolution. A number of variables influence one's progression through the grief process, and it should be viewed as a dynamic rather than linear process. Some individuals may reach acceptance only to revert to an earlier stage, some may never complete the sequence, and some may never progress beyond the initial stage.

A more contemporary grief specialist, J. William Worden (2009), offers a set of tasks that must be processed in order to complete the grief response. He suggests that it is possible for a person to accomplish some of these tasks and not others, resulting in an incomplete bereavement that impairs further growth and development. A comparison of the similarities among these four models of the normal grief response is presented in Table 37–1.

Elisabeth Kübler-Ross

These well-known stages of the grief process were identified by Kübler-Ross in her extensive work with dying patients. Behaviors associated with each of these stages can be observed in individuals experiencing the loss of any concept of personal value.

- **Stage I: Denial.** In this stage, the individual has difficulty believing that the loss has occurred. He or she may say, "No, it can't be true!" or "It's just not possible." This stage may protect the individual against the psychological pain of reality.
- **Stage II: Anger.** This is the stage when reality sets in. Feelings associated with this stage include sadness, guilt, shame, helplessness, and hopelessness. Self-blame or blaming of others may lead to feelings of anger toward the self and others. The anxiety level may be elevated, and the individual may experience confusion and a decreased ability to function independently. He or she may be preoccupied with an idealized image of what has been lost. Numerous somatic complaints are common.

TABLE 37–1 Stages and Tasks of the Normal Grief Response: A Comparison of Models by Elisabeth Kübler-Ross, John Bowlby, George Engel, and William Worden

STAGES/TASKS				POSSIBLE TIME DIMENSION	BEHAVIORS
KÜBLER-ROSS	**BOWLBY**	**ENGEL**	**WORDEN**		
I. Denial	I. Numbness/protest	I. Shock/disbelief	I. Accepting the reality of the loss	Occurs immediately on experiencing the loss. Usually lasts no more than a few weeks.	Individual has difficulty believing that the loss has occurred.
II. Anger	II. Disequilibrium	II. Developing awareness		In most cases begins within hours of the loss. Peaks within a few weeks.	Anger is directed toward self or others. Ambivalence and guilt may be felt toward the lost entity.
III. Bargaining					The individual fervently seeks alternatives to improve current situation.
		III. Restitution			Attends to various rituals associated with the culture in which the loss has occurred.
IV. Depression	III. Disorganization and despair	IV. Resolution of the loss	II. Processing the pain of grief	Very individual. Commonly 6 to 12 months. Longer for some.	The actual work of grieving. Preoccupation with the lost entity. Feelings of helplessness and loneliness occur in response to realization of the loss. Feelings associated with the loss are confronted.
			III. Adjusting to a world without the lost entity	Ongoing.	How the environment changes depends on the roles the lost entity played in the life of the bereaved person. Adaptations will have to be made as the changes are presented in daily life. New coping skills will have to be developed.
V. Acceptance	IV. Reorganization	V. Recovery	IV. Finding an enduring connection with the lost entity in the midst of embarking on a new life		Resolution is complete. The bereaved person experiences a reinvestment in new relationships and new goals. The lost entity is not purged or replaced, but relocated in the life of the bereaved. At this stage, terminally ill persons express a readiness to die.

■ **Stage III: Bargaining.** At this stage in the grief response, the individual attempts to strike a bargain with God for a second chance or for more time. The person acknowledges the loss or impending loss but holds out hope for additional alternatives, as evidenced by statements such as, "If only I could. . ." or "If only I had. . . ."

■ **Stage IV: Depression.** In this stage, the individual mourns for that which has been or will be lost. This is a very painful stage when the individual must confront feelings associated with having lost someone or something of value (called *reactive* depression). An example is the individual who is mourning a change in body image. Feelings associated with an impending loss (called *preparatory* depression) are also confronted. Examples include permanent lifestyle changes related to the altered body image or even an impending loss of life itself. Regression, withdrawal, and social isolation may be observed behaviors with this stage. Therapeutic intervention should be available but not imposed, with guidelines for implementation based on client readiness.

■ **Stage V: Acceptance.** At this time, the individual has worked through the behaviors associated with the other stages and accepts or is resigned to the loss. Anxiety decreases and methods for coping with the loss have been established. The client is less preoccupied with what has been lost and increasingly interested in other aspects of the environment. If this is an impending death of self, the individual is ready to die. The person may become very quiet and withdrawn, seemingly devoid of feelings. These behaviors are an attempt to facilitate the passage by slowly disengaging from the environment.

John Bowlby

John Bowlby hypothesized four stages in the grief process. He suggests that these behaviors can be observed in all individuals who have experienced the loss of something or someone of value, even in babies as young as 6 months of age.

■ **Stage I: Numbness or protest.** This stage is characterized by a feeling of shock and disbelief that the loss has occurred. Reality of the loss is not acknowledged.

■ **Stage II: Disequilibrium.** During this stage, the individual has a profound urge to recover what has been lost. Behaviors associated with this stage include a preoccupation with the loss, intense weeping and expressions of anger toward the self and others, and feelings of ambivalence and guilt associated with the loss.

■ **Stage III: Disorganization and despair.** Feelings of despair occur in response to realization that the loss has occurred. Activities of daily living become increasingly disorganized, and behavior is characterized by restlessness and aimlessness. Efforts to regain productive patterns of behavior are ineffective, and the individual experiences fear, helplessness, and hopelessness. Somatic complaints are common. Perceptions of visualizing or being in the presence of that which has been lost may occur. Social isolation is common, and the individual may feel a great deal of loneliness.

■ **Stage IV: Reorganization.** The individual accepts or becomes resigned to the loss. New goals and patterns of organization are established. The individual begins a reinvestment in new relationships and indicates a readiness to move forward within the environment. Grief subsides and recedes into valued remembrances.

George Engel

■ **Stage I: Shock and disbelief.** The initial reaction to a loss is a stunned, numb feeling and refusal by the individual to acknowledge the reality of the loss. Engel states that this stage is an attempt by the individual to protect the self "against the effects of the overwhelming stress by raising the threshold against its recognition or against the painful feelings evoked thereby."

■ **Stage II: Developing awareness.** This stage begins within minutes to hours of the loss. Behaviors associated with this stage include excessive crying and regression to a state of helplessness and a childlike manner. Awareness of the loss creates feelings of emptiness, frustration, anguish, and despair. Anger may be directed toward the self or toward others in the environment who are held accountable for the loss.

■ **Stage III: Restitution.** In this stage, the various rituals associated with loss within a culture are performed. Examples include funerals, wakes, special attire, a gathering of friends and family, and religious practices customary to the spiritual beliefs of the bereaved. Participation in these rituals is thought to assist the individual to accept the reality of the loss and facilitate the recovery process.

■ **Stage IV: Resolution of the loss.** This stage is characterized by a preoccupation with the loss. The concept of the loss is idealized, and the individual may even imitate admired qualities of the lost entity. Preoccupation with the loss gradually decreases over a year or more, and the individual eventually begins to reinvest feelings in others.

■ **Stage V: Recovery.** Obsession with the loss has ended, and the individual is able to go on with his or her life.

J. William Worden

Worden views the bereaved person as active and self-determining rather than a passive participant in the grief process. He proposes that bereavement includes a set of tasks that must be reconciled in order to complete the grief process. Worden's four tasks of mourning include the following:

■ **Task I. Accepting the reality of the loss.** When something of value is lost, it is common for individuals to refuse to believe that the loss has occurred. Behaviors include misidentifying individuals in the environment for their lost loved one, retaining possessions of the lost loved one as though he or she has not died, and removing all reminders of the lost loved one so as not to have to face the reality of the loss. Worden (2009) stated:

> Coming to an acceptance of the reality of the loss takes time since it involves not only an intellectual acceptance but also an emotional one. The bereaved person may be intellectually aware of the finality of the loss long before the emotions allow full acceptance of the information as true. (p. 42)

Belief and denial are intermittent while grappling with this task. It is thought that traditional rituals such as the funeral help some individuals move toward acceptance of the loss.

■ **Task II. Processing the pain of grief.** Pain associated with a loss includes both physical pain and emotional pain. This pain must be acknowledged and worked through. To avoid or suppress it serves only to delay or prolong the grieving process. People do this by refusing to allow themselves to think painful thoughts, by idealizing or avoiding reminders of lost entity, and by using alcohol or drugs. The intensity of the pain and the manner in which it is experienced are different for all individuals. However, the commonality is that it *must* be experienced. Failure to do so generally results in some form of depression that commonly requires therapy that focuses on working through the pain of grief that the individual failed to face at the time of the loss. In this very difficult Task II, individuals must "allow themselves to process the pain—to feel it and to know that one day it will pass" (p. 45).

■ **Task III. Adjusting to a world without the lost entity.** It usually takes a number of months for a bereaved person to realize what his or her world will be like without the lost entity. In the case of a lost loved one, how the environment changes will depend on the types of roles that person fulfilled in life. In the case of a changed lifestyle, the individual will be required to make adaptations to his or her environment in terms of the changes as they are presented in daily life. In addition, those individuals who had defined their identity through the lost entity will require an adjustment to their own sense of self. Worden states:

> The coping strategy of redefining the loss in such a way that it can redound to the benefit of the survivor is often part of the successful completion of Task III. (p. 47)

If the bereaved person experiences failures in his or her attempt to adjust in an environment without the lost entity, feelings of low self-esteem may result. Regressed behaviors and feelings of helplessness and inadequacy are not uncommon. Worden states:

> [Another] area of adjustment is to one's sense of the world. Loss through death can challenge one's fundamental life values and philosophical beliefs—beliefs that are influenced by our families, peers, education, and religion as well as life experiences. The bereaved person searches for meaning in the loss and its attendant life changes in order to make sense of it and to regain some control of his or her life. (pp. 48–49)

To be successful in Task III, bereaved individuals must develop new skills to cope and adapt to their new environment without the lost entity. Successful achievement of this task determines the outcome of the mourning process—that of continued growth or a state of arrested development.

■ **Task IV. Finding an enduring connection with the lost entity in the midst of embarking on a new life.** This task allows the bereaved person to identify a special place for the lost entity. Individuals need not purge from their history or find a replacement for that which has been lost. Instead, there is a continued presence of the lost entity that becomes *relocated* in the life of the bereaved. Successful completion of Task IV involves letting go of past attachments and forming new ones. However, there is also the recognition that although the relationship between the bereaved and what has been lost is changed, it is nonetheless still a relationship. Worden suggests that one never loses memories of a significant relationship. He states:

> For many people, Task IV is the most difficult one to accomplish. They get stuck at this point in their grieving and later realize that their life in some way stopped at the point the loss occurred. (p. 52)

Worden relates the story of a teenaged girl who had a difficult time adjusting to the death of her father. After 2 years, when she began to finally fulfill some of the tasks associated with successful grieving, she wrote these words that express rather clearly what bereaved people in Task IV are struggling with: "There are other people to be loved, and it doesn't mean that I love Dad any less" (p. 52).

Length of the Grief Process

Stages of grief allow bereaved persons an orderly approach to the resolution of mourning. Each stage presents tasks that must be overcome through a painful experiential process. Engel (1964) stated that successful resolution of the grief response is thought to have occurred when a bereaved individual is able "to remember comfortably and realistically both the pleasures and disappointments of [that which is lost]." The length of the grief process depends on the individual and can last for a number of years without being maladaptive. The acute phase of normal grieving usually lasts about 6 to 8 weeks—longer in older adults—but complete resolution of the grief response may take much longer. Sadock, Sadock, and Ruiz (2015) stated:

> Ample evidence suggests that the bereavement process does not end within a prescribed interval; certain aspects persist indefinitely for many otherwise high-functioning, normal individuals. Common manifestations of protracted grief occur intermittently . . . most grief does not fully resolve or permanently disappear; rather grief becomes circumscribed and submerged only to reemerge in response to certain triggers. (p. 1355)

A number of factors influence the eventual outcome of the grief response. The grief response can be more difficult if:

■ The bereaved person was strongly dependent on or perceived the lost entity as an important means of physical and/or emotional support.
■ The relationship with the lost entity was highly ambivalent. A love–hate relationship may instill feelings of guilt that can interfere with the grief work.
■ The individual has experienced a number of recent losses. Grief tends to be cumulative, and if previous losses have not been resolved, each succeeding grief response becomes more difficult.
■ The loss is that of a young person. Grief over loss of a child is often more intense than that over the loss of an elderly person. Traumatic death in general increases the likelihood of abnormal grief, but when a child dies a sudden or violent death, evidence supports an increased incidence of posttraumatic stress disorder (PTSD) in parents (Kearns, 2014). One study found PTSD symptoms in more than 25 percent of the mothers up to 5 years after the death (Parris, 2011). The state of the person's physical or psychological health is unstable at the time of the loss.
■ The bereaved person perceives (whether real or imagined) some responsibility for the loss.
■ The loss is secondary to suicide.
■ The loss is a traumatic death such as murder.

The grief response may be facilitated if:

■ The individual has the support of significant others to assist him or her through the mourning process.
■ The individual has the opportunity to prepare for the loss. Grief work is more intense when the loss is sudden and unexpected. The experience of *anticipatory grieving* is thought to facilitate the grief response that occurs at the time of the actual loss.

Worden (2009) states:

> There is a sense in which mourning can be finished, when people regain an interest in life, feel more hopeful, experience gratification again, and adapt to new roles. There is also a sense in which mourning is never finished. [People must understand] that mourning is a long-term process and that the culmination will not be a pre-grief state. (p. 77)

Anticipatory Grief

Anticipatory grieving is the experiencing of the feelings and emotions associated with the normal grief response before the loss actually occurs. One dissimilar aspect relates to the fact that conventional grief tends to diminish in intensity with the passage of time. Anticipatory grief can become more intense as the expected loss becomes imminent.

Although anticipatory grief is thought to facilitate the actual mourning process following the loss, there may be some problems. In the case of a dying person, difficulties can arise when the family members complete the process of anticipatory grief and detachment from the dying person occurs prematurely. The person who is dying experiences feelings of loneliness and isolation as the psychological pain of imminent death is faced without family support. Another example of difficulty associated with premature completion of the grief response is the reaction that can occur on the return of persons long absent and presumed dead (e.g., soldiers missing in action or prisoners of war). In this instance, resumption of the previous relationship may be difficult for the bereaved person.

Anticipatory grieving may serve as a defense for some individuals to ease the burden of loss when it actually occurs. It may prove to be less functional for others who, because of interpersonal, psychological, or sociocultural variables, are unable in advance of the actual loss to express the intense feelings that accompany the grief response.

One qualitative study examined the unique process of grief for family caregivers of a relative who has dementia. One common theme was that in addition to anticipatory grief related to the final loss, these family members were, at the same time, grieving actual losses throughout the journey of their family member's illness (Peacock, Hammond-Collins, & Ford, 2014).

These included grieving the loss of the ill person's personality, companionship, social self, and cognition as the disease progressed. The grief reactions of these active caregivers were similar to those of bereaved caregivers, although their family member was still alive. This study highlights the multiplicity of factors that can influence the grieving process.

Maladaptive Responses to Loss

When, then, is the grieving response considered to be maladaptive? Three types of pathological grief reactions have been described: delayed or inhibited grief, an exaggerated or distorted grief response, and chronic or prolonged grief.

Delayed or Inhibited Grief

Delayed or inhibited grief refers to the absence of evidence of grief when it ordinarily would be expected. Many times, cultural influences, such as the expectation to keep a "stiff upper lip," contribute to the delayed response.

Delayed or inhibited grief is potentially pathological because the person is simply not dealing with the reality of the loss. He or she remains fixed in the denial stage of the grief process, sometimes for many years. When this occurs, the grief response may be triggered, sometimes many years later, when the individual experiences a subsequent loss. Sometimes the grief process is triggered spontaneously or in response to a seemingly insignificant event. Overreaction to another person's loss may be one manifestation of **delayed grief.**

The recognition of delayed grief is critical because, depending on the profoundness of the loss, the failure of the mourning process may prevent assimilation of the loss and thereby delay a return to satisfying living. Without the learnings that the grief process can provide, subsequent losses may be compounded by previously unresolved grief work. Delayed grieving most commonly occurs because of ambivalent feelings toward the lost entity, outside pressure to resume normal function, or perceived lack of internal and external resources to cope with a profound loss.

Distorted (Exaggerated) Grief Response

In the distorted grief reaction, all of the symptoms associated with normal grieving are exaggerated. Feelings of sadness, helplessness, hopelessness, powerlessness, anger, and guilt, as well as numerous somatic complaints, render the individual dysfunctional in terms of management of daily living. Morrow (2016) describes this as a state of feeling "trapped" in one's grief during which the grief response either stays the same or intensifies over a prolonged period.

When the exaggerated grief reaction occurs, the individual remains fixed in the anger stage of the grief response. This anger may be directed toward others in the environment to whom the individual may be attributing the loss. However, many times the anger is turned inward on the self. When this occurs, depression is the result. Depressive mood disorder is a type of exaggerated grief reaction. This should be distinguished, though, from the depression that is considered part of the normal grieving process. (See Table 37–2.)

Chronic or Prolonged Grieving

Some authors have discussed a chronic or prolonged grief response as a type of maladaptive grief response. Care must be taken in making this determination because, as stated previously, length of the grief response depends on the individual. An adaptive response may take years for some people. A prolonged process may be considered maladaptive when certain behaviors are exhibited. Prolonged grief may be a problem when behaviors such as those that prevent the bereaved from adaptively performing activities of daily living are in evidence. An example is of a widow who refused to participate in family gatherings following the death of her husband. For many years until her own death, she took a sandwich to the cemetery on holidays, sat on the tombstone, and ate her "holiday meal" with her husband. Whether one's behaviors constitute prolonged or chronic grieving must consider cultural context. In some cultures, establishing a memorial ritual to the deceased is the norm, whereas in other cultures, it might be perceived as prolonged grieving.

Normal versus Maladaptive Grieving

Several authors have identified one crucial difference between normal and maladaptive grieving: the loss of self-esteem. Marked feelings of worthlessness are indicative of depression rather than uncomplicated bereavement. Corr and Corr (2013) state, "Normal grief reactions do not include the loss of self-esteem commonly found in most clinical depression" (p. 241). Pies (2013) affirmed:

> Unlike the person with [major depressive disorder] MDD, most recently bereaved individuals are usually not preoccupied with feelings of worthlessness, hopelessness, or unremitting gloom; rather, self-esteem is usually preserved; the bereaved person can envision a "better day;" and positive thoughts and feelings are often interspersed with negative ones.

Hensley and Clayton (2013) add that when clinically depressed inpatients were compared to individuals experiencing depression associated with bereavement, four symptoms were absent in the bereavement

population: suicidal thoughts, feeling like they were a burden to others, feeling like they would rather be dead, and psychomotor retardation. These may be considered associated symptoms of low self-esteem and feelings of worthlessness. The presence of suicide ideation automatically indicates an abnormal grief reaction and requires careful assessment and immediate intervention to prevent the risk for completed suicide.

It is thought that this major difference between normal grieving and a maladaptive grieving response (the feeling of worthlessness or low self-esteem) ultimately precipitates depression, which can be a progressive situation for some individuals. Studies have identified the incidence of major depressive disorder among the bereaved to be at around 35 percent at 1 month following a loss. While this tends to decrease over time, 8 to 11 percent develop chronic depression (Hensley & Clayton, 2013). The authors add that factors such as poor physical health, poor mental health, and substance use disorders prior to a loss increase the risk for chronic depression following loss. A summary of differences between normal grieving and clinical depression is presented in Table 37–2.

Application of the Nursing Process

Background Assessment Data: Concepts of Death—Developmental Issues

All individuals have their own unique concept of death, which is influenced by past experiences with death as well as age and level of emotional development. This section addresses the various perceptions of death according to developmental age.

Children

Birth to Age 2

Infants are unable to recognize and understand death, but they can experience the feelings of loss and separation. Infants who are separated from their mother may become quiet, lose weight, and sleep less. Children at this age will likely sense changes in the atmosphere of the home where a death has occurred. They often react to the emotions of adults by becoming more irritable and crying more.

Ages 3 to 5

Preschoolers and kindergartners have some understanding about death but often have difficulty distinguishing between fantasy and reality. They believe death is reversible, and their thoughts about death may include magical thinking. For example, they may believe that their thoughts or behaviors caused a person to become sick or to die.

Children of this age are capable of understanding at least some of what they see and hear from adult conversations or media reports. They become frightened if they feel a threat to themselves or their loved ones. They are concerned with safety issues and require a great deal of personal reassurance that they will be protected. Regressive behaviors, such as loss of bladder or bowel control, thumb sucking, and temper tantrums are common. Changes in eating and sleeping patterns may also occur.

TABLE 37–2 **Normal Grief Reactions versus Symptoms of Clinical Depression**	
NORMAL GRIEF	CLINICAL DEPRESSION
Self-esteem intact	Self-esteem is disturbed
May openly express anger	Usually does not directly express anger
Experiences a mixture of "good and bad days"	Persistent state of dysphoria
Able to experience moments of pleasure	Anhedonia is prevalent
Accepts comfort and support from others	Does not respond to social interaction and support from others
Maintains feeling of hope	Feelings of hopelessness prevail
May express guilt feelings over some aspect of the loss	Has generalized feelings of guilt
Relates feelings of depression to specific loss experienced	Does not relate feelings to a particular experience
May experience transient physical symptoms	Expresses chronic physical complaints

Philadelphia: Lippincott Williams & Wilkins.

Ages 6 to 9

Children at this age are beginning to understand the finality of death. They are able to understand a more detailed explanation of why or how a person died, although the concept of death is often associated with old age or with accidents. They may believe that death is contagious and avoid association with individuals who have experienced a loss by death. Death is often personified, in the form of a "bogey man" or a monster—someone who takes people away or someone whom they can avoid if they try hard enough. It is difficult for them to perceive their own death. Normal grief reactions at this age include regressive and aggressive behaviors, withdrawal, school phobias, somatic symptoms, and clinging behaviors.

Ages 10 to 12

Preadolescent children are able to understand that death is final and eventually affects everyone, including themselves. They are interested in the physical aspects of dying and the final disposition of the body. They may ask questions about how the death will affect them personally. Feelings of anger, guilt, and depression are common. Peer relationships and school performance may be disrupted. There may be a preoccupation with the loss and a withdrawal into the self. Adams (2014) states that evidence supports that young people who are bereaved are more likely to be poor school attenders, change schools, be excluded, and less likely to be involved in activities both in and out of school, which puts them at higher risk for underperformance, health problems, and feelings of hopelessness. They will require support, flexibility in management of anger responses, and reassurance of their own safety and self-worth.

Adolescents

Adolescents are usually able to view death on an adult level. They understand death to be universal and inevitable; however, they have difficulty tolerating the intense feelings associated with the death of a loved one. They may or may not cry. They may withdraw into themselves or attempt to go about usual activities in an effort to avoid dealing with the pain of the loss. Some teens exhibit acting-out behaviors, such as aggression and defiance. It is often easier for adolescents to discuss their feelings with peers than with their parents or other adults. Some adolescents may show regressive behaviors, whereas others react by trying to take care of their loved ones who are also grieving. In general, individuals of this age group have an attitude of immortality. Although they understand

that their own death is inevitable, the concept is so far-reaching as to be imperceptible.

Adults

The adult's concept of death is influenced by experiential, cultural, and religious backgrounds. Behaviors associated with grieving in the adult were discussed in the section "Theoretical Perspectives on Loss and Bereavement."

Older Adults

Philosophers and poets have described late adulthood as the "season of loss." By the time individuals reach their 60s and 70s, they have experienced numerous losses, and mourning has become a life-long process. Those who are most successful at adapting earlier in life will similarly cope better with the losses and grief inherent in aging. Unfortunately, with the aging process comes a convergence of losses, the timing of which makes it impossible for the aging individual to complete the grief process in response to one loss before another occurs. Because grief is cumulative, this can result in **bereavement overload,** in which the person is less able to adapt and reintegrate, complicated grief responses ensue, and mental and physical health may be jeopardized (Tousley, 2013). Bereavement overload has been implicated as a predisposing factor in the development of depressive disorder in older adults.

Some believe that bereavement among elderly couples is also associated with increased risk for mortality. While many variables influence mortality in this population, evidence suggests that, in cases where the loss is anticipated, there is not an increased risk for mortality, but when the loss was unexpected, there was indeed an increased risk (King et al., 2013, Shah et al., 2013). This research highlights the need for additional assessment and support during the bereavement period when loss, particularly of a spouse, is unexpected.

Background Assessment Data: Bereavement Risk Assessment

Several tools have been developed to assess the risk for maladaptive grief responses. They incorporate many of the issues previously discussed and are framed to identify multiple risk factors commonly associated with complicated grief reactions that may require additional resources and intervention. Some of the factors commonly assessed as indicators of increased risk for maladaptive grief follow:

■ Additional financial problems posed by the loss
■ Lack of coping skills or lack of experience in responding to loss

- Emotional or physical dependence on the lost person or item
- History of mental illness or substance abuse
- History of trauma, including abuse
- Multiple losses within a short time frame

While formalized tools are more often used in palliative care settings, they constitute an important aspect of assessment for all nurses responding to the needs of the bereaved client.

Background Assessment Data: Concepts of Death—Cultural Issues

As previously stated, bereavement practices are greatly influenced by cultural and religious backgrounds. It is important for health-care professionals to have an understanding of these individual differences to provide culturally sensitive care to their clients. Clinicians must be able to identify and appreciate what is culturally expected or required, because failure to carry out expected rituals may hinder the grief process and result in unresolved grief for some bereaved individuals. Box 37–1 provides a set of guidelines for assessing culturally specific death rituals. Following is a discussion of selected culturally specific death rituals.

African Americans

Customs of bereaved African Americans are similar to those of the dominant American culture of the same religion and social class, with a blending of cultural practices from the African heritage. Most African American Christians are affiliated with the Baptist and Methodist denominations.

Funeral services may differ from the traditional European American service with ceremonies and rituals modified by the musical rhythms and patterns of speech and worship that are unique to African

Americans. Often, feelings are expressed openly and publicly at the funeral, and some view eulogies as extremely important. Services usually conclude with a viewing of the body and burial at a cemetery. Burial rather than cremation is usually chosen (Hazell, 2016).

Many African Americans attempt to maintain a strong connection with their loved ones who have died. This connection may take the form of communication with the deceased's spirit through mediums who are believed to possess this special capability.

Asian Americans

Chinese Americans

Death and bereavement in the Chinese tradition are centered on ancestor worship. Chinese people have an intuitive fear of death and avoid references to it. Tsai (2013) states:

> Many Chinese are hesitant to purchase life insurance because of their fear that it is inviting death. The color white is associated with death and is considered bad luck. Black is also a bad luck color. (p. 189)

In the traditional Chinese culture, people often do not express their emotions openly. Mourners are recognized by black armbands and white strips of cloth tied around their heads (Tsai, 2013). The dead are honored by placing food, money for the person's spirit, or articles made of paper around the coffin. The purpose of these rituals is based on the belief that one must help the dead to live a comfortable and rich afterlife (Chang, 2017). Suicide is culturally prohibited since traditional Chinese teaching stresses that life is given by one's parents and no one has the right to take it away (Chang, 2017). While this might serve as a protective factor against suicide for traditional Chinese Americans, it also adds another dimension to the grief process when suicide does occur.

Japanese Americans

The dominant religion among the Japanese is Buddhism. On death of a loved one, the body is prepared by close family members. This is followed by a 2-day period of visitation by family and friends, during which there is prayer, burning of incense, and presentation of gifts. Funeral ceremonies are held at the Buddhist temple, and cremation is common. The mourning period is 49 days, the end of which is marked by a family prayer service and the serving of special rice dishes. It is believed that at this time, the departed has joined those already in the hereafter. Perpetual prayers may be donated through a gift to the temple (Ito & Hattori, 2013).

Vietnamese Americans

Buddhism is the predominant religion among the Vietnamese. Attitudes toward death are influenced by the Buddhist emphasis on cyclic continuity and reincarnation. Many Vietnamese people believe that birth and death are predestined.

Most Vietnamese people prefer to die at home, and most do not approve of autopsy. Cremation is common. The final moments before the funeral procession are a time of prayer for the immediate family. Individuals in mourning wear white clothing for 14 days. During the following year, men wear black armbands and women wear white headbands (Mattson, 2013). The 1-year anniversary of an individual's death is commemorated. Clergy should be called to visit the sick only at the request of the client or family and is usually associated with last rites, especially by Vietnamese people who practice Catholicism. For this reason, hospital visitation by clergy may be very upsetting to clients. Receiving flowers also may be distressing, as flowers usually are reserved for the rites of the dead (Appel, 2017).

Filipino Americans

Following a death in the Filipino community, a wake is held with family and friends. This wake usually takes place in the home of the deceased and lasts up to a week before the funeral. A large proportion of Filipinos are Catholic. Munoz (2013) states:

> Among Catholics, 9 days of novenas are held in the home or in the church. These special prayers ask God's blessing for the deceased. Depending upon the economic resources of the family, food and refreshments are served after each prayer day. Sometimes the last day of the novena takes on the atmosphere of a *fiesta* or a celebration. Filipino families in the United States follow variations of this ritual according to their social and economic circumstances. (p. 242)

Most follow the traditional custom of wearing dark clothing—black armbands for men and black dresses for women—for 1 year after the death, at which time ritualistic mourning officially ends. Emotional outbursts of uncontrolled crying are common expressions of grief. Fainting as a bereavement practice is not uncommon (Munoz, 2013). Burial of the body is most common, but cremation is acceptable.

Jewish Americans

Traditional Judaism believes in an afterlife where the soul continues to flourish, although today many dispute this interpretation (Selekman, 2013). However, most Jewish people show little concern about life after death, and focus is concentrated more on how one conducts one's present life. Taking one's own life is forbidden, and orthodox Jewish people may deny the person full burial honors; however, the more liberal view is to emphasize the needs of the survivors.

A dying person is never left alone. At death, the face is covered with a cloth, and the body is treated with respect. Autopsy is not allowed by Orthodox Jews unless it is required by law, the deceased person has requested it, or it may save the life of another (Bralock & Padgham, 2017).

For the funeral, the body is wrapped in a shroud and placed in a wooden, unadorned casket. No wake and no viewing are part of a Jewish funeral. Cremation is prohibited. Selekman (2013) states:

> After the funeral, mourners are welcomed to the home of the closest relative. Water to wash one's hands before entering is outside the front door, symbolic of cleansing the impurities associated with contact with the dead. The water is not passed from person to person, just as it is hoped that the tragedy is not passed. At the home, a meal is served to all the guests. This "meal of condolence" or "meal of consolation" is traditionally provided by the neighbors and friends. (p. 350)

The 7-day period beginning with the burial is called *shiva.* During this time, mourners do not work, and no activity is permitted that diverts attention from thinking about the deceased. Mourning lasts 30 days for a relative and 1 year for a parent, at which time a tombstone is erected and a graveside service is held (Selekman, 2013).

Mexican Americans

Most Mexican Americans view death as a natural part of life. The predominant religion is Catholic, and many of the death rituals are a reflection of these religious beliefs. A vigil by family members is kept over the sick or dying person. Following the death, large numbers of family and friends gather for a *velorio,* a festive watch over the body of the deceased person (Zoucha & Zamarripa, 2013). Mexican American culture values strong family ties and maintaining an ongoing connection with a deceased family member may be manifested in dreams, storytelling, ongoing rituals, and pictorial memorials (McMurry et al., 2017).

Mourning is called *luto* and is symbolized by wearing black, black and white, or dark clothing and by subdued behavior. Often the bereaved refrain from attending movies or social events and from listening to radio or watching television. For middle-aged or elderly Mexican Americans, the period of bereavement may last for 2 years or more. These mourning behaviors do not indicate a sign of respect for the dead; instead, they demonstrate evidence that the individual is grieving for a loved one. Burial is more common than cremation, and often the body is buried within 24 hours of death, which is required by law in Mexico (Zoucha & Zamarripa, 2013).

American Indian/Alaska Native

More than 500 American Indian/Alaska Native tribes are now recognized by the U.S. government. Although many of the tribal traditions have been modified throughout the years, some of their traditional values have been preserved.

The Navajo of the Southwest, the largest American Indian tribe in the United States, do not bury the body of a deceased person for 4 days after death. Beliefs require that a cleansing ceremony take place before burial to prevent the spirit of the dead person from trying to assume control of someone else's spirit (Purnell, 2014). The dead are buried with their shoes on the wrong feet and rings on their index fingers. The Navajo generally do not express their grief openly and are reluctant to touch the body of a dead person. Purnell (2014) states:

> One death taboo involves talking with clients concerning a fatal disease or illness. Effective discussions require that the issue be presented in the third person, as if the illness or disorder occurred with someone else. Never suggest that the patient is dying. To do so would imply that the provider wishes the patient dead. If the patient does die, it would imply that the provider might have evil powers. (p. 70)

Nursing Diagnosis and Outcome Identification

From analysis of the assessment data, appropriate nursing diagnoses are formulated for the client and family experiencing grief and loss. From these identified diagnoses, accurate planning of nursing care is executed. Possible nursing diagnoses for grieving persons include:

■ Risk for complicated grieving related to loss of a valued entity/concept; loss of a loved one
■ Risk for spiritual distress related to complicated grief process

The following criteria may be used for measurement of outcomes in the care of the grieving client:

The client:

■ Acknowledges awareness of the loss
■ Is able to express feelings about the loss
■ Verbalizes stages of the grief process and behaviors associated with each
■ Expresses personal satisfaction and support from spiritual practices

Planning and Implementation

Table 37–3 provides a plan of care for the grieving person. Selected nursing diagnoses are presented, along with outcome criteria, appropriate nursing interventions, and rationales for each.

Evaluation

In the final step of the nursing process, a reassessment is conducted to determine if the nursing actions have been successful in achieving the objectives of care. Evaluation of the nursing actions for the grieving

---

Table 37–3 | CARE PLAN FOR THE GRIEVING PERSON

NURSING DIAGNOSIS: RISK FOR COMPLICATED GRIEVING
RELATED TO: Loss of a valued entity/concept; loss of a loved one

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goals: • Client acknowledges awareness of the loss. • Client expresses feelings about the loss. • Client verbalizes own position in the grief process. Long-Term Goal: • Client progresses through the grief process in a healthful manner toward resolution.	1. Assess client's stage in the grief process. Assess for bereavement risk factors. 2. Develop trust. Show empathy, concern, and unconditional positive regard. 3. Help client actualize the loss by talking about it. "When did it happen? How did it happen?" and so forth. 4. Help client identify and express feelings. Some of the more problematic feelings include: a. *Anger.* The anger may be directed at the deceased, at	1. Accurate baseline data are required to provide appropriate assistance. 2. Developing trust provides the basis for a therapeutic relationship. 3. Reviewing the events of the loss can help client come to full awareness of the loss. 4. Until client can recognize and accept personal feelings regarding the loss, grief work cannot progress. a. Many people will not admit to angry feelings, believing it

Continued

Table 37–3 | CARE PLAN FOR THE GRIEVING PERSON—cont'd

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
	God, displaced onto others, or retroflected inward on the self. Encourage client to examine this anger and validate the appropriateness of this feeling. b. *Guilt.* Client may feel that he or she did not do enough to prevent the loss. Help client by reviewing the circumstances of the loss and the reality that it could not be prevented. c. *Anxiety and helplessness.* Help client to recognize the way that life was managed before the loss. Help client to put the feelings of helplessness into perspective by pointing out ways that he or she managed situations effectively without help from others. Role-play life events and assist with decision-making situations.	is inappropriate and unjustified. Expression of this emotion is necessary to prevent fixation in this stage of grief. b. Feelings of guilt prolong resolution of the grief process. c. Client may have fears that he or she may not be able to carry on alone.
	5. Interpret normal behaviors associated with grieving, and provide client with adequate time to grieve.	5. Understanding of the grief process will help prevent feelings of guilt generated by these responses. Individuals need adequate time to adjust to the loss and all its ramifications. This involves getting past birthdays and anniversaries of which the deceased was a part.
	6. Provide continuing support. If this is not possible by the nurse, then offer referrals to support groups. Support groups of individuals going through the same experiences can be very helpful for the grieving individual.	6. The availability of emotional support systems facilitates the grief process.
	7. Identify pathological defenses that client may be using (e.g., drug/alcohol use, somatic complaints, social isolation). Assist client in understanding why these are not healthy defenses and how they delay the process of grieving.	7. The bereavement process is impaired by behaviors that mask the pain of the loss.
	8. Encourage client to make an honest review of the relationship with the lost entity. Journal keeping is a facilitative tool with this intervention.	8. Only when client is able to see both positive and negative aspects related to the loss will the grieving process be complete.

Table 37–3 | CARE PLAN FOR THE GRIEVING PERSON–cont'd

NURSING DIAGNOSIS: RISK FOR SPIRITUAL DISTRESS
RELATED TO: Complicated grief process

OUTCOME CRITERIA	NURSING INTERVENTIONS	RATIONALE
Short-Term Goal: • Client identifies meaning and purpose in life, moving forward with hope for the future. Long-Term Goal: • Client expresses achievement of support and personal satisfaction from spiritual practices.	1. Be accepting and nonjudgmental when client expresses anger and bitterness (toward God, the universe, etc.). Stay with client. 2. Encourage client to ventilate feelings related to meaning of own existence in the face of current loss. 3. Encourage client as part of grief work to reach out to previously used religious practices for support. Encourage client to discuss these practices and how they provided support in the past. 4. Assure client that he or she is not alone when feeling inadequate in the search for life's answers. 5. Contact spiritual leader of client's choice, if he or she requests.	1. The nurse's presence and non-judgmental attitude increase client's feelings of self-worth and promote trust in the relationship. 2. Client may believe he or she cannot go on living without lost object. Catharsis can provide relief and put life back into realistic perspective. 3. Client may find comfort in religious rituals with which he or she is familiar. 4. Validation of client's feelings and assurance that they are shared by others offer encouragement and an affirmation of acceptability. 5. These individuals serve to provide relief from spiritual distress and often can do so when other support persons cannot.

client may be facilitated by gathering information using the following types of questions:

- Has the client discussed the recent loss with staff and family members?
- Is the client able to verbalize feelings and behaviors associated with each stage of the grieving process and recognize his or her own position in the process?
- Has obsession with and idealization of the lost entity subsided?
- Is anger toward the loss expressed appropriately?
- Is the client able to participate in usual religious practices and feel satisfaction and support from them?
- Is the client seeking out interaction with others in an appropriate manner?
- Is the client able to verbalize positive aspects about his or her life, past relationships, and prospects for the future?

Additional Assistance

Hospice

Hospice is a program that provides palliative and supportive care to meet the special needs of people who are dying and their families. Hospice care provides physical, psychological, spiritual, and social care for the person for whom aggressive treatment is no longer appropriate. Various models of hospice exist, including freestanding institutions that provide both inpatient and home care, those affiliated with hospitals and nursing homes in which hospice services are provided within the institutional setting, and hospice organizations that provide home care only. Historically, the hospice movement in the United States has evolved mainly as a system of home-based care.

Hospice helps clients achieve physical and emotional comfort so that they can concentrate on living life as fully as possible. Clients are urged to stay active for as long as they are able—to take part in activities they enjoy and to focus on the quality of life.

Hospice follows an interdisciplinary team approach to provide care for the terminally ill individual in the familiar surroundings of the home environment. The interdisciplinary team consists of nurses, attendants (homemakers, home health aides), physicians, social workers, volunteers, and health-care workers from other disciplines as required for individual clients.

The hospice approach is based on seven components: the interdisciplinary team, pain and symptom management, emotional support to client and family, pastoral and spiritual care, bereavement counseling, 24-hour on-call nurse/counselor, and staff support. These are the ideal, and not all hospice programs may include all of these services. The National Hospice and Palliative Care Organization (NHPCO) is an organization that publishes standards of care based on principles that are directed at the hospice program concept.

Interdisciplinary Team

Nurses

A registered nurse usually acts as case manager for care of hospice clients. The nurse assesses the client's and family's needs, establishes the goals of care, supervises and assists caregivers, evaluates care, serves as client advocate, and provides educational information as needed to client, family, and caregivers. He or she also provides physical care when needed, including IV therapy.

Attendants

These individuals are usually the members of the team who spend the most time with the client. They assist with personal care and all activities of daily living. Without these daily attendants, many individuals would be unable to spend their remaining days in their home. Attendants may be noncertified and provide basic housekeeping services; they may be certified nursing assistants who assist with personal care; or they may be licensed vocational or practical nurses who provide more specialized care, such as dressing changes or tube feedings.

Physicians

The client's primary physician and the hospice medical consultant have input into the care of the hospice client. Orders may continue to come from the primary physician, whereas pain and symptom management may come from the hospice consultant. Ideally, these physicians attend weekly client care conferences and provide in-service education for hospice staff as well as others in the medical community.

Social Workers

The social worker assists the client and family members with psychosocial issues, including those associated with the client's condition, financial issues, legal needs, and bereavement concerns. The social worker provides information on community resources from which client and family may receive support and assistance. Some of the functions of the nurse and social worker may overlap at times.

Trained Volunteers

Volunteers are vital to the hospice concept. They provide services that may otherwise be financially impossible. They are specially selected and extensively trained, and they provide services such as transportation, companionship, respite care, recreational activities, light housekeeping, and sensitivity to the needs of families in stressful situations.

Rehabilitation Therapists

Physical therapists may assist hospice clients in an effort to minimize physical disability. They may assist with strengthening exercises and provide assistance with special equipment needs. Occupational therapists may help the debilitated client learn to accomplish activities of daily living as independently as possible. Other consultants, such as speech therapists, may be called upon for the client with special needs.

Dietitian

A nutritional consultant may be helpful to the hospice client who is experiencing nausea and vomiting, diarrhea, anorexia, and weight loss. A nutritionist can ensure that the client is receiving the proper balance of calories and nutrients.

Counseling Services

The hospice client may require the services of a psychiatrist or psychologist if there is a history of mental illness or if neurocognitive disorder or depression has become a problem. Other types of counseling services are available to provide assistance in dealing with the special needs of each client.

Pain and Symptom Management

Improved quality of life at all times is a primary goal of hospice care. Thus, a major intervention for all caregivers is to ensure that the client is as comfortable as possible, whether experiencing pain or other types of symptoms common in the terminal stages of an illness.

Emotional Support

Members of the hospice team encourage clients and families to discuss the eventual outcome of the disease process. Some individuals find discussing issues associated with death and dying uncomfortable, and if so, their decision is respected. However, honest discussion of these issues provides a sense of relief for some people, and they are more realistically prepared for the future. It may even draw some clients and families closer together during this stressful time.

Pastoral and Spiritual Care

Hospice philosophy supports the individual's right to seek guidance or comfort in the spiritual practices most suited to that person. The hospice team members

help the client obtain the spiritual support and guidance for which he or she expresses a preference.

Bereavement Counseling

Hospice provides a service to surviving family members or significant others after the death of their loved one. This is usually provided by a bereavement counselor, but when one is not available, volunteers with special training in bereavement care may be of service. A grief support group may be helpful for the bereaved and provide a safe place for them to discuss their own fears and concerns about the death of a loved one.

24-Hour On-Call

The standards of care set forth by NHPCO state that care shall be available 24 hours a day, 7 days a week. A nurse or counselor is usually available by phone or for home visits around the clock. The knowledge that emotional or physical support is available at any time should it be required provides considerable support and comfort to significant others or family caregivers.

Staff Support

Team members (all who work closely and frequently with the client) often experience emotions similar to those of the client or their family and/or significant others. They may experience anger, frustration, or fears of death and dying—all of which must be addressed through staff support groups, team conferences, time off, and adequate and effective supervision. Burnout is a common problem among hospice staff. Stress can be reduced, trust enhanced, and team functioning more effective if lines of communication are kept open among all members (medical director through volunteer), if information is readily accessible through staff conferences and in-service education, and if staff know they are appreciated and feel good about what they are doing.

Advance Directives

The term **advance directive** refers to either a living will or a durable power of attorney for health care (also called a health-care proxy). Either document allows an individual to provide directions about his or her future medical care.

A living will is a written document made by a competent individual that provides instructions that should be used when that individual is no longer able to express his or her wishes for health-care treatment. The durable power of attorney for health care is a written form that gives another person legal power to make decisions regarding health care when an individual is no longer capable of making such decisions. Some states have adopted forms that combine the intent of the durable power of attorney for health care (i.e., to have a proxy) and the intent of the living will (i.e., to state choices for end-of-life medical treatment).

Doctors usually follow clearly stated directives. It is important that the physician be informed that an advance directive exists and what the specific wishes of the client are. Advance directives are legally binding in all 50 states in the United States (Sadock et al., 2015). In 1991, the U.S. Congress passed the *Patient Self-Determination Act.* This legislation requires that all health-care facilities must advise clients of their rights to refuse treatment, to make advance directives available to clients on admission, and to keep records of whether a client has an advance directive or a designated health-care proxy (Sadock et al., 2015). State laws also define how and under what circumstances individuals can refuse life-sustaining medical interventions. These are generally referred to as natural death acts. Nurses need to be aware of both federal law and the applicable state laws in the state where they practice nursing.

In spite of the laws allowing for an advance directive document, many people have not established this document for themselves—and even when advance directives exist, they may not be honored when circumstances are confusing or unclear. In emergency situations, treatment decisions sometimes must be made before information about an advanced directive is available. Catalano and Catalano (2015) identify additional reasons why advance directives are sometimes not honored:

■ Advance directives that were formulated long before their implementation may call into question whether the client understood the ramifications of their decisions for future medical problems and interventions at that time.
■ In general, the language used in standard living will documents is not specific enough to cover all health-care circumstances. Consequently, health-care providers may lack clarity about how to proceed because the advance directive lacks clarity.
■ Since state laws vary, when a client is in a state other than the one where the advance directive was established, it may raise questions about the document's legality.

Advance directives are designed to allow the client to be in control of decisions about his or her right to live or die. It is also a way to spare family and loved ones the burden of making choices without knowing the wishes of the person who is dying. Nurses can play an active role in discussing advance directives within a culturally sensitive framework and encouraging clients who have advance directives to review and update them periodically to assure that their wishes remain clear.

Summary and Key Points

- Loss is the experience of separation from something of personal importance.
- Loss is anything that is perceived as such by the individual.
- Loss of any concept of value to an individual can trigger the grief response.
- Elisabeth Kübler-Ross identified five stages that individuals pass through on their way to resolution of a loss: denial, anger, bargaining, depression, and acceptance.
- John Bowlby described similar stages: stage I, numbness or protest; stage II, disequilibrium; stage III, disorganization and despair; and stage IV, reorganization.
- George Engel's stages include shock and disbelief, developing awareness, restitution, resolution of the loss, and recovery.
- J. William Worden, a more contemporary clinician, has proposed that bereaved individuals must accomplish a set of four tasks in order to complete the grief process: accepting the reality of the loss, processing the pain of grief, adjusting to a world without the lost entity, and finding an enduring connection with the lost entity in the midst of embarking on a new life.
- The length of the grief process is highly individual and can last for a number of years without being maladaptive.
- The acute stage of the grief process typically lasts a couple of months, but resolution usually takes much longer.
- Anticipatory grieving is the experiencing of the feelings and emotions associated with the normal grief process in response to anticipation of the loss.
- Anticipatory grieving is thought to facilitate the grief process when the actual loss occurs.
- Three types of pathological grief reactions have been described:
  1. Delayed or inhibited grief in which there is absence of grief when it ordinarily would be expected
  2. Distorted or exaggerated grief response in which the individual remains fixed in the anger stage of the grief process and the symptoms associated with normal grieving are exaggerated
  3. Chronic or prolonged grieving in which the individual is unable to let go of grieving behaviors after an extended period of time and in which behaviors indicate that he or she is not accepting that the loss has occurred
- Several authors have identified one crucial difference between normal and maladaptive grieving: the loss of self-esteem.
- Feelings of worthlessness, feeling that one is a burden to others, suicidal ideation, and psychomotor retardation are indicative of clinical depression rather than uncomplicated bereavement.
- Very young children do not understand death but often react to the emotions of adults by becoming more irritable and crying more frequently. They often believe death is reversible.
- School-aged children understand the finality of death. Grief behaviors may reflect regression or aggression, school phobias, or sometimes a withdrawal into the self.
- Adolescents are usually able to view death on an adult level. Grieving behaviors may include withdrawal or acting out. Although they understand that their own death is inevitable, the concept is so far-reaching as to be imperceptible.
- By the time a person reaches the 60s or 70s, he or she has experienced numerous losses. Because grief is cumulative, this can result in bereavement overload. Depression is a common response.
- Nurses must be aware of the death rituals and grief behaviors common to various cultures. Some of these rituals associated with African Americans, Asian Americans, Filipino Americans, Jewish Americans, Mexican Americans, and Native Americans were presented in this chapter.
- Hospice is a program that provides palliative and supportive care to meet the special needs of people who are dying and their families.
- The term *advance directive* refers to either a living will or a durable power of attorney for health care. Advance directives allow clients to be in control of decisions at the end of life and spare family and loved ones the burden of making choices without knowing what is most important to the person who is dying.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Which of the following is most likely to initiate a grief response in an individual? (Select all that apply.)
   a. Death of a pet dog
   b. Being told by her doctor that she has begun menopause
   c. Failing an exam
   d. Losing a spouse through divorce

2. Nancy, who is dying of cancer, says to the nurse, "I just want to see my new grandbaby. If only God will let me live until she is born, then I'll be ready to go." This is an example of which of Kübler-Ross's stages of grief?
   a. Denial
   b. Anger
   c. Bargaining
   d. Acceptance

3. Gloria, a recent widow, states, "I'm going to have to learn to pay all the bills. Hank always did that. I don't know if I can handle all of that." This is an example of which of the tasks described by Worden?
   a. Task I: Accepting the reality of the loss
   b. Task II: Processing the pain of grief
   c. Task III: Adjusting to a world without the lost entity
   d. Task IV: Finding an enduring connection with the lost entity in the midst of embarking on a new life

4. Engel identifies which of the following as successful resolution of the grief process?
   a. When the bereaved person can talk about the loss without crying
   b. When the bereaved person no longer talks about the lost entity
   c. When the bereaved person puts all remembrances of the loss out of sight
   d. When the bereaved person can discuss both positive and negative aspects about the lost entity

5. Which of the following is thought to facilitate the grief process?
   a. The ability to grieve in anticipation of the loss
   b. The ability to grieve alone without interference from others
   c. Having recently grieved for another loss
   d. Taking personal responsibility for the loss

6. When Frank's wife of 34 years dies, he is very stoic, handles all the funeral arrangements, does not cry or appear sad, and comforts all of the other family members in their grief. Two years later, when Frank's best friend dies, Frank has sleep disturbances, difficulty concentrating, loss of weight, and difficulty performing on his job. This is an example of which of the following maladaptive responses to loss?
   a. Delayed grieving
   b. Distorted grieving
   c. Prolonged grieving
   d. Exaggerated grieving

7. A major difference between normal and maladaptive grieving has been identified by which of the following?
   a. There are no feelings of depression in normal grieving.
   b. There is no loss of self-esteem in normal grieving.
   c. Normal grieving lasts no longer than 1 year.
   d. In normal grief the person does not show anger toward the loss.

Review Questions—cont'd
Self-Examination/Learning Exercise

8. Which grief reaction can the nurse anticipate in a 10-year-old child?
   a. Statements that the deceased person will soon return
   b. Regressive behaviors, such as loss of bladder control
   c. A preoccupation with the loss
   d. Thinking that they may have done something to cause the death

9. Which of the following is a correct statement when attempting to distinguish normal grief from clinical depression?
   a. In clinical depression, anhedonia is prevalent.
   b. In normal grieving, the person has generalized feelings of guilt.
   c. The person who is clinically depressed relates feelings of depression to a specific loss.
   d. In normal grieving, there is a persistent state of dysphoria.

10. Which of the following is *not* true regarding grieving by an adolescent?
   a. Adolescents may not show their true feelings about the death.
   b. Adolescents tend to have an immortal attitude.
   c. Adolescents do not perceive death as inevitable.
   d. Adolescents may exhibit acting out behaviors as part of their grief.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Moriarty, J., Maguire, A., O'Reilly, D., & McCann, M. (2015). Bereavement after informal caregiving: Assessing mental health burden using linked population data. *American Journal of Public Health, 105*(8), 1630-1637. doi:10.2105/AJPH.2015.302597

DESCRIPTION OF THE STUDY: The researchers linked prescription records for antidepressant and antianxiety medications to characteristics and life event data for members of a longitudinal study in Northern Ireland to assess comparative mental health burdens for nonprofessional (family/household) bereaved caregivers, bereaved non-caregivers, and non-bereaved caregivers ($N = 317,264$). Their expressed intent was to identify who suffers most after the death of someone close to them so that resources for intervention can be targeted appropriately.

RESULTS OF THE STUDY: The first significant finding was that both caregivers and bereaved individuals were at 20 to 50 times greater risk for mental health problems than non-caregivers in similar circumstances. Another significant finding was that among working-aged people who were bereaved caregivers, mental health issues were greater than those of other caregivers; the greater the hours of caregiving, the greater their risks for sustained mental health issues in bereavement. The researchers identify that this finding was contrary to other studies that have found increased resilience among bereaved caregivers. This has been thought to be, among other things, a positive outcome of anticipatory grief. The idea that bereavement might provide a relief of sorts from the caregiving burden was found to be untrue for working-aged adults. Older adult bereaved caregivers, by contrast, seemed to recover more quickly from caregiver bereavement.

IMPLICATIONS FOR NURSING PRACTICE: The bereavement process for caregivers of an ill family member may carry additional risk for mental health problems in the bereavement process, but this study highlights the particular burden of working-aged caregivers and the potential impact on bereavement and their mental health. The researchers suggest that this prolonged risk may be related to disrupted work schedules, employability, and disrupted social networks. For nurses working with bereaved caregivers, these findings suggest the importance of assessing for mental health issues during bereavement, particularly for working-age adults. Education and provision of resources for ongoing support may be beneficial in reducing long-term, sustained mental health problems for this subgroup.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Sealey, M., Breen, L.J., O'Connor, M., & Aoun, J.M. (2015). A scoping review of bereavement risk assessment measures: Implications for palliative care. *Palliative Medicine, 29*(7), 577-589. doi:10.1177/0269216315576262

DESCRIPTION OF THE STUDY: This study attempts to address the concern that while palliative care standards and policies recommend bereavement support to family caregivers, there is uncertainty about whether interventions are being appropriately aligned with bereavement support needs. The authors conducted a scoping review of literature ($N = 3,142$) from 1982 to 2014 to identify the use and appropriateness of bereavement risk assessment tools.

RESULTS OF THE STUDY: The researchers identified 19 different measures used to assess bereavement risks: some for before the patient's death ($n = 5$), some for after the patient's death ($n = 10$), and some for screening for prolonged or complex grief ($n = 4$). Their analysis found that the majority had acceptable psychometric properties, but their feasibility for use in palliative care varied widely.

The authors note that while their primary aim was to identify those at risk for poor bereavement outcomes, the complexities and variables of the grief process make this a difficult challenge and that this study is a first step in an attempt to understand future needs.

IMPLICATIONS FOR NURSING PRACTICE: The researchers identify implications for practice that are relevant to nurses working with bereaved clients and in palliative care:

1. Risk assessment is an essential step for provision of bereavement support according to need.
2. These findings will help guide palliative care services toward evidence-based assessment and intervention and will inform palliative care standards and policies.

In general, nurses who work with currently bereaved clients or who are anticipating needs of future bereaved clients must be knowledgeable about identified risks associated with maladaptive or prolonged grieving. Systematic assessment will promote targeted intervention with the goal of facilitating the bereavement process toward adaptive outcomes.

Communication Exercises

1. Jane's husband has been hospitalized for several days in end-stage congestive heart failure, and Jane has just been told that he has died. She begins sobbing and screams at the nurse, "You killed my husband! I should have never brought him to the hospital!"
   • What would be an appropriate, empathic response by the nurse?
2. The doctor has shared with John test results revealing that his terminal cancer has not responded to treatment. John looks to the nurse and asks, "Am I dying?"
   • What would be an appropriate response by the nurse?
3. Nancy has been told that she has a terminal illness. She says to the nurse, "Why would God do this to me?"
   • What response by the nurse would demonstrate sensitivity to Nancy's spiritual distress?

Military Families

KEY TERMS

deployment
posttraumatic stress disorder (PTSD)

traumatic brain injury
veterans

OBJECTIVES
After reading this chapter, the student will be able to:

1. Discuss historical aspects and epidemiological statistics related to members and veterans of the U.S. military.
2. Describe the lifestyle of career military families.
3. Discuss the impact of deployment on families of service members.
4. Discuss concerns of women in the military.

5. Describe combat-related illnesses common in members and veterans of the U.S. military.
6. Apply steps of the nursing process in care of veterans with traumatic brain injury and posttraumatic stress disorder.
7. Discuss various modalities relevant to treatment of traumatic brain injury and posttraumatic stress disorder.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Name some positives and negatives associated with the military lifestyle.
2. Describe behaviors that may be exhibited by school-aged children in response to deployment of a parent.

3. How do feelings about leaving their children during a deployment differ between male and female service members?
4. Name some symptoms of posttraumatic stress disorder.

Because of U.S. involvement in Iraq and Afghanistan, perhaps at no time in modern history has so much attention been given to what individuals and families experience as a result of their lives in the military. There is an ongoing effort by organizations that provide services for active-duty military personnel and **veterans** of military combat to keep up with the growing demand, and resources for these services will be required for many years to come. The need for mental health care practitioners will rise as the increasing number of veterans and their family members struggle to cope with the effects of military deployment.

This chapter addresses issues associated with the lives of military families and veterans of military combat. A discussion of nursing care for these individuals is presented, and selected medical treatment modalities are described.

Historical Aspects

"To care for him who shall have borne the battle and for his widow and his orphan."
—Abraham Lincoln, 1865

There is little doubt that individuals who survive military combat return from battle with scars—physical, psychological, or both. Reports of war-related psychological symptoms have existed in writing throughout the centuries, identified by terms such as "shell shock" and "battle fatigue." Many veterans of World War I and World War II were expected to be stoic, to lock up their feelings, and to never speak of the scenes of carnage and combat that they witnessed. The abuse of alcohol became a common way to deal with the emotions that they did not feel comfortable discussing. **Posttraumatic stress disorder (PTSD)** has been related to the high rates of alcoholism among veterans, particularly those who have experienced active-duty combat. Only in recent history have the invisible wounds of combat veterans received the treatment they desperately require.

Very little was written about PTSD during the years between 1950 and 1970. This absence was followed in the 1970s and 1980s by an explosion in the amount of research and writing on the subject. Many of the papers written during this time were about Vietnam veterans. Clearly, the renewed interest in PTSD was linked to the psychological casualties of the Vietnam War. The diagnostic category of PTSD did not appear until the third edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-III)* in 1980, after a need was indicated by increasing numbers of problems with Vietnam veterans and victims of multiple disasters.

Epidemiological Statistics

Currently, more than 1.3 million individuals serve on active duty in the U.S. armed forces in more than 150 countries around the world, along with 736,964 civilian personnel and another 777,114 serving in the National Guard and Reserve forces (Department of Defense [DoD], 2015a). Approximately 16.1 percent of those in active duty are women. Veterans currently number more than 20 million, about 9 percent of whom are women (U.S. Census Bureau, 2016).

Since the beginning of the wars in Afghanistan and Iraq in 2001, more than 2.2 million U.S. military personnel have been deployed in 3 million tours of duty lasting more than 30 days as part of Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) (Institute of Medicine [IOM], 2013). According to the IOM report (2013) *Returning Home from Iraq and Afghanistan: Readjustment Needs of Veterans, Service Members, and Their Families,* 44 percent of these military personnel identify difficulty readjusting to daily living upon return from deployment, and 30 percent report unemployment after returning—twice the percentage of their nonveteran counterparts. The cost in deaths and physical and psychological injuries cannot be measured.

Application of the Nursing Process

Assessment

The Military Family

The military lifestyle offers both positive and negative aspects for those who choose this way of life. Hall (2011) summarizes a number of pros and cons about what is sometimes called the Warrior Society. Some advantages include:

■ Early retirement compared to civilian counterparts
■ A vast resource system to meet family needs
■ Job security with a guaranteed paycheck
■ Health-care benefits
■ Opportunities to see the world
■ Educational opportunities

Some disadvantages include:

■ Frequent familial separations and reunions
■ Regular household relocations
■ Living life under the maxim of "the mission must always come first"
■ A pattern of rigidity, regimentation, and conformity in family life
■ Feelings of detachment from nonmilitary community
■ The social effects of "rank"
■ The lack of control over pay, promotion, and other benefits

Mary Wertsch (1996), who conducted a vast amount of research on the culture of the military family, stated, "The great paradox of the military is that its members, the self-appointed frontline guardians of our cherished American democratic values, do not live in democracy themselves" (p. 15). The military is maintained by a rigid authoritarian structure, and these characteristics often extend into the structure of the home.

A class system is strikingly evident in the military, with two distinct subcultures: that of the officer and that of the enlisted ranks. Hall (2011) states:

> The United States has made great strides in the past five decades to affirm and equalize the differences in society, but the assumption of all military systems in the world is that it is essential for the functioning of the organization to maintain a rigid hierarchical system based on dominance and subordination. (p. 38)

Isolation and alienation are common facets of military life. To compensate for the extreme mobility, the focus of this lifestyle turns inward to the military world

rather than outward to the local community. Children of military families almost always report that no matter what school they attend, they feel "different" from the other students (Wertsch, 1996).

These descriptions apply principally to "career" military families. Another type of military family, those in the all-volunteer military, have become a familiar part of the American culture in recent years. The OEF and OIF military campaigns together make up the longest sustained U.S. military operation since the Vietnam War, and they are the first extended conflicts to depend on an all-volunteer military (IOM, 2013). There has been heavy dependence on the National Guard and Reserves and an escalation in the pace, duration, and number of deployments and redeployments experienced by these individuals. Many joined the National Guard or Reserves as a second job for financial reasons or for the educational opportunities available to them. Little thought had been given to the possibility of actually fighting in a war. As one anonymous reservist posted on his blog:

> The active forces have the harder role. They're required to be fully ready 24/7/365, and to deploy and fight on much shorter notice than the Reserve [forces]. It's their livelihood and (for many) their career. They're serving full-time; reservists aren't. That was once clearly true. But not really quite true anymore. Many reservists in critically needed specialties have already served multiple years on active duty since 9/11, and this situation doesn't look to change anytime soon. (Kelly Temps in Uniform, 2012)

In recent years, enlistees in the National Guard and Reserves are told that they should expect to serve an interval of active duty. The Iraq and Afghanistan conflicts have engaged more National Guard and Reserve forces members than previous conflicts, and more women and parents of young children are being deployed as well (IOM, 2013). Most individuals in the National Guard and Reserves are willing to serve when and where they are needed but consider themselves "part-timers." The extended OEF and OIF campaigns have changed this part-time concept for many who have served multiple tours of duty, creating a hardship on their families and their civilian careers. The IOM reports that, in general, recent military tours of duty are marked by longer deployments and shorter intervals at home. Many of these "temporary citizen soldiers," as well as their full-time military counterparts, now carry the physical and psychological scars of battle.

Military Spouses and Children

A military spouse inherently knows and lives with the concept of "mission first." Devries and colleagues (2012) state, "While the military works hard to value the family lives of service members and their welfare, the nature of the job is that the mission trumps all other concerns" (p. 11). However, times have changed from the days when life in the military was viewed as a two-person career, in which a woman was expected to "create the right family setting so that her husband's work reflected his life at home, by staying positive, being interested in his duty, and being flexible and adaptable" (Hall, 2012, p. 148). Many of today's military spouses have their own careers or are pursuing higher levels of education. They do not view the military as a joint career with their service member spouse.

The lives of military spouses and children are clearly affected when the service member's active-duty assignments require frequent family moves. Wakefield (2007) has stated, "The many short-term relationships, complications of spousal employment, university transfer issues, escalated misbehavior of the children, day care arrangements, spousal loneliness, and increased financial obligations are just some of the issues military personnel face that can lead to frustration." In most instances, when the service member receives orders for a new geographical assignment, the spouse's education, career, or both are put on hold, and the entire family is relocated. Other occasions may arise when the family is unable to immediately follow the service member to the new location. In certain instances, such as when a student may be about to complete a semester or is about to graduate, the service member may proceed to the new assignment without the family. This is difficult for the military spouse who is left alone to care for the children, as well as to deal with all aspects of the move.

Military children face unique challenges. There are almost 1.9 million children in military families, and the largest percentage (37.4%) are ages 5 and younger (DoD, 2013). Clever and Segal (2013) note that while the Department of Defense (DoD) collects substantial demographic research, more is needed on the effects of military family life on infants and toddlers. School-aged children primarily attend civilian public schools where they form a unique subculture among staff and peers who often do not understand their life experiences. Children who grow up in a career military family learn to adapt to changing situations very quickly and to hide a certain level of fear associated with the nomadic lifestyle. Hall (2008) states:

> It is not just a fear of what might happen to their family or their military parents but a fear of the unknown, of not being accepted, of being behind, of not finding friends, or of not being cool. One of the most common concerns expressed by students when they arrive in a new school is who they will eat lunch with. Another reality for student athletes is that a student could be the star of the basketball team in one school and be sitting on the bench at the next. (p. 103)

The Impact of Deployment

Not since the Vietnam War have so many U.S. military families been affected by deployment-related family separation, combat injury, and death. Many service members have been deployed multiple times. Those who are deployed most frequently describe their greatest fear as having to leave their spouse and children. Lengthy separations pose many challenges to all members of the family. Spouses undertake all the challenges of managing the household in addition to assuming the role of the single parent. The pressure and stress are intense as the spouse attempts to maintain an atmosphere of strength for the children, while experiencing the fears and anxiety associated with the life-threatening conditions facing his or her service member partner.

Approximately 2 million American children have experienced the **deployment** of a parent to Iraq or Afghanistan. More than 48,000 children either have lost a parent or have a parent who was wounded in these conflicts. Smith (2012) states:

> The stress that comes when a family member is deployed is significant, and that stress is multiplied when a loved one is wounded or killed. When parents return from deployment, they are not always the same as they were before. Major injuries, such as loss of a limb, traumatic brain injury, or posttraumatic stress disorder are life-altering, and children often have a hard time understanding the reason for a significant change in the appearance, personality, or behavior of a parent.

The following behaviors have been reported in children in response to the deployment of a parent (American Academy of Child & Adolescent Psychiatry, no date):

- Infants (birth to 12 months): May respond to disruptions in their schedule with decreased appetite, weight loss, irritability, and/or apathy.
- Toddlers (1 to 3 years): May become sullen, tearful, throw temper tantrums, or develop sleep problems.
- Preschoolers (3 to 6 years): May regress in areas such as toilet training, sleep, separation fears, physical complaints, or thumb sucking. May assume blame for parent's departure.
- School-age children (6 to 12 years): Are more aware of potential dangers to parent. May exhibit irritable behavior, aggression, or whininess. May become more regressed and fearful about parent's safety.
- Adolescents (13 to 18 years): May be rebellious, irritable, or more challenging of authority. Parents need to be alert to high-risk behaviors, such as problems with the law, sexual acting out, and drug or alcohol abuse.

Pincus and associates (2013) describe the cycle of deployment in five distinct stages: predeployment, deployment, sustainment, redeployment, and postdeployment.

Predeployment The time frame for this stage is variable, beginning with the receipt of the orders and ending when the service member departs. Family members alternate between feelings of denial and anticipation of loss. The soldier and family get their affairs in order, extended training periods result in long hours apart, and the anxiety of the anticipated departure promotes stress and irritability among family members.

Deployment This stage includes the time from actual deployment through the first month of separation. Military spouses report feeling disoriented and overwhelmed, and experience a range of emotions including numbness, sadness, loneliness, and abandonment. It is a time of disorganization as the spouse struggles to take charge of the details of living without his or her partner.

Sustainment Sustainment begins about 1 month into the deployment until about a month before the service member's expected return. During this stage, the spouse and children establish new support systems and institute new family routines. Technology makes it possible for the family and service member to keep in touch with each other by phone, video, and e-mail. Despite the difficulties and obstacles encountered, most military families successfully negotiate this stage and anxiously anticipate their loved one's return.

Redeployment This stage is defined as the month before the service member is scheduled to return home. There is excitement and apprehension associated with the homecoming. Pincus and associates (2013) identify concerns such as, "Will he (she) agree with the changes I have made?" "Will I have to give up my independence?" "Will we get along?"

Postdeployment This stage typically lasts 3 to 6 months and begins with the return of the service member to the home station. There is a period of adjustment beginning with the "honeymoon" period, when the spouses reconnect physically, but not necessarily emotionally. The returning service member may desire to "pick up where he or she left off," only to encounter resistance from the spouse who expresses a reluctance to relinquish the degree of independence and autonomy to which he or she has become accustomed during the separation. Pincus and associates (2013) state:

> Postdeployment is probably the most important stage for both soldier and spouse. Patient communication, going slow, lowering expectations, and taking time to get to know each other again is critical to the task of successful reintegration of the soldier back into the family.

Counseling may be required in the event that the service member has been injured or experiences a traumatic stress reaction.

Women in the Military

Women make up approximately 15 percent of the U.S. military and 18 percent of National Guard and Reserve members (CNN, 2013). Women have been serving in the military since the time of the Civil War, mostly as nurses, spies, and support persons. In recent years, the Pentagon has relaxed its ban on women serving in combat roles, and "women began to fly combat aircraft, staff missile placements, drive convoys in the desert, and participate in other roles that involved potential combat exposure" (Mathewson, 2011, p. 217). Early in 2013, the Secretary of Defense lifted the ban on combat jobs to women, gradually opening direct combat units to female troops. At the present time, certain specialty positions continue to remain off limits, although the plan is to eventually integrate women into these positions. Flexibility in the new law exists for exemptions to occur if further assessment reveals that some jobs are inappropriate for women.

Special Concerns of Women in the Military

A number of issues are of special concern to women in the military, including sexual harassment, sexual assault, differential treatment and conditions, and being a parent.

Sexual Harassment Sexual harassment is defined as "unwanted, unwelcome comments or physical contact of a sexual nature occurring in the workplace" (Mathewson, 2011, p. 221). From statements such as "you look nice this morning" or "hey, you smell good" to blatant suggestions or requests for sexual interactions, Wolfe and associates (1998), in a study of women on active duty during the Persian Gulf War, found that both physical and sexual harassment were higher than typically found in peacetime military samples. Reports by military therapists conveyed that women who were sexually harassed while in the military suffer higher than average rates of a range of problems following discharge, including poor self-image, relationship issues, drug use, depression, and PTSD.

Sexual Assault The DoD (2015b) reported 6,131 cases of active service member sexual assaults in 2014. They define this as "unwanted sexual contact" and now track reports annually. From 2012 to 2013, a 53 percent increase in reporting incidents was identified, a trend that continued in 2014 with an 11 percent annual increase. Despite that more incidents are now being reported, 62 percent of those who reported an incident expected professional or social retaliation.

Only an estimated 25 percent of sexual assaults in the military are reported. Reasons for not reporting include fear of causing trouble in their units, that their commanders and fellow soldiers would turn against them, that they would be passed over for well-deserved promotions, or that they would be transferred and removed from duty altogether (Vlahos, 2012). Some women who have reported incidents to their commanding officers have been told to "forget about it," "buckle up," or "pretend it didn't happen," and are made to feel as though they are perpetrators instead of victims. Wolf (2012) describes the way the military deals with rape as "a culture of cover-up."

In 2000, following incidents of military sexual assaults that were made public, the Veteran's Health Administration mandated universal health screening for sexual trauma among military personnel. But despite the efforts within the DoD to identify and correct this problem, incidents continue, suggesting that sexual assault remains a part of military culture (Burgess, Slattery, & Herlihy, 2013).

Some women who report their sexual assaults are discharged from the service with psychiatric diagnoses of personality disorder or adjustment disorder. Vlahos (2012) reports:

> For the veteran, getting a personality disorder or adjustment disorder discharge can be catastrophic. Not only does it carry a stigma for future employers, it cuts the veteran off from a series of benefits, including health care and service-related disability compensation.

Although they compose only 15 percent of military personnel, women constitute almost one-fourth of all personality disorder discharges. Survivors of sexual assault in the military report long-lasting effects, including PTSD, depression, suicidal ideation and attempts, eating disorders, anxiety disorders, relationship difficulties, and substance abuse. Wolf (2012) notes that among military veterans, the leading cause of PTSD for men is combat trauma, whereas for women it is sexual trauma. She states, "Our women veterans are more likely to be traumatized by a sexual assault by a fellow soldier or a commander than by their own battlefield or war experiences."

Differential Treatment and Conditions Although their numbers have increased, women still constitute a minority in the military. One female officer accounted that because of the small number of women in any given unit, officers and enlisted personnel are often housed together. She indicated that she missed being with other officers to discuss work and spend time with her peers. She also reported that the enlisted women were uncomfortable with an officer in their presence. Burgess and associates (2013) add that when sexual trauma occurs among military personnel, it is

occurring in the workplace, and as such, the victim often has ongoing contact with the perpetrator and may also be in a dependent position if the perpetrator was in a supervisory role.

Women's military careers are often limited by their exclusions from occupational specialties. These sanctions often preclude female officers and enlisted personnel from the most prestigious units and occupations in the military, their participation in which is essential to ascending in the ranks should they choose to make the military a career. Fear of additional occupational discrimination may prevent women from reporting sexual harassment and assault. Many bans have been lifted, and occupations that historically have been off limits are now open to women. However, the manner in which the culture within the military will respond to those changes remains to be seen.

Parenting Issues Women's feelings associated with leaving their children often differ from those of men. Women seem to struggle more with guilt feelings for "abandoning" their children, whereas men have stronger emotions tied to a sense of doing their duty. Although men also experience regret at leaving their children, they often rely on the assurance that the children have their mothers to care for them.

Veterans

Most veterans returning from a combat zone undergo a period of adjustment. A recent study of young veterans (Pedersen, Marshall, & Kurz, 2016) identified that 70 percent screened as positive for behavioral health problems, less than a third of whom received adequate psychotherapy or psychotropic treatment. Many veterans suffer from migraine headaches and experience cognitive difficulties such as memory loss. Hypervigilance, insomnia, and jitteriness are common. The Substance Abuse and Mental Health Services Administration (Substance Abuse and Mental Health Services Administration [SAMHSA], 2012) states, "Veterans may struggle to concentrate; engage in aggressive behavior, such as aggressive driving; and use alcohol, tobacco, and drugs excessively. However, the intensity and duration of these and other worrisome behaviors can indicate a more serious problem and the need for professional treatment" (p. 1). Plach and Sells (2013) identified in a study of veterans that over 50 percent screened positive for problem drinking and over 90 percent had engaged in hazardous drinking (Cogan, 2014).

Traumatic Brain Injury

The incidence of **traumatic brain injury (TBI)** is a significant consequence of the Iraq and Afghanistan conflicts. Mild TBI is so frequent that it has been referred to as the "signature injury" of the wars in these countries (Cogan, 2014). The Defense and Veterans Brain Injury Center (DVBIC) report a total of 339,462 TBIs since 2000 and over 18,000 cases in 2015 alone (2016).

The Department of Veterans Affairs (VA) and the DoD offer the following definition of TBI:

A traumatically induced structural injury and/or physiological disruption of brain function as a result of an external force that is indicated by new onset or worsening of at least one of the following clinical signs, immediately following the event:

- Any period of loss of or a decreased level of consciousness
- Any loss of memory for events immediately before or after the injury (posttraumatic amnesia)
- Any alteration in mental state at the time of the injury (confusion, disorientation, slowed thinking, etc.) (Alteration of consciousness/mental state)
- Neurological deficits (weakness, loss of balance, change in vision, praxis, paresis/plegia, sensory loss, aphasia, etc.) that may or may not be transient
- Intracranial lesion (VA/DoD, 2016, pp. 4–5)

Symptoms may be classified as mild, moderate, or severe. In the civilian population, the most common causes of TBI include child abuse in infants and toddlers, motor vehicle accidents in adolescents and young adults, and falls and associated subdural hematomas in older adults (Strong & Donders, 2012). Blasts from explosive devices are the leading cause of TBI for active-duty military personnel in combat (Birk, 2010; Cogan, 2014). While the mechanism of damage from explosive blasts is not completely understood, researchers believe that it is "the pressure wave passing through the brain that significantly disrupts brain function" (Mayo Clinic, 2014). TBI also results from penetrating wounds, severe blows to the head with shrapnel or debris, and falls or bodily collisions with objects following a blast. Symptoms of TBI according to level of severity are presented in Table 38–1.

Most soldiers who have sustained a mild TBI improve with no lasting clinical complications (VA/DoD, 2016). Many recover within hours, days, or at most, weeks. In a small minority, symptoms persist from 6 months to a year. The location and severity of the injury are factors that determine the long-term outcome for individuals with TBI. Severity is determined by the nature, speed, and location of the impact and the presence of complications such as hypoxemia, hypotension, intracranial hemorrhage, or increased intracranial pressure (Ribbers, 2013).

The most common long-term consequences of TBI include problems with cognition (e.g., thinking, memory, and reasoning) and behavior or mental

TABLE 38–1 Criteria and Symptomatology of Traumatic Brain Injury According to Level of Severity		
MILD	**MODERATE**	**SEVERE**
CRITERIA Structural imaging = normal Loss of consciousness 0–30 min Alteration of consciousness/mental state = a moment up to 24 hrs Posttraumatic amnesia = 0–1 day Glasgow Coma Scale = 13–15	**CRITERIA** Structural imaging = normal or abnormal Loss of consciousness >30 min and <24 hrs Alteration of consciousness/mental state = >24 hours. Severity based on other criteria. Posttraumatic amnesia = >1 and <7 Days Glasgow Coma Scale = 9–12	**CRITERIA** Structural imaging = normal or abnormal Loss of consciousness >24 hrs Alteration of consciousness/mental state = >24 hours. Severity based on other criteria. Posttraumatic amnesia = >7 days Glasgow Coma Scale = <9
SYMPTOMS Headache Dizziness, ringing in the ears Nausea Trouble concentrating, confusion Blurred vision Changes in sleep patterns Mood changes Sensitivity to light or sound	**SYMPTOMS** Any of the symptoms of mild TBI Headache that gets worse or does not go away Repeated nausea and vomiting Seizures Difficulty awakening from sleep Dilation of one or both pupils of the eyes Slurred speech Weakness or numbness in the extremities Loss of coordination Increased confusion Restlessness Agitation	**SYMPTOMS** Any of the symptoms of mild TBI Headache that gets worse or does not go away Repeated nausea and vomiting Seizures Inability to awaken from sleep Dilation of one or both pupils of the eyes Slurred speech Weakness or numbness in the extremities Loss of coordination Profound confusion Restlessness Agitation

health (e.g., depression, anxiety, personality changes, aggression, acting out, and social inappropriateness) (Ribbers, 2013). Seizures occur in about 15 to 20 percent of individuals with TBI and commonly develop within the first 24 hours following the injury. With mild TBI, seizures usually subside within a week after the initial trauma. The potential for chronic epilepsy increases with severity of the injury.

Language and communication problems, such as aphasia, dysarthria, and dysphasia, can result from TBI (Safaz et al., 2008). Difficulties may also exist in the subtle aspects of communication, such as body language and nonverbal expression.

Studies show that TBI has long-term adverse effects on social functioning and productivity. Temkin and associates (2009) stated:

Penetrating head injury sustained in wartime is clearly associated with increased unemployment. TBI also adversely affects leisure and recreation, social relationships, functional status, quality of life, and independent living. Although there is a dose-response relationship between severity of injury and social

outcomes, there is insufficient evidence to determine at what level of severity the adverse effects are demonstrated. (p. 460)

Neurocognitive disorders, such as Alzheimer's disease (AD) and Parkinson's disease, are related to TBI (Ribbers, 2013). The risk for AD in individuals with moderate TBI is 2.3 times greater than that of the general population. An association between Parkinson's disease and TBI has also been established. The disorder may develop years after TBI as a result of damage to the basal ganglia (Ribbers, 2013).

Several factors have been identified that may worsen the condition of military personnel sustaining a TBI. Being in a high-stress environment, extreme temperatures such as the 120-degree heat common in Iraq, and delay of TBI recognition until the postdeployment period may all interfere with healing (Cogan, 2014). The prevalence as well as potential short- and long-term consequences suggest that screening for TBI should be conducted for any military personnel returning from active duty who presents with physical, cognitive, or emotional symptoms.

Posttraumatic Stress Disorder

PTSD is the most common mental disorder among veterans returning from military combat. The VA cites statistics that identify the lifetime prevalence for PTSD in the general population at 6.8 percent (Gradus, 2017). In comparison, they identify the following prevalence estimates for military veterans:

■ Veterans of OEF and OIF, 13.8 to 18.5 percent
■ Gulf War veterans, 10 percent
■ Vietnam veterans, 30 percent

The diagnostic criteria for PTSD from the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*, 2013) are presented in Chapter 28, Trauma- and Stressor-Related Disorders, of this text. The disorder can occur when an individual is exposed to an accident or violence in which death or serious injury to others or oneself occurs or is threatened. Symptoms of PTSD include:

■ Reliving the trauma through flashbacks, nightmares, and intrusive thoughts
■ Intensive efforts to avoid activities, people, places, situations, or objects that arouse recollections of the trauma
■ Chronic negative emotional state and diminished interest or participation in significant activities
■ Aggressive, reckless, or self-destructive behavior
■ Hypervigilance and exaggerated startle response
■ Angry outbursts, problems with concentration, and sleep disturbances

Symptoms of PTSD may be delayed, in some instances for years. When emotions regarding the trauma are constricted, they may suddenly appear in the future following a major life event, stressor, or an accumulation of stressors over time that challenge the person's defenses. Symptoms also may be masked by other physical or mental health problems. In some instances, the symptoms do not appear to be problematic until the individual begins a readjustment to routine occupational or social functioning.

Reports indicate that some World War II veterans are only now, decades after returning from combat, being diagnosed with PTSD. At the time of their return, these veterans rarely spoke of their war experiences. But for many, the visions of horror have seeped to the surface in nightmares, flashbacks, anxiety, and emotional numbness. In a study at the University of Michigan, Dr. Helen Kales found that in a group of World War II veterans being treated for depression, 38 percent met the criteria for PTSD (Albrecht, 2009). Langer (2011) reported that the PTSD symptoms for these veterans seemed to become more prominent in midlife and that the most significant precipitant was retirement. For many, their work gave meaning to their lives, and without it the symptoms of depression, anxiety, substance abuse, and PTSD began to emerge. Langer (2011) stated:

> Besides retirement, other precipitants [to PTSD in midlife] include the deaths of friends, one's own deteriorating health, children becoming autonomous, divorce, and other losses associated with aging. Other precipitants include current events that trigger memories of one's own combat experience, e.g., 9/11, and other wars.

Veterans with PTSD experience marital and relationship difficulties, including higher rates of physical and verbal aggression against their partners and children and higher rates of divorce (Monson, Fredman, & Adair, 2008). In its report on the readjustment needs of veterans, the IOM (2013) identified a significant rise in domestic violence among veterans of the Iraq and Afghanistan wars and recommended this as a high priority for assessment and intervention. The burden of caregiving to a partner with PTSD has been noted as an etiological factor in relationship difficulties. The caregiver's perception of how caring for the impaired partner affects their social life, health, or financial status is directly associated with the degree of difficulty experienced in the relationship (Lavender & Lyons, 2012). Some caregivers may experience what has been termed *secondary trauma* or *vicarious traumatization,* a condition in which somatic symptoms and emotional distress occur as a response to caring for an individual who exhibits the symptoms of PTSD. Secondary symptoms are also common in children with a parent suffering from PTSD. Family members sometimes report having nightmares that mimic feelings and experiences of the veteran, difficulty sleeping, depression, and even visual hallucinations that are similar to the veteran's flashbacks.

Co-occurring disorders are common in individuals with PTSD, including major depressive disorder, substance use disorders, and anxiety disorders. Individuals with TBI also may develop PTSD, depending on the degree of amnesia experienced immediately following the cerebral trauma.

Depression and Suicide

Depressive disorders have been identified as a growing problem among Americans in general, with an estimated 16 million adults reporting at least one depressive episode each year (National Alliance on Mental Illness [NAMI], 2016). Depression has been identified as a significant problem among veterans as well. SAMHSA (2014) reports that 18.5 percent of veterans returning from Iraq or Afghanistan are diagnosed with depression or PTSD; the two are often comorbidities. Impairments are observed in the domains of home management, interpersonal relationships, and occupational and social functioning. The

Veteran's Health Administration (2015) reports that older adult veterans are a high-risk group for depression as well; 11 percent (twice that in the general population) have major depressive disorder, and 40 percent of veterans older than age 60 with depression also have PTSD. This finding highlights the importance of asking older veterans about past trauma.

Reports by the DoD and VA indicate that the number of suicides among veterans and active-duty military has risen dramatically since 2001, the year that detailed record-keeping began. This number reached an all-time high in 2012 with a rate of 22.7 suicides per 100,000 (319) active-duty military personnel. While that number declined somewhat in 2013 to 18.7 per 100,000 (259), the number of suicides among reservists and National Guard personnel remained alarmingly high at 23.4 to 28.9 per 100,000 respectively (Kime, 2015). When suicides among veterans are added to the numbers, the incidence is even higher. The IOM report (2013) identified that the VA policy against restricting access to privately owned weapons compounds suicide risk. In 2014, VA policies were expanded to allow commanders to discuss access to firearms with at-risk populations and provide for voluntary surrender of their firearms if they request it (Kime, 2015).

Suicide among military personnel is closely associated with the diagnoses of substance use disorder, major depressive disorder, PTSD, and TBI. A common theme among investigations of suicide attempts and completed suicides by military service members is marital/relationship distress. Devries and associates (2012) stated:

> From 2005 to 2009, relationship problems were a factor in over 50 percent of the suicides in the Army. The health of our military fighting force is directly related to the health of our military marriages. What we see in the military is a common drama of relationship problems played out in an environment of uncommon stressors. (p. 7)

A study by Jakupcak and associates (2010) concluded that veterans who are unmarried or report lower satisfaction with their social support networks are at increased risk for suicide.

The multiplicity of factors influencing these dramatic suicide rates makes it hard to pinpoint a specific cause, but it has captured the attention of the government and the general public. In 2015, President Obama signed into law the Clayton Hunt SAV (suicide prevention for American veterans) Act, which intends to expand peer support for troubled veterans, streamline transitions for exiting servicemen, and mandate annual surveying of VA mental health and suicide prevention programs, among other initiatives (NAMI, 2015). Clayton Hunt was a decorated Marine who struggled with PTSD and depression after returning home from active duty and took his own life in 2011.

Substance Use Disorder

In addition to rising suicide rates, substance use disorder has also been on the rise in the military. The Army Suicide Prevention Task Force reported that 29 percent of active-duty military suicides between 2005 and 2009 involved alcohol or drugs, and in 2009 about one-third involved prescription drugs (National Institute on Drug Abuse [NIDA], 2013). Substance use disorder is a common co-occurring condition with PTSD. One study reports that almost 22 percent of veterans with PTSD also receive a diagnosis of substance use disorder (Brancu, Straits-Troster, & Kudler, 2011). The combination of substance use, PTSD, depression, and TBI all contribute to a significant risk for mental health, relationship problems, difficult readjustment to home life, and in many cases risk for suicide.

Among veterans who sought treatment for substance use disorder, 65 percent (almost double that of the nonveteran population) identified alcohol as their primary substance of abuse, 10 percent identified heroin as their primary drug, and 6.2 percent primarily used cocaine (SAMHSA, 2015). As with U.S. civilians, opioid pain medication use and abuse among military personnel has been on the rise. NIDA (2013) reported that from 2005 to 2009, prescriptions for pain medications by military physicians quadrupled. Crosby (2015) reports that smoking tobacco among military personnel is also higher (24 percent) than in the general population. The IOM report (2013) on readjustment needs of veterans identified that as many as 39 percent of veterans are struggling with substance use issues. Their recommendations include supporting research to identify evidence-based treatments for substance use disorders as well as reevaluating policies about access to abused substances within the military. A firsthand account of what it was like for Sean, a soldier who served in Iraq, and his experiences afterward is presented in "Real People, Real Stories: The Military Experience."

Diagnosis and Outcome Identification

Nursing diagnoses are formulated from the data gathered during the assessment phase and with background knowledge regarding predisposing factors to the disorder. Table 38–2 presents a list of selected client behaviors and the NANDA nursing diagnoses that correspond to those behaviors, which may be used in planning assistance for families as they confront the unique challenges associated with military life. Outcome criteria are presented for each.

Real People, Real Stories: The Military Experience

(The individual requested that his real name not be used.)

Karyn: What was it like for you when you returned from your tour of duty?

Sean: I was in Iraq for 360 days, and when we landed in the U.S., there was a little welcome home ceremony, and then we went to hang out at the NCO club. The next day, there was a lot of paper to process for benefits and release forms. There was an assessment by a doctor that was about 5 minutes. Basically, they ask if you're okay and they take your word for it. If you say you're not okay, then you can't leave with everyone else. The third day, they encouraged us to join the American Legion and VFW clubs and then bussed us home.

Karyn: You've mentioned before that you had postconcussion headaches and some nightmares. Were you still having these symptoms when you got home?

Sean: Yeah, I had been in an area, during my tour of duty, where a roadside bomb detonated. At the time, I was having extreme headaches, and I got pain medications, but no one talked about what had happened or how I was handling that. The role of the military was to make the soldier mission-capable, so that meant just treating the symptoms. When I got home, I was still having some nightmares and headaches, but I couldn't talk about it. My wife was in the military too, so we had both learned not to talk about emotions. Within a year, I was drinking heavily and separated from my wife. I sought out treatment at the VA, but I only went three times. I felt like they were primarily trying to validate my story as if they wanted to defend themselves against a potential claim. They never asked about alcohol use. I felt angry, and I had some aggression. I felt abandoned. Then I found out my mom had stolen my military checks and had spent them. At that point, I lost faith in everything. All of my core beliefs were gone. The only thing I had faith in was my fellow soldiers, and now that we were back home, they weren't there.

Karyn: Do you get together with any fellow vets?

Sean: Mostly people connect over Facebook, so they don't really get together. The military clubs are all about drinking, so there aren't any healthy options. I do know, though, that sometimes when vets have gotten wind through Facebook that one of us is suicidal, they've traveled across the country to track them down and try to get them help.

Karyn: The suicide rates have been tragically high among vets. Have you ever had thoughts yourself about suicide?

Sean: I have. I was in a very dark place. I thought I was such an awful person that the best option was to kill myself. I was drinking, I was making bad moral decisions, and I was nasty to friends. I didn't care about anything or any consequences. I just wanted momentary relief, so I drank more, but, of course, that increased the depression. And it seems like every time we go to military exercises, we hear of another loss of someone to suicide. Last week, it was a fellow soldier who was a decorated hero for saving the lives of many of our guys. [Tearful.] So how do you rectify that someone saved all those lives and then comes home and takes their own life?

Karyn: It does seem like senseless, tragic loss. What has helped you get out of that dark place?

Sean: I have a brother who, even though he couldn't understand what I was going through, he kept checking in on me and repeatedly told me he was praying for me. He just kept showing up and telling me I had to get God back in my life. I knew he cared. I had a DUI and an accident, but I kept thinking, "I just have to suck it up and be stronger than this." Instead, the drinking just increases exponentially faster than you can respond or try to control it. One night, I went home and trashed my house. I was ripping sinks out of walls. I remember a neighbor came over and told me I just needed to sober up, but I called the police and told them to take me in. I knew I was out of control. When I got to the psych unit, I knew I wanted "fixed," but that mainly meant I wanted to be under control. I don't remember being asked if I wanted pills, but they gave me pills, and I didn't want to take them because it just made me feel less in control. There was an LPN there who told me that her husband was a vet and that she knew he was a good person. She said she never let his behavior define who he was. That gave me a lot of hope, like maybe I wasn't such an awful person. I reached out to God, and things started to change. I acknowledged that drinking was a primary issue, I cut ties with several unhealthy relationships, and there were supportive friends who came to visit me in the hospital, so I started to see that there were people who genuinely cared about me.

Karyn: What do you want health-care providers and fellow soldiers to learn from your experience?

Sean: First, a soldier is not who you are; it's a job you do. I wish I had spent more time before my deployment literally writing down all those things that define who I am, like, I'm a loving father and a good friend and what is most important to me; what am I willing to die for. I think it would have helped me, when I came back home, to concretely remind myself of who I am. It's easy to lose all sense of that in the military. Second, no mood-altering chemicals. There are a lot of things within the military that promote the use of chemicals such as alcohol and pain medication, and while it may keep people mission-ready or temporarily numb you, it becomes disastrous. Third, reach out for support or, if you are a health-care provider, help someone identify those people who will provide ongoing support. Supportive people and reaching out to God have been my lifelines.

Table 38–2 | NURSING DIAGNOSES: PLANNING CARE FOR MILITARY FAMILIES

RISK FACTORS/DEFINING CHARACTERISTICS	NURSING DIAGNOSES	OUTCOME CRITERIA
PTSD		
Rage reactions, aggression, irritability, substance use, flashbacks, startle reaction	Risk for other-directed violence	Client will demonstrate appropriate coping behaviors. Client will not harm others.
Depression, perception of lack of social support, physical disabilities from combat injuries, feelings of hopelessness	Risk for suicide	Client will not harm self.
Anger, aggression, depression, difficulty concentrating, flashbacks, guilt, headaches, hypervigilance, intrusive thoughts and dreams, nightmares, emotional numbness, panic attacks, substance abuse	Posttrauma syndrome related to having experienced the trauma of military combat	Client will begin a healthy grief resolution, initiating the process of psychological healing. Client will demonstrate ability to deal with emotional reactions in an individually appropriate manner.
Substance abuse	Ineffective coping; ineffective denial	Client will verbalize understanding of the destructiveness of substance abuse and demonstrate a more adaptive method of coping.
Confusion, fear, and anxiety among family members and their inability to deal with the affected member's unpredictable behavior; ineffective family decision-making process	Interrupted family processes related to crisis associated with veteran member's illness	Family will verbalize understanding of trauma-related illness, demonstrate ability to maintain anxiety at manageable level, and make appropriate decisions to stabilize family functioning.
TRAUMATIC BRAIN INJURY		
Impaired physical mobility, limited range of motion, decreased muscle strength and control, perceptual or cognitive impairment, seizures	Risk for injury	Client will remain free of physical injury.
Memory deficits; distractibility; altered attention span or concentration; impaired ability to make decisions, problem-solve, reason or conceptualize; personality changes	Disturbed thought processes*	Client will regain cognitive ability to execute mental functions realistic with the extent of the injury.
Inability to perform desired or appropriate activities of daily living	Self-care deficit (specify)	Client performs self-care activities within level of own ability.
Confusion, fear, and anxiety among family members and the inability to adapt to changes associated with veteran member's injury; difficulty accepting/receiving help; inability to express or to accept each other's feelings	Interrupted family processes related to situational transition and crisis; uncertainty about expectations and ultimate outcome	Family will verbalize understanding of trauma-related illness, demonstrate ability to maintain anxiety at manageable level, and make appropriate decisions to stabilize family functioning.
FAMILY MEMBERS' ISSUES		
Regressive behaviors, loss of appetite, temper tantrums, clinging behaviors, guilt and self-blame, sleep problems, irritability, aggression (children)	Risk for delayed development related to feelings of abandonment associated with parent's deployment	Parent/caregiver will identify behaviors at risk and initiate interventions to promote appropriate development.

Continued

Table 38–2	NURSING DIAGNOSES: PLANNING CARE FOR MILITARY FAMILIES—cont'd		
RISK FACTORS/DEFINING CHARACTERISTICS	**NURSING DIAGNOSES**	**OUTCOME CRITERIA**
Rebelliousness, irritability, acting out behaviors, promiscuity, substance use (adolescents)	Ineffective coping related to feelings of abandonment associated with parent's deployment	Child will develop healthy coping strategies and resume normal developmental progression. Client will work through stages of grief associated with the perceived loss and demonstrate healthy, age-appropriate coping strategies.
Depression, anxiety, loneliness, fear, feeling overwhelmed and powerless, anger (spouse/partner)	Risk for complicated grieving related to military deployment of spouse/partner	Client will work through stages of grief, achieve a healthy acceptance, and express a sense of control over the present situation and future outcome.
Anger, anxiety, frustration, ineffective coping, sleep deprivation, somatic symptoms, fatigue (spouse/partner/caregiver)	Caregiver role strain related to complexity of care-giving responsibilities; lack of respite	Caregiver will demonstrate effective problem-solving skills and develop adaptive coping mechanisms to regain equilibrium.

*This diagnosis has been resigned from the NANDA-I list of approved diagnoses. It is used in this instance because it is most compatible with the identified behaviors.

Planning, Implementation, and Evaluation

Nurses provide care for service members, veterans, and their families in a variety of settings, including general hospitals, VA hospitals, community health centers, doctors' offices, long-term care centers, and community-based clinics. The care required by veterans returning from combat in the war on terrorism is complex and multifaceted. War-related physical injuries are often striking and conspicuous in their visibility. However, it is the veterans' *invisible* injuries that psychiatric-mental health nurses are most often called upon to treat. The need for nurses to provide care for the increasing number of veterans with these invisible injuries is intensifying, and the VA continues to search for more effective ways to ensure that military veterans and families receive the care that they desperately need and deserve. Clever and Segal (2013) caution that even though military families have some unique challenges, including compounding issues when both spouses are in the military, they are a diverse group and their needs are dynamic as they move through transitions in their military career and family life.

Interventions for a selected number of nursing diagnoses relevant to veterans and military families are presented in Table 38–3. Evaluation is conducted by reassessing to determine if the nursing actions have been successful in meeting the outcome criteria.

Treatment Modalities

Posttraumatic Stress Disorder

Psychosocial Therapies

Cognitive therapy, prolonged exposure therapy, group and family therapy, and eye movement desensitization and reprocessing have all been used successfully in the treatment of PTSD.

Psychopharmacology

Selective serotonin reuptake inhibitors (SSRIs) are now considered the first-line treatment of choice for PTSD because of their efficacy, tolerability, and safety ratings. Other antidepressants that have been effective include trazadone, the tricyclics amitriptyline and imipramine, and the monoamine oxidase inhibitor phenelzine. Benzodiazepines are sometimes prescribed for their antipanic effects, although their addictive properties make them less desirable. Antihypertensives, such as propranolol and clonidine, have been successful in alleviating symptoms such as nightmares, intrusive recollections, hypervigilance, insomnia, startle responses, and angry outbursts. More recently, intravenous ketamine infusions (in combination with psychotherapy) have demonstrated efficacy in treating PTSD (Chaverneff, 2016). While these findings are still under further investigation, the researcher identifies that ketamine binds at *N*-methyl-D-aspartate receptors, which impacts fear learning and extinction.

TABLE 38–3 **Nursing Interventions for Veteran Clients and Military Families**	
Posttrauma syndrome (PTSD)	Stay with the client during periods of flashbacks and nightmares and offer reassurance of personal safety. Encourage the client to talk about the traumatic experience at his or her own pace. Discuss maladaptive coping mechanisms being employed. Assist the client in his or her effort to use more adaptive strategies. Include available support systems, and make referrals for additional assistance where required. Help client understand that use of substances merely numbs feelings and delays healing. Refer for treatment of substance use disorder. Discuss use of stress-management techniques, such as deep breathing, meditation, relaxation, and exercise. Administer medications as prescribed, and provide medication education.
Risk for suicide (PTSD, TBI)	Assess degree of risk according to seriousness of threat, existence of a plan, and availability and lethality of the means. Ask directly if person is thinking of acting on thoughts or feelings. Ascertain presence of significant others for support. Determine whether substance use is a factor. Encourage expression of feelings, including appropriate expression of anger. Ensure that environment is safe. Help client identify more appropriate solutions and offer hope for the future. Collaborate with the client to develop a plan for ongoing safety. Involve family/significant others in the planning.
Disturbed thought processes (TBI)	Evaluate mental status, including extent of impairment in thinking ability; remote and recent memory; orientation to person, place, and time; insight and judgment; changes in personality; attention span, distractibility, and ability to make decisions or problem-solve; ability to communicate appropriately; anxiety level; evidence of psychotic behavior. Report to physician any cognitive changes that become obvious. Note behavior indicative of potential for violence and take appropriate action to prevent harm to client and others. Provide safety measures as required. Institute seizure precautions if indicated. Assist with limited mobility issues. Monitor medication regimen. Refer to appropriate rehabilitation providers.
Interrupted family processes (PTSD; TBI)	Encourage the importance of continuous, open communication between family members to facilitate ongoing problem-solving. Assist the family to identify and use previously successful coping strategies. Encourage family participation in multidisciplinary team conference or group therapy. Involve family in social support and community activities of their interest and choice. Encourage use of stress-management techniques. Make necessary referrals (e.g., parent effectiveness training, specific disease or disability support groups, self-help groups, clergy, psychological counseling, or family therapy). Assist family to identify situations that may lead to fear or anxiety. Involve family in mutual goal-setting to plan for the future. Identify community agencies from which family may seek assistance (e.g., Meals on Wheels, visiting nurse, trauma support group, American Cancer Society, Veterans Administration).
Risk for complicated grieving (family of deployed service member)	Help family members to realize that all of the feelings they are having are a normal part of the grieving process. Validate their feelings of anger, loneliness, fear, powerlessness, dysphoria, and distress at separation from their loved one.

Continued

TABLE 38–3 **Nursing Interventions for Veteran Clients and Military Families—cont'd**	
	Help parent to understand that children's and adolescents' problematic behaviors are symptoms of grieving, and that they should not be deemed unacceptable and result in punishment, but rather be recognized as having their basis in grief.
	Children should be allowed an appropriate amount of time to grieve. Some experts believe children need at least 4 weeks to adjust to a parent's deployment (Gabany & Shellenbarger, 2010). Refer for professional help if improvement is not observed in a reasonable period of time.
	Assess if maladaptive coping strategies, such as substance abuse, are being used.
	Identify and encourage clients to employ previously used successful coping strategies.
	Encourage resuming involvement in usual activities.
	Caution against spending too much time alone.
	Suggest keeping a journal of experiences and feelings.
	Refer to other resources, as needed, such as psychotherapy, family counseling, religious references or pastor, or grief support group.
Caregiver role strain (spouse/caregiver of injured service member)	Assess the spouse/caregiver's ability to anticipate and fulfill the injured service member's unmet needs. Provide information to assist the caregiver with this responsibility.
	Ensure that the caregiver encourages the injured service member to be as independent as possible.
	Encourage the caregiver to express feelings and to participate in a support group.
	Provide information or demonstrate techniques for dealing with acting out, violent, or disoriented behavior by the injured service member.
	Identify additional needs and ensure that resources are provided (e.g., physical therapy, occupational therapy, nutritionist, financial and legal help, and respite care).
	Assess for abuse of substances as a coping strategy.
	Refer to counseling or psychotherapy as needed.

Keizer (2016; the researcher cited by Chaverneff) indicates that these treatments allow veterans to remember what happened to them but with less fear. He further notes that 50 percent of military veterans with PTSD also have chronic pain. The use of ketamine demonstrated efficacy in treating both issues.

Complementary Therapies

Acupuncture and pet therapy have been successful adjuncts to treatment for individuals with PTSD. Relaxation techniques have been shown to alleviate symptoms associated with physiological hyperreactivity, and hypnosis may be helpful for symptoms such as pain, anxiety, dissociation, and nightmares (Brancu et al., 2011).

Traumatic Brain Injury

The type of care for the client with TBI depends on severity of the injury and area of the brain involved. Brancu and associates (2011) state, "Since 90 percent of patients have mild cases and experience full recovery, early intervention involving education and a focus on recovery is strongly recommended" (p. 59).

Psychosocial Therapies

Cognitive-behavioral therapy (CBT) has been shown to be helpful to individuals with TBI. Scorer (2013) states,

"An advantage of [CBT] interventions is that, given their highly structured content, they are amenable to specialized adaptation for memory, attention, and problem-solving impairments, reflecting the difficulties people with TBI often experience." Chard and associates (2011), as cited by Cogan (2014), found that cognitive processing therapy, a modification of CBT, was effective in reducing psychological symptoms for individuals with comorbid PTSD and mild traumatic brain injury. Other therapies, such as prolonged exposure therapy, may also work well for veterans with mild TBI and emotional trauma (Brancu et al., 2011).

Rehabilitation Therapies

Rehabilitation therapy is multifaceted and determined by severity and location of the brain damage. Specialists in the care of the individual with TBI may include any or all of the following (Mayo Clinic, 2014):

- **Physiatrist:** A physician trained in the medical specialty of physical medicine and rehabilitation. This physician oversees other professionals involved in the rehabilitation process.
- **Occupational therapist:** Helps the individual learn, relearn, or improve skills for everyday living.
- **Physical therapist:** Assists the veteran with mobility and relearning movement patterns, balance, and walking.

- **Recreational therapist:** Assists with leisure activities.
- **Speech and language pathologist:** Helps the person improve communication skills and use assistive communication devices, if necessary.
- **Neuropsychologist or psychiatrist:** Helps the veteran manage behaviors or learn coping strategies, provides talk therapy as needed for emotional and psychological well-being, and prescribes medication as needed.
- **Social worker or case manager:** Coordinates access to services, assists with care decisions and planning, and facilitates communication among various professionals, care providers, and family members.

Psychopharmacology

Medications for the individual with TBI are given to ameliorate specific symptoms. Antidepressants are prescribed for depression, which is very prevalent in individuals with TBI. SSRIs are commonly the antidepressants of choice, although tricyclics and others, such as venlafaxine, trazodone, bupropion, and duloxetine, are also used. Benzodiazepines or SSRIs may be administered for treatment of anxiety symptoms, and antipsychotics are prescribed if aggression, agitation, or psychotic behaviors occur. Anticonvulsants are given if seizures are a problem, and the physician may prescribe skeletal muscle relaxants for muscle spasms or spasticity. Methylphenidate or modafinil has been used to treat attention deficits and hyperactivity, and donepezil has been shown to be effective in enhancing cognitive performance of individuals with TBI (Foster & Spiegel, 2008).

Summary and Key Points

- More than 3 million individuals are serving in the U.S. armed forces in more than 150 countries around the world.
- Veterans currently number 20.6 million.
- Since the beginning of the wars in Afghanistan and Iraq in 2001, more than 2.2 million U.S. military personnel have been deployed in 3 million tours of duty.
- The military lifestyle offers both positive and negative aspects for those who choose this way of life.
- To compensate for the extreme mobility, the focus of the military lifestyle turns inward to the military world rather than outward to the local community.
- In the OEF and OIF campaigns, there has been heavy dependence on the National Guard and Reserves and an escalation in the pace, duration, and number of deployments and redeployments experienced by these individuals.
- Military families face unique challenges, including frequent moves and many separations.
- Children and adolescents exhibit a number of problematic behaviors in response to the separation from a deployed parent.
- The cycle of deployment is described in five distinct stages: predeployment, deployment, sustainment, redeployment, and postdeployment.
- Special concerns of women in the military include sexual harassment, sexual assault, differential treatment and conditions, and issues related to being a parent.
- Evidence supports that a majority of young veterans screen positive for behavioral health problems and a third or less of those have had adequate health care treatment. Returning from a combat zone causes feelings and reactions that may contribute to difficulties with reintegration into civilian life.
- Traumatic brain injury (TBI) is a trauma-induced structural injury and/or physiological disruption of brain function as a result of an external force to the head.
- Symptoms of TBI are related to the severity of the injury and the area of the brain that has been injured.
- The most common long-term consequences of TBI include problems with cognition and behavior or mental health.
- PTSD is the most common mental disorder among veterans returning from military combat.
- Symptoms of PTSD may occur shortly after the trauma or may be delayed, in some instances for years.
- Depression among military veterans is quite common, and suicide rates among veterans and service members have continued to rise.
- Substance use disorder is a common co-occurring condition with PTSD.
- Nursing care of military families and veterans is multifaceted and requires reassessment over time using the six steps of the nursing process. Treatment modalities for PTSD and TBI include psychosocial therapies, psychopharmacology, complementary therapies, and rehabilitation therapies.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Dana's husband, who was deployed to Afghanistan a year ago, is returning home this week. Which of the following postdeployment situations may be likely to occur during the first few months of his return? (Select all that apply.)
   a. A honeymoon period of physical reconnection
   b. Resistance from the spouse regarding possible loss of autonomy
   c. Rejection by the children for perceived abandonment
   d. A period of adjustment to reconnect emotionally

2. Which of the following is the leading cause of TBI in active-duty military personnel in combat?
   a. Military vehicle accidents
   b. Blasts from explosive devices
   c. Falls
   d. Blows to the head from falling debris

3. Shane, a veteran of the war in Iraq, has been diagnosed with PTSD. He is a client of the VA outpatient clinic. He tells the nurse that he experiences panic attacks. Which of the following medications may be prescribed for Shane to treat his panic attacks?
   a. Alprazolam
   b. Lithium
   c. Carbamazepine
   d. Haldol

4. Shane, a veteran of the war in Iraq, has been diagnosed with PTSD. He has been hospitalized after swallowing a handful of his antipanic medication. His physical condition was stabilized in the emergency department, and he has been admitted to the psychiatric unit. In developing his initial plan of care, which is the priority nursing diagnosis that the nurse selects for Shane?
   a. Posttrauma syndrome
   b. Risk for suicide
   c. Complicated grieving
   d. Disturbed thought processes

5. Mike was injured during combat in Afghanistan. He has a diagnosis of TBI. Which of the following medications might the physician prescribe to improve Mike's memory and thinking capability?
   a. Carbamazepine
   b. Duloxetine
   c. Donepezil
   d. Bupropion

6. Juan, a veteran of the war in Iraq, has been diagnosed with PTSD. He has been hospitalized on the psychiatric unit following an attempted suicide. In the middle of the night, he wakes up yelling and tells the nurse he was having a flashback to when his unit transport drove over an improvised explosive device (IED) and most of his fellow soldiers were killed. He is breathing heavily, perspiring, and his heart is pounding. The nurse's most appropriate *initial* intervention is which of the following?
   a. Contact the doctor on call to report the incident.
   b. Administer the prn order for chlorpromazine.
   c. Stay with Juan and reassure him of his safety.
   d. Have Juan sit outside the nurses' station until he is calm.

Review Questions—cont'd
Self-Examination/Learning Exercise

7. Mike, a veteran of combat in Afghanistan, has a diagnosis of mild TBI. The psychiatric home health nurse from the VA medical center is assigned to make home visits to Mike and his wife, Marissa, who is his caregiver. Which of the following would be an appropriate nursing intervention by the home health nurse? (Select all that apply.)
   a. Assess for use of substances by Mike or Marissa.
   b. Encourage Marissa to do everything for Mike to prevent further deterioration in his condition.
   c. Assess Marissa's level of stress and potential for burnout.
   d. Encourage Marissa to allow Mike to be as independent as possible.
   e. Suggest that Marissa ask the physician for a nursing home placement for Mike.

8. Which of the following psychosocial therapies has been shown to be helpful for clients with TBI?
   a. Eye movement desensitization
   b. Psychoanalysis
   c. Reality therapy
   d. Cognitive-behavioral therapy

9. Amy's husband of 1 year left 2 weeks ago for a year-long deployment in Afghanistan. Amy makes an appointment with the psychiatric nurse practitioner at the community mental health clinic. She tells the nurse that she can't sleep, has no appetite, is chronically fatigued, and thinks about her husband constantly and fears for his life. Which of the following might the nurse suggest/prescribe for Amy? (Select all that apply.)
   a. A prescription for sertraline, 50 mg/day
   b. Participation in a support group
   c. Resuming involvement in usual activities
   d. Regular relaxation exercises

Complementary and Psychosocial Therapies

39

CORE CONCEPTS

Alternative Medicine

Complementary Medicine

KEY TERMS

abreaction	automatic thoughts	passive-aggressive
acupoints	catharsis	psychoanalysis
acupressure	chiropractic medicine	qi
acupuncture	cognitive therapy	reality therapy
aggressive	free association	subluxation
allopathic medicine	meridians	yoga
assertive	nonassertive	

OBJECTIVES
After reading this chapter, the student will be able to:

1. Compare and contrast various types of conventional and alternative therapies.
2. Describe the philosophies behind various complementary therapies, including herbal medicine, acupressure and acupuncture, diet and nutrition, chiropractic medicine, therapeutic touch and massage, yoga, and pet therapy.
3. Discuss the historical background of various complementary therapies.
4. Describe the techniques used in various complementary therapies.
5. Discuss objectives and therapeutic strategies of various psychosocial therapies, including individual psychotherapy, assertiveness training, relaxation therapy, and cognitive therapy.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. How do alternative medicine and complementary medicine differ?
2. What is the Western medical philosophy regarding the efficacy of acupressure and acupuncture?
3. What herbal remedy has been used effectively for relief of migraine headaches?
4. Define the process called *abreaction.*

Complementary Therapies

The History of Medicine
  2000 BC—Here, eat this root.
  AD 1000—That root is heathen. Here, say this prayer.
  AD 1850—That prayer is superstition. Here, drink this potion.
  AD 1940—That potion is snake oil. Here, swallow this pill.
  AD 1985—That pill is ineffective. Here, take this antibiotic.
  AD 2000—That antibiotic is ineffective and dangerous. Here, eat this root.

                              —Anonymous

The connection between mind and body and the influence of each on the other is well recognized by all clinicians, and particularly by psychiatrists. Conventional medicine as it is currently practiced in the United States is based solely on scientific methodology. Known as **allopathic medicine,** this is the type of medicine historically taught in U.S. medical schools. Many individuals today are choosing to move away from conventional medicine by trying a variety of *alternative* approaches to health care.

CORE CONCEPT

Alternative Medicine

Interventions that differ from the traditional or conventional biomedical treatment of disease. "Alternative" refers to an intervention that is used *instead* of conventional treatment.

Some individuals do not completely abandon conventional medicine for alternative therapies. Instead, they may choose to *complement* the conventional methods with the addition of alternative strategies.

CORE CONCEPT

Complementary Medicine

A complementary therapy is an intervention that is different from but used *in conjunction with* traditional or conventional medical treatment.

In the United States, approximately 34 percent of adults use some form of complementary or alternative therapy (Clarke et al., 2015). The most commonly used complementary approaches are vitamins and prayer, followed by nonvitamin, nonmineral dietary supplements such as fish oil and glucosamine chondroitin. According to Clarke and associates' analysis

of National Health Interview Survey (NHIS) data, probiotic or prebiotic use has quadrupled since 2007, and melatonin use has doubled over the same time period. Deep-breathing exercises and yoga continue to be the next most frequently used complementary approaches after dietary supplements, and yoga showed a linear increase in popularity from 2002 to 2012 (the most recent year in the survey data). Years ago it was predicted that all complementary therapies would continue to increase in popularity over time, but the survey data have not supported that trend. In 2002, roughly 32 percent of the U.S. population used complementary approaches; in 2007, that number increased to 35 percent and then, in 2012, as previously mentioned, declined to 34 percent. Some individual approaches, such as yoga, have gained popularity in recent years, whereas others, such as the use of echinacea, have declined.

In 1991, the National Institutes of Health (NIH) established the Office of Alternative Medicine to study nontraditional therapies and evaluate their usefulness and effectiveness. Since that time, the name was changed to the National Center for Complementary and Alternative Medicine (NCCAM) and most recently has been changed to the National Center for Complementary and Integrative Health (NCCIH). According to the mission statement of NCCIH:

> The mission of NCCIH is to define, through rigorous scientific investigation, the usefulness and safety of complementary and integrative health interventions and their roles in improving health and health care. (National Institutes of Health [NIH], 2016)

Although there is no universal classification for complementary and alternative medicine (CAM), NCCIH (while it was still NCCAM) grouped CAM practices and modalities into five domains. Some types of practices may overlap; that is, they may fall within more than one domain (e.g., qi gong is considered part of both Chinese medicine and energy therapy). Within the five major domains, the practices have been subdivided into three categories: (1) those that fall under CAM, (2) those that are found in conventional health care but are classified as behavioral medicine, and (3) those that overlap between the two (DeSantis, 2015). A list of the five domains of complementary and alternative medicine practices and examples of each is presented in Table 39–1. Figure 39–1 shows the 10 most common CAM therapies among adults.

Some health insurance companies and health maintenance organizations appear to be bowing to public pressure by including providers of alternative therapies in their networks of providers for treatments such as acupuncture and massage therapy. Chiropractic care has been covered by some third-party payers for many

FIGURE 39–1 The 10 most common CAM therapies among adults. (Source: National Health Interview Survey, 2012, as cited by Clarke et al., 2015).

years. Individuals who seek alternative therapy, however, are often reimbursed at lower rates than those who choose conventional practitioners. Some provisions of the Affordable Care Act appear to promote coverage for CAM therapies, since the law prohibits discrimination against coverage of licensed health-care providers—including practitioners of alternative medicine. However, insurance companies can still limit coverage if they deem the therapy to be experimental or medically unnecessary or if there is insufficient evidence of safety and effectiveness (Renter, 2015). The need for ongoing research is clear.

Client education is an important part of complementary care. Positive lifestyle changes are encouraged, and practitioners serve as educators as well as treatment specialists. Complementary medicine is viewed as *holistic* health care, which deals not only with the physical perspective, but also the emotional and spiritual components of the individual. Interest in holistic health care is increasing worldwide. A large number of U.S. medical schools—among them Harvard, Yale, Johns Hopkins, and Georgetown Universities—now offer coursework in holistic methods. In recent policy statements, the American Medical Association resolves to support the incorporation of CAM in medical education and continuing medical education curricula, covering CAM's benefits, risks, and efficacy (CAM Law, 2015).

Terms such as *harmony* and *balance* are often associated with complementary care. Restoring harmony and balance between body and mind is often the goal of these health-care approaches.

This chapter examines various complementary therapies by describing the therapeutic approach and identifying the conditions for which the therapy is intended. Although most are not founded in scientific principle, they have been shown to be effective in the treatment of certain disorders and merit further examination as a viable component of holistic health care.

Commonalities and Contrasts

A number of commonalities and contrasts exist between complementary medicine and conventional health care. DeSantis (2015) states,

> Conventional medicine focuses on the physical or material part of the person, the body. It is concerned with the structure, function, and connections or communication between material elements that compose the body, such as bones, muscles, and nerves. Conventional medicine generally views all humans as being very similar biologically. Disease is seen as a deviation from what is generally considered to be a normal biological or somatic state. (p. 623)

In contrast, the alternative approach views the person-body as consisting of multiple, integrated elements that incorporate both the materialistic and nonmaterialistic aspects of existence. These elements include the physical, spiritual, energetic, and social bodies. From this viewpoint, diagnostic measures and interventions cannot be based on only one aspect of the person's being, but must be tailored to the person-body of each individual (p. 625).

A summary of these characteristics is presented in Table 39–2.

TABLE 39–2	Commonalities and Contrasts Between Conventional and Complementary or Alternative Therapies
CONVENTIONAL	**COMPLEMENTARY/ALTERNATIVE**
Chemotherapy	Plants and other natural products
Curing/treating	Healing/ministering care
Individual viewed as disease category	Individual is viewed as a unique being
End stage	Hope/hopefulness
Focus is on disease and illness	Focus is on health and wellness
Illness treatment	Health promotion and illness prevention
Nutrition is adjunct and supportive to treatment	Nutrition is the basis of health, wellness, and treatment
Objectivism: Person is separate from his or her disease	Subjectivism: Person is integral to the illness
Patient/client	Person
Practitioner as authority	Practitioner as facilitator
Practitioner paternalism/client dependency	Practitioner as partner/person empowerment
Positivism/materialism: Data are physically measurable	Metaphysical: Entity is energy system or vital force
Reductionist	Holistic
Specialist care	Self-care
Symptom relief	Alleviation of causative factors
Somatic (biological and physiological) model	Behavioral-psycho-social-spiritual model
Science is only source of knowledge and truth	Multiple sources of knowledge and truth
Technology/invasive	Natural/noninvasive

Types of Complementary Therapies

Herbal Medicine

The use of plants to heal is probably as old as humankind. Virtually every culture in the world has relied on herbs and plants to treat illness. Clay tablets from about 4000 BC reveal that the Sumerians had apothecaries for dispensing medicinal herbs. At the root of Chinese medicine is the *Pen Tsao,* a text written around 3000 BC, which contained hundreds of herbal remedies. When the Pilgrims came to America in the 1600s, they brought a variety of herbs to be established and used for medicinal purposes. The new settlers soon discovered that the Native Americans also had their own varieties of plants used for healing.

Many people are seeking a return to herbal remedies because they perceive these remedies as being less potent than prescription drugs and as being free of adverse side effects. However, because the U.S. Food and Drug Administration (FDA) classifies herbal remedies as dietary supplements or food additives, their labels cannot indicate medicinal uses. They are not subject to FDA approval, and they lack uniform standards of quality control.

Several organizations have been established to attempt regulation and control of the herbal industry. They include the Council for Responsible Nutrition, the American Herbal Association, and the American Botanical Council. The Commission E of the German Federal Health Agency is the group responsible for researching and regulating the safety and efficacy of herbs and plant medicines in Germany. All of the Commission E monographs of herbal medicines have been translated into English and compiled into one text (Blumenthal, 1998).

Until more extensive testing has been completed on humans and animals, the use of herbal medicines must be approached with caution and responsibility. *The notion that something being "natural" means it is therefore completely safe is a myth.* In fact, some of the plants from which even prescription drugs are derived are highly toxic in their natural state. Also, because of lack of regulation and standardization, ingredients may be adulterated. Their method of manufacture also may alter potency. For example, dried herbs lose potency rapidly because of exposure to air. In addition, it is often safer to use preparations that contain only one herb. There is a greater likelihood of unwanted side effects with combined herbal preparations.

Table 39–3 lists information about common herbal remedies, with possible implications for psychiatric-mental health nursing. Botanical names, medicinal uses, and safety profiles are included.

TABLE 39–3 **Herbal Remedies**		
COMMON NAME (BOTANICAL NAME)	MEDICINAL USES/POSSIBLE ACTION	SAFETY PROFILE
Black cohosh (*Cimicifuga racemosa*)	May provide relief of menstrual cramps; improved mood; calming effect. Extracts from the roots are thought to have action similar to estrogen.	Generally considered safe in low doses. Occasionally causes gastrointestinal (GI) discomfort. Toxic in large doses, causing dizziness, nausea, headaches, stiffness, and trembling. Should not take with heart problems, concurrently with antihypertensives, or during pregnancy.
Cascara sagrada (*Rhamnus purshiana*)	Relief of constipation	Generally recognized as safe; sold as over-the-counter (OTC) drug in United States. Should not be used during pregnancy. Contraindicated in bowel obstruction or inflammation.
Chamomile (*Matricaria chamomilla*)	As a tea, is effective as a mild sedative in the relief of insomnia. May also aid digestion, relieve menstrual cramps, and settle upset stomach.	Generally recognized as safe when consumed in reasonable amounts.
Echinacea (*Echinacea angustifolia* and *Echinacea purpurea*)	Stimulates the immune system; may have value in fighting infections and easing the symptoms of colds and flu.	Considered safe in reasonable doses. Observe for side effects of allergic reaction.

TABLE 39–3 Herbal Remedies–cont'd

COMMON NAME (BOTANICAL NAME)	MEDICINAL USES/POSSIBLE ACTION	SAFETY PROFILE
Fennel (*Foeniculum vulgare* or *Foeniculum officinale*)	Used to ease stomachaches and to aid digestion. Taken in a tea or in extracts to stimulate the appetites of people with anorexia (1–2 tsp seeds steeped in boiling water for making tea).	Generally recognized as safe when consumed in reasonable amounts.
Feverfew (*Tanacetum parthenium*)	Prophylaxis and treatment of migraine headaches. Effective in either the fresh leaf or freeze-dried forms (two to three fresh leaves [or equivalent] per day).	A small percentage of individuals may experience the adverse effect of temporary mouth ulcers. Considered safe in reasonable doses.
Ginger (*Zingiber officinale*)	Ginger tea to ease stomachaches and to aid digestion. Two powdered ginger root capsules have shown to be effective in preventing motion sickness.	Generally recognized as safe in designated therapeutic doses.
Ginkgo (*Ginkgo biloba*)	Used to treat senility, short-term memory loss, and peripheral insufficiency. Has been shown to dilate blood vessels. Usual dosage is 120–240 mg/day.	Safety has been established with recommended dosages. Possible side effects include headache, GI problems, and dizziness. Contraindicated in pregnancy and lactation and in patients with bleeding disorder. Possible compound effect with concomitant use of aspirin or anticoagulants.
Ginseng (*Panax ginseng*)	The ancient Chinese saw this herb as one that increased wisdom and longevity. Current studies support a possible positive effect on the cardiovascular system. Action not known.	Generally considered safe. Side effects may include headache, insomnia, anxiety, skin rashes, and diarrhea. Avoid concomitant use with anticoagulants.
Hops (*Humulus lupulus*)	Used in cases of nervousness, mild anxiety, and insomnia. Also may relieve the cramping associated with diarrhea. May be taken as a tea, in extracts, or capsules.	Generally recognized as safe when consumed in recommended dosages.
Kava-kava (*Piper methysticum*)	Used to reduce anxiety while promoting mental acuity. Dosage: 150–300 mg bid.	Scaly skin rash may occur when taken at a high dosage for long periods. Motor reflexes and judgment when driving may be reduced while taking the herb. Concurrent use with central nervous system (CNS) depressants may produce additive tranquilizing effects. Reports of potential for liver damage. Investigations continue. Should not be taken for longer than 3 months without a doctor's supervision.
Passion flower (*Passiflora incarnata*)	Used in tea, capsules, or extracts to treat nervousness and insomnia. Depresses the CNS to produce a mild sedative effect.	Generally recognized as safe in recommended doses.
Peppermint (*Mentha piperita*)	Used as a tea to relieve upset stomachs and headaches and as a mild sedative. Pour boiling water over 1 tbsp dried leaves and steep to make a tea. Oil of peppermint is also used for inflammation of the mouth, pharynx, and bronchus.	Considered to be safe when consumed in designated therapeutic dosages.

Continued

TABLE 39–3 Herbal Remedies–cont'd		
COMMON NAME (BOTANICAL NAME)	MEDICINAL USES/POSSIBLE ACTION	SAFETY PROFILE
Psyllium (Plantago ovata)	Psyllium seeds are a popular bulk laxative commonly used for chronic constipation. Also found to be useful in the treatment of hypercholesterolemia.	Approved as an OTC drug in the United States.
Skullcap (Scutellaria lateriflora)	Used as a sedative for mild anxiety and nervousness.	Considered safe in reasonable amounts.
St. John's wort (Hypericum perforatum)	Used in the treatment of mild to moderate depression. May block reuptake of serotonin/norepinephrine and have a mild monoamine oxidase inhibiting effect. Effective dose: 900 mg/day. May also have antiviral, antibacterial, and anti-inflammatory properties.	Generally recognized as safe when taken at recommended dosages. Side effects include mild GI irritation that is lessened with food; photosensitivity when taken in high dosages over long periods. Should not be taken with other psychoactive medications.
Valerian (Valeriana officinalis)	Used to treat nervousness and insomnia. Produces restful sleep without morning "hangover." The root may be used to make a tea, or capsules are available in a variety of dosages. Mechanism of action is similar to benzodiazepines, but without addicting properties. Daily dosage range: 100–1000 mg.	Generally recognized as safe when taken at recommended dosages. Side effects may include mild headache or upset stomach. Taking doses higher than recommended may result in severe headache, nausea, morning grogginess, and blurry vision. Should not be taken concurrently with CNS depressants.

(2015). *Synopsis of psychiatry: Behavioral sciences/clinical psychiatry* (11th ed.). Philadelphia: Lippincott Williams & Wilkins.

CLINICAL PEARL It is important to ask the client about any herbal preparations he or she may be taking. The client may not think to mention these supplements when questioned about current medications. Herbals may interact with other medications, resulting in adverse physiological reactions. Document and report the client's history and current use of any herbal and over-the-counter preparations.

Acupressure and Acupuncture

Acupressure and **acupuncture** are healing techniques based on the ancient philosophies of traditional Chinese medicine dating back to 3000 BC. The main concept behind Chinese medicine is that healing energy (**qi**) flows through the body along specific pathways called **meridians** and that obstructions or unbalanced flow of energy can result in symptoms of illness. It is believed that these meridians of qi connect various parts of the body, similarly to the way in which lines on a road map link various locations. The pathways link a conglomerate of points called **acupoints.** Therefore, it is possible to treat a part of the body distant from another if the two points are linked by a meridian.

In acupressure, the fingers, thumbs, palms, or elbows are used to apply pressure to the acupoints. This pressure is thought to dissolve any obstructions in the flow of healing energy and to restore the body to healthier functioning. In acupuncture, hair-thin, sterile, disposable, stainless-steel needles are inserted into acupoints to dissolve the obstructions along the meridians. The needles may be left in place for a specified length of time, they may be rotated, or a mild electric current may be applied.

The Western medical philosophy regarding acupressure and acupuncture is that they stimulate the body's own painkilling chemicals—the morphine-like substances known as *endorphins.* Some studies have found that several factors, including expectation and beliefs, may account for the effectiveness of these procedures for treating pain conditions (NIH, 2016). Acupuncture has a wealth of research behind it that indicates effectiveness in treating pain conditions, but the benefits in treating other conditions remain uncertain (NIH, 2016).

Despite limitations in research, acupuncture is gaining wide acceptance in the United States by both patients and physicians. This treatment can be administered at the same time other techniques are being used, including conventional Western techniques, although it is essential that all health-care providers have knowledge of all treatments being received. One

recent study found evidence that acupuncture, when combined with nimodipine to treat mild cognitive impairment following a cerebral infarction, enhanced the effectiveness of the medication to a greater extent than either treatment used alone (Wang et al, 2016). Ongoing research may reveal additional benefits of combination therapies.

Properly performed acupuncture has minimal adverse effects, but improperly administered acupuncture can have serious side effects, including infection from improperly sterilized needles, punctured organs, and damage to the central nervous system. Acupuncture should be administered by a physician or an acupuncturist who is licensed by the state in which the service is provided. Typical training for licensed acupuncturists, doctors of oriental medicine, and acupuncture physicians is a 3- or 4-year program of 2,500 to 3,500 hours. Medical doctors and chiropractors who practice acupuncture must undergo 50 to 200 hours of acupuncture training. The National Commission for the Certification of Acupuncture and Oriental Medicine (NCCAOM) is attempting to set minimal competency standards in the United States through certification by their organization. A number of states have adopted NCCAOM's examination as part of their licensing criteria.

Diet and Nutrition

The value of nutrition in the healing process has long been underrated. Lutz and Przytulski (2015) state:

> Good nutrition is essential for good health and important for physical growth and development, good body composition, and mental development. A person's nutritional state can protect him from or predispose him toward chronic disease. Only recently has it been discovered that nutrition influences our genetic code. Medical treatment for many diseases includes diet therapy. Nutrition is thus both a preventive and a therapeutic science. (p. 5)

Individuals select the foods they eat on the basis of a number of factors, not the least of which is enjoyment. Eating must serve social and cultural as well as nutritional needs. The U.S. Departments of Agriculture (USDA) and Health and Human Services (USDHHS) have collaborated on a set of guidelines to help individuals understand what types of foods to eat and the healthy lifestyle they need to pursue in order to promote health and prevent disease. Following is a list of key recommendations from these guidelines (USDA/USDHHS, 2015).

Five key guidelines for establishing healthy eating patterns

> The latest edition of Dietary Guidelines for Americans (2015) shifts the focus from food groups to developing healthy eating patterns. The key guidelines are stated as such:

> 1. Follow a healthy eating pattern across the life span. All food and beverage choices matter. Choose a healthy eating pattern at an appropriate calorie level to help achieve and maintain a healthy body weight, support nutrient adequacy, and reduce the risk of chronic disease.
> 2. Focus on variety, nutrient density, and amount. To meet nutrient needs within calorie limits, choose a variety of nutrient-dense foods across and within all food groups in recommended amounts.
> 3. Limit calories from added sugars and saturated fats and reduce sodium intake. Consume an eating pattern low in added sugars, saturated fats, and sodium. Cut back on foods and beverages higher in these components to amounts that fit within healthy eating patterns.
> 4. Shift to healthier food and beverage choices. Choose nutrient-dense foods and beverages across and within all food groups in place of less healthy choices. Consider cultural and personal preferences to make these shifts easier to accomplish and maintain.
> 5. Support healthy eating patterns for all. Everyone has a role in helping to create and support healthy eating patterns in multiple settings nationwide, from home to school to work to communities.

Two premises within this model are that nutritional needs should primarily be met through food (rather than supplements) and that physical activity guidelines (also established by the USDA/USDHHS) should be incorporated in tandem with dietary patterns. Vitamin D deficiency may be an exception, as its link to depression has been well documented in research (Archer, 2013; Penckofer et al., 2010). The need for sunshine in the body's production of vitamin D and the benefits of supplementation to treat deficiencies have been supported as treatment options.

Foods and Food Components to Reduce

- Reduce daily sodium intake to less than 2,300 mg per day and further reduce intake to 1,500 mg among persons older than age 50 and those of any age who are African American or have hypertension, diabetes, or chronic kidney disease. The 1,500 mg recommendation applies to about half of the U.S. population, including children and the majority of adults.
- Consume less than 10 percent of calories from saturated fatty acids by replacing them with monounsaturated and polyunsaturated fatty acids.
- Consume less than 300 mg per day of dietary cholesterol.
- Keep trans-fatty acid consumption as low as possible by limiting foods that contain synthetic sources

of trans fats, such as partially hydrogenated oils, and by limiting other solid fats.

■ Consume less than 10 percent of daily calories from added sugars. Limit consumption of foods that contain refined grains, especially refined grain foods that contain solid fats, added sugars, and sodium.

■ If alcohol is consumed, it should be consumed in moderation—up to one drink per day for women and two drinks per day for men—and only by adults of legal drinking age. One drink is defined as
  ■ 12 ounces of regular beer (150 calories).
  ■ 5 ounces of wine (100 calories).
  ■ 1.5 ounces of 80-proof distilled spirits (100 calories).

Alcohol should be avoided by individuals who are unable to restrict their intake; women who are pregnant, may become pregnant, or are breastfeeding; and individuals who are taking medications that may interact with alcohol or who have specific medical conditions.

Foods and Nutrients to Increase

Individuals should meet the following recommendations as part of a healthy eating pattern while staying within their caloric needs.

■ Increase vegetable and fruit intake.
■ Eat a variety of vegetables, especially dark green, red, and orange vegetables, and beans and peas.
■ Consume at least half of all grains as whole grains. Increase whole-grain intake by replacing refined grains with whole grains.

■ Increase intake of fat-free or low-fat milk and milk products, such as milk, yogurt, cheese, or fortified soy beverages.

■ Eat a variety of protein foods that includes seafood, lean meat and poultry, eggs, beans and peas, soy products, and unsalted nuts and seeds.

■ Increase the amount and variety of seafood consumed by choosing seafood in place of some meat and poultry.

■ Replace protein foods that are higher in solid fats with choices lower in solid fats and calories and/or are sources of oils.

■ Use oils to replace solid fats where possible.

■ Choose foods that provide more potassium, dietary fiber, calcium, and vitamin D, which are nutrients of concern in American diets. These foods include vegetables, fruits, whole grains, and milk and milk products.

■ Meet recommended intakes within energy needs by adopting a balanced eating pattern, such as the USDA Food Guide (Table 39–4). Table 39–5 provides a summary of information about essential vitamins and minerals.

Building Healthy Eating Patterns

■ Select an eating pattern that meets nutrient needs over time at an appropriate calorie level.

■ Account for all foods and beverages consumed and assess how they fit within a healthy eating pattern.

■ Follow food safety recommendations when preparing and eating foods to reduce the risk of food-borne illnesses.

TABLE 39–4 Sample USDA Healthy Eating Pattern at the 2000-Calorie Level

FOOD GROUPS AND SUBGROUPS	USDA FOOD GUIDE DAILY AMOUNT	EXAMPLES/EQUIVALENT AMOUNTS
Fruit group	2 cups (4 servings)/day	½ cup equivalent is: ■ ½ cup fresh, frozen, or canned fruit ■ 1 medium fruit ■ ¼ cup dried fruit ■ ½ cup fruit juice
Vegetable group	2.5 cups (5 servings) ■ Dark green vegetables: 1.5 cups/wk ■ Red and orange vegetables: 5.5 cups/wk ■ Legumes (dry beans/peas): 1.5 cups/wk ■ Starchy vegetables: 5 cups/wk ■ Other vegetables: 4 cups/wk	½ cup equivalent is: ■ ½ cup cut-up raw or cooked vegetable ■ 1 cup raw leafy vegetable ■ ½ cup vegetable juice
Grain group	6 oz equivalents (eq) ■ Whole grains: 3 oz eq/day ■ Other grains: 3 oz eq/day	1 oz equivalent is: ■ 1 slice bread ■ 1 cup dry cereal ■ ½ cup cooked rice, pasta, cereal

TABLE 39–4 Sample USDA Healthy Eating Pattern at the 2000-Calorie Level—cont'd

FOOD GROUPS AND SUBGROUPS	USDA FOOD GUIDE DAILY AMOUNT	EXAMPLES/EQUIVALENT AMOUNTS
Protein foods	5.5 oz eq Seafood 8 oz eq/wk Meat, poultry, eggs 26 oz eq/wk Nuts, seeds, soy products 5 oz eq/wk	1 oz equivalent is: ■ 1 oz cooked lean meat, poultry, or fish ■ 1 egg ■ ¼ cup cooked dry beans or tofu ■ 1 tbsp peanut butter ■ ½ oz nuts or seeds
Dairy	3 cups	1 cup equivalent is: ■ 1 cup low fat/fat-free milk ■ 1 cup low fat/fat-free yogurt ■ 1½ oz low-fat or fat-free natural cheese ■ 2 oz low-fat or fat-free processed cheese
Oils	27 grams (6 tsp)	1 tsp equivalent is: ■ 1 tbsp low-fat mayo ■ 2 tbsp light salad dressing ■ 1 tsp vegetable oil ■ 1 tsp soft margarine with zero trans fat
Discretionary calorie allowance	270 calories Example of distribution: ■ Solid fats, 18 grams (e.g., saturated and trans fats) ■ Added sugars, 8 tsp (e.g., sweetened cereals)	1 added sugar equivalent is: ■ ½ oz jelly beans ■ 8 oz lemonade Examples of solid fats: ■ Fat in whole milk/ice cream ■ Fatty meats Essential oils (above) are not considered part of the discretionary calories

TABLE 39–5 Essential Vitamins and Minerals

VITAMIN/MINERAL	FUNCTION	DRI (UL)*	FOOD SOURCES	COMMENTS
Vitamin A	Prevention of night blindness; calcification of growing bones; resistance to infection	Men: 900 mcg (3,000 mcg) Women: 700 mcg (3,000 mcg)	Liver, butter, cheese, whole milk, egg yolk, fish, green leafy vegetables, carrots, pumpkin, sweet potatoes	May be of benefit in prevention of cancer, because of its antioxidant properties which are associated with control of free radicals that damage DNA and cell membranes.[†]
Vitamin D (also known as calciferol)	Promotes absorption of calcium and phosphorus in the small intestine; prevention of rickets	Men and women: 15 mcg (100 mcg) Men and women age >70: 20 mcg (100 mcg)	Fortified milk and dairy products, egg yolk, fish liver oils, liver, oysters; formed in the skin by exposure to sunlight	Without vitamin D, very little dietary calcium can be absorbed.
Vitamin E	An antioxidant that prevents cell membrane destruction	Men and women: 15 mg (1,000 mg)	Vegetable oils, wheat germ, whole grain or fortified cereals, green leafy vegetables, nuts	As an antioxidant, may have implications in the prevention of Alzheimer's disease, heart disease, breast cancer.[†]

Continued

TABLE 39–5 Essential Vitamins and Minerals—cont'd

VITAMIN/MINERAL	FUNCTION	DRI (UL)*	FOOD SOURCES	COMMENTS
Vitamin K	Synthesis of prothrombin and other clotting factors; normal blood coagulation	Men: 120 mcg (ND) Women: 90 mcg (ND)	Green vegetables (collards, spinach, lettuce, kale, broccoli, Brussels sprouts, cabbage), plant oils, and margarine	Individuals on anticoagulant therapy should monitor vitamin K intake.
Vitamin C	Formation of collagen in connective tissues; a powerful antioxidant; facilitates iron absorption; aids in the release of epinephrine from the adrenal glands during stress	Men: 90 mg (2,000 mg) Women: 75 mg (2,000 mg)	Citrus fruits, tomatoes, potatoes, green leafy vegetables, strawberries	As an antioxidant, may have implications in the prevention of cancer, cataracts, heart disease. It may stimulate the immune system to fight various types of infection.[†]
Vitamin B_1 (thiamine)	Essential for normal functioning of nervous tissue; coenzyme in carbohydrate metabolism	Men: 1.2 mg (ND) Women: 1.1 mg (ND)	Whole grains, legumes, nuts, egg yolk, meat, green leafy vegetables	Large doses may improve mental performance in people with Alzheimer's disease.
Vitamin B_2 (riboflavin)	Coenzyme in the metabolism of protein and carbohydrate for energy	Men: 1.3 mg (ND) Women: 1.1 mg (ND)	Meat, dairy products, whole or enriched grains, legumes, nuts	May help in the prevention of cataracts; high dose therapy may be effective in migraine prophylaxis (Schoenen, Jacquy, & Lenaerts, 1998).
Vitamin B_3 (niacin)	Coenzyme in the metabolism of protein and carbohydrates for energy	Men: 16 mg (35 mg) Women: 14 mg (35 mg)	Milk, eggs, meats, legumes, whole grain and enriched cereals, nuts	High doses of niacin have been successful in decreasing levels of cholesterol in some individuals.
Vitamin B_6 (pyridoxine)	Coenzyme in the synthesis and catabolism of amino acids; essential for metabolism of tryptophan to niacin	Men and women: 1.3 mg (100 mg) Men age >50: 1.7 mg Women age >50: 1.5 mg	Meat, fish, grains, legumes, bananas, nuts, white and sweet potatoes	May decrease depression in some individuals by increasing levels of serotonin; deficiencies may contribute to memory problems; also used in the treatment of migraines and premenstrual discomfort.
Vitamin B_{12} (also known as cobalamin)	Necessary in the formation of DNA and the production of red blood cells; associated with folic acid metabolism	Men and women: 2.4 mcg (ND)	Found in animal products (e.g., meats, eggs, dairy products)	Deficiency may contribute to memory problems. Vegetarians can get this vitamin from fortified foods. Intrinsic factor must be present in the stomach for absorption of vitamin B_{12}.

TABLE 39–5 **Essential Vitamins and Minerals—cont'd**				
VITAMIN/MINERAL	**FUNCTION**	**DRI (UL)***	**FOOD SOURCES**	**COMMENTS**
Folic acid (folate)	Necessary in the formation of DNA and the production of red blood cells	Men and women: 400 mcg (1,000 mcg) Pregnant women: 600 mcg	Meat; green leafy vegetables; beans; peas; fortified cereals, breads, rice, and pasta	Important in women of childbearing age to prevent fetal neural tube defects; may contribute to prevention of heart disease and colon cancer.
Calcium	Necessary in the formation of bones and teeth; neuron and muscle functioning; blood clotting	Men and women: 1,000 mg (max 2,500 mg) Women age >50: 1,200 mg (max 2,000) Men age >70: 1,200 mg	Dairy products, kale, broccoli, spinach, sardines, oysters, salmon	Calcium has been associated with preventing headaches, muscle cramps, osteoporosis, and premenstrual problems. Requires vitamin D for absorption.
Phosphorus	Necessary in the formation of bones and teeth; a component of DNA, RNA, ADP, and ATP; helps control acid-base balance in the blood	Men and women: 700 mg (4,000 mg)	Milk, cheese, fish, meat, yogurt, ice cream, peas, eggs	
Magnesium	Protein synthesis and carbohydrate metabolism; muscular relaxation following contraction; bone formation	Men: 420 mg (350 mg)‡ Women: 320 mg (350 mg)‡	Green vegetables, legumes, seafood, milk, nuts, meat	May aid in prevention of asthmatic attacks and migraine headaches. Deficiencies may contribute to insomnia, premenstrual problems.
Iron	Synthesis of hemoglobin and myoglobin; cellular oxidation	Men: 8 mg (45 mg) Women: (45 mg) Childbearing age: 18 mg Women age >50: 8 mg Pregnant women: 27 mg Women who are breastfeeding: 9 mg	Meat, fish, poultry, eggs, nuts, dark green leafy vegetables, dried fruit, enriched pasta and bread	Iron deficiencies can result in headaches and feeling chronically fatigued.
Iodine	Aids in the synthesis of T_3 and T_4	Men and women: 150 mcg (1,100 mcg)	Iodized salt, seafood	Exerts strong controlling influence on overall body metabolism.
Selenium	Works with vitamin E to protect cellular compounds from oxidation	Men and women: 55 mcg (400 mcg)	Seafood, low-fat meats, dairy products, liver	As an antioxidant combined with vitamin E, may have some anticancer effect.† Deficiency has also been associated with depressed mood.

Continued

TABLE 39–5 **Essential Vitamins and Minerals–cont'd**				
VITAMIN/MINERAL	**FUNCTION**	**DRI (UL)***	**FOOD SOURCES**	**COMMENTS**
Zinc	Involved in synthesis of DNA and RNA; energy metabolism and protein synthesis; wound healing; increased immune functioning; necessary for normal smell and taste sensation.	Men: 11 mg (40 mg) Women: 8 mg (40 mg)	Meat, seafood, fortified cereals, poultry, eggs, milk	An important source for the prevention of infection and improvement in wound healing.

*Dietary Reference Intakes (DRIs) are based on the upper limits (ULs) advised in the most recent set of dietary recommendations for adults established by the Food and Nutrition Board of the Institute of Medicine, © 2004, with updated recommendations for calcium and vitamin D (2011). UL is the upper limit of intake considered to be safe for use by adults (includes total intake from food, water, and supplements). In addition to the UL, DRIs are composed of the Recommended Dietary Allowance (RDA, the amount considered sufficient to meet the requirements of 97% to 98% of all healthy individuals) and the Adequate Intake (the amount considered sufficient where no RDA has been established).
†The health benefits of antioxidants continue to be investigated.
‡UL for magnesium applies only to intakes from dietary supplements, excluding intakes from food and water.
ND = Not determined.

(2015). *Synopsis of psychiatry: Behavioral sciences/clinical psychiatry* (11th ed.). Philadelphia: Lippincott Williams & Wilkins.

Chiropractic Medicine

Chiropractic medicine is one of the most widely used forms of alternative healing in the United States. It was developed in the late 1800s by a self-taught healer named David Palmer and later reorganized and expanded by his son Joshua, a trained practitioner. Palmer's objective was to find a cure for disease and illness that did not use drugs but instead relied on more natural methods of healing. Palmer's theory behind chiropractic medicine was that energy flows from the brain to all parts of the body through the spinal cord and spinal nerves. When vertebrae of the spinal column become displaced, they may press on a nerve and interfere with the normal nerve transmission. Palmer named the displacement of these vertebrae **subluxation,** and he alleged that the way to restore normal function was to manipulate the vertebrae back into their normal positions. These manipulations are called *adjustments.*

Adjustments are usually performed by hand, although some chiropractors have special treatment tables equipped to facilitate these manipulations (Figure 39–2). Other processes used to facilitate the outcome of the spinal adjustment by providing muscle relaxation include massage tables, application of heat or cold, and ultrasound treatments.

The chiropractor takes a medical history and performs a clinical examination, which usually includes x-ray films of the spine. Today's chiropractors may practice "straight" therapy, meaning subluxation adjustments are the only procedure provided. *Mixer* is a term applied to a chiropractor who combines adjustments with adjunct therapies such as exercise, heat treatments, or massage.

Individuals seek treatment from chiropractors for many types of ailments and illnesses, most commonly back pain. In addition, chiropractors treat clients with headaches, neck injuries, scoliosis, carpal tunnel syndrome, respiratory and gastrointestinal disorders, menstrual difficulties, allergies, sinusitis, and certain sports injuries. Some chiropractors are employed by professional sports teams as their team physicians.

Chiropractors are licensed to practice in all 50 states, and treatment costs are covered by government and most private insurance plans. There are roughly 77,000 licensed chiropractors who collectively treat more than 27 million people in the United States annually (American Chiropractic Association, 2016).

Therapeutic Touch and Massage
Therapeutic Touch

Therapeutic touch was developed in the 1970s by Dolores Krieger, a nurse associated with the New York University School of Nursing. It is based on the philosophy that the human body projects a field of energy. When this field becomes blocked, pain or illness occurs. Practitioners of therapeutic touch use this method to correct these blockages, thereby relieving the discomfort and improving health.

The premise that the energy field extends beyond the surface of the body means the practitioner need not actually touch the client's skin. Instead, the therapist's hands are passed over the client's body, remaining 2 to 4 inches from the skin. The goal is to repattern

FIGURE 39–2 Chiropractic adjustments.

the energy field by performing slow, rhythmic, sweeping hand motions over the entire body. Heat should be felt where the energy is blocked. The therapist "massages" the energy field in that area, smoothing it out and thus correcting the obstruction. Therapeutic touch is thought to reduce pain and anxiety and promote relaxation and health maintenance. It has proved to be useful in the treatment of chronic health conditions.

Massage

Massage is the technique of manipulating the muscles and soft tissues of the body. Chinese physicians prescribed massage for the treatment of disease more than 5,000 years ago. The Eastern style focuses on balancing the body's vital energy (qi) as it flows through pathways (meridians), as described earlier in the discussion of acupressure and acupuncture. The Western style of massage focuses on muscles, connective tissues (e.g., tendons and ligaments), and the cardiovascular system. Its benefits are believed to include improved blood circulation, lymph flow, and muscle tone as well as tranquilizing effects (Sadock, Sadock, & Ruiz, 2015). Swedish massage, which is probably the best-known Western style, uses a variety of gliding and kneading strokes along with deep circular movements and vibrations to relax the muscles, improve circulation, and increase mobility.

Massage has been shown to be beneficial in reducing anxiety and pain perception, particularly pain associated with joint disease (Sadock et al., 2015). However, it is contraindicated in certain conditions, including for those with high blood pressure, acute infection, osteoporosis, phlebitis, skin conditions, and varicose veins. It also should not be performed over the site of a recent injury, bruise, or burn.

Massage therapists require specialized training in a program accredited by the American Massage Therapy Association and must pass the National Certification Examination for Therapeutic Massage and Bodywork. Laws related to licensure requirements vary from state to state.

Yoga

Yoga is thought to have developed in India some 5,000 years ago and is attributed to an Indian physician and Sanskrit scholar named Patanjali. The objective of yoga is to integrate the physical, mental, and spiritual energies that enhance health and well-being. Yoga has been found especially helpful in relieving stress and improving overall physical and psychological wellness. Proper breathing is a major component of yoga. It is believed that yoga breathing—a deep, diaphragmatic breathing—increases oxygen to brain and body tissues, thereby easing stress and fatigue and boosting energy.

Another component of yoga is meditation. Individuals who practice the meditation and deep breathing associated with yoga find that they are able to achieve a profound feeling of relaxation (Figure 39–3).

The most familiar type of yoga practiced in Western countries is hatha yoga. Hatha yoga uses body postures along with the meditation and breathing exercises to achieve a balanced, disciplined workout that releases muscle tension, tones the internal organs, and energizes the mind, body, and spirit to allow natural healing to occur. The complete routine of poses is designed to work all parts of the body, stretching and toning muscles, and keeping joints flexible. Studies have shown that yoga has provided benefits to some individuals with chronic low back pain, anxiety, depression, high blood pressure, rapid heart rate, and limited mobility (Sadock et al., 2015).

Pet Therapy

The therapeutic value of pets is no longer just theory. Evidence has shown that animals can directly influence a person's mental and physical well-being. Many pet therapy programs have been established across the country, and the numbers are increasing regularly.

FIGURE 39–3 Achieving relaxation through the practice of yoga.

Several studies have provided information about the positive results of human interaction with pets. Some of these include the following:

1. Petting a dog or cat has been shown to lower blood pressure. In one study, volunteers experienced a 7.1 mm Hg decrease in systolic and an 8.1 mm Hg decrease in diastolic blood pressure when they talked to and petted their dogs, compared with blood pressure when reading aloud or resting quietly (Whitaker, 2000).

2. Bringing a pet into a nursing home or other institution for the elderly has been shown in numerous studies to enhance a client's mood and social interaction (Banks & Banks, 2002; Godenne, 2001; Marx et al., 2010; Moretti et al., 2011). One study of 96 patients who were admitted to a coronary care unit for heart attack or angina revealed that in the year following hospitalization, the mortality rate among those who did not own pets was 22 percent higher than among pet owners (Whitaker, 2000).

3. Multiple studies have demonstrated the efficacy of pet therapy in reducing symptoms of depression (Siegel et al., 1999; Souter & Miller, 2007).

Some researchers believe that having a pet actually may slow the aging process among those who live alone (Figure 39–4). Loneliness often results in premature death, and having a pet mitigates the effects of loneliness and isolation. Whitaker (2000) suggests:

> Though owning a pet doesn't make you immune to illness, pet owners are, on the whole, healthier than those who don't own pets. Study after study shows that people with pets have fewer minor health problems, require fewer visits to the doctor and less medication, and have fewer risk factors for heart disease, such as high blood pressure or cholesterol levels. (p. 7)

FIGURE 39–4 Healthy aging with a pet.

It should be noted, however, that some studies have raised concerns over infection-control risks associated with pet therapy in institutional health-care settings and particularly among those who may be immunocompromised (Green, 2012). Certainly, hand washing before and after contact with a pet is recommended, but some clinicians oppose pet therapy in health-care institutions on the basis of the belief that risks for nosocomial infection outweigh the benefits.

It may never be known precisely why animals affect humans the way they do, but for those who have pets to love, the therapeutic benefits come as no surprise. Pets provide unconditional, nonjudgmental love and affection, which can be the perfect antidote for a depressed mood or a stressful situation. The role of animals in the human healing process still requires more research, but its validity is now widely accepted in both the medical and lay communities.

Psychosocial Therapies

Individual Psychotherapies

Individual psychotherapy takes place on a one-to-one basis between a client and a therapist. Mental health professionals who usually perform individual

psychotherapy include advanced practice registered nurses, psychiatric social workers, psychiatrists, psychologists, and licensed mental health counselors. An agreement is established and, within a therapeutic environment, the therapist assists the client to overcome behavioral symptoms or resolve interpersonal problems. Several models of individual psychotherapy are discussed in this section.

Psychoanalysis and Psychoanalytic Psychotherapy

Psychoanalysis is considered by many to be the foundation for individual psychotherapy. It was originated by Freud in the early 20th century. In **psychoanalysis,** a major goal is for the client to gain insight and understanding about current relationships and behavior patterns by confronting unconscious conflicts that surface in the transference relationship with the analyst. Psychoanalysis is a lengthy and costly type of treatment. Psychoanalytic psychotherapy is typically briefer and may be focused on specific conflicts. Some of the techniques used in psychoanalysis are described in the following subsections.

Free Association

Free association is a technique in which the therapist is largely nonverbal, perhaps simply introducing words or phrases. The client then verbalizes whatever thoughts come to mind. Proponents of this form of therapy believe that through freely associating, a conflict or issue may surface. Psychoanalytic psychotherapy rarely uses free association, since it is more focused on already-identified conflicts (Sadock et al., 2015).

Dream Analysis

In psychoanalysis, dreams are considered a symbolic window to unconscious conflict, so interpreting dreams is an important tool in this type of therapy. Freud even believed that some symbols that occur in dreams are universal symbols. Analyzing dreams may include free association as well as exploring the meaning of symbols expressed in dream content.

Hypnosis

Hypnotherapy is sometimes used in psychoanalysis as a tool for unlocking the unconscious or for searching further into "past-life regression." Hypnosis is very deep relaxation during which the therapist, who has been trained in techniques of trance formation, asks certain questions of the client. Guided imagery also may be used to help the client envision the situation in an effort to find the cause of the problem. At the close of the session, while the individual is still in the trance state, the therapist may offer some posthypnotic suggestions. These typically include positive, affirming statements for the client to think about and to assist the client with changes in behavior he or she wants to accomplish.

Catharsis

Black and Andreasen (2014) define **catharsis** as a process of talking about thoughts, events, and feelings to release into awareness issues or conflicts that have been repressed. Catharsis is used in psychoanalysis to allow the client to purge the repressed mental contents from the psyche. Maladaptive symptoms may be resolved by bringing unconscious thoughts and feelings into consciousness. Sometimes the individual not only may recall the painful experience but also may actually *relive* it, experiencing by the feelings and emotions associated with the event. This process is called **abreaction.**

Interpersonal Psychotherapy

Interpersonal psychotherapy (IPT) is a time-limited therapy that was developed for the treatment of major depression. Time-limited psychotherapies (also called *brief psychotherapy*) have a specific focus, identified goals, and a limited number of sessions. Theoretical approaches include psychoanalytic, psychodynamic, interpersonal, and integrative.

IPT is based on the concepts of Harry Stack Sullivan, assuming that the symptoms and social dysfunction associated with depression (and other psychiatric disorders) are correlated with difficulties in interpersonal relations. The overall goal of IPT is improvement in current interpersonal skills. Sessions generally occur weekly for about 12 to 16 weeks.

In the initial sessions, the therapist gathers information by taking a psychiatric history, identifying the major problem, establishing a diagnosis, and, together with the client, outlining the goals of therapy. A plan of action for the remaining therapy sessions defines specific interventions targeted at resolving the identified problem. Markowitz (2008) states:

> Sessions open with the question: "How have things been since we last met?" This focuses the patient on the recent interpersonal events and recent mood, which the therapist helps the patient to link. Therapists take an active, nonneutral, supportive, and hopeful stance to counter the depressed patient's pessimism. They elicit and emphasize the options that exist for change in the patient's life, options that the depressive episode may have kept the patient from seeing or exploring fully. Understanding the situation does not suffice: therapists stress the need for patients to test these options in order to improve their lives and simultaneously treat their depressive episodes. (p. 1194)

IPT as monotherapy has been used successfully with mild to moderate major depressive disorder. Studies

have shown that in clients with severe or recurrent major depressive disorder, a combination of psychotherapy and pharmacotherapy is better than either alone (Holland, 2013; Karasu et al., 2006). Clinical trials failed to demonstrate efficacy of IPT with substance use disorders (Markowitz, 2008). However, one study recommended that adaptations to IPT, such as incorporating elements of motivational interviewing and using the therapeutic relationship to develop the capacity for self-soothing, may improve outcomes of IPT with this population (Brache, 2012).

Reality Therapy

Reality therapy was developed in the mid-1960s by the American psychiatrist William Glasser. Based on control theory, reality therapy suggests that all individuals are responsible for what they choose to do. It includes the principle that human beings are born with the following five basic needs:

■ Power (includes achievement, competence, and accomplishment)
■ Belonging (includes social groups, as well as families and loved ones)
■ Freedom (includes independence and personal autonomy)
■ Fun (includes enjoyment and pleasure)
■ Survival (includes physiological needs, such as food, shelter, and sexual expression)

Personality development is viewed as an attempt to fulfill these five basic needs. Individuals choose behaviors and subsequently discover whether the chosen behaviors are effective or ineffective in satisfying those needs. In reality therapy, emphasis is on the present—the here and now. Past behavior is addressed only as it impacts present choices or future behavior. A primary function of the therapist is to assist the client in dealing with getting needs met in the present. The therapist helps the client identify needs that are not being met, correlate the unmet needs to current ineffective behaviors, and make conscious choices to change to more effective patterns of behavior in an effort to satisfy basic needs.

In reality therapy, psychopathology is viewed in terms of ineffective behaviors. Diagnoses and labels (e.g., neurotic or dysfunctional) are perceived as stereotypical and not particularly useful. The concept of *responsibility* is emphasized. Accepting responsibility for one's own behavior is equated with mental health. An individual who behaves responsibly is able to fulfill his or her basic needs without interfering with others' attempts at need fulfillment. An important part of the therapist's role is serving as a positive role model for responsible behavior.

Reality therapy can be very self-empowering for a client. Hope is instilled when therapy does not dwell on past failures, and the client is able to look forward to a change in behavior. Reality therapy promotes the conviction that although an individual is a product of the past, he or she need not continue as its victim.

Relaxation Therapy

Stress is a part of our everyday lives. It can be positive or negative, but it cannot be eliminated. Keeping stress at a manageable level is a lifelong process.

Individuals under stress respond with a physiological arousal that can be dangerous over long periods. Indeed, the stress response has been shown to be a major contributor, either directly or indirectly, to coronary heart disease, cancer, lung ailments, accidental injuries, cirrhosis of the liver, and suicide—six of the leading causes of death in the United States.

Relaxation therapy is an effective means of reducing the stress response in some individuals. The degree of anxiety that an individual experiences in response to stress is related to certain predisposing factors, such as innate temperament, past experiences resulting in learned patterns of responding, and existing conditions, such as health status, coping strategies, and adequacy of support systems.

Deep relaxation can counteract the physiological and behavioral manifestations of stress. Various methods of relaxation are described in the following subsections.

Deep-Breathing Exercises

Tension is released when the lungs are allowed to breathe in as much oxygen as possible. Deep-breathing exercises involve inhaling slowly and deeply through the nose, holding the breath for a few seconds, and then exhaling slowly through the mouth, pursing the lips as if trying to whistle.

Progressive Relaxation

This method of deep-muscle relaxation is based on the premise that the body responds to anxiety-provoking thoughts and events with muscle tension. Each muscle group is tensed for 5 to 7 seconds and then relaxed for 20 to 30 seconds, during which time the individual concentrates on the difference in sensations between the two conditions. Soft, slow background music may facilitate relaxation. A modified version of this technique (called *passive progressive relaxation*) involves relaxation of the muscles by concentrating on the feeling of relaxation within the muscle, rather than on the actual tensing and relaxing of the muscle.

Meditation

The goal of meditation is to gain mastery over attention. It brings on a special state of consciousness as attention is concentrated solely on one thought or object. During meditation, as the individual becomes

totally preoccupied with the selected focus, the respiration rate, heart rate, and blood pressure decrease. The overall metabolism declines and the need for oxygen consumption is reduced.

Mental Imagery

Mental imagery uses the imagination in an effort to reduce the body's response to stress. The frame of reference is very personal, based on what each individual considers to be a relaxing environment. The relaxing scenario is most useful when taped and played back at a time when the individual wishes to achieve relaxation.

Biofeedback

Biofeedback is the use of instrumentation to become aware of processes in the body that usually go unnoticed and to help bring them under voluntary control. Biological conditions, such as muscle tension, skin surface temperature, blood pressure, and heart rate, are monitored by the biofeedback equipment. With special training, the individual learns to use relaxation and voluntary control to modify the biological condition, in turn indicating a modification of the autonomic function it represents. Biofeedback is often used together with other relaxation techniques such as deep breathing, progressive relaxation, and mental imagery.

Assertiveness Training

Assertive behavior helps individuals feel better about themselves by encouraging them to stand up for their own basic human rights, which have equal representation for all individuals. However, along with rights come an equal number of responsibilities, and part of being assertive includes living up to these responsibilities.

Assertive behavior increases self-esteem and the ability to develop satisfying interpersonal relationships. This is accomplished through honesty, directness, appropriateness, and respecting one's own rights as well as the rights of others.

Individuals develop patterns of responding in various ways, such as through role modeling, receiving positive or negative reinforcement, or conscious choice. These patterns can take the form of nonassertiveness, assertiveness, aggressiveness, or passive-aggressiveness.

Nonassertive patterns of communication have the effect of pleasing others at the expense of denying one's own basic human rights. **Assertive** patterns of communication have the effect of expressing one's needs or rights while protecting the rights of others. Those who respond **aggressively** defend their own rights by violating the basic rights of others. Individuals who respond in a **passive-aggressive** manner defend their own rights by expressing resistance to social and occupational demands.

Some important behavioral considerations of assertive behavior include eye contact, body posture, personal distance, physical contact, gestures, facial expression, voice, fluency, timing, listening, thoughts, and content. Various techniques have been developed to assist individuals in the process of becoming more assertive. Some of these include the following:

■ **Standing up for one's basic human rights:**

EXAMPLE

"I have the right to express my opinion."

■ **Assuming responsibility for one's own statements:**

EXAMPLE

"I *don't want* to go out with you tonight," instead of "I *can't* go out with you tonight." The latter implies a lack of power or ability.

■ **Responding as a "broken record":** Persistently repeating in a calm voice what is wanted.

EXAMPLE

TELEPHONE SALESPERSON: "I want to help you save money by changing long-distance services."

ASSERTIVE RESPONSE: "I don't want to change my long-distance service."

TELEPHONE SALESPERSON: "I can't believe you don't want to save money!"

ASSERTIVE RESPONSE: "I don't want to change my long-distance service."

■ **Agreeing assertively:** Assertively accepting negative aspects about oneself. Admitting when an error has been made.

EXAMPLE

MS. JONES: "You sure let that meeting get out of hand. What a waste of time."

MS. SMITH: "Yes, I didn't do a very good job of conducting the meeting today."

■ **Inquiring assertively:** Seeking additional information about critical statements.

EXAMPLE

MALE BOARD MEMBER: "You made a real fool of yourself at the board meeting last night."

FEMALE BOARD MEMBER: "Oh, really? Just what about my behavior offended you?"

MALE BOARD MEMBER: "You were so damned pushy!"

FEMALE BOARD MEMBER: "Were you offended that I spoke up for my beliefs, or was it because my beliefs are in direct opposition to yours?"

■ **Shifting from content to process:** Changing the focus of the communication from discussing the

topic at hand to analyzing what is actually going on in the interaction.

EXAMPLE

WIFE: "Would you please call me if you will be late for dinner?"

HUSBAND: "Why don't you just get off my back! I always have to account for every minute of my time with you!"

WIFE: "Sounds to me like we need to discuss some other things here. What are you *really* angry about?"

■ **Clouding/fogging:** Concurring with the critic's argument without becoming defensive and without agreeing to change.

EXAMPLE

NURSE 1: "You make so many mistakes. I don't know how you ever got this job!"

NURSE 2: "You're right. I have made some mistakes since I started this job."

■ **Defusing:** Putting off further discussion with an angry individual until he or she is calmer.

EXAMPLE

"You are very angry right now. I don't want to discuss this matter with you while you are so upset. I will discuss it with you in my office at 3 o'clock this afternoon."

■ **Delaying assertively:** Putting off further discussion with another individual until one is calmer.

EXAMPLE

"That's a very challenging position you have taken, Mr. Brown. I'll need time to give it some thought. I'll call you later this afternoon."

■ **Responding assertively with irony:** Using a response that conveys a meaning that is opposite of its literal meaning.

EXAMPLE

MAN: "I bet you're one of them so-called 'women's libbers,' aren't you?"

WOMAN: "Why, yes, I am. Thank you for noticing."

The basic goal in assertive communication training is to help develop skill in one's ability to express what he or she feels and needs without becoming defensive and without violating the rights of others. Some clients beginning to learn these skills believe that assertive communication will get people to respond in certain ways or will get what is wanted from another person. That is manipulation and is not the goal of assertive communication. Further, we do not really have any control over another person's behaviors or responses, and if clients do not understand this at the outset, they may be setting themselves up for failure. It is important to educate clients that assertive communication skills are designed to empower them to express themselves and their needs more effectively.

Cognitive Therapy

Cognitive therapy, developed by Aaron Beck, is commonly used in the treatment of mood disorders. In cognitive therapy, the individual is taught to control the thought distortions that are considered a factor in the development and maintenance of mood disorders. In the cognitive model, depression is characterized by a triad of negative distortions related to expectations of the environment, self, and future. The environment and activities within it are viewed as unsatisfying, the self is unrealistically devalued, and the future is perceived as hopeless. In the same model, mania is characterized by a positive cognitive triad—the self is seen as highly valued and powerful, experiences within the environment are viewed as overly positive, and the future is seen as one of unlimited, though often unrealistic, opportunity.

The general goals in cognitive therapy are to obtain symptom relief as quickly as possible, to assist the client in identifying dysfunctional patterns of thinking and behaving, and to guide the client to evidence and logic that effectively tests the validity of the dysfunctional thinking. Therapy focuses on changing **automatic thoughts** that occur spontaneously and contribute to the distorted affect. Examples of automatic thoughts in depression include the following:

■ **Personalizing:** "I'm the only one who failed."
■ **All or nothing:** "I'm a complete failure."
■ **Mind reading:** "He thinks I'm foolish."
■ **Discounting positives:** "The other questions were so easy. Any dummy could have gotten them right."

Examples of automatic thoughts in mania include the following:

■ **Personalizing:** "She's this happy only when she's with me."
■ **All or nothing:** "Everything I do is great."
■ **Mind reading:** "She thinks I'm wonderful."
■ **Discounting negatives:** "None of those mistakes are really important."

The client is asked to describe evidence that both supports and disputes the automatic thought. The logic underlying the inferences is then reviewed with the client. Another technique involves evaluating what would most likely happen if the client's automatic thoughts were true. Implications of consequences are then discussed. In general, cognitive therapy involves a critical thinking process of exploring your thoughts about your thoughts. Cognitive behavior therapy adds

the elements of exploring how the way you think impacts the way you feel and behave.

Clients should not become discouraged if a specific technique seems ineffective. There is no single technique that works with all clients. He or she should be reassured that a number of techniques may be used, and both therapist and client may explore these possibilities. Cognitive therapy has been shown to be an effective treatment for mood disorders, particularly in conjunction with psychopharmacological intervention.

Summary and Key Points

- *Alternative* medicine includes practices that differ from the conventional ones used to treat disease.
- *Complementary* therapies work in partnership with conventional medical practice.
- Complementary therapies help the practitioner view the client in a holistic manner.
- Most complementary therapies consider the mind and body connection and strive to enhance the body's own natural healing powers.
- The NCCIH of the NIH has established a list of complementary and alternative therapies to be used in practice and for investigative purposes.
- Many people use herbal remedies because they consider them completely safe, but they are chemicals with both beneficial and adverse effects. They do not require approval by the FDA, so quality and strength may vary. Clients should be asked specifically if they use any herbal remedies because these supplements may interact with or potentiate other medications.
- With acupressure and acupuncture, pressure is applied or small needles are inserted into points along specific pathways of the body called meridians. This is done in an effort to dissolve obstructions in the flow of healing energy and restore the body to a healthier functioning.
- The value of nutrition in the healing process has long been underrated. Nutrition is, in part, a preventive science. The USDA and the USDHHS have collaborated on a set of guidelines to help individuals understand what types of foods to eat and the healthy lifestyle they need to pursue in order to promote health and prevent disease.
- The theory behind chiropractic medicine is that energy flows from the brain to all parts of the body through the spinal cord and spinal nerves. When vertebrae become displaced, it interferes with normal nerve transmission. Chiropractic adjustments manipulate the displacements back into position, thereby restoring normal functioning.
- Therapeutic touch promotes relaxation and repatterns the body's energy field by unblocking obstructions. Massage relaxes muscles, improves circulation, and increases mobility.
- Yoga serves to integrate the physical, mental, and spiritual energies that enhance health and well-being. Body postures, breathing exercises, and meditation combine to achieve a balanced workout and allow natural healing to occur.
- The therapeutic benefits of pet ownership are widely accepted. The role of animals in the human healing process still requires more research, but its validity is now widely accepted in both the medical and lay communities.
- Nurses must be familiar with these therapies, as more and more clients seek out the healing properties of alternative and complementary care strategies.
- Psychosocial therapies are the tools of practitioners who work in psychiatry.
- Selected psychosocial therapies were discussed in this chapter: psychoanalysis, interpersonal psychotherapy, reality therapy, relaxation therapy, assertiveness training, and cognitive therapy. Advanced practice psychiatric nurses may use some of these therapies in their practices.
- It is important for all nurses to understand the concepts associated with these therapies in order to be effective members of the treatment team.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for the following questions.

1. Which of the following herbs is thought to be helpful in cases of nervousness, anxiety, and/or insomnia? (Select all that apply.)
   a. Chamomile
   b. Echinacea
   c. Kava-kava
   d. Ginseng
   e. Valerian
   f. Hops

2. Which of the following food groups do the USDA/USDHHS food guidelines recommend using in moderation? (Select all that apply.)
   a. Refined carbohydrates
   b. Fats
   c. Milk and milk products
   d. Sodium chloride
   e. Whole grains

3. Which of the following herbs is thought to be helpful in relieving menstrual cramping? (Select all that apply.)
   a. Feverfew
   b. Ginger
   c. Chamomile
   d. Black cohosh

4. With which of the following conditions should massage not be performed? (Select all that apply.)
   a. High blood pressure
   b. Neck pain
   c. Arthritis
   d. Phlebitis
   e. Osteoporosis

5. Which of the following applies to vitamin C?
   a. Coenzyme in protein metabolism; found in meat and dairy products
   b. Necessary in formation of DNA; found in beans and other legumes
   c. A powerful antioxidant; found in tomatoes and strawberries
   d. Necessary for blood clotting; found in whole grains and bananas

6. Which of the following applies to calcium?
   a. Coenzyme in carbohydrate metabolism; found in whole grains and citrus fruits
   b. Facilitates iron absorption; found in vegetable oils and liver
   c. Prevents night blindness; found in egg yolk and cantaloupe
   d. Important for nerve and muscle functioning; found in dairy products and oysters

7. Subluxation is a term used by chiropractic medicine to describe:
   a. Displacement of vertebrae in the spine.
   b. Adjustment of displaced vertebrae in the spine.
   c. Interference with the flow of energy from the brain.
   d. Pathways along which energy flows throughout the body

Review Questions—cont'd
Self-Examination/Learning Exercise

8. Tanya has been diagnosed with Dysthymic Disorder. The physician has just prescribed 20 mg/day of fluoxetine. Tanya tells the nurse that she has been taking St. John's wort but still feels depressed. Which of the following is the appropriate response by the nurse?
   a. "St. John's wort is not effective for depression."
   b. "Do not take fluoxetine and St. John's wort together."
   c. "You probably just need to increase your dose of St. John's wort."
   d. "Go ahead and take the St. John's wort with the fluoxetine. Maybe both of them together will be more helpful."

9. In reality therapy, a primary function of the therapist is
   a. Assisting the client to deal with getting current needs fulfilled.
   b. Hypnotizing the client to delve into the unconscious.
   c. Analyzing the possible meanings behind the client's dreams.
   d. Taking a psychiatric history and establishing a diagnosis.

10. A fellow worker often borrows small amounts of money from you with the promise that she will pay you back "tomorrow." She currently owes you $15 and has not yet paid back any money she has borrowed. She asks if she can borrow a couple of dollars for lunch. Which of the following is a *nonassertive* response?
    a. "I've decided not to loan you any more money until you pay me back what you already borrowed."
    b. "I'm so sorry. I only have enough to pay for my own lunch today."
    c. "Get a life, will you? I'm tired of you sponging off me all the time!"
    d. "Sure, here's two dollars." Then to the other workers in the office, "Be sure you never lend Cindy any money. She never pays her debts. I'd be sure never to go to lunch with her if I were you!"

11. Mallory's new in-laws came to dinner for the first time. When Mallory's mother-in-law left some food on her plate, Mallory thought, "I must be a lousy cook!" This is an example of which type of "automatic thought"?
    a. All or nothing
    b. Discounting positives
    c. Catastrophic thinking
    d. Personalizing

Relaxation Therapy

40

CORE CONCEPTS
Relaxation
Stress

KEY TERMS

biofeedback

meditation

mental imagery

progressive relaxation

stress management

OBJECTIVES
After reading this chapter, the student will be able to:

1. Identify conditions for which relaxation is appropriate therapy.
2. Describe physiological and behavioral manifestations of relaxation.
3. Discuss various methods of achieving relaxation.
4. Describe the role of the nurse in relaxation therapy.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Describe the physiological manifestations of relaxation.
2. What is the major difference in the techniques of progressive relaxation and modified (or passive) progressive relaxation?
3. What is the goal of meditation?
4. How does physical exercise work to decrease anxiety and depression?

Researchers now know that stress has a definite effect on the body, that stress can be caused by both negative and positive events, and that prolonged stress contributes to many physiological illnesses. Many times we hear, "Relax, take it easy, don't work so hard, don't worry so much; you'll live longer that way." This is good advice no doubt, but it is easier said than done.

Nurses are in an ideal position to assist individuals in managing stress in their lives. This chapter discusses the therapeutic benefits to the individual of regular participation in relaxation exercises. Various methods of achieving relaxation are described, and the nurse's role in helping individuals learn how to use relaxation techniques adaptively is explored.

CORE CONCEPT
Stress
A biological, psychological, social, or chemical factor that causes physical or emotional tension and may be a factor in the etiology of certain illnesses.

The Stress Epidemic

Individuals experience stress as a daily fact of life; it cannot be avoided. It is generated by both positive and negative experiences that require adjustment to various changes in one's current routine. Whether or not there is more stress today than in the past is unknown, but some experts have suggested that it has become more pervasive. This could be attributed to the many uncertainties and salient risks that challenge our most basic value systems.

In Chapter 1, The Concept of Stress Adaptation, a lengthy discussion was presented regarding the fight-or-flight response of the human body to stressful situations. This response served our ancestors well. The extra burst of adrenaline primed their muscles and focused their attention on the danger at hand, providing early *Homo sapiens* with the essentials to deal with life-and-death situations such as an imminent attack by a saber-toothed tiger or grizzly bear.

Today, with stress permeating our society, large segments of the population frequently experience the fight-or-flight response. However, the physiological reinforcements are not used in a manner that quickly returns the individual to homeostasis. The fight-or-flight emergency response is inappropriate to today's psychosocial stresses that persist over long periods. In fact, in today's society, rather than assisting with life-and-death situations, the response may actually be a contributing factor in some life-and-death situations. Stress is now known to be a major contributor, either directly or indirectly, to headaches, coronary heart disease, asthma, diabetes, skin conditions, arthritis, cancer, depression, and anxiety (National Institutes of Health, 2012; Paddock, 2013; WebMD, 2016). **Stress management** has become a multimillion-dollar business in the United States. Corporation managers have realized increases in production by providing employees with stress-reduction programs. Hospitals and clinics have responded to the need for services that offer stress management information to individuals and groups.

When, then, is relaxation therapy required? The answer to this question depends largely on *predisposing factors*—the genetic influences, past experiences, and existing conditions that influence how an individual perceives and responds to stress. For example, temperament (i.e., behavioral characteristics that are present at birth) often plays a determining role in the individual's manner of responding to stressful situations. Some individuals, by temperament, naturally respond with a greater degree of anxiety than others do.

Past experiences result in learned patterns that can influence an individual's adaptation response. They include previous exposure to the stressor or other stressors, learned coping responses, and degree of adaptation to previous stressors.

Existing conditions are the individual vulnerabilities that can influence the adequacy of the physical, psychological, and social resources for dealing with stressful situations. Examples include current health status, motivation, developmental maturity, severity and duration of the stressor, financial and educational resources, age, existing coping strategies, and a support system of caring others.

All individuals react to stress with predictable physiological and psychosocial responses. These predisposing factors determine the degree of severity of the response. Undoubtedly, there are very few people who would not benefit from some form of relaxation therapy. Miller and Rahe (1997) developed the Recent Life Changes Questionnaire, which correlates an individual's susceptibility to physical or psychological illness with his or her level of stress (see Chapter 1 of the textbook). The lay literature now provides various self-tests that individuals may perform to determine their vulnerability to stress. Two of these are presented in Boxes 40–1 and 40–2.

CORE CONCEPT

Relaxation
A decrease in tension or intensity, resulting in refreshment of body and mind. A state of refreshing tranquility.

Physiological, Cognitive, and Behavioral Manifestations of Relaxation

The physiological, cognitive, and behavioral manifestations of stress are well documented (see Chapter 1 and Chapter 2, Mental Health and Mental Illness: Historical and Theoretical Concepts, of the textbook). A review of these symptoms is presented in Table 40–1. The persistence of these symptoms over long periods can contribute to the development of numerous stress-related illnesses.

The achievement of relaxation can counteract many of these symptoms. In a state of deep relaxation, the respiration rate may slow to as few as four to six breaths per minute and the heart rate to as low as 24 beats per minute (Pelletier, 1992). Blood pressure decreases and the metabolic rate slows down. Muscle tension diminishes, pupils constrict, and blood vessels in the periphery dilate, leading to increased temperature and a feeling of warmth in the extremities.

One's level of consciousness moves from beta activity, which occurs when one is mentally alert and actively thinking, to alpha activity, a state of altered

BOX 40–1 How Vulnerable Are You to Stress?

Score each item from 1 (almost always) to 5 (never), according to how much of the time each statement applies to you.

_____ 1. I eat at least one hot, balanced meal a day.
_____ 2. I get 7 to 8 hours of sleep at least four nights a week.
_____ 3. I give and receive affection regularly.
_____ 4. I have at least one relative within 50 miles on whom I can rely.
_____ 5. I exercise to the point of perspiration at least twice a week.
_____ 6. I smoke less than half a pack of cigarettes a day.
_____ 7. I take fewer than five alcoholic drinks a week.
_____ 8. I am the appropriate weight for my height.
_____ 9. I have an income adequate to meet basic expenses.
_____ 10. I get strength from my religious beliefs.
_____ 11. I regularly attend club or social activities.
_____ 12. I have a network of friends and acquaintances.
_____ 13. I have one or more friends to confide in about personal matters.
_____ 14. I am in good health (including eyesight, hearing, and teeth).
_____ 15. I am able to speak openly about my feelings when angry or worried.
_____ 16. I have regular conversations with the people I live with about domestic problems (e.g., chores, money, and daily living issues).
_____ 17. I do something for fun at least once a week.
_____ 18. I am able to organize my time effectively.
_____ 19. I drink fewer than three cups of coffee (or tea or colas) a day.
_____ 20. I take quiet time for myself during the day.
_____   TOTAL

   To get your score, add up the figures and subtract 20. Any number over 30 indicates a vulnerability to stress. You are seriously vulnerable if your score is between 50 and 75, and extremely vulnerable if it is over 75.

BOX 40–2 Are You Stressed Out?

Check yes or no for each of the following questions.

	Yes	No
1. Do you have recurrent headaches, neck tension, or back pain?	___	___
2. Do you often have indigestion, nausea, or diarrhea?	___	___
3. Have you unintentionally gained or lost 5–10 lb in the last month?	___	___
4. Do you have difficulty falling or staying asleep?	___	___
5. Do you often feel restless?	___	___
6. Do you have difficulty concentrating?	___	___
7. Do you drink alcohol, smoke, or take drugs to relax?	___	___
8. Have you had a major illness, surgery, or an accident in the past year?	___	___
9. Have you lost 5 or more days of work due to illness in the past 6 months?	___	___
10. Have you had a change in job status (been fired, laid off, promoted, demoted, and so on) in the past 6 months?	___	___
11. Do you work more than 48 hr a week?	___	___
12. Do you have serious financial problems?	___	___
13. Have you recently experienced family or marital problems?	___	___
14. Has a person of significance in your life died in the past year?	___	___
15. Have you been divorced or separated in the past year?	___	___
16. Do you find you've lost interest in hobbies, physical activity, and leisure time?	___	___
17. Have you lost interest in your relationship with your spouse, relatives, or friends?	___	___
18. Do you find yourself watching more TV than you should?	___	___

BOX 40–2 **Are You Stressed Out?—cont'd**

19. Are you emotional or easily irritated lately? ___ ___
20. Do you seem to experience more distress and discomfort than most people? ___ ___

SCORING:
Each yes is worth 1 point; each no is worth 0.
   Total your points:

0–3 = mildly stressed
4–6 = moderately stressed
7 or more = extremely vulnerable. You may be at risk for stress-related illness.

TABLE 40–1 **Physiological, Cognitive, and Behavioral Manifestations of Stress**

PHYSIOLOGICAL	COGNITIVE	BEHAVIORAL
Epinephrine and norepinephrine are released into the bloodstream	Anxiety increases	Restlessness
Pupils dilate	Confusion and disorientation may be evident	Irritability
Respiration rate increases	The person is unable to solve problems	Use or misuse of defense mechanisms
Heart rate increases	The person is unable to concentrate	Disorganized routine functioning
Blood pressure increases	Cognitive processes focus on achieving relief from anxiety	Insomnia and anorexia
Digestion subsides	Learning is inhibited. Thoughts may reflect obsessions and ruminations	Compulsive or bizarre behaviors (depending on level of anxiety being experienced)
Blood sugar increases		
Metabolism increases		
Serum-free fatty acids, cholesterol, and triglycerides increase		

---

consciousness (Davis, Eshelman, & McKay, 2008). Benefits associated with achievement of alpha consciousness include an increase in creativity, memory, and the ability to concentrate. Ultimately, an improvement in adaptive functioning may be realized.

When deeply relaxed, individuals are less attentive to distracting stimuli in the external environment. They will respond to questions directed at them but do not initiate verbal interaction. Physical demeanor is very composed. Virtually no muscle activity is observed. Eyes are closed, jaws may be slightly parted, and palms are open with fingers curled, but not clenched. Head may be slightly tilted to the side.

A summary of the physiological, cognitive, and behavioral manifestations of relaxation is presented in Table 40–2.

TABLE 40–2 **Physiological, Cognitive, and Behavioral Manifestations of Relaxation**

PHYSIOLOGICAL	COGNITIVE	BEHAVIORAL
Lower levels of epinephrine and norepinephrine in the blood	Change from beta consciousness to alpha consciousness	Distractibility to environmental stimuli is decreased
Respiration rate decreases (sometimes as low as 4–6 breaths per minute)	Creativity and memory are enhanced	Will respond to questions but does not initiate verbal interaction
Heart rate decreases (sometimes as low as 24 beats per minute)	Increased ability to concentrate	Calm, tranquil demeanor; no evidence of restlessness
Blood pressure decreases		Common mannerisms include eyes closed, jaws parted, palms open, fingers curled, and head slightly tilted to the side
Metabolic rate slows down		
Muscle tension diminishes		
Pupils constrict		
Vasodilation and increased temperature in the extremities		

Methods of Achieving Relaxation

Deep-Breathing Exercises

Deep breathing is a simple technique that is basic to most other relaxation skills. Tension is released when the lungs are allowed to breathe in as much oxygen as possible. Breathing exercises have been found to be effective in reducing anxiety, depression, irritability, muscular tension, and fatigue (Davis et al., 2008; Sobel & Ornstein, 1996). An advantage of this exercise is that it may be accomplished anywhere at any time. A good guideline is to practice deep breathing for a few minutes three or four times a day or whenever a feeling of tenseness occurs.

Technique

1. Sit, stand, or lie in a comfortable position, relaxing your shoulders, ensuring that the spine is straight.
2. Place one hand on your abdomen and the other on your chest.
3. Inhale slowly and deeply through your nose. The abdomen should be expanding and pushing up on your hand. The chest should be moving only slightly.
4. When you have breathed in as much as possible, hold your breath for a few seconds before exhaling.
5. Begin exhaling slowly through the mouth, pursing your lips as if you were going to whistle. Pursing the lips helps to control how fast you exhale and keeps airways open as long as possible.
6. Feel the abdomen deflate as the lungs are emptied of air.
7. Begin the inhale-exhale cycle again. Focus on the sound and feeling of your breathing as you become more and more relaxed.
8. Continue the deep-breathing exercises for 5 to 10 minutes at a time. Once mastered, the technique may be used as often as required to relieve tension.

Progressive Relaxation

Progressive relaxation, a method of deep-muscle relaxation, was developed in 1929 by Chicago physician Edmond Jacobson. His technique is based on the premise that the body responds to anxiety-provoking thoughts and events with muscle tension. Excellent results have been observed with this method in the treatment of muscular tension, anxiety, insomnia, depression, fatigue, irritable bowel, muscle spasms, neck and back pain, high blood pressure, mild phobias, and stuttering (Davis et al., 2008).

Technique

Each muscle group is tensed for 5 to 7 seconds and then relaxed for 20 to 30 seconds during which time the individual concentrates on the difference in sensations between the two conditions. Soft, slow background music may facilitate relaxation.

1. Sit in a comfortable chair with your hands in your lap, your feet flat on the floor, and your eyes closed.
2. Begin by taking three deep, slow breaths, inhaling through the nose and releasing the air slowly through the mouth.
3. Now starting with the feet, flex your toes and lift them upward toward the knees, stiffen your calves, and hold for a count of five.
4. Now release the hold. Let go of the tension. Feel the sensation of relaxation and warmth as the tension flows out of the muscles.
5. Next, tense the muscles of the thighs and buttocks, and hold for a count of five.
6. Now release the hold. Feel the tension drain away, and be aware of the difference in sensation—perhaps a heaviness or feeling of warmth that you did not feel when the muscles were tensed. Concentrate on this feeling for a few seconds.
7. Next, tense the abdominal muscles. Hold for a count of five.
8. Now release the hold. Concentrate on the feeling of relaxation in the muscles. You may feel a warming sensation. Hold on to that feeling for 15 to 20 seconds.
9. Next, tense the muscles in the back and hold for a count of five.
10. Now release the hold. Feel the sensation of relaxation and warmth as the tension flows out of the muscles.
11. Next, tense the muscles of your hands, biceps, and forearms. Clench your hands into a tight fist. Hold for a count of five.
12. Now release the hold. Notice the sensations. You may feel tingling, warmth, or a light, airy feeling. Recognize these sensations as tension leaves the muscles.
13. Next, tense the muscles of the shoulders and neck. Shrug the shoulders tightly and hold for a count of five.
14. Now release the hold. Sense the tension as it leaves the muscles and experience the feeling of relaxation.
15. Next, tense the muscles of the face. Wrinkle the forehead, frown, squint the eyes, and purse the lips. Hold for a count of five.
16. Now release the hold. Recognize a light, warm feeling flowing into the muscles.
17. Now feel the relaxation in your whole body. As the tension leaves your entire being, you feel completely relaxed.
18. Open your eyes and enjoy renewed energy.

Modified (or Passive) Progressive Relaxation

Technique

In this version of total-body relaxation, the muscles are not tensed. Instead, the individual learns to relax muscles by concentrating on the feeling of relaxation within the muscle. These instructions may be presented by one person for another or they may be self-administered. Playing soft, slow background music during the activity may facilitate relaxation.

1. Assume a comfortable position. Some suggestions include the following:
   a. Sitting straight up in a chair with hands in the lap or at sides and feet flat on the floor
   b. Sitting in a reclining chair with hands in the lap or at sides and legs up on an elevated surface
   c. Lying flat with head slightly elevated on pillow and arms at sides
2. Close your eyes and take three deep breaths through your nose, slowly releasing the air through your mouth.
3. Allow a feeling of peacefulness to descend over you—a pleasant, enjoyable sensation of being comfortable and at ease.
4. Remain in this state for several minutes.
5. It is now time to turn your attention to various parts of your body.
6. Begin with the muscles of the head, face, throat, and shoulders. Concentrate on these muscles, paying particular attention to those in the forehead and jaws. Feel the tension leave the area. The muscles start to feel relaxed, heavy, and warm. Concentrate on this feeling for a few minutes.
7. Now let the feeling of relaxation continue to spread downward to the muscles of your biceps, forearms, and hands. Concentrate on these muscles. Feel the tension dissolve; the muscles begin to feel relaxed and heavy. A feeling of warmth spreads through these muscles all the way to the fingertips. They are feeling very warm and very heavy. Concentrate on this feeling for a few minutes.
8. The tension is continuing to dissolve now, and you are feeling very relaxed. Turn your attention to the muscles in your chest, abdomen, and lower back. Feel the tension leave these areas. Allow these muscles to become very relaxed. They start to feel very warm and very heavy. Concentrate on this feeling for a few minutes.
9. The feeling of relaxation continues to move downward now as you move to the muscles of the thighs, buttocks, calves, and feet. Feel the tension moving down and out of your body. These muscles feel very relaxed now. Your legs are feeling very heavy and very limp. A feeling of warmth spreads over the area, all the way to the toes. You can feel that all the tension has been released.
10. Your whole body feels relaxed and warm. Listen to the music for a few moments and concentrate on this relaxed, warm feeling. Take several deep, slow breaths through your nose, releasing the air through your mouth. Continue to concentrate on how relaxed and warm you feel.
11. It is now time to refocus your concentration on the present and wake up your body to resume activity. Open your eyes and stretch or massage your muscles. Wiggle your fingers and toes. Take another deep breath, arise, and enjoy the feeling of renewed energy.

Meditation

Records and phenomenological accounts of meditative practices date back more than 2000 years, but only recently have empirical studies revealed the psychophysiological benefits of regular use (Walton, 2015). Research on the brain has demonstrated that meditation influences increased gray matter volume, decreased amygdala volume, increased connectivity between regions in the brain, and increased concentration and attention. Psychological studies have demonstrated the benefits of mindfulness meditation in treatment of anxiety, depression, and anxiety disorders (Walton, 2015). The goal of **meditation** is to gain "mastery over attention." It brings on a special state of consciousness as attention is concentrated solely on one thought or object. The term *mindfulness meditation* describes an aspect of meditation that focuses on developing awareness of the present moment. Learning how to become more aware in the present is considered foundational not only to relaxation but also to problem solving and behavioral change. It is a basic skill taught in cognitive-behavioral therapy.

Historically, meditation has been associated with religious doctrines and disciplines by which individuals sought enlightenment with God or another higher power. However, meditation can be practiced independently from any religious philosophy and purely as a means of achieving inner harmony and increasing self-awareness.

During meditation, the respiration rate, heart rate, and blood pressure decrease. The overall metabolism declines, and the need for oxygen consumption is reduced. Alpha brain waves—those associated with brain activity during periods of relaxation—predominate (Pelletier, 1992).

Technique

1. Select a quiet place and a comfortable position. Various sitting positions are appropriate for meditation. Examples include sitting:
   a. In a chair with your feet flat on the floor approximately 6 inches apart, arms resting comfortably in your lap
   b. Cross-legged on the floor or on a cushion
   c. In the Japanese fashion with knees on floor, great toes together, pointed backward, and buttocks resting comfortably on bottoms of feet
   d. In the lotus yoga position sitting on the floor with the legs flexed at the knees, the ankles are crossed and each foot rests on top of the opposite thigh.
2. Select an object, word, or thought on which to dwell. During meditation, the individual becomes preoccupied with the selected focus. This total preoccupation serves to prevent distractions from interrupting attention. Examples of foci include:
   a. *Counting one's breaths.* All attention is focused on breathing in and out.
   b. *Mantras.* A *mantra* is a syllable, word, or name that is repeated many times as the mind is cleared of thoughts. Any mantra is appropriate if it works to focus attention and prevent distracting thoughts.
   c. *Objects for contemplation.* Select an object, such as a rock, a marble, or anything that does not hold a symbolic meaning that might cause distraction. Contemplate the object both visually and tactilely. Focus total attention on the object.
   d. *A thought that has special meaning for you.* With eyes closed, focus total attention on a specific thought or idea.
3. Practice directing attention on your selected focus for 10 to 15 minutes a day for several weeks. It is essential that the individual does not become upset if intrusive thoughts find their way into the meditation practice. They should merely be dealt with and dismissed as the individual returns to the selected focus of attention. Worrying about one's progress in the ability to meditate is a self-inhibiting behavior.

Mental Imagery

Mental imagery uses the imagination in an effort to reduce the body's response to stress. The frame of reference is very personal, based on what each individual considers a relaxing environment. Some might select a scene at the seashore, some might choose a mountain atmosphere, and some might choose floating through the air on a fluffy white cloud. The choices are as limitless as one's imagination. Following is an example of how one individual uses imagery for relaxation. The information is most useful when taped and played back at a time when the individual wishes to achieve relaxation.

Technique

Sit or lie down in a comfortable position. Close your eyes. Imagine that you and someone you love are walking along the seashore. No other people are in sight in any direction. The sun is shining, the sky is blue, and a gentle breeze is blowing. You select a spot to stop and rest. You lie on the sand and close your eyes. You hear the sound of the waves as they splash against the shore. The sun feels warm on your face and body. The sand feels soft and warm against your back. An occasional wave splashes you with a cool mist that dries rapidly in the warm sun. The coconut fragrance of your sunscreen lotion wafts gently and pleasantly in the air. You lie in this quiet place for what seems like a very long time, taking in the sounds of the waves, the warmth of the sun, and the cooling sensations of the mist and ocean breeze. It is very quiet. It is very warm. You feel very relaxed, very contented. This is your special place. You may come to this special place whenever you want to relax.

Biofeedback

Biofeedback is the use of instrumentation to become aware of processes in your body that you usually do not notice and to bring them under voluntary control. Biofeedback machines give immediate information about an individual's biological conditions, such as muscle tension, skin surface temperature, brain wave activity, skin conductivity, blood pressure, and heart rate (Sadock, Sadock, & Ruiz, 2015). Some conditions that can be treated successfully with biofeedback include spastic colon, hypertension, tension and migraine headaches, muscle spasms/pain, anxiety, phobias, stuttering, and teeth grinding.

Technique

Biological conditions are monitored by the biofeedback equipment. Sensors relate muscle spasticity, body temperature, brain wave activity, heart rate, and blood pressure. Each of these conditions will elicit a signal from the equipment, such as a blinking light, a measure on a meter, or an audible tone. The individual practices using relaxation and voluntary control to modify the signal, in turn indicating a modification of the autonomic function it represents.

Various types of biofeedback equipment have been developed for home use. Often they are less than effective, however, because they usually measure only one autonomic function. In fact, modification of several functions may be required to achieve the benefits of total relaxation.

Biofeedback can help monitor an individual's progress toward learning to relax. It is often used

together with other relaxation techniques such as deep breathing, progressive relaxation, and mental imagery.

Special training is required to become a biofeedback practitioner. Nurses can support and encourage individuals learning to use this method of stress management. Nurses can also teach other techniques of relaxation that enhance the results of biofeedback training.

Physical Exercise

Regular exercise is viewed by many as one of the most effective methods for relieving stress. Physical exertion provides a natural outlet for the tension produced by the body in its state of arousal for fight or flight. Following exercise, physiological equilibrium is restored, resulting in a feeling of relaxation and revitalization. Physical inactivity increases all causes of mortality and doubles the risk of cardiovascular disease, type 2 diabetes, and obesity. It also increases the risks of colon and breast cancer, high blood pressure, lipid disorders, osteoporosis, depression, and anxiety (World Health Organization, 2016). Physical activity is identified as an important area of focus in the government initiative *Healthy People 2020* (Office of Disease Prevention and Health Promotion, 2017).

Aerobic exercises strengthen the cardiovascular system and increase the body's ability to use oxygen more efficiently. Aerobic exercises include brisk walking, jogging, running, cycling, swimming, and dancing, among other activities. To achieve the benefits of aerobic exercises, they must be performed regularly—for at least 30 minutes, three times per week.

Individuals can also benefit from low-intensity physical exercise. Although there is little benefit to the cardiovascular system, low-intensity exercise can help prevent obesity, relieve muscular tension, prevent muscle spasms, improve balance, and increase flexibility. Examples of low-intensity exercise include slow walking, house cleaning, shopping, light gardening, calisthenics, and weight lifting.

Studies indicate that physical exercise can be effective in reducing general anxiety and depression. Vigorous exercise has been shown to increase levels of beta-endorphins, monoamines (serotonin, norepinephrine, and dopamine) and gamma-aminobutyric acid (GABA), all of which have been implicated in mood regulation (Cunha, Ribeiro, & Oliveira, 2008; Schoenfeld et al., 2013; Weir, 2011). Depressed people are often deficient in these monoamines. Endorphins act as natural narcotics and mood elevators.

The Role of the Nurse in Relaxation Therapy

Nurses work with anxious clients in all hospital departments and in community and home health services. Individuals experience stress daily; it cannot be eliminated. Stress is a response to both pleasant and unpleasant events and usually requires some adaptation on the part of the individual.

> **CLINICAL PEARL** Management of stress must be considered a lifelong function. Nurses can help individuals recognize the sources of stress in their lives and identify methods of adaptive coping.

Assessment

Stress management requires a holistic approach. Physical and psychosocial dimensions are considered in determining the individual's adaptation to stress. Following are some examples of assessment data for collection. Other assessments may need to be made depending on the specific circumstances of each individual.

1. Genetic influences
   a. Identify medical and psychiatric history of client and biological family members.
2. Past experiences
   a. Describe your living and working conditions.
   b. When did you last have a physical examination?
   c. Do you have a spiritual or religious position from which you derive support?
   d. Do you have a job? Have you experienced any recent employment changes or other difficulties on your job?
   e. What significant changes have occurred in your life in the last year?
   f. What is your usual way of coping with stress?
   g. Do you have someone to whom you can go for support when you feel stressed?
3. Client's perception of the stressor
   a. What do you feel is the major source of stress in your life right now?
4. Adaptation responses
   a. Do you ever feel anxious? Confused? Unable to concentrate? Fearful?
   b. Do you have tremors? Stutter or stammer? Sweat profusely?
   c. Do you often feel angry? Irritable? Moody?
   d. Do you ever feel depressed? Do you ever feel like harming yourself or others?
   e. Do you have difficulty communicating with others?
   f. Do you experience pain? What part of your body? When do you experience it? When does it worsen?
   g. Do you ever experience stomach upset? Constipation? Diarrhea? Nausea and vomiting?
   h. Do you ever feel your heart pounding in your chest?
   i. Do you take any drugs (prescription, over-the-counter, or street)?

j. Do you drink alcohol? Smoke cigarettes? How much?

k. Are you eating more or less than usual?

l. Do you have difficulty sleeping?

m. Do you have a significant other? Describe the relationship.

n. Describe your relationship with other family members.

o. Do you perceive any problems in your sexual lifestyle or behavior?

Diagnosis

Possible nursing diagnoses for individuals requiring assistance with stress management are listed here. Others may be appropriate for individuals with particular problems.

■ Risk-prone health behavior
■ Anxiety (specify level)
■ Disturbed body image
■ Coping, defensive
■ Coping, ineffective
■ Decisional conflict (specify)
■ Denial, ineffective
■ Fear
■ Grieving
■ Grieving, complicated
■ Hopelessness
■ Deficient knowledge (specify)
■ Pain (acute or chronic)
■ Parental role conflict
■ Posttrauma syndrome
■ Powerlessness
■ Rape-trauma syndrome
■ Role performance, ineffective
■ Low self-esteem
■ Sexual dysfunction
■ Sexuality patterns, ineffective
■ Sleep pattern, disturbed
■ Social interaction, impaired
■ Social isolation
■ Spiritual distress
■ Violence, risk for self-directed or other-directed

Outcome Identification and Implementation

The immediate goal for nurses working with individuals needing assistance with stress management is to help minimize current maladaptive symptoms. The long-term goal is to assist individuals in achieving their highest potential for wellness. Examples of outcome criteria may include:

■ Client will verbalize a reduction in pain following progressive relaxation techniques.

■ Client will be able to voluntarily control a decrease in blood pressure following 3 weeks of biofeedback training.

■ Client will be able to maintain stress at a manageable level by performing deep-breathing exercises when feeling anxious.

Implementation of nursing actions has a strong focus on the role of client educator. Relaxation therapy, as described in this chapter, is one way to help individuals manage stress. These techniques are well within the scope of nursing practice.

Evaluation

Evaluation requires that the nurse and client assess whether these techniques are achieving the desired outcomes. Various alternatives may be attempted and reevaluated.

Relaxation therapy provides alternatives to old, maladaptive methods of coping with stress. Lifestyle changes may be required and change does not come easily. Nurses must help individuals analyze the usefulness of these techniques in the management of stress in their daily lives.

Summary and Key Points

■ Stress is part of our everyday lives. It can be positive or negative, but it cannot be eliminated.

■ Keeping stress at a manageable level is a lifelong process.

■ Individuals under stress respond with physiological arousal that can be dangerous over long periods.

■ The stress response has been shown to be a major contributor, either directly or indirectly, to coronary heart disease, cancer, lung ailments, accidental injuries, cirrhosis of the liver, and suicide—six of the leading causes of death in the United States.

■ Relaxation therapy is an effective means of reducing the stress response in some individuals.

■ The degree of anxiety an individual experiences in response to stress is related to certain predisposing factors such as inborn temperament, past experiences resulting in learned patterns of responding, and existing conditions such as health status, coping strategies, and adequate support systems.

■ Deep relaxation can counteract the physiological and behavioral manifestations of stress.

■ Some examples of relaxation therapy include deep-breathing exercises, progressive relaxation, passive-progressive relaxation, meditation, mental imagery, biofeedback, and physical exercise.

■ Nurses use the nursing process to assist individuals in the management of stress.

■ Assessment data are collected from which nursing diagnoses are derived.

- Outcome criteria that help individuals reduce current maladaptive symptoms and ultimately achieve their highest potential for wellness are identified.
- Implementation includes instructing clients and their families in the various techniques for achieving relaxation. Behavioral changes provide objective measurements for evaluation.

Review Questions
Self-Examination/Learning Exercise

Select the best response to each of the following questions.

1. Which of the following are considered good forms of aerobic exercise? (Select all that apply.)
   a. Swimming
   b. Cycling
   c. Shopping
   d. House cleaning
   e. Running

2. Which of the following are cognitive manifestations of stress? (Select all that apply.)
   a. Inability to concentrate
   b. Obsessive thoughts
   c. Beta brain waves predominate
   d. Increased anxiety
   e. Enhanced creativity

3. John tells the nurse that he suffers from test anxiety and gets very stressed prior to and during exams. The nurse suggests to John that he take short breaks during the exam to relieve stress. Which of the following relaxation exercises would be *most* appropriate for the nurse to suggest to John under these circumstances?
   a. Deep-breathing exercises
   b. Progressive relaxation exercises
   c. Meditation
   d. Mental imagery

4. Linda has just been promoted from the typing pool to a position as personal secretary to the CEO of a large corporation. She is now expected to attend and take minutes of all board meetings, screen calls and visitors for her boss, keep track of his schedule and remind him of important appointments, and make decisions for him in his absence. She tells the nurse that she is fearful of making mistakes and is constantly "nervous." She is having trouble sleeping and has lost 10 pounds since taking over the job. Which of the following nursing diagnoses would be a priority for Linda?
   a. Decisional conflict
   b. Powerlessness
   c. Anxiety (severe)
   d. Low self-esteem

5. Based on the answer in question 4, which of the following would be appropriate outcome criteria for Linda?
   a. Linda will verbalize choices in a plan to maintain control over her life.
   b. Linda verbalizes a positive perception about herself.
   c. Linda will make a decision about whether to stay in her current position.
   d. Linda will demonstrate ability to maintain anxiety at manageable level.

Theoretical Models of Personality Development

CORE CONCEPT

Personality

KEY TERMS

cognitive development	id	surrogate
cognitive maturity	libido	symbiosis
counselor	psychodynamic nursing	technical expert
ego	superego	temperament

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define *personality*.
2. Identify the relevance of knowledge associated with personality development to nursing in the psychiatric/mental health setting.
3. Discuss the major components of the following developmental theories:
   a. Psychoanalytic theory—Freud
   b. Interpersonal theory—Sullivan
   c. Theory of psychosocial development— Erikson
   d. Theory of object relations development— Mahler
   e. Cognitive development theory—Piaget
   f. Theory of moral development—Kohlberg
   g. A nursing model of interpersonal development—Peplau

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. Which part of the personality as described by Freud develops as the child internalizes the values and morals set forth by primary caregivers?
2. According to Erikson, what happens when the adolescent does not master the tasks of *identity vs. role confusion*?
3. According to Mahler's theory, the individual with borderline personality disorder harbors fears of abandonment and underlying rage based on fixation in what stage of development?
4. When Joey sees an old woman struggling with a heavy bag of groceries, he runs to help her carry them to her car. This describes behavior at which stage of moral development?

The American Psychological Association (2017) describes personality as the characteristic patterns of thinking, feeling, and behaving that define individual differences and clarify how the various parts of a person come together as a whole. Nurses must have a basic knowledge of human personality development to understand maladaptive behavioral responses commonly seen in psychiatric clients. Developmental theories identify behaviors associated with various *stages* through which individuals pass, thus specifying what is appropriate or inappropriate at each developmental level.

Child development specialists believe that infancy and early childhood are the major life periods for developmental change. Specialists in life-cycle development believe that people continue to develop and change throughout life, thereby suggesting the possibility for renewal and growth in adults.

Developmental stages are identified by age. Behaviors can then be evaluated by whether they are age-appropriate. Ideally, an individual successfully fulfills all the tasks associated with one stage before moving on to the next stage at the appropriate age. Realistically, however, this seldom happens. One reason is **temperament,** or the inborn personality characteristics that influence an individual's manner of reacting to the environment and ultimately his or her developmental progression (Chess & Thomas, 1986). Recent research has identified specific temperamental types that are heritable, manifested early in life, developmentally stable, and consistent in different cultures (Sadock, Sadock, & Ruiz, 2015).

Despite a person's inborn temperament, environment may also influence one's personality development. Individuals reared in a dysfunctional family system often have retarded ego development. According to specialists in life-cycle development, behaviors from an unsuccessfully completed stage can be modified and corrected in a later stage. Stages overlap, and an individual may be working on tasks associated with several stages at one time. When an individual becomes fixed in a lower level of development, with age-inappropriate behaviors focused on fulfillment of those tasks, psychopathology may become evident. Only when personality traits become inflexible and personality functioning becomes individually and interpersonally impaired does delayed development constitute a *personality disorder.*

Mayer (2014) adds that a more current focus in understanding personality includes an individual's "personal intelligence," or the ability to reason accurately about one's own personality traits and those of others. Current research is attempting to identify the influences that contribute to personal intelligence about personality and the ways that personal intelligence influences interpersonal relationships. Whereas

traditional theories focused more on the static nature of "ingrained" personality traits, newer research emphasizes the potential for adaptation and change. Thus, while it is important to understand theories about how personality development evolves, ongoing research is shedding new light on how personality may adapt in a personal, social, and cultural context.

CORE CONCEPT
Personality
The combination of character, behavioral, temperamental, emotional, and mental traits that are unique to each individual.

Psychoanalytic Theory

Sigmund Freud (1961), who has been called the father of psychiatry, is credited as the first to identify development by stages. He considered the first 5 years of a child's life the most important, as he believed that an individual's basic character was formed by age 5.

Freud's personality theory can be conceptualized according to structure and dynamics of the personality, topography of the mind, and stages of personality development.

Structure of the Personality

Freud organized the structure of the personality into three major components: the **id, ego,** and **superego,** each distinguished by unique functions and characteristics.

Id

The *id* is the locus of instinctual drives—the "pleasure principle." Present at birth, it endows the infant with instinctual drives that seek to satisfy needs and achieve immediate gratification. Id-driven behaviors are impulsive and may be irrational.

Ego

The *ego,* also called the *rational self* or the "reality principle," begins to develop between the ages of 4 and 6 months. The ego experiences the reality of the external world, adapts to it, and responds to it. As the ego develops and gains strength, it seeks to bring the influences of the external world to bear upon the id, substituting the reality principle for the pleasure principle. A primary function of the ego is that of mediator: to maintain harmony among the external world, the id, and the superego.

Superego

If the id is identified as the pleasure principle, and the ego the reality principle, the *superego* might be

referred to as the "perfection principle." The superego, which develops between ages 3 and 6, internalizes the values and morals set forth by primary caregivers. Derived out of a system of rewards and punishments, the superego is composed of two major components: the *ego-ideal* and the *conscience*. When a child is consistently rewarded for "good" behavior, self-esteem is enhanced, and this behavior becomes part of the ego-ideal; that is, it is internalized as part of his or her value system. The conscience is formed when the child is punished consistently for "bad" behavior. The child learns what is considered morally right or wrong from feedback received from parental figures and from society and culture. When moral and ethical principles or even internalized ideals and values are disregarded, the conscience generates a feeling of guilt. The superego is important in socialization because it assists the ego in controlling id impulses. When the superego becomes rigid and punitive, problems with low self-confidence and low self-esteem arise. Examples of behaviors associated with these components of the personality are presented in Box 41–1.

Topography of the Mind

Freud classified all mental contents and operations into three categories: the conscious, the preconscious, and the unconscious.

■ The *conscious* includes all memories within an individual's awareness. It is the smallest of the three categories. Events and experiences that are easily remembered or retrieved are considered within one's conscious awareness. Examples include telephone numbers, birthdays of oneself and significant others, the dates of special holidays, and what one had for lunch today. The conscious mind is thought to be under the control of the ego, the rational and logical structure of the personality.

■ The *preconscious* includes all memories that are not in present awareness but with attention can be readily recalled into consciousness. Examples include telephone numbers or addresses once known but little used and feelings associated with significant life events that occurred in the past. The preconscious enhances awareness by helping to *suppress* unpleasant or nonessential memories from consciousness. It is thought to be partially under the control of the superego, which helps to suppress unacceptable thoughts and behaviors.

■ The *unconscious* includes all memories one is unable to bring to conscious awareness. It is the largest of the three topographical levels. Unconscious material consists of unpleasant or nonessential memories that have been *repressed* and can be retrieved only through therapy, hypnosis, and with certain substances that alter awareness and have the capacity to restructure repressed memories. Unconscious material may also emerge in dreams and in seemingly incomprehensible behavior.

Dynamics of the Personality

Freud believed that *psychic energy* is the force or impetus required for mental functioning. Originating in the id, it instinctually fulfills basic physiological needs. Freud called this psychic energy (or the drive to fulfill basic physiological needs such as hunger, thirst, and sex) the **libido.** As a child matures, psychic energy is diverted from the id to form the ego and then from the ego to form the superego. Psychic energy is distributed within these three components, with the ego retaining the largest share to maintain a balance between the impulsive behaviors of the id and the idealistic behaviors of the superego. If an excessive amount of psychic energy is stored in one of these personality components, behavior will reflect that part of the personality. For instance, impulsive behavior prevails when excessive psychic energy is stored in the id. Overinvestment in the ego reflects self-absorbed, or narcissistic, behaviors; an excess within the superego results in rigid, self-deprecating behaviors.

Freud used the terms *cathexis* and *anticathexis* to describe the forces within the id, ego, and superego that are used to invest psychic energy in external sources to satisfy needs. Cathexis is the process by which the

---

BOX 41–1 Structure of the Personality

BEHAVIORAL EXAMPLES

Id	Ego	Superego
"I found this wallet; I will keep the money."	"I already have money. This money doesn't belong to me. Maybe the person who owns this wallet doesn't have any money."	"It is never right to take something that doesn't belong to you."
"Mom and Dad are gone. Let's party!!!!!"	"Mom and Dad said no friends over while they are away. Too risky."	"Never disobey your parents."
"I'll have sex with whomever I please, whenever I please."	"Promiscuity can be very dangerous."	"Sex outside of marriage is always wrong."

---

id invests energy in an object to achieve gratification. An example is the individual who instinctively turns to alcohol to relieve stress. Anticathexis is the use of psychic energy by the ego and the superego to control id impulses. In the example cited, the ego would attempt to control the use of alcohol with rational thinking, such as, "I already have ulcers from drinking too much. I will call my AA counselor for support. I will not drink." The superego would exert control with thinking such as, "I shouldn't drink. If I drink, my family will be hurt and angry. I should think of how it affects them. I'm such a weak person." Freud believed that an imbalance between cathexis and anticathexis resulted in internal conflicts, producing tension and anxiety within the individual. Freud's daughter Anna devised a comprehensive list of defense mechanisms believed to be used by the ego as a protective device against anxiety in mediating between the excessive demands of the id and the excessive restrictions of the superego (see Chapter 2, Mental Health and Mental Illness: Historical and Theoretical Concepts).

Freud's Stages of Personality Development

Freud described formation of the personality through five stages of *psychosexual* development. He believed that characteristics developed during the first 5 years of life bore heavily on one's adaptation patterns and personality traits in adulthood. According to Freud, fixation in an early stage of development will almost certainly result in psychopathology. An outline of these five stages is presented in Table 41–1.

TABLE 41–1	**Freud's Stages of Psychosexual Development**	
AGE	**STAGE**	**MAJOR DEVELOPMENTAL TASKS**
Birth–18 months	Oral	Relief from anxiety through oral gratification of needs
18 months–3 years	Anal	Learning independence and control; focus on the excretory function
3–6 years	Phallic	Identification with parent of same gender; development of sexual identity; focus on genital organs
6–12 years	Latency	Sexuality repressed; focus on relationships with same-gender peers
13–20 years	Genital	Libido reawakened as genital organs mature; focus on relationships with members of the opposite gender

Oral Stage: Birth to 18 Months

During the oral stage, behavior is directed by the id with the goal of immediate gratification of needs. The focus of energy is the mouth, with behaviors that include sucking, chewing, and biting. The infant feels a sense of attachment and is unable to differentiate the self from the person providing the mothering. Because of this lack of differentiation, a pervasive feeling of anxiety on the part of the mother may be passed on to her infant, leaving the child vulnerable to similar feelings of insecurity. With the beginning of development of the ego at age 4 to 6 months, the infant starts to view the self as separate from the mothering figure. A sense of security and the ability to trust others is derived from the gratification of fulfilling basic needs during this stage.

Anal Stage: 18 Months to 3 Years

The major task in the anal stage is gaining independence and control, with particular focus on the excretory function. Freud believed that the manner in which the parents and other primary caregivers approach the task of toilet training may have far-reaching effects on the child in terms of values and personality characteristics. When toilet training is strict and rigid, the child may choose to retain the feces, becoming constipated. Adult retentive personality traits influenced by this type of training include stubbornness, stinginess, and miserliness. An alternate reaction to strict toilet training is for the child to expel feces in an unacceptable manner or at inappropriate times. Far-reaching effects of this behavior pattern include malevolence, cruelty to others, destructiveness, disorganization, and untidiness.

Toilet training that is more permissive and accepting attaches the feeling of importance and desirability to feces production. The child becomes extroverted, productive, and altruistic.

Phallic Stage: 3 to 6 Years

In the phallic stage, the focus of energy shifts to the genital area. Discovery of differences between genders results in a heightened interest in the sexuality of self and others. This interest may be manifested in sexual self-exploratory or group exploratory play. Freud proposed that the development of the *Oedipus complex* (males) or *Electra complex* (females) occurred during this stage of development. He described these complexes as the child's unconscious desire to eliminate the parent of the same gender and to possess the parent of the opposite gender for him- or herself. Guilt feelings result with the emergence of the superego during these years. Resolution of this internal conflict occurs when the child develops a strong identification with the parent of the same gender and internalizes that parent's attitudes, beliefs, and value system.

Latency Stage: 6 to 12 Years

During the elementary school years, the focus changes from egocentrism to interest in group activities, learning, and socialization with peers. Sexuality is not absent during this period but remains obscure and imperceptible to others. The preference is for same-gender relationships, even rejecting members of the opposite gender.

Genital Stage: 13 to 20 Years

In the genital stage, the maturing of these organs results in a reawakening of the libido. The focus is on relationships with members of the opposite gender and preparations for selecting a mate. The development of sexual maturity evolves from self-gratification to behaviors deemed acceptable by societal norms. Interpersonal relationships are based on genuine pleasure derived from the interaction rather than from the self-serving implications of childhood associations.

Relevance of Psychoanalytic Theory to Nursing Practice

Knowledge of the structure of the personality can assist nurses who work in the mental health setting. The ability to recognize behaviors associated with the id, the ego, and the superego assists in the assessment of developmental level. Understanding the use of ego defense mechanisms is important in making determinations about maladaptive behaviors, planning care for clients to assist in creating change if desired, and helping clients accept themselves as unique individuals.

CLINICAL PEARL: Assessing Patient Behaviors

Id Behaviors
Those behaviors that follow the principle of "if it feels good, do it." Social and cultural acceptability are not considered. It reflects a need for immediate gratification. Individuals with a strong id show little if any remorse for their unacceptable behavior.

Ego Behaviors
Behaviors that reflect the rational part of the personality. An effort is made to delay gratification and satisfy societal expectations. The ego uses defense mechanisms to cope and regain control over id impulses.

Superego Behaviors
Behaviors that are somewhat uncompromising and rigid, based on morality and society's values. Behaviors of the superego strive for perfection. Violation of the superego's standards generates guilt and anxiety in an individual who has a strong superego.

Interpersonal Theory

Harry Stack Sullivan (1953) believed that individual behavior and personality development are the direct result of interpersonal relationships. Before the development of his own theoretical framework, Sullivan embraced the concepts of Freud. Later, he changed the focus of his work from the *intrapersonal* view of Freud to one with a more *interpersonal* flavor in which human behavior could be observed in social interactions with others. His ideas, which were not universally accepted at the time, have been integrated into the practice of psychiatry through publication only since his death in 1949. Sullivan's major concepts include the following:

■ *Anxiety* is a feeling of emotional discomfort, with all behavior aimed at relieving or preventing that feeling. Sullivan believed that anxiety is the "chief disruptive force in interpersonal relations and the main factor in the development of serious difficulties in living" (p. XV). It arises out of one's inability to satisfy needs or to achieve interpersonal security.

■ *Satisfaction of needs* is the fulfillment of all requirements associated with an individual's physiochemical environment. Sullivan identified examples of these requirements as oxygen, food, water, warmth, tenderness, rest, activity, sexual expression—virtually anything that, when absent, produces discomfort in the individual.

■ *Interpersonal security* is the feeling associated with relief from anxiety. When all needs have been met, one experiences a sense of total well-being, which Sullivan termed *interpersonal security*. He believed individuals have an innate need for interpersonal security.

■ *Self-system* is a collection of experiences, or security measures, adopted by the individual to protect against anxiety. Sullivan identified three components of the self-system, based on interpersonal experiences early in life:
   ■ The *"good me"* is the part of the personality that develops in response to positive feedback from the primary caregiver. Feelings of pleasure, contentment, and gratification are experienced. The child learns which behaviors elicit this positive response as it becomes incorporated into the self-system.
   ■ The *"bad me"* is the part of the personality that develops in response to negative feedback from the primary caregiver. Anxiety is experienced, eliciting feelings of discomfort, displeasure, and distress. The child learns to avoid these negative feelings by altering certain behaviors.
   ■ The *"not me"* is the part of the personality that develops in response to situations that produce intense anxiety in the child. Feelings of horror, awe, dread, and loathing are experienced in response to these situations, leading the child to deny these feelings in an effort to relieve anxiety. These feelings, having been denied, become "not

me" but someone else. This withdrawal from emotions has serious implications for mental disorders in adult life.

Sullivan's Stages of Personality Development

Sullivan described six stages of personality development. An outline of the stages of personality development according to Sullivan's interpersonal theory is presented in Table 41–2.

Infancy: Birth to 18 Months

During the beginning stage, the major developmental task for the child is the gratification of needs. This is accomplished through activity associated with the mouth, such as crying, nursing, and thumb sucking.

Childhood: 18 Months to 6 Years

From ages 18 months to 6 years, the child learns that interference with fulfillment of personal wishes and desires may result in delayed gratification. He or she learns to accept this and feel comfortable with it, recognizing that delayed gratification often results in parental approval, a more lasting reward. Tools of this stage include the mouth, the anus, language, experimentation, manipulation, and identification.

Juvenile: 6 to 9 Years

The major task of the juvenile stage is formation of satisfactory relationships within peer groups. This is accomplished through competition, cooperation, and compromise.

Preadolescence: 9 to 12 Years

The tasks at the preadolescence stage focus on developing relationships with persons of the same gender. One's ability to collaborate with and show love and affection for another person begins at this stage.

Early Adolescence: 12 to 14 Years

During early adolescence, the child is struggling with developing a sense of identity that is separate and independent from the parents. The major task is formation of satisfactory relationships with members of the opposite gender. Sullivan saw the emergence of lust in response to biological changes as a major force during this period.

Late Adolescence: 14 to 21 Years

The late adolescent period is characterized by tasks associated with the attempt to achieve interdependence within the society and the formation of a lasting, intimate relationship with a selected member of the opposite gender. The genital organs are the major developmental focus of this stage.

Relevance of Interpersonal Theory to Nursing Practice

The interpersonal theory has significant relevance to nursing practice. Relationship development, a major concept of this theory, is a significant psychiatric nursing intervention. Nurses develop therapeutic relationships with clients to help them generalize this ability to interact successfully with others.

Knowledge about the behaviors associated with all levels of anxiety and methods for alleviating anxiety allows nurses to help clients achieve interpersonal security and a sense of well-being. Nurses use the concepts of Sullivan's theory to help clients reach a higher degree of independent and interpersonal functioning.

Theory of Psychosocial Development

Erik Erikson (1963) studied the influence of social processes on the development of the personality. He described eight stages of the life cycle during which

TABLE 41–2 Stages of Development in Sullivan's Interpersonal Theory		
AGE	STAGE	MAJOR DEVELOPMENTAL TASKS
Birth–18 months	Infancy	Relief from anxiety through oral gratification of needs
18 months–6 years	Childhood	Learning to experience a delay in personal gratification without undue anxiety
6–9 years	Juvenile	Learning to form satisfactory peer relationships
9–12 years	Preadolescence	Learning to form satisfactory relationships with persons of same gender; initiating feelings of affection for another person
12–14 years	Early adolescence	Learning to form satisfactory relationships with persons of the opposite gender; developing a sense of identity
14–21 years	Late adolescence	Establishing self-identity; experiencing satisfying relationships; working to develop a lasting, intimate opposite-gender relationship

individuals struggle with developmental "crises." Specific tasks associated with each stage must be completed for resolution of the crisis and for emotional growth to occur. An outline of Erikson's stages of psychosocial development is presented in Table 41–3.

Erikson's Stages of Personality Development
Trust versus Mistrust: Birth to 18 Months
Major Developmental Task

From birth to 18 months, the major task is to develop a basic trust in the mothering figure and learn to generalize this trust to others.

- Achievement of the task results in self-confidence, optimism, faith in the gratification of needs and desires, and hope for the future. The infant learns to trust when basic needs are met consistently.
- Nonachievement results in emotional dissatisfaction with the self and others, suspiciousness, and difficulty with interpersonal relationships. The task remains unresolved when primary caregivers fail to respond to the infant's distress signal promptly and consistently.

Autonomy versus Shame and Doubt: 18 Months to 3 Years
Major Developmental Task

The major task during the ages of 18 months to 3 years is to gain some self-control and independence within the environment.

- Achievement of the task results in a sense of self-control and the ability to delay gratification, and a feeling of self-confidence in one's ability to perform. Autonomy is achieved when parents encourage and provide opportunities for independent activities.
- Nonachievement results in a lack of self-confidence, a lack of pride in the ability to perform, a sense of being controlled by others, and a rage against the self. The task remains unresolved when primary caregivers restrict independent behaviors, both physically and verbally, or set the child up for failure with unrealistic expectations.

Initiative versus Guilt: 3 to 6 Years
Major Developmental Task

During the ages of 3 to 6 years, the goal is to develop a sense of purpose and the ability to initiate and direct one's own activities.

- Achievement of the task results in the ability to exercise restraint and self-control of inappropriate social behaviors. Assertiveness and dependability increase, and the child enjoys learning and personal achievement. The conscience develops, thereby controlling the impulsive behaviors of the id. Initiative is achieved when creativity is encouraged and performance is recognized and positively reinforced.
- Nonachievement results in feelings of inadequacy and a sense of defeat. Excessive guilt is experienced to the point of accepting liability in situations for which one is not responsible. The child may view him- or herself as evil and deserving of punishment.

TABLE 41–3 **Stages of Development in Erikson's Psychosocial Theory**		
AGE	**STAGE**	**MAJOR DEVELOPMENTAL TASKS**
Infancy (Birth–18 months)	Trust vs. mistrust	To develop a basic trust in the mothering figure and learn to generalize it to others
Early childhood (18 months–3 years)	Autonomy vs. shame and doubt	To gain some self-control and independence within the environment
Late childhood (3–6 years)	Initiative vs. guilt	To develop a sense of purpose and the ability to initiate and direct own activities
School age (6–12 years)	Industry vs. inferiority	To achieve a sense of self-confidence by learning, competing, performing successfully, and receiving recognition from significant others, peers, and acquaintances
Adolescence (12–20 years)	Identity vs. role confusion	To integrate the tasks mastered in the previous stages into a secure sense of self
Young adulthood (20–30 years)	Intimacy vs. isolation	To form an intense, lasting relationship or a commitment to another person, cause, institution, or creative effort
Adulthood (30–65 years)	Generativity vs. stagnation	To achieve the life goals established for oneself while also considering the welfare of future generations
Old age (65 years–death)	Ego integrity vs. despair	To review one's life and derive meaning from both positive and negative events, while achieving a positive sense of self-worth

The task remains unresolved when creativity is stifled and parents continually expect a higher level of achievement than the child produces.

Industry versus Inferiority: 6 to 12 Years

Major Developmental Task

The major task for 6- to 12-year-olds is to achieve a sense of self-confidence by learning, competing, performing successfully, and receiving recognition from significant others, peers, and acquaintances.

- Achievement of the task results in a sense of satisfaction and pleasure in interaction and involvement with others. The individual masters reliable work habits and develops attitudes of trustworthiness. He or she is conscientious, feels pride in achievement, and enjoys play but desires a balance between fantasy and "real world" activities. Industry is achieved when encouragement is given to activities and responsibilities in the school and community, as well as those within the home, and recognition is given for accomplishments.
- Nonachievement results in difficulty in interpersonal relationships because of feelings of personal inadequacy. The individual can neither cooperate and compromise with others in group activities nor problem solve or complete tasks successfully. He or she may become either passive and meek or overly aggressive to cover up for feelings of inadequacy. If the latter occurs, the individual may manipulate or violate the rights of others to satisfy his or her own needs or desires or become a workaholic with unrealistic expectations for personal achievement. This task remains unresolved when parents set unrealistic expectations for the child, when discipline is harsh and impairs self-esteem, and when accomplishments are consistently met with negative feedback.

Identity versus Role Confusion: 12 to 20 Years

Major Developmental Task

At 12 to 20 years, the goal is to integrate the tasks mastered in the previous stages into a secure sense of self.

- Achievement of the task results in a sense of confidence, emotional stability, and a view of the self as a unique individual. Commitments are made to a value system, to a chosen career, and to relationships with members of both genders. Identity is achieved when adolescents are allowed to experience independence by making decisions that influence their lives. Parents should be available to offer support when needed but gradually relinquish control to the maturing individual to encourage the development of an independent sense of self.
- Nonachievement results in a sense of self-consciousness, doubt, and confusion about one's

role in life. Personal values or goals for one's life are absent. Long-term commitments to relationships with others are nonexistent. A lack of self-confidence is often expressed by delinquent and rebellious behavior. Entering adulthood, with its accompanying responsibilities, may be an underlying fear. This task can remain unresolved for many reasons. Examples include:
  - When independence is discouraged by the parents and the adolescent is nurtured in the dependent position
  - When discipline within the home has been overly harsh, inconsistent, or absent
  - When there has been parental rejection or frequent shifting of parental figures

Intimacy versus Isolation: 20 to 30 Years

Major Developmental Task

The objective for 20- to 30-year-olds is to form an intense, lasting relationship with or commitment to another person, cause, institution, or creative effort (Murray, Zentner, & Yakimo, 2009).

- Achievement of the task results in the capacity for mutual love and respect between two people and the ability of an individual to pledge a total commitment to another. The intimacy goes far beyond the sexual contact. It describes a commitment in which personal sacrifices are made for another, whether it be another person or a career or cause to which a person elects to devote his or her life. Intimacy is achieved when an individual has developed the capacity for giving of oneself to another, learned when one has been the recipient of this type of giving within the family unit.
- Nonachievement results in withdrawal, social isolation, and aloneness. The individual is unable to form lasting, intimate relationships, often seeking intimacy through numerous superficial sexual contacts. No career is established; he or she may have a history of occupational changes (or may fear change and thus remain in an undesirable job situation). The task remains unresolved when love in the home has been deprived or distorted through the younger years (Murray et al., 2009). One fails to achieve the ability to give of the self without having been the recipient early on from primary caregivers.

Generativity versus Stagnation or Self-Absorption: 30 to 65 Years

Major Developmental Task

The major task at this stage is to achieve the life goals established for oneself while also considering the welfare of future generations.

- Achievement of the task results in a sense of gratification from personal and professional achievements

and from meaningful contributions to others. The individual is active in service to society. Generativity is achieved when the individual expresses satisfaction with this stage in life and demonstrates responsibility for leaving the world a better place in which to live.

■ Nonachievement results in lack of concern for the welfare of others and total preoccupation with the self. He or she becomes withdrawn, isolated, and highly self-indulgent, with no capacity for giving of the self to others. The task remains unresolved when earlier developmental tasks are not fulfilled and the individual does not achieve the degree of maturity required to derive gratification from concern for the welfare of others.

Ego Integrity versus Despair: 65 Years to Death
Major Developmental Task

After age 65, the goal is to review one's life and derive meaning from both positive and negative events while achieving a positive sense of self.

■ Achievement of the task results in a sense of self-worth and self-acceptance as one reviews life goals, accepting that some were achieved and some were not. The individual derives dignity from his or her life experiences and does not fear death, rather viewing it as another stage of development. Ego integrity is achieved when individuals have successfully completed the developmental tasks of the other stages and have little desire to make major changes in how their lives have progressed.

■ Nonachievement results in a sense of self-contempt and disgust with how life has progressed. The individual would like to start over and have a second chance at life. He or she feels worthless and helpless to change. Anger, depression, and loneliness are evident. The focus may be on past failures or perceived failures. Impending death is feared or denied, or ideas of suicide may prevail. The task remains unresolved when earlier tasks are not fulfilled: self-confidence, a concern for others, and a strong sense of self-identity were never achieved.

The life span was significantly different when Erikson's developmental tasks and stages were first identified, and in the late 1990s, Erikson expanded the concept of transcendence as an additional stage that occurs after the stage of integrity versus despair (Erikson & Erikson, 1997). McCarthy, Ling, and Carini (2013) identify transcendence as a concept within the spiritual domain and cite McCarthy and Bockweg's (2012) definition:

> Transcendence [is] an inherent developmental process, resulting in a shift from a rational, materialistic view to a wider world view characterized by broadened personal boundaries, within interpersonal, intrapersonal, transpersonal, and temporal dimensions resulting in an increased sense of meaning in life, well-being, and life satisfaction. (p. 180)

Relevance of Psychosocial Development Theory to Nursing Practice

Erikson's theory is particularly relevant to nursing practice in that it incorporates sociocultural concepts into the development of personality. Erikson provides a systematic, stepwise approach and outlines specific tasks that should be completed during each stage. This information can be used quite readily in psychiatric-mental health nursing. Many individuals with mental health problems are still struggling to achieve tasks from earlier developmental stages. Nurses can plan care to assist these individuals in fulfilling tasks and ascending to a higher developmental level.

> **CLINICAL PEARL** During assessment, nurses can determine if a client is experiencing difficulties associated with specific life tasks as described by Erikson. Knowledge about a client's developmental level, along with other assessment data, can help to identify appropriate nursing interventions.

Theory of Object Relations

Margaret Mahler (Mahler, Pine, & Bergman, 1975) formulated a theory that describes the separation-individuation process of the infant from the maternal figure (primary caregiver). She describes this process as progressing through three major phases, and she further delineates phase III, the separation-individuation phase, into four subphases. Mahler's developmental theory is outlined in Table 41–4.

Phase I: The Autistic Phase (Birth to 1 Month)

In the autistic phase, also called *normal autism,* the infant exists in a half-sleeping, half-waking state and does not perceive the existence of other people or an external environment. The fulfillment of basic needs for survival and comfort is the focus and is merely accepted as it occurs.

Phase II: The Symbiotic Phase (1 to 5 Months)

Symbiosis is a type of "psychic fusion" of mother and child. The child views the self as an extension of the mother, but with a developing awareness that it is she who fulfills the child's every need. Mahler suggested that absence of or rejection by the maternal figure at this phase can lead to symbiotic psychosis.

TABLE 41–4 Stages of Development in Mahler's Theory of Object Relations

AGE	PHASE/SUBPHASE	MAJOR DEVELOPMENTAL TASKS
Birth–1 month	I. Normal autism	Fulfillment of basic needs for survival and comfort
1–5 months	II. Symbiosis III. Separation-Individuation	Development of awareness of external source of need fulfillment
5–10 months	a. Differentiation	Commencement of a primary recognition of separateness from the mothering figure
10–16 months	b. Practicing	Increased independence through locomotor functioning; increased sense of separateness of self
16–24 months	c. Rapprochement	Acute awareness of separateness of self; learning to seek "emotional refueling" from mothering figure to maintain feeling of security
24–36 months	d. Consolidation	Sense of separateness established; on the way to object constancy (i.e., able to internalize a sustained image of loved object/person when it is out of sight); resolution of separation anxiety

Phase III: Separation-Individuation (5 to 36 Months)

This third phase represents what Mahler calls the "psychological birth" of the child. *Separation* is defined as the physical and psychological attainment of a sense of personal distinction from the mothering figure. *Individuation* occurs with a strengthening of the ego and an acceptance of a sense of "self," with independent ego boundaries. Four subphases through which the child evolves in his or her progression from a symbiotic extension of the mothering figure to a distinct and separate being are described.

Subphase 1: Differentiation (5 to 10 Months)

The differentiation phase begins with the child's initial physical movements away from the mothering figure. A primary recognition of separateness commences.

Subphase 2: Practicing (10 to 16 Months)

With advanced locomotor functioning, the child experiences feelings of exhilaration from increased independence. He or she is now able to move away from and return to the mothering figure. A sense of omnipotence is manifested.

Subphase 3: Rapprochement (16 to 24 Months)

This third subphase, rapprochement, is critical to the child's healthy ego development. During this time, the child becomes increasingly aware of his or her separateness from the mothering figure, while the sense of fearlessness and omnipotence diminishes. The child, now recognizing the mother as a separate individual, wishes to reestablish closeness with her but shuns the total re-engulfment of the symbiotic stage. Instead, the mothering figure must be available to provide "emotional refueling" on demand.

Critical to this subphase is the mothering figure's response to the child. If the mothering figure is available to fulfill emotional needs as they arise, the child develops a sense of security in the knowledge that he or she is loved and will not be abandoned. However, if emotional needs are inconsistently met or if the mother rewards clinging, dependent behaviors and withholds nurturing when the child demonstrates independence, feelings of rage and a fear of abandonment develop and often persist into adulthood.

Subphase 4: Consolidation (24 to 36 Months)

With achievement of the consolidation subphase, a definite individuality and sense of separateness of self are established. Objects are represented as whole, with the child having the ability to integrate both "good" and "bad." A degree of object constancy is established as the child is able to internalize a sustained image of the mothering figure as enduring and loving, while maintaining the perception of her as a separate person in the outside world.

Relevance of Object Relations Theory to Nursing Practice

Understanding of the concepts of Mahler's theory of object relations helps the nurse assess the client's level of individuation from primary caregivers. The emotional problems of many individuals can be traced to lack of fulfillment of the tasks of separation-individuation. Examples include problems related to dependency and excessive anxiety. The individual with borderline personality disorder is thought to be fixed in the rapprochement phase of development, harboring fears of abandonment and underlying rage. This knowledge is important in the provision of nursing care to these individuals.

Cognitive Development Theory

Jean Piaget (Piaget & Inhelder, 1969) has been called the father of child psychology. His work concerning **cognitive development** in children is based on the premise that human intelligence is an extension of biological adaptation, one's ability to adapt psychologically to the environment. He believed that human intelligence progresses through a series of stages related to age, demonstrating at each successive stage a higher level of logical organization than at the previous stages.

From his extensive studies of cognitive development in children, Piaget discovered four major stages, each of which he believed to be a necessary prerequisite for the one that follows. An outline is presented in Table 41–5.

Stage 1: Sensorimotor (Birth to 2 Years)

At the beginning of his or her life, the child is concerned only with satisfying basic needs and comforts. The self is not differentiated from the external environment. As the sense of differentiation occurs with increasing mobility and awareness, the mental system is expanded. The child develops a greater understanding of objects in the external environment and their effects upon him or her. Knowledge is gained regarding the ability to manipulate objects and experiences within the environment. The sense of *object permanence*—the notion that an object will continue to exist when it is no longer present to the senses—is initiated.

Stage 2: Preoperational (2 to 6 years)

Piaget believed that preoperational thought is characterized by egocentrism. Personal experiences are thought to be universal, and the child is unable to accept the differing viewpoints of others. Language development progresses, as does the ability to attribute special meaning to symbolic gestures (e.g., bringing a storybook to mother is a symbolic invitation to have a story read). Reality is often given to inanimate objects. Object permanence culminates in the ability to conjure up mental representations of objects or people.

Stage 3: Concrete Operations (6 to 12 Years)

The ability to apply logic to thinking begins in this stage; however, "concreteness" still predominates. An understanding of the concepts of reversibility and spatiality is developed. For example, the child recognizes that changing the shape of objects does not necessarily change the amount, weight, volume, or ability of the object to return to its original form. Another achievement of this stage is the ability to classify objects by any of several characteristics. For example, he or she can classify all poodles as dogs but recognizes that all dogs are not poodles.

The concept of a lawful self is developed at this stage as the child becomes more socialized and rule conscious. Egocentrism decreases, the ability to cooperate in interactions with other children increases, and understanding and acceptance of established rules grow.

Stage 4: Formal Operations (12 to 15+ Years)

At this stage, the individual is able to think and reason in abstract terms. He or she can make and test hypotheses using logical and orderly problem solving. Current situations and reflections of the future are idealized, and a degree of egocentrism returns. There may be difficulty reconciling idealistic hopes with more rational prospects. Formal operations, however, enable individuals to distinguish between the ideal and the real. Piaget's theory suggests that most individuals achieve **cognitive maturity,** the capability to perform all mental operations needed for adulthood, in middle to late adolescence.

TABLE 41–5	**Piaget's Stages of Cognitive Development**	
AGE	STAGE	MAJOR DEVELOPMENTAL TASKS
Birth–2 years	Sensorimotor	With increased mobility and awareness, development of a sense of self as separate from the external environment; the concept of object permanence emerges as the ability to form mental images evolves
2–6 years	Preoperational	Learning to express self with language; development of understanding of symbolic gestures; achievement of object permanence
6–12 years	Concrete operations	Learning to apply logic to thinking; development of understanding of reversibility and spatiality; learning to differentiate and classify; increased socialization and application of rules
12–15+ years	Formal operations	Learning to think and reason in abstract terms; making and testing hypotheses; capability of logical thinking and reasoning expand and are refined; cognitive maturity achieved

Relevance of Cognitive Development Theory to Nursing Practice

Nurses who work in psychiatry are likely to be involved in helping clients, particularly depressed clients, with techniques of cognitive therapy. In cognitive therapy, the individual is taught to control thought distortions that are considered a factor in the development and maintenance of mood disorders. In the cognitive model, depression is characterized by a triad of negative distortions related to expectations of the environment, self, and future. In this model, depression is viewed as a distortion in cognitive development, the self is unrealistically devalued, and the future is perceived as hopeless. Therapy focuses on changing "automatic thoughts" that occur spontaneously and contribute to the distorted affect. Nurses who assist with this type of therapy must have knowledge of how cognition develops to help clients identify the distorted thought patterns and make the changes required to improve affective functioning (see Chapter 19, Cognitive Therapy).

Theory of Moral Development

Lawrence Kohlberg's (1976) stages of moral development are not closely tied to specific age groups. Research was conducted with males from 10 to 28 years old. Kohlberg believed that each stage is necessary and basic to the next stage and that all individuals must progress through each stage sequentially. He defined three major levels of moral development, each of which is further subdivided into two stages. An outline of Kohlberg's developmental stages is presented in Table 41–6. Most people do not progress through all six stages.

Level I: Preconventional Level (Prominent from Ages 4 to 10 Years)

Stage 1: Punishment and Obedience Orientation

At the punishment and obedience orientation stage, the individual is responsive to cultural guidelines of good or bad and right or wrong, but primarily in terms of the known related consequences. Fear of punishment is likely to be the incentive for conformity (e.g., "I'll do it, because if I don't, I can't watch TV for a week").

Stage 2: Instrumental Relativist Orientation

Behaviors at the instrumental relativist orientation stage are guided by egocentrism and concern for self. There is an intense desire to satisfy one's own needs, but occasionally the needs of others are considered. For the most part, decisions are based on personal benefits derived (e.g., "I'll do it if I get something in return," or occasionally, ". . . because you asked me to").

Level II: Conventional Level (Prominent From Ages 10 to 13 Years and Into Adulthood)*

Stage 3: Interpersonal Concordance Orientation

Behavior at the interpersonal concordance orientation stage is guided by the expectations of others. Approval and acceptance within one's societal group provide the incentive to conform (e.g., "I'll do it

---

*Eighty percent of adults are fixed in level II, with a majority of women in stage 3 and a majority of men in stage 4.

TABLE 41–6 Kohlberg's Stages of Moral Development		
LEVEL/AGE	**STAGE**	**MAJOR DEVELOPMENTAL TASKS**
I. Preconventional (common from age 4–10 years)	**1.** Punishment and obedience orientation **2.** Instrumental relativist orientation	Behavior motivated by fear of punishment Behavior motivated by egocentrism and concern for self
II. Conventional (common from age 10–13 years, and into adulthood)	**3.** Interpersonal concordance orientation **4.** Law and order orientation	Behavior motivated by expectations of others; strong desire for approval and acceptance Behavior motivated by respect for authority
III. Postconventional (can occur from adolescence on)	**5.** Social contract legalistic orientation **6.** Universal ethical principle orientation	Behavior motivated by respect for universal laws and moral principles; guided by internal set of values Behavior motivated by internalized principles of honor, justice, and respect for human dignity; guided by the conscience

*Ages in Kohlberg's theory are not well defined. The stage of development is determined by the motivation behind the individual's behavior.

because you asked me to," ". . . because it will help you," or ". . . because it will please you").

Stage 4: Law and Order Orientation

In the law and order orientation stage, there is a personal respect for authority. Rules and laws are required and override personal principles and group mores. The belief is that all individuals and groups are subject to the same code of order and no one shall be exempt (e.g., "I'll do it because it is the law").

Level III: Postconventional Level (Can Occur From Adolescence Onward)

Stage 5: Social Contract Legalistic Orientation

Individuals who reach stage 5 have developed a system of values and principles that determine for them what is right or wrong; behaviors are acceptably guided by this value system, provided they do not violate the human rights of others. They believe that all individuals are entitled to certain inherent human rights and live according to universal laws and principles. However, they hold the idea that the laws are subject to scrutiny and change as needs within society evolve and change (e.g., "I'll do it because it is the moral and legal thing to do, even though it is not my personal choice").

Stage 6: Universal Ethical Principle Orientation

Behavior at stage 6 is directed by internalized principles of honor, justice, and respect for human dignity. Laws are abstract and unwritten, such as the "Golden Rule," "equality of human rights," and "justice for all." They are not the concrete rules established by society. The conscience is the guide, and when one fails to meet the self-expected behaviors, the personal consequence is intense guilt. The allegiance to these ethical principles is so strong that the individual will stand by them even knowing that negative consequences will result (e.g., "I'll do it because I believe it is the right thing to do, even though it is illegal and I will be imprisoned for doing it").

Relevance of Moral Development Theory to Nursing Practice

Moral development has relevance to psychiatric nursing in that it affects critical thinking about how individuals ought to behave and treat others. Moral behavior reflects the way a person interprets basic respect for others, such as the respect for human life, freedom, justice, or confidentiality. Psychiatric nurses must be able to assess the level of moral development of their clients in order to help them progress to a higher level of developmental maturity.

A Nursing Model—Hildegard E. Peplau

Peplau (1991) applied interpersonal theory to nursing practice and, most specifically, to nurse-client relationship development. She provided a framework for "psychodynamic nursing," the interpersonal involvement of the nurse with a client in a given nursing situation. Peplau stated, "Nursing is helpful when both the patient and the nurse grow as a result of the learning that occurs in the nursing situation" (p. ix).

Peplau correlated the stages of personality development in childhood to stages through which clients advance during the progression of an illness. She also viewed these interpersonal experiences as learning situations for nurses to facilitate forward movement in the development of personality. She believed that when there is fulfillment of psychological tasks associated with the nurse-client relationship, the personalities of both can be strengthened. Key concepts include the following:

- *Nursing* is a human relationship between an individual who is sick or in need of health services and a nurse educated to recognize and to respond to the need for help.
- **Psychodynamic nursing** is the ability to understand one's own behavior, help others identify felt difficulties, and apply principles of human relations to the problems that arise at all levels of experience.
- *Roles* are sets of values and behaviors specific to functional positions within social structures. Peplau identifies the following *nursing roles*:
  - A nurse is at first a *stranger* to the client. The client is also a stranger to the nurse. Peplau (1991) stated:

    Respect and positive interest accorded a stranger is at first nonpersonal and includes the same ordinary courtesies that are accorded to a new guest who has been brought into any situation. This principle implies: (1) accepting the patient as he is; (2) treating the patient as an emotionally able stranger and relating to him on this basis until evidence shows him to be otherwise. (p. 44)

  - A *resource person* provides specific, needed information that helps the client understand his or her problem and the new situation.
  - A **counselor** is one who listens as the client reviews feelings related to difficulties he or she is experiencing in any aspect of life. "Interpersonal techniques" have been identified to facilitate the nurse's interaction in the process of helping the client solve problems and make decisions concerning these difficulties.
  - A *teacher* is one who identifies learning needs and provides information to the client or family that may aid in improvement of the life situation.

- A *leader* is one who directs the nurse-client interaction and ensures that appropriate actions are undertaken to facilitate achievement of the designated goals.
- A **technical expert** is one who understands various professional devices and possesses the clinical skills necessary to perform interventions in the best interest of the client.
- A **surrogate** is one who serves as a substitute figure for another.

Phases of the nurse-client relationship are stages of overlapping roles or functions in relation to health problems, during which the nurse and client learn to work cooperatively to resolve difficulties. Peplau identified four phases:

- *Orientation* is the phase during which the client, nurse, and family work together to recognize, clarify, and define the existing problem.
- *Identification* is the phase after which the client's initial impression has been clarified and when he or she begins to respond selectively to those who seem to offer the help that is needed. Clients may respond in one of three ways: (1) on the basis of participation or interdependent relations with the nurse, (2) on the basis of independence or isolation from the nurse, or (3) on the basis of helplessness or dependence on the nurse (Peplau, 1991).
- *Exploitation* is the phase during which the client proceeds to take full advantage of the services offered to him or her. Knowing which services are available, feeling comfortable within the setting, and serving as an active participant in his or her own health care, the client exploits the services available and explores all possibilities of the changing situation.
- *Resolution* occurs when the client is freed from identification with helping persons and gathers strength to assume independence. Resolution is the direct result of successful completion of the other three phases.

Peplau's Stages of Personality Development

Psychological tasks are developmental lessons that must be learned to achieve maturity of the personality. Peplau (1991) identified four psychological tasks that she associated with the stages of infancy and childhood described by Freud and Sullivan. She stated:

> When psychological tasks are successfully learned at each era of development, biological capacities are used productively and relations with people lead to productive living. When they are not successfully learned they carry over into adulthood and attempts at learning continue in devious ways, more or less impeded by conventional adaptations that provide a superstructure over the baseline of actual learning. (p. 166)

In the context of nursing, Peplau related four psychological tasks to the demands made on nurses in their relations with clients. She maintained that:

> Nursing can function as a maturing force in society. Since illness is an event that is experienced along with feelings that derive from older experiences but are reenacted in the relationship of nurse to patient, the nurse-patient relationship is seen as an opportunity for nurses to help patients to complete the unfinished psychological tasks of childhood in some degree. (p. 159)

Peplau's psychological tasks of personality development include the four stages outlined in the following paragraphs. An outline of the stages of personality development according to Peplau's theory is presented in Table 41–7.

Learning to Count on Others

Nurses and clients first come together as strangers. Both bring to the relationship certain "raw materials," such as inherited biological components, personality characteristics *(temperament),* individual intellectual capacity, and specific cultural or environmental influences. Peplau relates these to the same "raw materials"

TABLE 41–7	Stages of Development in Peplau's Interpersonal Theory	
AGE	STAGE	MAJOR DEVELOPMENTAL TASKS
Infancy	Learning to count on others	Learning to communicate in various ways with the primary caregiver in order to have comfort needs fulfilled
Toddlerhood	Learning to delay satisfaction	Learning the satisfaction of pleasing others by delaying self-gratification in small ways
Early childhood	Identifying oneself	Learning appropriate roles and behaviors by acquiring the ability to perceive the expectations of others
Late childhood	Developing skills in participation	Learning the skills of compromise, competition, and cooperation with others; establishment of a more realistic view of the world and a feeling of one's place in it

with which an infant comes into the world. The newborn is capable of experiencing *comfort* and *discomfort*. He or she soon learns to communicate feelings in a way that results in the fulfillment of comfort needs by the mothering figure, who provides love and care unconditionally. However, fulfillment of these dependency needs is inhibited when goals of the mothering figure become the focus, and love and care are contingent on meeting the needs of the caregiver rather than the infant.

Clients with unmet dependency needs regress during illness and demonstrate behaviors that relate to this stage of development. Other clients regress to this level because of physical disabilities associated with their illness. Peplau believed that when nurses provide unconditional care, they help these clients progress toward more mature levels of functioning. This may involve the role of "surrogate mother," in which the nurse fulfills needs for the client with the intent of helping him or her grow, mature, and become more independent.

Learning to Delay Satisfaction

Peplau related this stage to that of toddlerhood, or the first step in the development of interdependent social relations. Psychosexually, it is compared to the anal stage of development, when a child learns that because of cultural mores, he or she cannot empty the bowels for relief of discomfort at will but must delay to use the toilet, which is considered more culturally acceptable. When toilet training occurs too early or is very rigid, or when appropriate behavior is set forth as a condition for love and caring, tasks associated with this stage remain unfulfilled. The child feels powerless and fails to learn the satisfaction of pleasing others by delaying self-gratification in small ways. He or she may also exhibit rebellious behavior toward the mothering figure to counter the feelings of powerlessness. The child may accomplish this by withholding the fecal product or failing to deposit it in the culturally acceptable manner.

Peplau cited Fromm (1949) in describing the following potential behaviors of individuals who have failed to complete the tasks of the second stage of development:

- Exploitation and manipulation of others to satisfy their own desires because they are unable to do so independently
- Suspiciousness and envy of others; directing hostility toward others in an effort to enhance their own self-image
- Hoarding and withholding possessions from others; miserliness
- Inordinate neatness and punctuality
- Inability to relate to others through sharing of feelings, ideas, or experiences

- Ability to vary the personality characteristics to those required to satisfy personal desires at any given time

When nurses observe these types of behaviors in clients, it is important to encourage full expression and convey unconditional acceptance. When the client learns to feel safe and unconditionally accepted, he or she is more likely to let go of the oppositional behavior and advance in the developmental progression. Peplau (1991) stated:

> Nurses who aid patients to feel safe and secure, so that wants can be expressed and satisfaction eventually achieved, also help them to strengthen personal power that is needed for productive social activities. (p. 207)

Identifying Oneself

A concept of self develops as a product of interaction with adults (Peplau, 1991, p. 211). A child learns to structure self-concept by observing how others interact with him or her. Roles and behaviors are established from the child's perception of the expectations of others. When a child perceives that adults expect him or her to permanently remain an infant, he or she develops a perception of self as helpless and dependent. When the perceived expectation is that the child must behave in a manner beyond his or her maturational level, the child is deprived of the fulfillment of emotional and growth needs at the lower levels of development. Children who are given freedom to respond to situations and experiences unconditionally (i.e., with behaviors that are appropriate to their feelings) learn to improve on and reconstruct behavioral responses at their own pace. Peplau stated, "The ways in which adults appraise the child and the way he functions in relation to his experiences and perceptions are taken in or introjected and become the child's view of himself" (p. 213).

The nurse must recognize cues that communicate how the client feels about him- or herself and about the presenting medical problem. In the initial interaction, it is difficult for the nurse to perceive the "wholeness" of the client, because the focus is on the condition that has caused him or her to seek help. Likewise, it is difficult for the client to perceive the nurse as a "mother (or father)" or "somebody's wife (or husband)" or as having a life aside from offering assistance with the immediate problem. As the relationship develops, nurses must be able to recognize client behaviors that indicate unfulfilled needs and provide experiences that promote growth. For example, the client who very proudly announces that she has completed activities of daily living independently and wants the nurse to come and inspect her room may still be craving the positive reinforcement associated with lower levels of development.

Nurses must also be aware of the predisposing factors they bring to the relationship. Attitudes and beliefs about certain issues can have a deleterious effect on the client and interfere not only with the therapeutic relationship but also with the client's ability for growth and development. For example, a nurse who has strong beliefs against abortion may treat a client who has just undergone an abortion with disapproval and disrespect. The nurse may respond in this manner without even realizing he or she is doing so. Attitudes and values are introjected during early development and can be integrated so completely as to become a part of the self-system. Nurses must have knowledge and appreciation of their own concept of self in order to develop the flexibility required to accept all clients as they are, unconditionally. Effective resolution of problems that arise in the interdependent relationship can allow both client and nurse to reinforce positive personality traits and modify more negative views of self.

Developing Skills in Participation

Peplau cited Sullivan's (1953) description of the "juvenile" stage of personality development (ages 6 through 9). During this stage, the child develops the capacity to "compromise, compete, and cooperate" with others. These skills are considered basic to one's ability to participate collaboratively with others. If a child tries to use the skills of an earlier level of development (e.g., crying, whining, demanding), he or she may be rejected by peers. As this stage progresses, children begin to view themselves through the eyes of their peers. Sullivan called this "consensual validation." Preadolescents take on a more realistic view of the world and a feeling of their place in it. The capacity to love others (besides the mother figure) develops at this time and is expressed in relation to one's self-acceptance.

Failure to develop appropriate skills at any point along the developmental progression results in an individual's difficulty in confronting the recurring problems of life. It is not the responsibility of the nurse to teach solutions to problems, but rather to help clients improve their problem-solving skills so that they may achieve their own resolutions. This is accomplished through development of the skills of competition, compromise, cooperation, consensual validation, and love of self and others. Nurses can help clients develop or refine these skills by assisting them in identifying the problem, defining a goal, and taking responsibility for the actions necessary to reach that goal. Peplau (1991) stated:

> Participation is required by a democratic society. When it has not been learned in earlier experiences, nurses have an opportunity to facilitate learning in the present and thus to aid in the promotion of a democratic society. (p. 259)

Relevance of Peplau's Model to Nursing Practice

Peplau's model provides nurses with a framework to interact with clients, many of whom are fixed in—or because of illness have regressed to—an earlier level of development. She suggested roles that nurses may assume to assist clients to progress, thereby achieving or resuming their appropriate developmental level. Appropriate developmental progression arms the individual with the ability to confront the recurring problems of life. Nurses serve to facilitate learning of that which has not been learned in earlier experiences.

Summary and Key Points

- Growth and development are unique with each individual and continue throughout the life span.
- Personality is defined as the combination of character, behavioral, temperamental, emotional, and mental traits that are unique to each individual.
- Sigmund Freud, who has been called the father of psychiatry, believed the basic character has been formed by the age of 5.
- Freud's personality theory can be conceptualized according to structure and dynamics of the personality, topography of the mind, and stages of personality development.
- Freud's structure of the personality includes the id, ego, and superego.
- Freud classified all mental contents and operations into three categories: the conscious, the preconscious, and the unconscious.
- Harry Stack Sullivan, author of *The Interpersonal Theory of Psychiatry,* believed that individual behavior and personality development are the direct result of interpersonal relationships. Major concepts include *anxiety, satisfaction of needs, interpersonal security,* and *self-system.*
- Erik Erikson studied the influence of social processes on the development of the personality.
- Erikson described eight stages of the life cycle from birth to death. He believed that individuals struggled with developmental crises, and that each must be resolved for emotional growth to occur.
- Margaret Mahler formulated a theory that describes the separation-individuation process of the infant from the maternal figure (primary caregiver). Stages of development describe the progression of the child from birth to object constancy at age 36 months.
- Jean Piaget has been called the father of child psychology. He believed that human intelligence progresses through a series of stages related to age,

demonstrating at each successive stage a higher level of logical organization than at the previous stages.

■ Lawrence Kohlberg outlined stages of moral development. His stages are not closely tied to specific age groups or the maturational process. He believed that moral stages emerge out of our own thinking and the stimulation of our mental processes.

■ Hildegard Peplau provided a framework for "psychodynamic nursing," the interpersonal involvement of the nurse with a client in a given nursing situation.

■ Peplau identified the nursing roles of stranger, resource person, counselor, teacher, leader, technical expert, and surrogate.

■ Peplau described four psychological tasks that she associated with the stages of infancy and childhood as identified by Freud and Sullivan.

■ Peplau believed that nursing is helpful when both the patient and the nurse grow as a result of the learning that occurs in the nursing situation.

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Mr. J. is a new client on the psychiatric unit. He is 35 years old. Theoretically, in which level of psychosocial development (according to Erikson) would you place Mr. J.?
   a. Intimacy vs. isolation
   b. Generativity vs. self-absorption
   c. Trust vs. mistrust
   d. Autonomy vs. shame and doubt

2. Mr. J. has been diagnosed with schizophrenia. He refuses to eat and told the nurse he knew he was "being poisoned." According to Erikson's theory, in what developmental stage would you place Mr. J.?
   a. Intimacy vs. isolation
   b. Generativity vs. self-absorption
   c. Trust vs. mistrust
   d. Autonomy vs. shame and doubt

3. Janet, a psychiatric client diagnosed with borderline personality disorder, has just been hospitalized for threatening suicide. According to Mahler's theory, Janet did not receive the critical "emotional refueling" required during the rapprochement phase of development. What are the consequences of this deficiency?
   a. She has not yet learned to delay gratification.
   b. She does not feel guilt about wrongdoings to others.
   c. She is unable to trust others.
   d. She has internalized rage and fears of abandonment.

4. John is on the Alcohol Treatment Unit. He walks into the dayroom where other clients are watching a program on TV. He picks up the remote and changes the channel and says, "That's a stupid program! I want to watch something else!" In what stage of development is John fixed according to Sullivan's interpersonal theory?
   a. Juvenile. He is learning to form satisfactory peer relationships.
   b. Childhood. He has not learned to delay gratification.
   c. Early adolescence. He is struggling to form an identity.
   d. Late adolescence. He is working to develop a lasting relationship.

Review Questions—cont'd
Self-Examination/Learning Exercise

5. Adam has antisocial personality disorder. He says to the nurse, "I'm not crazy. I'm just fun-loving. I believe in looking out for myself. Who cares what anyone thinks? If it feels good, do it!" Which of the following describes the psychoanalytical structure of Adam's personality?
   a. Weak id, strong ego, weak superego
   b. Strong id, weak ego, weak superego
   c. Weak id, weak ego, punitive superego
   d. Strong id, weak ego, punitive superego

6. Larry, who has antisocial personality disorder, feels no guilt about violating the rights of others. He does as he pleases without thought to possible consequences. In which of Peplau's stages of development would you place Larry?
   a. Learning to count on others
   b. Learning to delay gratification
   c. Identifying oneself
   d. Developing skills in participation

7. Danny has been diagnosed with schizophrenia. On the unit he appears very anxious, paces back and forth, and darts his head from side to side in a continuous scanning of the area. He has refused to eat, making some barely audible comment related to "being poisoned." In planning care for Danny, which of the following would be the primary focus for nursing?
   a. To decrease anxiety and develop trust
   b. To set limits on his behavior
   c. To ensure that he gets to group therapy
   d. To attend to his hygiene needs

8. The nurse has just admitted Madison to the psychiatric unit. The psychiatrist has diagnosed Madison with major depressive disorder. The nurse says to Madison, "Please tell me what it was like when you were growing up." Which nursing role described by Peplau is the nurse fulfilling in this instance?
   a. Surrogate
   b. Resource person
   c. Counselor
   d. Technical expert

9. The nurse has just admitted Madison to the psychiatric unit. The psychiatrist has diagnosed Madison with major depressive disorder. The nurse says to Madison, "What questions do you have about being here on the unit?" Which nursing role described by Peplau is the nurse fulfilling in this instance?
   a. Resource person
   b. Counselor
   c. Surrogate
   d. Technical expert

10. The nurse has just admitted Madison to the psychiatric unit. The psychiatrist has diagnosed Madison with major depressive disorder. The nurse says to Madison, "Some changes will have to be made in your behavior. I care about what happens to you." Which nursing role described by Peplau is the nurse fulfilling in this instance?
    a. Counselor
    b. Surrogate
    c. Technical expert
    d. Resource person

Forensic Nursing

42

CORE CONCEPT

Forensic

KEY TERMS

colposcope

forensic nursing

sexual assault nurse examiner (SANE)

OBJECTIVES
After reading this chapter, the student will be able to:

1. Define the terms *forensic* and *forensic nursing.*
2. Discuss historical perspectives of forensic nursing.
3. Identify areas of nursing within which forensic nurses may practice.
4. Describe forensic nursing specialties.
5. Apply the nursing process within the role of clinical forensic nursing in trauma care.
6. Apply the nursing process within the role of forensic mental health nursing in correctional facilities.

HOMEWORK ASSIGNMENT
Please read the chapter and answer the following questions:

1. When deaths occur in the emergency department, it is critical to determine if the death was natural or unnatural. What is the difference?
2. What is a colposcope?
3. Name four rationales for imprisonment as a punishment for criminal behavior.
4. In what ways is HIV infection commonly spread in prisons?

The various roles of nurses continue to increase along with the ever-expanding health service delivery system. **Forensic nursing** is one nursing role with a rapidly increasing scope of practice. Nurses practicing in this unique specialty may apply their skills to the care of both victims and perpetrators of crime and in a variety of settings, including primary care facilities, hospitals, and correctional institutions. This chapter focuses on defining forensic nursing within varied aspects of the role. A discussion of historical perspectives is included and care of the client is presented within the context of the nursing process.

What Is Forensic Nursing?

CORE CONCEPT
Forensic
Pertaining to the law; legal.

The International Association of Forensic Nurses (IAFN) and the American Nurses Association (ANA) define *forensic nursing* as "the practice of nursing globally when health and legal systems intersect" (2009, p. 3).

Catalano (2015) offers the following:

Forensic nursing is an emerging field that forms an alliance between nursing, law enforcement, and the forensic sciences. The term forensic means anything belonging to, or pertaining to, the law. Forensic nurses provide a continuum of care to victims and their families beginning in the emergency room or crime scene and leading to participation in the criminal investigation and the courts of law. (p. 674)

Constantino, Crane, and Young (2013) state:

Forensic nursing is defined as the application of forensic science, biopsychosocial knowledge, and clinical nursing skills in the scientific investigation, collection, preservation, analysis, and examination of evidence. (p. vii)

Because this area of nursing is a pioneering effort, roles, definitions, and educational programs are still being formulated.

Historical Perspectives

Forensic nursing has its roots in 1975 Alberta, Canada, where nurses served as investigators for medical examiners. They were valued for their biomedical education, their sensitivity in dealing with family members, and their ability to act in the role of the medical examiner when required. These qualities were often found lacking in medically untrained criminal investigative personnel.

The forensic nursing discipline has made great advances since that time. The role of these nurses has expanded from the area of death investigation to include the living: the survivors of violent crime and the perpetrators of criminal acts. In 1992, 74 nurses, primarily sexual assault nurse examiners, met to form the IAFN. By 1997, this organization had grown to more than a thousand members. It currently boasts a membership of more than 3,700 nurses from 24 countries (IAFN, 2016a).

Violence has reached epidemic proportions in the United States and is identified as a major public health problem. More than 1 in 3 women (35.6%) and 1 in 4 men (28%) have experienced rape, physical violence, and/or stalking during their lifetime (Centers for Disease Control and Prevention [CDC], 2016). It is with this in mind that the health-care system and the legal system have joined in an attempt to respond to the increasing needs of crime victims. Stokowski (2008b) states, "The zone where health-care needs intersect with the law is expanding, and forensic nurses have stepped in to become leaders in the health-care response to violence."

The Context of Forensic Nursing Practice

The IAFN (2016b) has identified a variety of assignments within which the forensic nurse may practice. Some of these include the following:

- Interpersonal violence
  - Domestic violence
  - Elder abuse and neglect
  - Child abuse and neglect
- Sexual assault
- Death investigation
  - Medical/social history
  - Examination of the body
  - Scene investigation
- Mass disasters
- Forensic mental health
- Correctional nursing
- Legal nurse consulting
- Public health and safety
  - Environmental hazards
  - Drug and alcohol abuse
  - Epidemiological issues
- Emergency/trauma services
  - Automobile and pedestrian accidents
  - Work-related injuries
  - Suicide attempts

Forensic Nursing Specialties*

Clinical Forensic Nursing

Clinical forensic nursing is the management of crime victims from trauma to trial. Nurses working in clinical forensics collect evidence through assessment of living victims, survivors of traumatic injury, or those whose death is pronounced in the clinical environment. Clinical forensic nursing involves making judgments related to patient treatment associated with court-related issues. The clinical forensic nurse assesses victims of child and elder abuse and domestic violence. Forensic nurses are asked to differentiate between conditions that simulate accidental injury and those that are purposely inflicted. An essential skill is the ability to assess patterned injury by differentiating marks such as defense wounds, grab marks, and fingernail marks. Clinical forensic nurses focus on observation of the communication and interaction patterns of suspected abuse victims and perpetrators. Many nurses come to forensic nursing from

---

acute care settings such as emergency department nursing, critical care nursing, and perioperative nursing.

In the coroner's office, death notification entails stabilization of the family situation and grief support, skills that are basic to nursing practice. Expert skills in physical assessment, clinical history taking and interviewing, and use of technology have helped advance this nursing role.

Because of their awareness of the effects of violence in society and their ability to assess situations in which potential for violence exists, clinical forensic nurses are often called upon for consultation. By identifying risk factors and cues for violence in health-care and workplace settings, these nurses can assist in the development of strategies, policies, and protocols to manage risk and reduce violence and injury. They also assist in the debriefing or resolution of violent events in a workplace or community.

The Sexual Assault Nurse Examiner

The **sexual assault nurse examiner (SANE)** is a clinical forensic registered nurse who has received specialized training to care for the sexual assault victim. Responsibilities include interviewing the victim, completing the physical examination, collecting specimens for forensic evidence, and documenting findings. SANEs also provide emotional support for victims and family members. When the case goes to court, the SANE testifies as an expert legal witness regarding how the evidence was collected and the physical and psychological condition of the client. The SANE may offer an opinion as to whether a crime occurred.

Forensic Mental Health Nursing

The practice of forensic mental health nursing integrates psychiatric-mental health nursing philosophy and practice with knowledge of the criminal justice system. The forensic mental health nurse assesses sociocultural influences on the individual client, the family, and the community to provide clients with comprehensive psychosocial care. They help victims of crime cope with their emotional wounds and assist in the assessment and care of mentally ill offenders. They focus on assisting the client to identify and change behaviors that may increase their vulnerability to victimization. These nurses assist perpetrators and victims of crime in dealing with the courts and other aspects of the criminal justice system, thus minimizing further victimization and promoting functional abilities.

Applications of forensic mental health nursing include assessment of inmates for physical fitness, criminal responsibility, disposition, and early release. Forensic mental health nurses also provide treatment for convicted offenders and those who are not found criminally responsible. In the criminal justice system, forensic mental health nurses deal with destructive, aggressive, and socially unacceptable behavior. These nurses provide interventions that encourage individuals to exercise self-control, foster an individual change in behavior, and, in the process, protect other members of society and property.

There has been an increase in the involvement of forensic mental health nurses (especially those prepared for advanced practice) in the assessment and treatment of forensic psychiatric patients. These practitioners develop and refine clinical roles in forensic mental health nursing and promote intervention strategies that increase the likelihood of rehabilitation and reintegration of the forensic client into society.

Forensic Correctional Nursing

Forensic correctional nurses work in secure settings providing treatment, rehabilitation, and health promotion to clients who have been charged with or convicted of crimes. Settings include jails, juvenile centers, state and federal prisons, and halfway houses. Correctional facilities reflect the demographics of the general population, with an increasing population of incarcerated seniors who have age-related health problems. Forensic correctional nurses manage acute and chronic illness, develop health-care plans, dispense medications, and perform health screenings and health education. They also conduct psychiatric assessments and respond to emergency situations. The role of the forensic correctional nurse offers a high level of autonomy compared with other nursing roles.

Legal Nurse Consultant

The legal nurse consultant is a licensed registered nurse who critically evaluates and analyzes health-care issues in medically related lawsuits. Because the legal system is involved, nurses who act as consultants are practicing forensic nursing. They uniquely combine their medical expertise with legal knowledge to assess compliance with accepted standards of health-care practice.

Legal nurse consultants work in collaboration with attorneys and other legal and health-care professionals. They may have independent practices, work in the hospital setting in risk management, or be employed by law firms or health insurance companies.

Forensic Nurse Death Investigator

A death investigator is a professional with experiential and scientific knowledge who can accurately determine the cause of death. The forensic nurse death investigator is a registered nurse with specialized education who functions in the death investigator's role. Forensic nurse death investigators respond to death and accidents and work in collaboration with law enforcement. At the scene, they examine the body, pronounce death,

and take tissue and blood samples, as well as photograph the body and related evidence. Forensic nurse death investigators must be able to recognize and integrate other evidence collected during the investigation, such as patterns of injury, types of wounds, and estimated time of death. They are responsible for record-keeping and arranging for the transport of the body to the morgue or to the coroner's office to undergo autopsy for further examination. Nurse death investigators work with the forensic pathologist to collect additional evidence in the laboratory during autopsy.

Nurses in General Practice

In addition to these specialty practices, nurses in general practice find forensic nursing knowledge of growing importance. Forensic applications in the acute care setting emphasize the use of forensic knowledge and awareness of criminal justice implications for assessment, documentation of care, and reporting of information to police or other law enforcement agencies. Nurses who work in emergency departments and critical care units are often in positions to preserve evidence from potential criminal offenses. Automobile accidents or apparent accidental overdoses are not always what they appear to be. Knowledge of what to look for and how to collect evidence, as well as whom to call and when, can be valuable in finding out what really happened in such cases. Preservation of evidence such as stomach contents, clothing residue, or marks on the skin surface can provide a very different picture—one of injury caused by a self-inflicted wound or violence perpetrated by another.

This chapter focuses on two specialties in forensic nursing: the clinical forensic nurse specialist in trauma-care settings and the forensic mental health nurse in correctional facilities. The ANA and IAFN (2009) Standards of Practice and Standards of Professional Performance for forensic nursing are presented in Box 42–1.

Application of the Nursing Process in Clinical Forensic Nursing in Trauma Care

Assessment

Forensic nurse examiners (FNEs) are included as valuable members of trauma units in many emergency departments. Dougherty (2011) states:

In addition to performing sexual assault examinations, these nursing specialists provide other services such as formal assessments for abuse and neglect, forensic photography, wound identification, evidence collection, and expert testimony. (p. 155)

All traumatic injuries in which liability is suspected are considered within the scope of forensic nursing.

Reports to legal agencies are required to ensure follow-up investigation; however, the protection of clients' rights remains a nursing priority. FNEs who work with sexual assault victims should have additional training and SANE certification.

McPeck (2002) reported on the performance of forensic nurses in the aftermath of the September 11, 2001, attacks on New York City and Washington, DC. He states:

[Forensic nurses] worked as mortuary assistants to collect and process biological and evidentiary remains of the victims. The forensic nurses provided clinical care and support for about 2,000 police officers, firefighters, and emergency workers who were at Ground Zero at any one time. Forensic nurses are trained to intervene in crises and offer that kind of mental support. (p. 25)

With the rise of violence in our society, the role of the clinical forensic nurse in the care of trauma clients in the emergency department is expanding. The forensic clinical nurse specialist may be the ideal liaison between legal and medical agencies. Areas of assessment in which the clinical forensic nurse specialist may become involved include the preservation of evidence, investigation of wound characteristics, and deaths in the emergency department. The IAFN provides educational resources, position papers, and networking opportunities designed to expand the skill and knowledge base of nurses working in this specialty and provide guidelines that support general practice nurses' identification and assessment of trauma in the emergency department or other practice areas.

Preservation of Evidence

Intentional traumas in the emergency department may be crime related or self-inflicted. Crime-related evidence is essential and must be safeguarded in a manner consistent with the investigation. Brown (2013) identifies common types of evidence as clothing, bullets, gunshot powder on the skin, bloodstains, hairs, fibers, grass, and any other debris found on the individual such as fragments of glass, paint, and wood. Often, this type of evidence is destroyed in the clinical setting when health-care personnel are unaware of its potential value in an investigation. This type of evidence must be saved and documented in all medical or accident cases that have legal implications.

Investigation of Wound Characteristics

When clients present in the emergency department with wounds from undiagnosed trauma, it is important for the clinical forensic nurse specialist to make a detailed documentation of the injuries. Failure to do so may interfere with the administration of justice

BOX 42–1 Standards of Practice and Standards of Professional Performance for Forensic Nursing

STANDARDS OF PRACTICE

Standard 1. Assessment
The forensic nurse collects comprehensive data pertinent to the patient's health or the situation.

Standard 2. Diagnosis
The forensic nurse analyzes the assessment data to determine the diagnoses or issues.

Standard 3. Outcome Identification
The forensic nurse identifies expected outcomes for a plan individualized to the patient or the situation.

Standard 4. Planning
The forensic nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes.

Standard 5. Implementation
The forensic nurse implements the identified plan.

Standard 5A. Coordination of Care
The forensic nurse coordinates care delivery.

Standard 5B. Health Teaching and Health Promotion
The forensic nurse employs strategies to promote health and a safe environment.

Standard 5C. Consultation
The Forensic Advanced Practice Registered Nurse and the nursing role specialist provide consultation to influence the identified plan, enhance the abilities of others, and effect change.

Standard 5D. Prescriptive Authority and Treatment
The Forensic Advanced Practice Registered Nurse uses prescriptive authority, procedures, referrals, treatments, and therapies in accordance with state and federal laws and regulations.

Standard 6. Evaluation
The forensic nurse evaluates progress towards attainment of outcomes.

STANDARDS OF PROFESSIONAL PERFORMANCE

Standard 7. Quality of Care
The forensic nurse systematically evaluates the quality and effectiveness of forensic nursing practice.

Standard 8. Education
The forensic nurse attains knowledge and competency that reflect current nursing practice.

Standard 9. Professional Practice Evaluation
The forensic nurse evaluates one's own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.

Standard 10. Collegiality
The forensic nurse interacts with and contributes to the professional development of peers and colleagues.

Standard 11. Collaboration
The forensic nurse collaborates with patient, family, and others in the conduct of nursing practice.

Standard 12. Ethics
The forensic nurse integrates ethical provisions into all areas of practice.

Standard 13. Research
The forensic nurse integrates research findings into practice.

Standard 14. Resource Utilization
The forensic nurse considers factors related to safety, effectiveness, cost, and impact on practice in the planning and delivery of nursing services.

Standard 15. Leadership
The forensic nurse provides leadership in the professional practice setting and the profession.

SOURCE: American Nurses Association (ANA) and International Association of Forensic Nurses. (2009). Forensic nursing: Scope and standards of practice. Silver Spring, MD: ANA. With permission.

should legal implications later arise. The following categories of medicolegal injuries are identified (Besant-Matthews, 2011; Brown, 2013):

- **Sharp force injuries:** Includes stab wounds and other wounds resulting from penetration with a sharp object
- **Blunt force injuries:** Includes cuts and bruises resulting from the impact of a blunt object against the body
- **Dicing injuries:** Multiple, minute cuts and abrasions caused by contact with shattered glass that often occur in motor vehicle accidents
- **Patterned injuries:** Specific injuries that reflect the pattern of the weapon used
- **Bite mark injuries:** Patterned injury inflicted by a human or animal

- **Defense wounds:** Injuries that reflect the victim's attempt to defend himself or herself from attack
- **Hesitation wounds:** Usually superficial, sharp force wounds; often found perpendicular to the lower part of the body and may reflect self-inflicted wounds
- **Fast-force injuries:** Usually gunshot wounds; may reflect various patterns of injury

Recently the IAFN (2016c) advanced a position paper on assessment of nonfatal strangulation, identifying it as another type of wound that often goes unnoticed when there is no visible evidence of injury. They note that 47 to 68 percent of women who report domestic violence have experienced one or more events of strangulation, and fatalities have occurred in victims who demonstrated no visible

external injuries. Serious internal injuries, including fractured trachea, carotid aneurysm, cerebral artery infarct, and death may occur days or weeks after the event. Child victims of strangulation are at increased risk for spinal cord injuries. The IAFN (2016c) recommends universal screening for strangulation events using a collaborative, trauma-informed care approach, including protocols for medical/radiologic evaluation, danger assessment, and safety plan development. They note that strangulation events are a strong predictor of future violence and risk for homicide.

Nurses managing the client's care in the emergency department must be able to make assessments about the type of wound, the weapon involved, and an estimated length of time between the injury and presentation for treatment.

Deaths in the Emergency Department

When deaths occur in the emergency department as a result of abuse or accident, evidence must be retained, the death reported to legal authorities, and an investigation conducted. It is therefore essential that the nurse carefully document the appearance, condition, and behavior of the victim upon arrival at the hospital. The information gathered from the client and family (or others accompanying the client) may facilitate the postmortem investigation and be used during criminal justice proceedings.

The critical factor is to determine if the cause of death is natural or unnatural. *Natural* deaths occur because of disease pathology of the internal organs or the degenerative aging process (Lynch & Koehler, 2011). In the emergency department, most deaths are sudden and unexpected. Those that are considered natural most commonly involve the cardiovascular, respiratory, and central nervous systems. Deaths that are considered *unnatural* include those from trauma, self-inflicted acts, or injuries inflicted by another. Legal authorities must be notified of all deaths related to unnatural circumstances.

Nursing Diagnosis

Clinical forensic nurse specialists in the trauma care setting analyze information gathered during assessment of the client to formulate nursing diagnoses. Common nursing diagnoses relevant to forensic clients in the emergency department include:

■ Impaired tissue integrity
■ Risk for posttrauma syndrome
■ Fear
■ Anxiety
■ Risk for self-mutilation
■ Risk for suicide
■ Risk for complicated grieving

Planning and Implementation

Preservation of Evidence

When a trauma victim is admitted to the emergency department, the most obvious priority intervention is medical stabilization. This must be balanced against the need to protect rapidly deteriorating physical evidence that can determine if a crime has occurred.

Wounds must be examined to speculate about the type of weapon used and estimate age of the wound. Clothing must be checked for blood, semen, gunshot residue, or trace materials such as hair, fibers, and other debris. Clothing that is removed from a victim should not be shaken, so that any evidence adhering to it is not lost. Each separate item of clothing should be carefully placed in a paper bag, sealed, dated, timed, and signed. Plastic bags should never be used because of the tendency for condensation to occur. Condensation promotes the growth of mold and the decay of biological tissue, which results in contamination of the evidence (Brown, 2013; Saferstein, 2011).

When the trauma is sexual assault, a SANE may be called to the emergency department. SANEs usually work on call, and because most sexual assault victims are women, female nurses are employed as SANEs. Male victims of sexual assault also most often prefer to work with a female SANE because the perpetrators are usually men and because of the subsequent mistrust of men following the attack.

Ledray (2009) suggested the following essential components of a forensic examination of the sexual assault survivor in the emergency department:

Treatment and Documentation of Injuries

Emergency department staff typically performs the initial assessments when a sexual assault victim arrives. Vital signs and treatment of serious injuries often occur before the arrival of the SANE. Unless the injuries are life threatening, the forensic examination should occur before medical treatment is administered so as not to destroy physical evidence needed to establish that a sexual crime has occurred.

The nurse may use a **colposcope** to examine for tears and abrasions inside the vaginal area. This instrument contains a magnifying lens and a light source and can be appended with a 35-mm camera.

It is often expected that a sexual assault survivor will exhibit cuts and bruises in the genital or nongenital area. Ledray (2009) reports on a number of studies indicating that without the use of colposcope or camera with lens for magnification, genital and nongenital trauma are quite similar: 1 percent have severe injuries and 10 to 30 percent have less serious injuries. However, with colposcopic examination, genital trauma has been identified in up to 87 percent of sexual assault

cases. The absence of physical trauma (either genital or nongenital) does not necessarily mean that no force was used or that consent was given. This, however, is the case often used by defense attorneys in court. Some clinicians suggest the use of a traumagram—a diagram of a nude figure on which the locations of visible injuries are made. A written description of the color, size, and location of each wound, abrasion, and laceration is then documented. With the client's permission, photographs of the wounds should be taken for accuracy.

Some states have legally mandated procedures, and some acute care settings have established protocols for gathering evidence in cases of sexual assault. In some instances, rape kits are available for collecting specimens and laboratory samples in a competent manner that is consistent with legal requirements and will not interfere with the victim's option to pursue criminal charges. In addition to the vaginal examination, oral and rectal examinations may be conducted. Fingernail scrapings and body, head, and pubic hair samples should also be collected. Client hair samples are important to differentiate from those of the assailant. All evidence that requires further processing should be sealed in paper bags to prevent the possible growth of mildew (as might occur in a plastic container), which could contaminate the evidence.

Some states may require a urine specimen to test for pregnancy or screen for drugs. It is best, if possible, to wait until the initial internal examination is complete before collecting the urine sample. Because this is not always possible, specific circumstances related to acquisition of the sample must be carefully documented.

Maintaining the Proper Chain of Custody

Stokowski (2008a) states, "*Chain of custody* is a legal process referring to the paper trail that assures the integrity and security of the evidence." Unless the proper chain of custody has been maintained, evidence cannot be used successfully in a court of law to convict an assailant. To preserve and maintain the chain of custody, each item of evidence is sealed, labeled with the client's name, a description and source of the item, the name of the person who sealed the evidence, and the date and time it was sealed. Stokowski (2008a) further states:

> Collected evidence must remain on the person of the nurse, in plain view, or in a secure location to maintain the chain of custody. Evidence should never be left unattended or handled by patients, parents, support persons, or caseworkers. Sealed and correctly labeled evidence kits or bags may be stored in a secure location until they are transferred to law enforcement officials. The best place to store evidence is in a locked drop box and locked refrigerator, located in a limited access room that requires a key entry.

Treatment and Evaluation of Sexually Transmitted Diseases

Survivors of sexual assault should be counseled regarding the possibility of having been exposed to a sexually transmitted disease (STD). Several tests and interventions are available if conducted within 72 hours of the attack. Prophylactic antibiotics may be given to prevent chlamydia, gonorrhea, trichomoniasis, and bacterial vaginosis according to guidelines from the Centers for Disease Control and Prevention (CDC, 2015a). The CDC also recommends postexposure prophylaxis using hepatitis B immunoglobulin and human papillomavirus vaccination. Information should be provided about symptoms of STDs for which there are no preventive measures. Because incubation periods vary, the importance of follow-up testing must be emphasized.

There is no proven prophylactic intervention for human HIV exposure, a serious concern for sexual assault victims. Even though the CDC (2015a) reports that the risk for acquiring HIV infection through sexual assault is low in most cases, some states mandate testing for HIV as part of the sexual assault protocol. The CDC (2015a) suggests that a risk assessment for HIV transmission be conducted by a specialist, and if the survivor chooses to go forward with antiretroviral prophylaxis, information about the medication including toxicity and lack of proven benefit should be given. Baseline complete blood count and serum chemistry analyses are performed, and the individual is reevaluated after 3 to 7 days to assess tolerance of the medication. An HIV antibody test is conducted at original assessment and repeated at 6 weeks, 3 months, and 6 months. Use of a barrier device for subsequent intercourse is recommended for the 6-month period until results are determined.

Pregnancy Risk Evaluation and Prevention

It is important that sexual assault victims receive information related to risks and interventions for prevention of conception as a result of the assault. Evaluation of pregnancy risk is based on the client's ability to relay accurate information about the occurrence of her last menses so that an estimate can be made of time of ovulation. A combined regimen of ethinyl estradiol and levonorgestrel (Ovral) has been available for a number of years. Two tablets are taken at the time of treatment and two tablets are taken 12 hours later. An antiemetic, such as trimethobenzamide (Tigan), may be given to prevent nausea and vomiting, the most common side effects of the medication. A progestin-only contraceptive (Plan B One-Step; Next Choice) has been available over the counter to individuals ages 17 and older and by prescription to those younger than age 17. In April 2013, a federal judge

ruled that the U.S. Food and Drug Administration must make these pills available over the counter for all ages. These single-medication treatments appear to be somewhat more effective than the combined-medication treatment and consequently have become the emergency contraceptive of choice. Some studies have shown the risk of pregnancy is reduced by 88 percent with the single-medication treatment and by 75 percent with the combined-medication contraceptive (Office of Population Research, 2012). The effectiveness of both methods decreases as the time between the assault and administration of the first dose increases.

Crisis Intervention and Arrangements for Follow-Up Counseling

In the hours immediately following the sexual assault, the rape victim experiences an overwhelming sense of violation and helplessness that began with the powerlessness and intimidation experienced during the rape. Burgess (2010) has identified two emotional response patterns that may occur within hours after a rape and that health-care workers may encounter in the emergency department or rape crisis center. In the expressed response pattern, the victim expresses feelings of fear, anger, and anxiety through such behaviors as crying, sobbing, smiling, restlessness, and tension. In the controlled response pattern, the feelings are masked or hidden, and a calm, composed, or subdued affect is seen. During this crisis period, helping the victim to regain a sense of control—that is, helping her to make decisions about what she wants to do—can be an effective method of enhancing recovery. Ensuring that the survivor of a sexual attack is provided with as much control as possible within safety guidelines often greatly increases her comfort level.

This is also an important time to ensure that the individual understands that she is not to blame for what has happened. She may be blaming herself and feeling guilty for certain behaviors, such as drinking or walking alone late at night, that placed her in a vulnerable position. It is important to communicate the following to the victim of sexual assault:

- You are safe here.
- I'm sorry that it happened.
- I'm glad you survived.
- It's not your fault. No one deserves to be treated this way.
- You did the best that you could.

Before she leaves the emergency department, the individual should be advised about the importance of returning for follow-up counseling. She should be given the names of individuals to call for support. Often a survivor will not follow up with aftercare because she is too ashamed or is fearful of having to relive the nightmare of the attack by sharing the information in group or individual counseling. For this reason, it may be important for the nurse to get permission from the individual to allow a counselor to call her to make a follow-up appointment.

Deaths in the Emergency Department

The emergency department becomes the scene of legal investigation when death occurs in the trauma-care setting. Evidence is preserved and the body is protected until the investigation has been completed. Lynch (2011) states:

> The medical examiner and the crime laboratory rely on the attending staff to provide an accurate and detailed description of wounds, to collect and preserve admission or postmortem blood and body fluids, and to recognize and recover trace evidence. The forensic nurse examiner on duty will be responsible for gathering essential documents, contacting appropriate authorities and agencies, ensuring notification of death, and intervening with the decedent's family. (p. 203)

Anatomical Gifts

When a sudden and unexpected death occurs in the trauma-care setting, the clinical forensic nurse may become involved in organ and/or tissue donation. Some states now require that a request for organ and/or tissue donation be made of the family when a death occurs under certain circumstances. This is a very painful period for family members, and nurses may feel it is inappropriate to present the information associated with an anatomical request. However, most nurses employed in trauma care recognize that organ and/or tissue recovery for transplantation is a requisite component of their work. Shafer (2011) states:

> The forensic nurse examiner (FNE) can serve as a bridge between families of the bereaved and the medical examiner. Time spent with grieving families, helping them to cope with the events surrounding the death of their loved one, is certainly a role in which the FNE, as a nurse, would excel. Organ and tissue donation are often the only comfort that a family gains in an otherwise tragic situation. The FNE works closely with the organ recovery coordinator by coordinating information in donation situations, and she or he works jointly with other healthcare professionals by assisting families in moving forward through their loss. (p. 596)

Evaluation

Evaluation of the clinical forensic nursing process in the trauma care setting involves ongoing measurement of the diagnostic criteria aimed at resolving real or potential problems. The following types

of questions may provide assistance in the evaluation process:

■ Have the physical and psychological needs of the survivors who present themselves to the emergency department been met?
■ Has the evidence in potential criminal investigations been handled such that it can be used in a credible manner?
■ Has the sexual assault survivor received information related to choices pertaining to STDs, pregnancy, and follow-up counseling?
■ In the instance of sudden and unexpected death in the emergency department, have the needs of the grieving family been met?
■ Has the importance of anatomical donations been communicated?

The role of the clinical forensic nurse in trauma care continues to expand. With the widespread prevalence of societal violence, clinical forensic nurses potentially may intervene in the examination of victims of all types of abuse situations. The clinical forensic nurse specialist must also strive to be proactive, beginning with educating emergency department staff in the philosophy and interventions of clinical forensic nursing practice. Within the community, proactive responsibilities may include providing information about environmental hazards and issues that may affect public health and safety. Effectiveness of these changes provides measurement for ongoing evaluation.

Application of the Nursing Process in Forensic Mental Health Nursing in Correctional Facilities

Assessment

Notwithstanding the positive intentions of deinstitutionalization, some negative consequences may have ensued. Raphael and Stoll (2013) state:

> The research findings regarding the relationship between severe mental illness and criminal activity, combined with the overrepresentation of the mentally ill behind bars, suggest that deinstitutionalization may be an important contributor to U.S. prison population growth during the last few decades of the twentieth century. The current high incidence of severe mental illness among those behind bars begs the question of whether the mentally ill have simply been transinstitutionalized from mental hospitals to prisons and jails. (pp. 189; 198)

It was believed that deinstitutionalization increased the freedom of individuals with mental illness in accordance with the principle of "least restrictive alternative." Because of inadequate community-based services, however, many of these individuals drifted into poverty

and homelessness, increasing their vulnerability to criminalization. Because the bizarre behavior of individuals with mental illness living on the street is sometimes in opposition to community standards, law enforcement officials have the authority to protect the welfare of the public and the safety of the individual by initiating emergency hospitalization. Legal criteria for commitment are so stringent in most cases, however, that arrest becomes an easier way of getting the person with mental illness off the street if a criminal statute has been violated. The fact that a majority of prisoners also have mental illness is well documented (Khazan, 2015). Some of these individuals are incarcerated as a result of the increasingly popular "guilty but mentally ill" verdict. With this verdict, the individual is deemed mentally ill yet is held criminally responsible for his or her actions. He or she is incarcerated and receives special treatment, if needed, but no different from that available for and needed by any prisoner. The implementation of mental health courts designed to mandate therapy for individuals in the community who have mental illness and criminal charges has attempted to decrease the prison population of those with mental illness, but not all states or counties have such programs, and there have been mixed results about their effectiveness (Khazan, 2015).

The U.S. Department of Justice has reported that U.S. prisons and jails held more than two million inmates in 2011 (Glaze & Parks, 2012). The Federal Bureau of Prisons (2013a) reports that 59 percent of those incarcerated are white (including Hispanic), 37 percent are African American, 2 percent are Native American, and the remainder are of another or more than one race. Men accounted for 93 percent of the total. Khazan (2015) reports that 55 percent of all male inmates and 73 percent of female inmates have mental illness; the majority have depression (21%) or bipolar disorder (12%).

Care of the mentally ill offender population is a highly specialized area of nursing practice. The rationale of imprisonment for criminal behavior has been identified as:

■ Retribution to society
■ Deterrence of future crimes
■ Rehabilitation and repentance
■ Protection of society

If an institution bases its orientation on retribution and deterrence of criminal activity, the prison will reflect a punishment-oriented atmosphere. If rehabilitation and repentance are accepted as a basis for change, mental health programs that encourage reflection and insight may be a part of the correctional setting. Because at times these basic objectives

may seem incompatible with each other, nurses who work in correctional facilities may struggle with a cognitive dissonance founded in their basic nursing value system.

Assessing Mental Health Needs of the Incarcerated

Is the provision of mental health care within the custodial environment possible? Or are clinical care concerns incompatible with security issues? What special knowledge and skills must a psychiatric nurse possess to be successful in caring for the mentally ill offender?

Psychiatric diagnoses commonly identified in incarcerated individuals include schizophrenia, bipolar disorder, major depression, substance use disorders, and personality disorders; many clients have dual diagnoses. Common psychiatric behaviors include hallucinations, suspiciousness, thought disorders, anger and/or agitation, and impulsivity. Denial of problems is a common behavior among this population. Use of substances and nonadherence to medication regimen are common obstacles to rehabilitation. Substance abuse has been shown to have a strong correlation with recidivism among the prison population. Many individuals report that they were under the influence of substances at the time of their criminal actions. Detoxification frequently occurs in jails and prisons, and some deaths have occurred from the withdrawal syndrome because of inadequate treatment during this process.

Although many people use the terms *prison* and *jail* interchangeably, there is a fundamental difference between the two. Local jails are usually administered by city or county officials and house defendants awaiting a trial, sentencing, or transfer to a prison. They commonly confine defendants convicted of misdemeanors and for periods of less than a year. In contrast, prisons, which are run by state or federal administrations, are correctional facilities that house individuals convicted of major crimes or felonies and who are serving sentences that are usually in excess of a year. A large portion of offenders who are mentally ill, particularly the acutely psychotic, never reach the prison system. Frequent arrests for minor offenses may lead to numerous jail incarcerations, a sense of loss of control, and a continual state of crisis.

The U.S Bureau of Justice (2015) reports that in both local jails and prisons, death of inmates has been on the rise since 2000. Suicide has consistently been the leading cause of death and in 2013 reached 34 percent (46/100,000) of all inmate deaths. Drug- and alcohol-related deaths among inmates is also on the rise, increasing 23 percent from 2012 to 2013. Clearly, the mental health needs of jail and prison inmates are an important concern for forensic nurses in these settings.

Special Concerns
Overcrowding and Violence

Numerous studies have shown that crowding affects the level of violence in prisons. The prison system is not capable of handling the burden of large numbers of prisoners for which it has become responsible, and many of the infractions by prisoners are violent in nature. The growing number of prisoners is thought to be related to the increasing war on drugs, longer mandatory sentencing, and "three strikes and you're out" laws. As this population continues to grow, larger and larger complexes are constructed to house the growing numbers of inmates. The unfortunate truth lies in the fact that violent behavior often proves to be resourceful for the individuals who use it in prison.

Inmate violence directed toward prison staff is also a common occurrence. Light (1991) reported the most frequently cited motives as inmate resistance to officer's commands, protest of unjust treatment, resistance to searches and attempts to remove contraband, and staff intervention in fights between inmates. Actual or implied verbal threats and swearing are the common everyday language of most offender clients. Nurses who work in correctional facilities must be skilled in responding to the commonality of physical and verbal aggression if they are to prevail in this chosen area of specialization.

Sexual Assault

On September 4, 2003, President George W. Bush signed into law the Prison Rape Elimination Act of 2003. This legislation required the Bureau of Justice Statistics (BJS) to develop a national data collection system to determine the incidence and prevalence of sexual violence within correctional facilities. Currently, it is estimated that at least 13 percent of inmates in the United States have been sexually assaulted in prison, with many suffering repeated assaults (Cornell University Law School, 2012). The majority of these assaults go unreported because the consequences of "ratting" on fellow prisoners are often far more serious than the rape itself.

Rape in prison is viewed as an act of dominance and power rather than one that is sexually motivated, and the majority of both victims and victimizers are heterosexuals. The typical victim is a young person convicted of a nonviolent crime. They are most likely to be first-time offenders who are small, weak, shy, and inexperienced with prison life. In some instances, sexual assault is used as a means of punishment and social control when the victim is believed to have violated certain unwritten prison codes. Gang rape is not uncommon, and severe physical injury is often the result if the victim attempts to defend himself.

HIV Infection in the Prison Population

According to the CDC (2015b), over 20,000 inmates in state and federal prisons had a diagnosis of HIV/AIDS in 2010, 91 percent of whom were men. Although AIDS-related deaths among inmates declined 16 percent over the period of study (from 2000 to 2010), it continues to be a significant health concern for this population. In addition to sexual conduct, HIV may be transmitted among inmates through fights that result in lacerations, bites, or bleeding. Body piercing and tattooing are popular in prison, and clean instruments for these activities are not available. Intravenous drug use results in sharing of unsterilized injection equipment.

HIV has placed an enormous financial burden on a prison system that was already financially distressed. Some terminally ill prisoners with advanced HIV disease are being granted early compassionate release to family or hospice care and with access to community health services.

The CDC (2015a) has taken an active role in funding selected health departments to provide education, voluntary testing programs, and promote condom use. They continue to explore research evidence to identify which programs are most effective. In one initiative (CDC, 2015b), designed to provide rapid voluntary HIV testing in a local jail, jail nurses administered over 12,000 tests and identified 52 new cases of HIV. The CDC has since identified guidelines for HIV testing in correctional facilities, including the recommendation that inmates be tested on entry, during incarceration, and immediately upon release. They further recommend that inmates be educated on high-risk practices that may increase vulnerability to HIV/AIDS. Forensic nurses play an active role in providing these education and primary prevention interventions.

Female Offenders

Women comprise approximately 7 percent of the total population in prisons and jails (Federal Bureau of Prisons, 2013a). As a minority group, they appear to be discriminated against within the prison system. Their facilities are usually more isolated, making it more difficult for family visits. In some instances, separate institutions do not exist, making it necessary to house male and female offenders in the same facilities. Men are given a greater number of opportunities regarding education and vocational training services. Allen (2015) reports that characteristics of women in prisons more often reflect poverty, marginalization, discrimination in education, and a history of victimization through violence and sexual abuse; the vast majority are imprisoned for drug-related offenses,

Many women are single mothers who are unable to make adequate provision for their children while they serve their time in prison and often lose custody of them to the state. Prison health care is mostly inadequate, and the unique health needs of women often go unmet. Many of these women had very little before they were incarcerated and have come to expect that little is what they deserve. Many report long histories of sexual and emotional abuse throughout their lives. Depression and acting-out behaviors are common in women's prisons.

Nursing Diagnosis

Forensic mental health nurse specialists in correctional facilities analyze the information gathered during assessment of the client to formulate nursing diagnoses. Common nursing diagnoses relevant to forensic clients in correctional facilities include:

- Defensive coping
- Complicated grieving
- Anxiety/fear
- Ineffective denial
- Powerlessness
- Low self-esteem
- Risk for self-mutilation
- Risk for suicide
- Risk for other-directed violence
- Ineffective coping
- Risk for infection
- Rape-trauma syndrome

Planning and Implementation

Psychiatric-mental health nurses who work in correctional facilities must be armed with extraordinary psychosocial skills and the knowledge to apply them in the most appropriate manner.

Development of a Therapeutic Relationship

Incarcerated individuals have difficulty trusting anyone associated with authority, including nurses. For most, this likely relates to a lack of nurturing, particularly during the very early stages of development.

Aside from the added difficulty of dealing with this special population, development of a therapeutic relationship in the correctional facility encompasses the same phases of interaction as it does with other clients. Chapter 7, Relationship Development, discusses the dynamics of this process at length.

Preinteraction Phase

During this phase, the nurse must examine his or her feelings, fears, and anxieties about working with prisoners, and in particular violent offenders—perhaps murderers, rapists, or pedophiles. This is the phase in which the nurse must determine whether he or she is able to separate the *person* from the *behavior* and provide the unconditional positive regard that Rogers

(1951) believed identifies each individual as a worthwhile and unique human being. At the same time, recognizing that individuals with antisocial personality disorder traits are common in correctional facilities, the forensic nurse must have a strong sense of awareness about establishing clear boundaries, setting limits, and identifying interventions to avoid being manipulated.

Orientation (Introductory) Phase

This is the phase in which the nurse works to establish trust with the client. This is a lengthy and intense process with the prisoner population. The characteristics identified as significant to the development of a therapeutic nurse-client relationship—rapport, trust, and genuineness—are commonly met with suspicion on the part of the offender. Empathy may be used as a tool for manipulating the nurse. It is therefore imperative that limits be established and enforced by all of the nursing staff. Testing of limits is commonplace, so consequences for violation must be consistently administered. Pitting treatment team members against each other is a common ploy among inmates. Open communication with team members and clearly communicated boundaries with an inmate that there will be no secrets kept from other team members establishes clear expectations for the one-to-one relationship.

Touch and self-disclosure, two elements used in the establishment of trust with clients, are most commonly unacceptable with the prisoner population. A handshake may be appropriate, but any other form of touch between nurse and inmate of the opposite gender is restricted in most settings. Self-disclosure is commonly used to convey empathy and to promote trust by helping the client view the nurse as an ordinary human being. With the prisoner population, however, the client may seek personal information about the nurse to maintain control of the relationship. Nurses must stay aware in the relationship and ensure that personal boundaries are not being violated.

Communication within the correctional facility may prove to be a challenge for the nurse. Slang terminology is commonplace and changes rapidly. Some of these terms are presented in Box 42–2.

BOX 42–2 Glossary of Prison Slang

ad-seg. Administrative segregation. A prisoner placed on ad-seg is being investigated and will go into isolation (the "hole") until the investigation is complete.

beef. Criminal charges, as in "I caught a burglary beef this time around." Also used to mean a problem: "I have a beef with that guy."

big yard. The main recreation yard.

bit. A prison sentence, usually relatively short: "I got a three-year bit" (opposite of *jolt*).

bitch, bitched (v). To be sentenced as a "habitual offender."

blocks. Cell houses.

books. An administratively controlled account ledger that lists each prisoner's account balance.

bone yard. The visiting trailers used for overnight visits of wives and/or families.

bum beef. A false accusation; also, a wrongful conviction.

catch a ride. To ask a friend with drugs to get you high: "Hey man, can I catch a ride?"

the chain. The bus that transports the offenders to prison; the prisoner is shackled and chained when transported, as in "I've been riding the chain," or "I just got in on the chain," or "Is there anyone we know on the chain?"

check-in. Someone who has submitted to pressure, intimidation, debts, and so on, and no longer feels secure in population and "checks in" to a protective custody (PC) unit.

chi-mo. A child molester, "chester," "baby-raper," "short-eyes" (as in "He has short-eyes," meaning he goes after young kids); the worst of the *rapo* class in the eyes of *convicts*.

convict. Guys who count in prison, are loyal to the code, are not stool pigeons, and whose word is good (opposite of *inmate*).

CUS. A custody unit supervisor/cell house supervisor.

de-seg. Disciplinary segregation. When a person is on de-seg, he is in isolation (the "hole") for an infraction.

ding. A disrespectful term for a prisoner with mental illness.

dry snitching. To inform on someone indirectly by talking loudly or performing suspicious actions when officers are in the area.

dummy up, get on the dummy. To shut up, to pipe down, to be quiet, especially about one's knowledge of a crime.

EPRD. The earliest possible release date.

fish. A new arrival, a first-timer, a bumpkin, not wise to prison life.

gate money. Money the state gives a prisoner upon his release.

gate time. At most prisons, they yell "gate time," meaning prisoners can get in or out of their cells. See *lockup.*

hacks, hogs, pigs, snouts, screws, cops, bulls. The guards; more formally known as correctional officers. They and the inmates call them "corrections officers."

heat wave. Being under constant suspicion, thereby bringing attention to those around you.

hit it. Go away, leave, get lost.

BOX 42-2 Glossary of Prison Slang–cont'd

hold your mud. Do not tell, even under pressure of punishment.

the hole. An isolation ("segregation") cell used as punishment for offenses.

house. A cell.

hustle. A professional criminal's avocation; also refers to any scheme to obtain money or drugs while in prison.

IK. Inmate kitchen.

IMU. Intensive management unit. This is the administration's name for "segregation" or "the hole."

inmate. A derogatory term for prisoners; used by guards, administrators, other inmates, or by new arrivals who do not yet know the language (opposite of *convict*).

jacket. A prison file containing all the information on a prisoner: "He's a child molester; it's in his jacket." Also, reputation. Prisoners can put false jackets on other prisoners to discredit them.

jolt. A long sentence: "I got a life jolt"; (opposite of *bit*).

jumping out. Turning to crime: "I've been jumping out since I was a kid."

keister. To hide something in the anal cavity.

lag. A convict, as in "He's an old lag, been at it all his life."

lifer or all day. Anyone doing a life sentence; a life *jolt.*

lockdown. When prisoners are confined to their cells.

lockup. A free movement period for prisoners; see also *gate time.*

lop. Same as *inmate.*

mule. A person who smuggles drugs into the institution.

on the leg. A prisoner who is always chatting with and befriending guards.

paper. A small quantity of drugs packaged for selling.

PC. Protective custody. Also, weak or untrustworthy, as in "He's a PC case."

point, outfit. A syringe.

pruno. Homemade wine.

punk. A derogatory term meaning homosexual or weak individual.

rapo. Anyone with a sex crime—generally looked down upon by convicts.

rat, snitch, stool pigeon. Informant (noun); to inform (verb).

stand point. Watch for "the man" (guard).

tag, write-up. An infraction of institution rules.

the bag/sack. Dope.

Tom or George. Means "no good" (Tom) or "okay" (George). Used in conversation to indicate whether or not someone or something is okay.

turned out. To be forced into homosexual acts or to turn someone out to do things for you; to use someone for your own needs.

white money. Currency within the institution.

yard-in, yard-out. Closing of the recreation yard (yard-in); recreation yard opens (yard-out).

Working Phase

Nursing skills are implemented during the working phase of the relationship, and promoting behavioral change is the primary goal. This is extremely difficult with offenders who commonly deny problems and resist change. Transference and countertransference issues (see Chapter 7) are more common in working with this population than with other psychiatric clients. Issues are discussed in the treatment team meetings, and ongoing modifications are made as required. Following are some of the interventions associated with forensic mental health nursing in correctional institutions.

Counseling and Supportive Psychotherapy Nurses may work with inmates who are experiencing feelings of powerlessness and grief. Women who have left children behind may fear the permanent loss of custody or of never seeing them again. Helping these individuals work through a period of mourning is an important nursing intervention.

Nurses may also counsel victims of sexual assault. Victims of sexual assault in prison often experience the symptoms associated with rape-trauma syndrome. Feelings of helplessness and vulnerability coupled with shame, humiliation, and embarrassment are characteristic. Internalized rage can become paralytic. Perception of gender identity may even be compromised.

These individuals often become withdrawn and isolated and are at high risk for suicide. The nurse can recognize these symptoms and intervene as required. All unusual behavior should be shared with the treatment team. Interventions for treating specific behaviors (such as depression and suicide, psychotic behaviors, and antisocial behaviors) are provided in Unit 3, Therapeutic Approaches in Psychiatric Nursing Care, and Unit 4, Nursing Care of Clients With Alterations in Psychosocial Adaptation.

Crisis Intervention Behaviors such as aggression, self-mutilation, suicide attempts, acute psychotic episodes, and posttrauma responses require that the nurse be proficient in crisis intervention. Feelings of helplessness and loss of control are pervasive in the prison population. The chaotic, overburdened prison system lacks the resources to provide the kind of services

needed to prevent the continual state of crisis these conditions engender. Suicide risk is higher in jails and prisons than in the community. Noncompliance with prison rules, feelings of hopelessness, psychopathology, substance abuse, and overcrowded conditions all contribute to the potential for violence. Threatening behaviors must be reported immediately to all members of the treatment team. A strong foundation in crisis intervention theory and techniques is mandatory for nurses who work in correctional institutions.

Education Opportunities for teaching abound in the correctional facility. However, because of the level of education of many incarcerated individuals and because there may be language barriers, the teaching plan must be highly individualized. Many have no desire or motivation to learn and resist cooperating with these efforts. Important educational endeavors with these clients include:

- **Health teaching:** Most criminals are not in good physical condition when they reach prison. They have lived rough lives of smoking, poor diets, substance abuse, and minimal health care. This is an opportunity for nurses to provide information about ways to achieve optimum wellness.
- **HIV/AIDS education:** Education includes the importance of voluntary testing, factors that increase risk for infection such as tattooing or any other potential exchange of body fluids, and the importance of condom use. Some correctional institutions now provide condoms to inmates, but this remains a point of controversy between legal and public health officials.
- **Stress management:** Nurses can present information about and demonstration of stress management techniques. They can help individuals practice reduction of anxiety without resorting to medications or substances.
- **Substance abuse:** The Federal Bureau of Prisons (2013b) has established a comprehensive substance abuse treatment strategy in an effort to change inmates' criminal and drug-use behaviors. This strategy begins with drug abuse education and ends with a strong community transition component. The individuals receive information about alcohol and drugs and the physical, social, and psychological impacts of abusing these substances. Since its inception, this program has proved highly successful in decreasing recidivism and relapse rates among its participants.

Nurses can participate in substance abuse treatment programs by providing client education (e.g., the effects of substances on the body and the consequences of sharing needles). They can also form support groups for individuals who abuse substances if one does not exist in the institution. A large percentage of the prison population has a history of substance abuse, and many correlate the commission of their crimes with substance use. This is an important area of need for nursing intervention in the correctional system.

Termination Phase

Ideally, the termination phase of the nurse-client relationship ensures therapeutic closure. This is not always possible in the correctional environment. Prisoners are transferred from one institution to another and from one part of an institution to another for a variety of reasons, not the least of which are safety and security of self or others. When possible, it is important for nurses to initiate termination with clients so that at least some semblance of closure can be achieved and a review of goal attainment can be accomplished. Community facilities for ex-offenders with mental illness are few, and recidivism is rampant. Johnson (2013) states:

> Psychiatric nurses and social workers in correctional settings often act as case managers, beginning prerelease planning upon the initial contact with inmates. Continuation of any treatment and medication from jail and transition to the community-based treatment in a swift manner is critical to success. Unfortunately, resources in this area are often lacking. Many inmates may not have predetermined release dates, thereby leading to releases at all hours of the day and night. Prerelease planning and coordination with community-based programs are necessary to promote continuity of care and prevent recidivism. Nurses and social workers are vital members of the interdisciplinary team and play significant roles in the assessment, planning, implementation, and evaluation of the case management plan to best meet the needs of patients.

Evaluation

Evaluation of the forensic mental health nursing process in the correctional environment involves ongoing measurement of the diagnostic criteria aimed at resolution of identified real or potential problems. The following questions may provide assistance in the evaluation process:

- Has a degree of trust been established in the nurse-client relationship?
- Has violence by the offender to self or others been prevented?
- If victimization has occurred, has appropriate care and support been provided to the survivor?
- Have limits been set on inappropriate behaviors, and has consistency of consequences for violation of the limits been administered by all staff?
- Have educational programs been established to provide information about health and wellness, HIV/AIDS, stress management, and substance abuse?

Evaluation is an ongoing process and must be assumed by the entire treatment team. Modification of the treatment plan as required is part of the ongoing evaluation process, and positive change within the system is the ultimate outcome. Nurses who work in correctional facilities are pioneers within the nursing profession. To share the knowledge gleaned from this specialty area is an important part of the nursing process.

Summary and Key Points

■ Forensic nursing, a growing area within the profession, is composed of a variety of areas of expertise.
■ Forensic nurses take care of both victims and perpetrators of crime in a variety of settings, including primary care facilities, hospitals, and correctional institutions.
■ The International Association of Forensic Nurses, founded in 1992, now has more than 3,700 members.
■ Forensic nursing specialties include clinical forensic nursing, the sexual assault nurse examiner (SANE), forensic mental health nursing, forensic correctional nursing, legal nurse consultant, and forensic nurse death investigator.
■ Nurses in general practice also find forensic nursing knowledge of importance in their practices, particularly in emergency departments and intensive care units.

■ Forensic nurses in trauma care are involved with preservation of evidence, investigation of wound characteristics, and management responsibilities associated with deaths that occur in the emergency department, including assisting with requests for anatomical gifts.
■ Forensic mental health nursing in correctional facilities involves care of the offender with mental illness and the emotional needs of all incarcerated individuals.
■ Interventions for the forensic mental health nurse include establishment of a therapeutic relationship; providing counseling and supportive psychotherapy; intervening in crises; and providing education concerning health and wellness issues, HIV/AIDS, stress management, and substance abuse.
■ The number of educational offerings pertaining to forensic nursing is growing. Some content is taught in traditional nursing courses whereas some colleges and universities are establishing forensic nursing courses as electives.
■ Forensic nursing is fertile ground for nursing research, and the complex nature of the specialty lends itself well to those nurses who seek a challenge within the profession.

TEST YOUR CRITICAL THINKING SKILLS

Kim is a 27-year-old woman who recently moved from a small town in Texas to work in the city of Dallas as a reporter for one of the major newspapers. She is 5 feet 6 inches tall and weighs 115 pounds. To keep in shape, she likes to jog, which she did regularly in her hometown. She does not know anyone in Dallas and has been lonely for her family since arriving. But she has moved into a small apartment in a quiet neighborhood and hopes to meet young people soon through her work and church.

On the first Saturday morning after she moved into her new apartment, Kim decided to get up early and go jogging. It was still dark out, but Kim was not afraid. She had been jogging alone in the dark many times in her hometown. She donned her jogging clothes and headed down the quiet street toward a nearby park. As she entered the park, an individual came out from behind a dense clump of bushes, put a knife to her throat, and ordered her to the ground. She was raped and beaten into unconsciousness. She remained in that condition until sunrise when she was found by another jogger who called emergency services, and Kim was taken to the nearest emergency department. Upon regaining consciousness, Kim was hysterical, but a sexual assault nurse examiner (SANE) was called to the scene, and Kim was assigned to a quiet area of the hospital where the postrape examination was initiated.

Answer the following questions related to Kim:

1. What are the initial nursing interventions for Kim?
2. What treatments must the nurse ensure that Kim is aware are available for her?
3. What nursing diagnosis would the nurse expect to focus on with Kim in follow-up care?

Review Questions
Self-Examination/Learning Exercise

Select the answer that is most appropriate for each of the following questions.

1. Deaths that occur in the emergency department are identified as *natural* or *unnatural*. Which of the following would be considered a natural death?
   a. A young man who died in a motorcycle accident
   b. A young woman who was a victim of domestic violence
   c. A middle-aged man who died of myocardial infarction
   d. An elderly female victim who fell down a flight of stairs

2. A young woman has been transported to the emergency department by emergency services. She has been physically beaten and sexually assaulted. Which of the following is the priority nursing intervention for this client?
   a. Take photographs of the injuries.
   b. Ensure stability of her physical injuries.
   c. Check her clothing for evidence of blood or semen.
   d. Notify her nearest relative.

3. Psychiatric behaviors observed to be common among offenders with mental illness include which of the following? (Select all that apply.)
   a. Denial of problems
   b. Thought disorders
   c. Self-mutilative behaviors
   d. Dissociative behaviors
   e. Anger and impulsivity

4. When a victim of physical and sexual assault is admitted to the emergency department, his or her clothing is an important aspect of potential criminal evidence. Which of the following are correct procedures in the preservation of clothing as evidence? (Select all that apply.)
   a. Remove the clothing from the victim.
   b. Shake the clothing to remove anything that is adhering to it.
   c. Separately place each piece of clothing into a plastic bag.
   d. Seal each bag.
   e. Date, time, and sign each bag.

5. Which of the following is a true statement about the populations in U.S. prisons and jails?
   a. Females constitute about half of the total inmate population.
   b. HIV disease is prevalent in the inmate population.
   c. There is a disparity in U.S. prisons in the treatment of male and female prisoners.
   d. About a third of the U.S. prison and jail population has some form of mental health problem.

6. The forensic mental health nurse is working with a client who fatally injured a person while driving in an intoxicated condition. He says to the nurse, "It had nothing to do with my drinking. I've been drinking since I was 12 years old! I can handle my liquor just fine!" In preparing a care plan for this client, the nurse selects which of the following nursing diagnoses to address this problem?
   a. Defensive coping
   b. Ineffective coping
   c. Disturbed thought processes
   d. Denial

Review Questions—cont'd
Self-Examination/Learning Exercise

7. In attempting to establish a trusting relationship with an individual incarcerated in a correctional facility, the nurse must recognize which of the following to be a true statement?
   a. The offender population responds readily to genuineness on the part of the nurse.
   b. Touch is an important element of the nurse-client relationship with individuals in a correctional facility.
   c. In establishing a therapeutic relationship with an offender-client, the nurse may use self-disclosure to promote trust and convey empathy to the client.
   d. Empathy is essential to development of a trusting relationship but may be used as manipulation by the prisoner population.

8. A woman is admitted to the emergency department with multiple physical injuries and reports that she was mugged on the street by two men who beat her up and stole her purse. She has multiple bruises and abrasions on her arms and notable cuts on the palms of her hands. The nurse recognizes the wounds on the woman's hands as most probably which of the following types?
   a. Blunt force injuries from impact of a blunt object
   b. Defense wounds from her attempts to defend herself
   c. Dicing injuries caused by contact with shattered glass
   d. Fast-force injuries, probably caused by gunshot wounds

9. Which of the following types of care may be given to a female sexual assault victim in the emergency department? (Select all that apply.)
   a. Prophylactic treatment for gonorrhea
   b. Prophylactic treatment for hepatitis C
   c. Emergency prevention for conception as a result of the assault
   d. Crisis intervention in the hours immediately following the assault
   e. Arrangements for follow-up counseling

10. Because follow-up counseling is crucial to the healing process for a sexual assault victim, and because these individuals often fail to follow up after they leave the emergency department, which of the following is the most effective way to ensure that the client receives the appropriate aftercare?
   a. Tell her that she needs to call the counselor's office and make an appointment as soon as possible.
   b. Make an appointment for her and give her the date and time written on an appointment card.
   c. Obtain permission from the client to have a follow-up counselor call her.
   d. Contact significant others to tell them that they need to ensure that the client sees a follow-up counselor.

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE

Lombardi, M., Canter, J. Patrick, P.A., & Altman, R. (2015). Is fluorescence under an alternate light source sufficient to accurately diagnose subclinical bruising? *Journal of Forensic Science, 60*(2). doi:10.1111/1556-4029.12698

DESCRIPTION OF THE STUDY: This single-blinded, randomized validation study was conducted to evaluate whether fluorescence under alternate light sources (ALS) is sufficient to diagnose subclinical bruising (bruising not visible under white light). Standardized trauma was induced on randomly selected ventral forearms. On days 1, 7, and 14, investigators

independently examined case forearms under white light for perceived bruising and under ALS for fluorescence and compared body maps. Fifty-six case and 62 control forearms ($N = 118$) were examined.

RESULTS OF THE STUDY: Fluorescence under an ALS increased sensitivity for detecting subclinical bruises but was found to be insufficient as an accurate and reliable tool. The investigators conclude that since a variety of substances, such as skin infections, lint, body lotions, deodorants, and body fluids, may fluoresce under ALS, there is the potential

Continued

IMPLICATIONS OF RESEARCH FOR EVIDENCE-BASED PRACTICE–cont'd

for false positives. Nonetheless, this intervention may have potential as a screening tool to identify individuals needing further evaluation and to confirm a pattern of bruising that has been reported by a patient that was not visible under white light alone.

IMPLICATIONS FOR NURSING PRACTICE: This study highlights one of the many special considerations when conducting a forensic examination. Previously, ALSs have been advanced as a tool for use in forensic evaluation, but these authors point out that medical and legal professionals

(including forensic nurses) must be aware that since a high number of false positives occur, " there is no evidence base to support using alternate light source as an independent tool to definitively interpret fluorescence as subclinical bruising." The knowledge base required for forensic nursing practice is both specialized and rapidly expanding. Nurses practicing in any setting where victims of violence are being assessed can be an advocate for patients by recognizing the multifaceted special considerations of forensic examination and promoting the need for specially trained practitioners.

Glossary

A

abandonment. A unilateral severance of the professional relationship between a health-care provider and a client without reasonable notice at a time when there is still a need for continuing health care.

abreaction. "Remembering with feeling"; bringing into conscious awareness painful events that have been repressed, and reexperiencing the emotions that were associated with the events.

abuse. To use wrongfully or in a harmful way. Improper treatment or conduct that may result in injury.

acculturation. The cultural modification of a group or individual through borrowing traits of another culture, often through prolonged contact.

acupoints. In Chinese medicine, acupoints represent areas along the body that link pathways of healing energy.

acupressure. A technique in which the fingers, thumbs, palms, or elbows are used to apply pressure to certain points along the body. This pressure is thought to dissolve any obstructions in the flow of healing energy and to restore the body to a healthier functioning.

acupuncture. A technique in which hair-thin, sterile, disposable, stainless-steel needles are inserted into points along the body to dissolve obstructions in the flow of healing energy and restore the body to a healthier functioning.

adaptation. Restoration of the body to homeostasis following a physiological and/or psychological response to stress.

adaptive responses. Behaviors that contribute to maintaining an individual's health and integrity.

addiction. A compulsive or chronic requirement. The need is so strong as to generate distress (either physical or psychological) if left unfulfilled.

adjustment. The process of modifying one's behavior in changed circumstances or an altered environment in order to fulfill psychological, physiological, and social needs.

adjustment disorder. A maladaptive reaction to an identifiable psychosocial stressor that occurs within 3 months after onset of the stressor. The individual shows impairment in social and occupational functioning or exhibits symptoms that are in excess of a normal and expectable reaction to the stressor.

advance directive. A legal document that a competent individual may sign to convey wishes regarding future health-care decisions intended for a time when the individual is no longer capable of informed consent. It may include one or both of the following: (1) a living will, in which the individual identifies the type of care that he or she does or does not wish to have performed, and (2) a durable power of attorney for health care, in which the individual names another person who is given the right to make health-care decisions for the individual who is incapable of doing so.

advocacy. The act of pleading for, supporting, or representing a cause or individual. Advocacy in nursing applies to any act in which the nurse is serving in the best interests of the patient, from simple procedures such as hand washing to protect the patient from infection to complex ethically and morally charged issues in which certain clients are unable to advocate for themselves. Nurses also advocate for their patients indirectly by serving in organizations that support and serve to improve health care for all individuals, and by participating in policy-making legislation that affects health care of the public.

affect. The behavioral expression of emotion; may be appropriate (congruent with the situation); inappropriate (incongruent with the situation); constricted or blunted (diminished range and intensity); or flat (absence of emotional expression).

affective domain. A category of learning that includes attitudes, feelings, and values.

aggression. Harsh physical or verbal actions intended (either consciously or unconsciously) to harm or injure another.

aggressiveness. Behavior that defends an individual's own basic rights by violating the basic rights of others (as contrasted with **assertiveness**).

agoraphobia. The fear of being in places or situations from which escape might be difficult (or embarrassing) or in which help might not be available in the event of a panic attack.

agranulocytosis. Extremely low levels of white blood cells. Symptoms include sore throat, fever, and malaise. This may be a side effect of long-term therapy with some antipsychotic medications.

akathisia. Restlessness; an urgent need for movement. A type of extrapyramidal side effect associated with some antipsychotic medications.

akinesia. Muscular weakness; or a loss or partial loss of muscle movement; a type of extrapyramidal side effect associated with some antipsychotic medications.

Alcoholics Anonymous (AA). A major self-help organization for the treatment of alcoholism. It is based on a 12-step program to help members attain and maintain sobriety. Once individuals have achieved sobriety, they in turn are expected to help other alcoholic persons.

allopathic medicine. Traditional medicine. The type traditionally, and currently, practiced in the United States and taught in U.S. medical schools.

alternative medicine. Practices that differ from usual traditional (allopathic) medicine.

altruism. One therapeutic factor of group therapy (identified by Yalom) in which individuals gain self-esteem through mutual sharing and concern. Providing assistance and support to others creates a positive self-image and promotes self-growth.

altruistic suicide. Suicide that occurs in response to the expectations of a group to which an individual is excessively integrated.

amenorrhea. Cessation of the menses; may be a side effect of some antipsychotic medications.

amnesia. An inability to recall important personal information that is too extensive to be explained by ordinary forgetfulness.

amnesia, generalized. The inability to recall anything that has happened during the individual's entire lifetime.

amnesia, localized. The inability to recall all incidents associated with a traumatic event for a specific time period following the event.

amnesia, selective. The inability to recall only certain incidents associated with a traumatic event for a specific time period following the event.

amphetamine. A racemic sympathomimetic amine that acts as a central nervous system stimulant. It (and its derivatives, such as methamphetamine and dextroamphetamine) is a commonly abused substance, but has therapeutic use in the treatment of narcolepsy and attention-deficit/hyperactivity disorder.

andropause. A term used to identify the male climacteric. Also called *male menopause.* A syndrome of symptoms related to the decline of testosterone levels in men. Some symptoms include depression, weight gain, insomnia, hot flashes, decreased libido, mood swings, decreased strength, and erectile dysfunction.

anger. An emotional response to one's perception of a situation. Anger has both positive and negative functions.

anger management. The use of various techniques and strategies to control responses to anger-provoking situations. The goal of anger management is to reduce both the emotional feelings and the physiological arousal that anger engenders.

anhedonia. The inability to experience or even imagine any pleasant emotion.

anomic suicide. Suicide that occurs in response to changes that occur in an individual's life that disrupt cohesiveness from a group and cause that person to feel without support from the formerly cohesive group.

anorexia. Loss of appetite.

anorexiants. Drugs that suppress appetite.

anorgasmia. Inability to achieve orgasm.

anosmia. Inability to smell.

anosognosia. An individual's lack of awareness of having any illness or disorder even when symptoms appear obvious to others.

anticipatory grief. A subjective state of emotional, physical, and social responses to an anticipated loss of a valued entity. The grief response is repeated once the loss actually occurs, but it may not be as intense as it might have been if anticipatory grieving has not occurred.

antisocial personality disorder. A pattern of socially irresponsible, exploitative, and guiltless behavior, evident in the tendency to fail to conform to the law, develop stable relationships, or sustain consistent employment; exploitation and manipulation of others for personal gain is common.

anxiety. Vague diffuse apprehension that is associated with feelings of uncertainty and helplessness.

aphasia. Inability to communicate through speech, writing, or signs, caused by dysfunction of brain centers.

aphonia. Inability to speak.

apraxia. Inability to carry out motor activities despite intact motor function.

arbitrary inference. A type of thinking error in which the individual automatically comes to a conclusion about an incident without the facts to support it, or even sometimes despite contradictory evidence to support it.

ascites. Excessive accumulation of serous fluid in the abdominal cavity, occurring in response to portal hypertension caused by cirrhosis of the liver.

assault. An act that results in a person's genuine fear and apprehension that he or she will be touched without consent. Nurses may be guilty of assault for threatening to place an individual in restraints against his or her will.

assertive behavior. Behavior that enables individuals to act in their own best interests, to stand up for themselves without undue anxiety, to express their honest feelings comfortably, or to exercise their own rights without denying those of others.

assessment. A systematic process of collecting and analyzing data relevant to planning, providing, and evaluating patient care. Assessment may include several dimensions of the client's history and present functioning including physical, emotional, cognitive, social, sexual, cultural, environmental, occupational, and spiritual.

assimilation. The process by which a minority individual or group adapts to the cultural norms of the majority culture.

ataxia. Muscular incoordination.

attachment theory. The hypothesis that individuals who maintain close relationships with others into old age are more likely to remain independent and less likely to be institutionalized than those who do not.

attention-deficit/hyperactivity disorder. A disorder that is characterized by a persistent pattern of inattention and/or hyperactivity and impulsivity, or both. Motor activity is excessive, and the ability to concentrate is impaired.

attitude. A frame of reference around which an individual organizes knowledge about his or her world. It includes an emotional element and can have a positive or negative connotation.

autism. A focus inward on a fantasy world, while distorting or excluding the external environment; common in schizophrenia.

autism spectrum disorder. A disorder that is characterized by impairment in social interaction skills and interpersonal communication, and a restricted repertoire of activities and interests.

autocratic. A leadership style in which the leader makes all decisions for the group. Productivity is very high with this type of leadership, but morale is often low because of the lack of member input and creativity.

autoimmunity. A condition in which the body produces a disordered immunological response against itself. In this situation, the body fails to differentiate between what is normal and what is a foreign substance. When this occurs, the body produces antibodies against normal parts of the body to such an extent as to cause tissue injury.

automatic thoughts. Thoughts that occur rapidly in response to a situation, and without rational analysis. They are often negative and based on erroneous logic.

autonomy. Independence; self-governance. An ethical principle that emphasizes the status of persons as autonomous moral agents whose right to determine their destinies should always be respected.

aversive stimulus. A stimulus that follows a behavioral response and decreases the probability that the behavior will recur; also called punishment.

axon. The cellular process of a neuron that carries impulses away from the cell body.

B

battering. A pattern of repeated physical assault, usually of a woman by her spouse or intimate partner. Men are also battered, although this occurs much less frequently.

battery. The unconsented touching of another person. Nurses may be charged with battery should they participate in the treatment of a client without his or her consent and outside of an emergency situation.

behavior modification. A treatment modality aimed at changing undesirable behaviors, using a system of reinforcement to bring about the modifications desired.

behavior therapy. A form of psychotherapy, the goal of which is to modify maladaptive behavior patterns by reinforcing more adaptive behaviors.

behavioral objectives. Statements that indicate to an individual what is expected of him or her. Behavioral objectives are a way of measuring learning outcomes, and are based on the affective, cognitive, and psychomotor domains of learning.

belief. A belief is an idea that one holds to be true. It can be rational, irrational, taken on faith, or a stereotypical idea.

beneficence. An ethical principle that refers to one's duty to benefit or promote the good of others.

bereavement overload. An accumulation of grief that occurs when an individual experiences many losses over a short period of time and is unable to resolve one before another is experienced. This phenomenon is common among the elderly.

binge and purge. A syndrome associated with eating disorders, especially bulimia nervosa, in which an individual consumes thousands of calories of food at one sitting, and then purges through the use of laxatives or self-induced vomiting.

bioethics. The term used with ethical principles that refer to concepts within the scope of medicine, nursing, and allied health.

biofeedback. The use of instrumentation to become aware of processes in the body that usually go unnoticed and to bring them under voluntary control (e.g., the blood pressure or pulse); used as a method of stress reduction.

bipolar disorder. Characterized by mood swings from profound depression to extreme euphoria (mania), with intervening periods of normalcy. Psychotic symptoms may or may not be present.

body image. One's perception of his or her own body. It may also be how one believes others perceive his or her body. (See also **physical self.**)

borderline personality disorder. A disorder characterized by a pattern of intense and chaotic relationships, with affective instability, fluctuating and extreme attitudes regarding other people, impulsivity, direct and indirect self-destructive behavior, and lack of a clear or certain sense of identity, life plan, or values.

boundaries. The level of participation and interaction between individuals and between subsystems. Boundaries denote physical and psychological space individuals identify as their own. They are sometimes

referred to as limits. Boundaries are appropriate when they permit appropriate contact with others while preventing excessive interference. Boundaries may be clearly defined (healthy) or rigid or diffuse (unhealthy).

bulimia. Excessive, insatiable appetite.

C

cachexia. A state of ill health, malnutrition, and wasting; extreme emaciation.

cannabis. The dried flowering tops of the hemp plant. It produces euphoric effects when ingested or smoked and is commonly used in the form of marijuana or hashish.

carcinogen. Any substance or agent that produces or increases the risk of developing cancer in humans or lower animals.

case management. A health-care delivery process, the goals of which are to provide quality health care, decrease fragmentation, enhance the client's quality of life, and contain costs. A case manager coordinates the client's care from admission to discharge and sometimes following discharge. Critical pathways of care are the tools used for the provision of care in a case management system.

case manager. The individual responsible for negotiating with multiple health-care providers to obtain a variety of services for a client.

catastrophic thinking. Always thinking that the worst will occur without considering the possibility of more likely, positive outcomes.

catatonia. A type of psychological disturbance that is typified by stupor or excitement. Stupor is characterized by extreme psychomotor retardation, mutism, negativism, and posturing; excitement by psychomotor agitation, in which the movements are frenzied and purposeless. Catatonic symptoms may be associated with other mental or physical disorders.

catharsis. One therapeutic factor of group therapy (identified by Yalom), in which members in a group can express both positive and negative feelings in a nonthreatening atmosphere.

cell body. The part of the neuron that contains the nucleus and is essential for the continued life of the neuron.

Centers for Medicare and Medicaid Services (CMS). The division of the U.S. Department of Health and Human Services responsible for Medicare funding.

child sexual abuse. Any sexual act, such as indecent exposure or improper touching to penetration (sexual intercourse), that is carried out with a child.

chiropractic medicine. A system of alternative medicine based on the premise that the relationship between structure and function in the human body is a significant health factor and that such relationships between the spinal column and the nervous system are important because the normal transmission and expression of nerve energy are essential to the restoration and maintenance of health.

Christian ethics. The ethical philosophy that states one should treat others as moral equals, and recognize the equality of other persons by permitting them to act as we do when they occupy a position similar to ours; sometimes referred to as "the ethic of the golden rule."

circadian rhythm. A 24-hour biological rhythm controlled by a "pacemaker" in the brain that sends messages to other systems in the body. Circadian rhythm influences various regulatory functions, including the sleep-wake cycle, body temperature regulation, patterns of activity such as eating and drinking, and hormonal and neurotransmitter secretion.

circumstantiality. In speaking, the delay of an individual to reach the point of a communication, owing to unnecessary and tedious details.

civil law. Law that protects the private and property rights of individuals and businesses.

clang association. A pattern of speech in which the choice of words is governed by sounds. Clang associations often take the form of rhyming.

classical conditioning. A type of learning that occurs when an unconditioned stimulus (UCS) that produces an unconditioned response (UCR) is paired with a conditioned stimulus (CS), until the CS alone produces the same response, which is then called a conditioned response (CR). Pavlov's example: food (i.e., UCS) causes salivation (i.e., UCR); ringing bell (i.e., CS) with food (i.e., UCS) causes salivation (i.e., UCR), ringing bell alone (i.e., CS) causes salivation (i.e., CR).

codependency. An exaggerated dependent pattern of learned behaviors, beliefs, and feelings that make life painful. It is a dependence on people and things outside the self, along with neglect of the self to the point of having little self-identity.

cognition. Mental operations that relate to logic, awareness, intellect, memory, language, and reasoning powers.

cognitive. Relating to the mental processes of thinking and reasoning.

cognitive development. A series of stages described by Piaget through which individuals progress, demonstrating at each successive stage a higher level of logical organization than at each previous stage.

cognitive domain. A category of learning that involves knowledge and thought processes within the individual's intellectual ability. The individual must be able to synthesize information at an intellectual level before the actual behaviors are performed.

cognitive maturity. The capability to perform all mental operations needed for adulthood.

cognitive therapy. A type of therapy in which the individual is taught to control thought distortions that are considered to be a factor in the development and maintenance of emotional disorders.

collectivist culture. A culture that values close dependence on and interconnectedness with family and tribe. AI/AN groups are collectivist cultures.

colposcope. An instrument that contains a magnifying lens and to which a 35-mm camera can be attached. A colposcope is used to examine for tears and abrasions inside the vaginal area of a sexual assault victim.

common law. Laws that are derived from decisions made in previous cases.

communication. An interactive process of transmitting information between two or more entities.

community. A group of people living close to and depending to some extent on each other.

compensation. An ego defense mechanism in which an individual covers up a real or perceived weakness by emphasizing a trait one considers more desirable.

complementary medicine. Practices that differ from usual traditional (allopathic) medicine, but may in fact supplement it in a positive way.

compounded rape reaction. Symptoms that are in addition to the typical rape response of physical complaints, rage, humiliation, fear, and sleep disturbances. They include depression and suicide, substance abuse, and even psychotic behaviors.

compulsions. Unwanted repetitive behavior patterns or mental acts (e.g., praying, counting, repeating words silently) that are intended to reduce anxiety, not to provide pleasure or gratification (APA, 2013). They may be performed in response to an obsession or in a stereotyped fashion.

concept mapping. A diagrammatic teaching and learning strategy that allows students and faculty to visualize interrelationships between medical diagnoses, nursing diagnoses, assessment data, and treatments. A diagram of client problems and interventions.

concrete thinking. Thought processes that are focused on specifics rather than on generalities and immediate issues rather than eventual outcomes. Individuals who are experiencing concrete thinking are unable to comprehend abstract terminology.

conditioned response. In classical conditioning, a response that is a *learned* response (not reflexive) following repeated exposure to a target stimulus.

conditioned stimulus. In classical conditioning, an unrelated stimulus that is presented to a subject with a target stimulus, and that, with repeated exposure, comes to elicit the same response as the original target stimulus.

confabulation. Creating imaginary events to fill in memory gaps.

confidentiality. The right of an individual to the assurance that his or her case will not be discussed outside the boundaries of the health-care team.

contextual stimuli. Conditions present in the environment that support a focal stimulus and influence a threat to self-esteem.

contingency contracting. A written contract between individuals used to modify behavior. Benefits and consequences for fulfilling the terms of the contract are delineated.

controlled response pattern. The response to rape in which feelings are masked or hidden, and a calm, composed, or subdued affect is seen.

counselor. One who listens as the client reviews feelings related to difficulties he or she is experiencing in any aspect of life; one of the nursing roles identified by H. Peplau.

countertransference. In psychoanalytic theory, countertransference refers to the counselor's behavioral and emotional response to the client. These responses may be related to unresolved feelings toward significant others from the counselor's past, or they may be generated in response to the client's behavior toward the counselor.

covert sensitization. An aversion technique used to modify behavior that relies on the individual's imagination to produce unpleasant symptoms. When the individual is about to succumb to undesirable behavior, he or she visualizes something that is offensive or even nauseating in an effort to block the behavior.

criminal law. Law that provides protection from conduct deemed injurious to the public welfare. It provides for punishment of those found to have engaged in such conduct.

crisis. Psychological disequilibrium in a person who confronts a hazardous circumstance that constitutes an important problem which for the time he or she can neither escape nor solve with usual problem-solving resources.

crisis intervention. An emergency type of assistance in which the intervener becomes a part of the individual's life situation. The focus is to provide guidance and support to help mobilize the resources needed to resolve the crisis and restore or generate an improvement in previous level of functioning. Usually lasts no longer than 6 to 8 weeks.

critical pathways of care. An abbreviated plan of care that provides outcome-based guidelines for goal achievement within a designated length of time.

cultural syndromes. Medical and psychiatric symptoms that are specific to a cultural group and do not share an exact correlation to any *DSM-5* diagnostic category.

culture. A particular society's entire way of living, encompassing shared patterns of belief, feeling, and knowledge that guide people's conduct and are passed down from generation to generation.

curandera. A female folk healer in Latino culture.

curandero. A male folk healer in Latino culture.

cycle of battering. Three phases of predictable behaviors that are repeated over time in a relationship between a batterer and a victim: tension-building phase; the acute battering incident; and the calm, loving, respite (honeymoon) phase.

cyclothymic disorder. A chronic mood disturbance involving numerous episodes of hypomania and depressed mood, of insufficient severity or duration to meet the criteria for bipolar disorder.

D

date rape. A type of acquaintance rape in which the rapist is known to the victim through dating.

decatastrophizing. In cognitive therapy, with this technique the therapist assists the client to examine the validity of a negative automatic thought. Even if some validity exists, the client is then encouraged to review ways to cope adaptively, moving beyond the current crisis situation.

defamation of character. An individual may be liable for defamation of character by sharing with others information about a person that is detrimental to that person's reputation.

defense mechanisms. Mechanisms used by the ego in efforts to relieve anxiety posed by threats to biological or psychological integrity.

deinstitutionalization. The removal of mentally ill individuals from institutions and the subsequent plan to provide care for these individuals in the community setting.

delayed grief. The absence of evidence of grief when it ordinarily would be expected.

delayed ejaculation. Delayed or absent ejaculation, even though the man has a firm erection and has had more than adequate stimulation.

delirious mania. A grave form of mania characterized by severe clouding of consciousness and representing an intensification of the symptoms associated with mania. The symptoms of delirious mania have become relatively rare since the availability of antipsychotic medications.

delirium. A state of mental confusion and excitement characterized by disorientation for time and place, often with hallucinations, incoherent speech, and a continual state of aimless physical activity.

delusions. False personal beliefs, not consistent with a person's intelligence or cultural background. The individual continues to have the belief in spite of obvious proof that it is false and/or irrational.

dementia. See **neurocognitive disorder.**

democratic. A leadership style in which the leader promotes shared decision making. The leader provides guidance and expertise as needed.

dendrites. The cellular processes of a neuron that carry impulses toward the cell body.

denial. Refusal to acknowledge the existence of a real situation and/or the feelings associated with it.

density. The number of people in a given environmental space, influencing interpersonal interaction.

depersonalization. An alteration in the perception or experience of the self so that the feeling of one's own reality is temporarily lost.

depression. An alteration in mood that is expressed by feelings of sadness, despair, and pessimism. There is a loss of interest in usual activities, and somatic symptoms may be evident. Changes in appetite and sleep patterns are common.

derealization. An alteration in the perception or experience of the external world so that it seems strange or unreal.

detoxification. The process of withdrawal from a substance to which one has become addicted.

diagnosis related groups (DRGs). A system used to determine prospective payment rates for reimbursement of hospital care based on the client's diagnosis.

Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5). Standard nomenclature of emotional illness published by the American Psychiatric Association (APA) and used by all healthcare practitioners. It classifies mental illness and presents guidelines and diagnostic criteria for various mental disorders.

dichotomous thinking. In this type of thinking, situations are viewed in all-or-nothing, black-or-white, good-or-bad terms.

directed association. A technique used to help clients bring into consciousness events that have been repressed. Specific thoughts are guided and directed by the psychoanalyst.

disaster. A natural or man-made occurrence that overwhelms the resources of an individual or community, and increases the need for emergency evacuation and medical services.

discriminative stimulus. A stimulus that precedes a behavioral response and predicts that a particular reinforcement will occur. Individuals learn to discriminate between various stimuli that will produce the responses they desire.

disengagement. In family theory, disengagement refers to extreme separateness among family members. It is

promoted by rigid boundaries or lack of communication among family members.

disengagement theory. The hypothesis that there is a process of mutual withdrawal of aging persons and society from each other that is correlated with successful aging. This theory has been challenged by many investigators.

displacement. Feelings are transferred from one target to another that is considered less threatening or neutral.

dissociation. The splitting off of clusters of mental contents from conscious awareness, a mechanism central to hysterical conversion and dissociative disorder.

distance. The means by which various cultures use space to communicate.

distraction. In cognitive therapy, when dysfunctional cognitions have been recognized, activities are identified that can be used to distract the client and divert him or her from the intrusive thoughts or depressive ruminations that are contributing to the client's maladaptive responses.

disulfiram. A drug that is administered to individuals who abuse alcohol as a deterrent to drinking. Ingestion of alcohol while disulfiram is in the body results in a syndrome of symptoms that can produce a great deal of discomfort, and can even result in death if the blood alcohol level is high.

domains of learning. Categories in which individuals learn or gain knowledge and demonstrate behavior. There are three domains of learning: affective, cognitive, and psychomotor.

double-bind communication. An emotionally distressing situation in which an individual receives conflicting messages in the communication process, whereby one message is negated by another. This creates a condition in which a successful response to one message results in a failed response to the other.

dual diagnosis. A client has a dual diagnosis when it is determined that he or she has a coexisting substance disorder and mental illness. Treatment is designed to target both problems.

dysthymia. A depressive neurosis. The symptoms are similar to, if somewhat milder than, those ascribed to major depression. There is no loss of contact with reality.

dystonia. Involuntary muscular movements (spasms) of the face, arms, legs, and neck; may occur as an extrapyramidal side effect of some antipsychotic medications.

E

echolalia. The parrot-like repetition, by an individual with loose ego boundaries, of the words spoken by another.

echopraxia. An individual with loose ego boundaries attempting to identify with another person by imitating movements that the other person makes.

ego. One of the three elements of the personality identified by Freud as the rational self or "reality principle." The ego seeks to maintain harmony between the external world, the id, and the superego.

ego defense mechanisms. Strategies employed by the ego for protection in the face of threat to biological or psychological integrity. (See individual defense mechanisms.)

egoistic suicide. The response of an individual who feels separate and apart from the mainstream of society.

electroconvulsive therapy (ECT). A type of somatic treatment in which electric current is applied to the brain through electrodes placed on the temples. A grand mal seizure produces the desired effect. This is used with severely depressed patients refractory to antidepressant medications.

emaciated. The state of being excessively thin or physically wasted.

emotional abuse. A pattern of behavior on the part of the parent or caretaker that results in serious impairment of the child's social, emotional, or intellectual functioning.

emotional intelligence (EI). A set of competencies related to one's emotional health that includes self-awareness, empathy, emotional self-control, and effective relationship management.

emotional neglect. A chronic failure by the parent or caretaker to provide the child with the hope, love, and support necessary for the development of a sound, healthy personality.

empathy. The ability to see beyond outward behavior, and sense accurately another's inner experiencing. With empathy, one can accurately perceive and understand the meaning and relevance in the thoughts and feelings of another.

enculturation. The process of acquiring cultural behavior through socialization.

enmeshment. Exaggerated connectedness among family members. It occurs in response to diffuse boundaries in which there is overinvestment, overinvolvement, and lack of differentiation between individuals or subsystems.

esophageal varices. Veins in the esophagus become distended because of excessive pressure from defective blood flow through a cirrhotic liver.

essential hypertension. Persistent elevation of blood pressure for which there is no apparent cause or associated underlying disease.

ethical dilemma. A situation that arises when on the basis of moral considerations an appeal can be made for taking each of two opposing courses of action.

ethical egoism. An ethical theory espousing that what is "right" and "good" is what is best for the individual making the decision.

ethics. A branch of philosophy dealing with values related to human conduct, to the rightness and wrongness of certain actions, and to the goodness and badness of the motives and ends of such actions.

ethnicity. The concept of people identifying with each other because of a shared heritage.

evaluation. The process of determining the progress toward attainment of expected outcomes, including the effectiveness of care (ANA, 2010).

exhibitionistic disorder. A paraphilic disorder characterized by a recurrent urge to expose one's genitals to a stranger.

expressed response pattern. Pattern of behavior in which the victim of rape expresses feelings of fear, anger, and anxiety through such behavior as crying, sobbing, restlessness, and tenseness; in contrast to the rape victim who withholds feelings in the **controlled response pattern.**

extinction. In behavior therapy, the gradual decrease in frequency or disappearance of a response when the positive reinforcement is withheld.

extrapyramidal symptoms (EPS). A variety of symptoms that originate outside the pyramidal tracts and in the basal ganglion of the brain. Symptoms may include tremors, chorea, dystonia, akinesia, akathisia, and others. May occur as a side effect of some antipsychotic medications.

F

factitious disorder. Factitious disorders involve conscious, intentional feigning of physical or psychological symptoms. Individuals with factitious disorder pretend to be ill in order to receive emotional care and support commonly associated with the role of "patient."

false imprisonment. The deliberate and unauthorized confinement of a person within fixed limits by the use of threat or force. A nurse may be charged with false imprisonment by placing a patient in restraints against his or her will in a non-emergency situation.

family. Two or more individuals who depend on one another for emotional, physical, and economical support. The members of the family are self-defined (Kaakinen, Hanson, & Denham, 2010).

family structure. Family structure is founded on a set of invisible principles that influence the interaction among family members. These principles are established over time and become the "laws" that govern the conduct of various family members.

family system. The entirety of the family as a unit that includes patterns for social and emotional interaction, interdependence, and the subsystems within the family. These subsystems may include a marital dyad, parent-child dyad, and sibling groups.

family therapy. A type of therapy in which the focus is on relationships within the family. The family is viewed as a system in which the members are interdependent, and a change in one creates change in all.

fetishistic disorder. A paraphilic disorder characterized by recurrent sexual urges and sexually arousing fantasies involving the use of nonliving objects.

fight-or-flight syndrome. A syndrome of physical symptoms that results from an individual's real or perceived notion that harm or danger is imminent.

flexible boundary. A personal boundary is flexible when, because of unusual circumstances, individuals can alter limits that they have set for themselves. Flexible boundaries are healthy boundaries.

flooding. Sometimes called *implosion therapy*, this technique is used to desensitize individuals to phobic stimuli. The individual is "flooded" with a continuous presentation (usually through mental imagery) of the phobic stimulus until it no longer elicits anxiety.

focal stimulus. A situation of immediate concern that results in a threat to self-esteem.

Focus Charting®. A type of documentation that follows a data, action, and response (DAR) format. The main perspective is a client "focus," which can be a nursing diagnosis, a client's concern, a change in status, or a significant event in the client's therapy. The focus cannot be a medical diagnosis.

folk medicine. A system of health care within various cultures that is provided by a local practitioner, not professionally trained, but who uses techniques specific to that culture in the art of healing.

forensic. Pertaining to the law; legal.

forensic nursing. The application of forensic science combined with the bio-psychological education of the registered nurse, in the scientific investigation, evidence collection and preservation, analysis, prevention and treatment of trauma and/or death related medical-legal issues.

free association. A technique in psychoanalytic therapy used to help individuals bring to consciousness material that has been repressed. The individual is encouraged to verbalize whatever comes into his or her mind, drifting naturally from one thought to another.

frotteuristic disorder. A paraphilic disorder characterized by the recurrent preoccupation with intense sexual urges or fantasies involving touching or rubbing against a nonconsenting person.

fugue. A sudden unexpected travel away from home or customary work locale with the assumption of a

new identity and an inability to recall one's previous identity; usually occurring in response to severe psychosocial stress.

G

Gamblers Anonymous (GA). An organization of inspirational group therapy, modeled after Alcoholics Anonymous (AA), for individuals who desire to, but cannot, stop gambling.

gay. The term used to describe males in same-sex relationships.

gender. The condition of being either male or female.

gender dysphoria. A sense of discomfort associated with an incongruence between biologically assigned gender and subjectively experienced gender.

general adaptation syndrome. The general biological reaction of the body to a stressful situation, as described by Hans Selye. It occurs in three stages: the alarm reaction stage, the stage of resistance, and the stage of exhaustion.

generalized anxiety disorder. A disorder characterized by chronic (at least 6 months), unrealistic, and excessive anxiety and worry.

genetics. Study of the biological transmission of certain characteristics (physical and/or behavioral) from parent to offspring.

genogram. A graphic representation of a family system. It may cover several generations. Emphasis is on family roles and emotional relatedness among members. Genograms facilitate recognition of areas requiring change.

genotype. The total set of genes present in an individual at the time of conception, and coded in the DNA.

genuineness. The ability to be open, honest, and "real" in interactions with others; the awareness of what one is experiencing internally and the ability to project the quality of this inner experiencing in a relationship.

geriatrics. The branch of clinical medicine specializing in the care of the elderly and concerned with the problems of aging.

gerontology. The study of normal aging.

geropsychiatry. The branch of clinical medicine specializing in psychopathology of the elderly.

granny-dumping. Media-generated term for abandoning elderly individuals at emergency departments, nursing homes, or other facilities—literally leaving them in the hands of others when the strain of caregiving becomes intolerable.

grief. A subjective state of emotional, physical, and social responses to the real or perceived loss of a valued entity. Change and failure can also be perceived as losses. The grief response consists of a set of relatively predictable behaviors that describe the subjective state that accompanies mourning.

grief, exaggerated. A reaction in which all of the symptoms associated with normal grieving are exaggerated out of proportion. Pathological depression is a type of exaggerated grief.

grief, inhibited. The absence of evidence of grief when it ordinarily would be expected.

group. A collection of individuals whose association is founded on shared commonalities of interest, values, norms, or purpose. Membership in a group is generally by chance (born into the group), by choice (voluntary affiliation), or by circumstance (the result of life-cycle events over which an individual may or may not have control).

group therapy. A therapy group, founded in a specific theoretical framework, led by a person with an advanced degree in psychology, social work, nursing, or medicine. The goal is to encourage improvement in interpersonal functioning.

gynecomastia. Enlargement of the breasts in men; may be a side effect of some antipsychotic medications.

H

hallucinations. False sensory perceptions not associated with real external stimuli. Hallucinations may involve any of the five senses.

hepatic encephalopathy. A brain disorder resulting from the inability of the cirrhotic liver to convert ammonia to urea for excretion. The continued rise in serum ammonia results in progressively impaired mental functioning, apathy, euphoria or depression, sleep disturbances, increasing confusion, and progression to coma and eventual death.

HIV-associated neurocognitive disorder. A neuropathological syndrome, possibly caused by chronic HIV encephalitis and myelitis and manifested by cognitive, behavioral, and motor symptoms that become more severe with progression of the disease.

home care. A wide range of health and social services that are delivered at home to recovering, disabled, chronically or terminally ill persons in need of medical, nursing, social, or therapeutic treatment and/or assistance with essential activities of daily living.

homocysteine. An amino acid produced by the catabolism of methionine. Elevated levels may be linked to increased risk of cardiovascular disease.

homosexuality. A sexual preference for persons of the same gender.

hope. A foundational principle in the recovery model stressing that recovery emerges from the client's sense that recovery is attainable.

hospice. A program that provides palliative and supportive care to meet the special needs arising out of the physical, psychosocial, spiritual, social, and economic stresses that are experienced during the final stages of illness and during bereavement.

humors. The four body fluids described by Hippocrates: blood, black bile, yellow bile, and phlegm. Hippocrates associated insanity and mental illness with dysequilibrium among these four fluids.

hypersomnia. Excessive sleepiness or seeking excessive amounts of sleep.

hyperactivity. Excessive psychomotor activity that may be purposeful or aimless, accompanied by physical movements and verbal utterances that are usually more rapid than normal. Inattention and distractibility are common with hyperactive behavior.

hypertensive crisis. A potentially life-threatening syndrome that results when an individual taking monoamine oxidase (MAO) inhibitors eats a product high in tyramine. Symptoms include severe occipital headache, palpitations, nausea and vomiting, nuchal rigidity, fever, sweating, marked increase in blood pressure, chest pain, and coma. Foods with tyramine include aged cheeses or other aged, overripe, and fermented foods; broad beans; pickled herring; beef or chicken liver; preserved meats; beer and wine; yeast products; chocolate; caffeinated drinks; canned figs; sour cream; yogurt; soy sauce; and some over-the-counter cold medications and diet pills.

hypnosis. A treatment for disorders brought on by repressed anxiety. The individual is directed into a state of subconsciousness and assisted, through suggestions, to recall certain events that he or she cannot recall while conscious.

hypomania. A mild form of mania. Symptoms are excessive hyperactivity, but not severe enough to cause marked impairment in social or occupational functioning or to require hospitalization.

hysteria. A polysymptomatic disorder characterized by recurrent, multiple somatic complaints often described dramatically.

I

id. One of the three components of the personality identified by Freud as the "pleasure principle." The id is the locus of instinctual drives; is present at birth; and compels the infant to satisfy needs and seek immediate gratification.

identification. An attempt to increase self-worth by acquiring certain attributes and characteristics of an individual one admires.

illusion. A misperception of a real external stimulus.

implosion therapy. See **flooding**.

impulsive. The urge or inclination to act without consideration to the possible consequences of one's behavior.

incest. Sexual exploitation of a child under 18 years of age by a relative or non-relative who holds a position of trust in the family.

individualist culture. A culture that values independence, self reliance, and freedom.

informed consent. Permission granted to a physician by a client to perform a therapeutic procedure, prior to which information about the procedure has been presented to the client with adequate time given for consideration about the pros and cons.

insomnia. Difficulty initiating or maintaining sleep.

insulin coma therapy. The induction of a hypoglycemic coma aimed at alleviating psychotic symptoms; a dangerous procedure, questionably effective, no longer used in psychiatry.

integration. The process used with individuals with dissociative identity disorder in an effort to bring all the personalities together into one; usually achieved through hypnosis.

intellectualization. An attempt to avoid expressing actual emotions associated with a stressful situation by using the intellectual processes of logic, reasoning, and analysis.

interdisciplinary care. A concept of providing care for a client in which members of various disciplines work together with common goals and shared responsibilities for meeting those goals.

intimate distance. The closest distance that individuals will allow between themselves and others. In the United States, this distance is 0 to 18 inches.

intoxication. A physical and mental state of exhilaration and emotional frenzy or lethargy and stupor.

introjection. The beliefs and values of another individual are internalized and symbolically become a part of the self, to the extent that the feeling of separateness or distinctness is lost.

isolation. The separation of a thought or a memory from the feeling, tone, or emotions associated with it (sometimes called *emotional isolation*).

J

justice. An ethical principle reflecting that all individuals should be treated equally and fairly.

K

Kantianism. The ethical principle espousing that decisions should be made and actions taken out of a sense of duty.

kleptomania. A recurrent failure to resist impulses to steal objects not needed for personal use or monetary value.

Korsakoff's psychosis. A syndrome of confusion, loss of recent memory, and confabulation in alcoholics, caused by a deficiency of thiamine. It often occurs together with Wernicke's encephalopathy and may be termed *Wernicke-Korsakoff syndrome*.

L

laissez-faire. A leadership style in which the leader lets group members do as they please. There is no

direction from the leader. Member productivity and morale may be low, owing to frustration from lack of direction.

lesbian. The term used to describe females in same-sex relationships.

libel. An action with which an individual may be charged for sharing with another individual, in writing, information that is detrimental to someone's reputation.

libido. Freud's term for the psychic energy used to fulfill basic physiological needs or instinctual drives such as hunger, thirst, and sexuality.

limbic system. A system of brain structures under the cortex sometimes called the "emotional brain." It is associated with feelings of fear and anxiety; anger and aggression; love, joy, and hope; and with sexuality and social behavior.

long-term memory. Memory for remote events, or those that occurred many years ago. The type of memory that is preserved in the elderly individual.

loose association. A thinking process characterized by speech in which ideas shift from one unrelated subject to another. The individual is unaware that the topics are unconnected.

loss. The experience of separation from something of personal importance.

luto. In Mexican culture, the period of mourning following the death of a loved one which is symbolized by wearing black, black and white, or dark clothing and by subdued behavior.

M

magical thinking. A primitive form of thinking in which an individual believes that thinking about a possible occurrence can make it happen.

magnification. A type of thinking in which the negative significance of an event is exaggerated.

maladaptation. A failure of the body to return to homeostasis following a physiological and/or psychological response to stress, disrupting the individual's integrity.

maladaptive responses. Behaviors that are considered unhealthy and destructive to one's integrity.

malpractice. The failure of one rendering professional services to exercise that degree of skill and learning commonly applied under all the circumstances in the community by the average prudent reputable member of the profession with the result of injury, loss, or damage to the recipient of those services or to those entitled to rely upon them.

managed care. A concept purposefully designed to control the balance between cost and quality of care. Examples of managed care are health maintenance organizations (HMOs) and preferred provider organizations (PPOs). The amount and type of health care that the individual receives is determined by the organization providing the managed care.

mania. A manifestation of bipolar disorder in which the predominant mood is elevated, expansive, or irritable. Motor activity is frenzied and excessive. Psychotic features may or may not be present.

marital rape. Sexual violence directed at a marital partner against that person's will.

marital schism. A state of severe chronic disequilibrium and discord within the marital dyad, with recurrent threats of separation.

marital skew. A marital relationship in which there is lack of equal partnership. One partner dominates the relationship and the other partner.

Medicaid. A system established by the federal government to provide medical care benefits for indigent Americans. The Medicaid program is jointly funded by state and federal governments, and coverage varies significantly from state to state.

Medicare. A system established by the federal government to provide medical care benefits for elderly Americans.

meditation. A method of relaxation in which an individual sits in a quiet place and focuses total concentration on an object, word, or thought.

melancholia. A severe form of major depressive episode. Symptoms are exaggerated, and interest or pleasure in virtually all activities is lost.

menopause. The period marking the permanent cessation of menstrual activity; usually occurs at approximately 48 to 51 years of age.

mental health. The successful adaptation to stressors from the internal or external environment, evidenced by thoughts, feelings, and behaviors that are age-appropriate and congruent with local and cultural norms.

mental illness. Maladaptive responses to stressors from the internal or external environment, evidenced by thoughts, feelings, and behaviors that are incongruent with the local and cultural norms, and interfere with the individual's social, occupational, and/or physical functioning.

mental imagery. A method of stress reduction that employs the imagination. The individual focuses imagination on a scenario that is particularly relaxing to him or her (e.g., a scene on a quiet seashore, a mountain atmosphere, or floating through the air on a fluffy white cloud).

meridians. In Chinese medicine, pathways along the body in which the healing energy (qi) flows, and which are links between acupoints.

migraine personality. Personality characteristics that have been attributed to the migraine-prone person. The characteristics include perfectionistic, overly conscientious, somewhat inflexible, neat and tidy, compulsive, hard worker, intelligent, exacting, and

places a very high premium on success, setting high (sometimes unrealistic) expectations on self and others.

milieu. French for "middle"; the English translation connotes "surroundings, or environment."

milieu therapy. Also called therapeutic community, or therapeutic environment, this type of therapy consists of a scientific structuring of the environment in order to effect behavioral changes and to improve the individual's psychological health and functioning.

minimization. A type of thinking in which the positive significance of an event is minimized or undervalued.

mobile outreach units. Programs in which volunteers and paid professionals drive or walk around and seek out homeless individuals who need assistance with physical or psychological care.

modeling. Learning new behaviors by imitating the behaviors of others.

mood. An individual's sustained emotional tone, which significantly influences behavior, personality, and perception.

moral behavior. Conduct that results from serious critical thinking about how individuals ought to treat others; reflects respect for human life, freedom, justice, or confidentiality.

moral-ethical self. That aspect of the personal identity that functions as observer, standard setter, dreamer, comparer, and most of all evaluator of who the individual says he or she is. This component of the personal identity makes judgments that influence an individual's self-evaluation.

motivational interviewing. An evidence-based, patient-centered style of communicating that promotes behavior change by guiding clients to explore their own motivation for change and the advantages and disadvantages of their decisions.

mourning. The psychological process (or stages) through which the individual passes on the way to successful adaptation to the loss of a valued entity.

multidisciplinary care. A concept of providing care for a client in which individual disciplines provide specific services for the client without formal arrangement for interaction between the disciplines.

Munchausen syndrome. See **factitious disorder.**

N

narcissism. Self-love or self-admiration.

narcissistic personality disorder. A disorder characterized by an exaggerated sense of self-worth. These individuals lack empathy and are hypersensitive to the evaluation of others.

narcolepsy. A disorder in which the characteristic manifestation is sleep attacks. The individual cannot prevent falling asleep, even in the middle of a sentence or performing a task.

natural law theory. The ethical theory that has as its moral precept to "do good and avoid evil" at all costs. Natural law ethics are grounded in a concern for the human good that is based on people's ability to live according to the dictates of reason.

negative reinforcement. Increasing the probability that a behavior will recur by removal of an undesirable reinforcing stimulus.

negativism. Strong resistance to suggestions or directions; exhibiting behaviors contrary to what is expected.

neglect of a child. *Physical neglect* of a child includes refusal of or delay in seeking health care, abandonment, expulsion from the home or refusal to allow a runaway to return home, and inadequate supervision. *Emotional neglect* refers to a chronic failure by the parent or caretaker to provide the child with the hope, love, and support necessary for the development of a sound, healthy personality.

negligence. The failure to do something that a reasonable person, guided by those considerations that ordinarily regulate human affairs, would do, or doing something that a prudent and reasonable person would not do.

neologism. New words that an individual invents that are meaningless to others, but have symbolic meaning to the psychotic person.

neurocognitive disorder. Global impairment of cognitive functioning that is progressive and interferes with social and occupational abilities.

neuroendocrinology. The study of hormones functioning within the neurological system.

neuroleptic. Antipsychotic medication used to prevent or control psychotic symptoms.

neuroleptic malignant syndrome (NMS). A rare but potentially fatal complication of treatment with neuroleptic drugs. Symptoms include severe muscle rigidity, high fever, tachycardia, fluctuations in blood pressure, diaphoresis, and rapid deterioration of mental status to stupor and coma.

neuron. A nerve cell; consists of a cell body, an axon, and dendrites.

neurosis. An unconscious conflict that produces anxiety and other symptoms and leads to maladaptive use of defense mechanisms.

neurotic disorder. A psychiatric disturbance, characterized by excessive anxiety and/or depression, disrupted bodily functions, unsatisfying interpersonal relationships, and behaviors that interfere with routine functioning. There is no loss of contact with reality.

neurotransmitter. A chemical that is stored in the axon terminals of the presynaptic neuron. An electrical

impulse through the neuron stimulates the release of the neurotransmitter into the synaptic cleft, which in turn determines whether or not another electrical impulse is generated.

nonassertive. A communication and behavioral approach (sometimes called passive) in which the individual seeks to please others at the expense of denying their own basic human rights.

nonmaleficence. The ethical principle that espouses abstaining from negative acts toward another, including acting carefully to avoid harm.

nursing diagnosis. A clinical judgment about individual, family, or community responses to actual and potential health problems/life processes. Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable.

Nursing Interventions Classification (NIC). A comprehensive, research-based, standardized classification of interventions that nurses perform.

Nursing Outcomes Classification (NOC). A comprehensive, standardized classification of patient/client outcomes developed to evaluate the effects of nursing interventions.

nursing process. A dynamic, systematic process by which nurses assess, diagnose, identify outcomes, plan, implement, and evaluate nursing care. It has been called "nursing's scientific methodology." Nursing process gives order and consistency to nursing intervention.

O

obesity. The state of having a body mass index of 30 or above.

object constancy. The phase in the separation/individuation process when the child learns to relate to objects in an effective, constant manner. A sense of separateness is established, and the child is able to internalize a sustained image of the loved object or person when out of sight.

obsessions. Unwanted, intrusive, persistent ideas, thoughts, impulses, or images that cause marked anxiety or distress. Common ones include repeated thoughts about contamination, doubts, a need to have things in a particular order, aggressive or sexual impulses, and fears of harm to oneself or others (APA, 2013).

obsessive-compulsive disorder. Recurrent thoughts or ideas (obsessions) that an individual is unable to put out of his or her mind, and actions that an individual is unable to refrain from performing (compulsions). The obsessions and compulsions are severe enough to interfere with social and occupational functioning.

oculogyric crisis. An attack of involuntary deviation and fixation of the eyeballs, usually in the upward position. It may last for several minutes or hours and may occur as an extrapyramidal side effect of some antipsychotic medications.

operant conditioning. The learning of a particular action or type of behavior that is followed by a reinforcement.

opioids. A group of compounds that includes opium, opium derivatives, and synthetic substitutes.

orgasm. A peaking of sexual pleasure, with release of sexual tension and rhythmic contraction of the perineal muscles and pelvic reproductive organs.

osteoporosis. A reduction in the mass of bone per unit of volume that interferes with the mechanical support function of bone. This process occurs because of demineralization of the bones, and is escalated in women about the time of menopause.

outcomes. End results that are measurable, desirable, and observable, and translate into observable behaviors.

overgeneralization. Also called "absolutistic thinking." With overgeneralization, sweeping conclusions are made based on one incident—an "all or nothing" type of thinking.

overt sensitization. A type of aversion therapy that produces unpleasant consequences for undesirable behavior. An example is the use of disulfiram therapy with alcoholics, which induces an undesirable physical response if the individual has consumed any alcohol.

P

palilalia. Repeating one's own sounds or words (a type of vocal tic associated with Tourette's disorder).

panic. A sudden overwhelming feeling of terror or impending doom. This most severe form of emotional anxiety is usually accompanied by behavioral, cognitive, and physiological signs and symptoms considered to be outside the expected range of normalcy.

panic disorder. A disorder characterized by recurrent panic attacks, the onset of which are unpredictable, and manifested by intense apprehension, fear, or terror, often associated with feelings of impending doom, and accompanied by intense physical discomfort.

paradoxical intervention. In family therapy, "prescribing the symptom." The therapist requests that the family continue to engage in the behavior that they are trying to change. Tension is relieved, and the family is able to view more clearly the possible solutions to their problem.

paralanguage. The gestural component of the spoken word. It consists of pitch, tone, and loudness of spoken messages, the rate of speaking, expressively placed pauses, and emphasis assigned to certain words.

paranoia. A term that implies extreme suspiciousness. In schizophrenia, paranoia is characterized by persecutory delusions and hallucinations of a threatening nature.

paraphilic disorder. Repetitive behaviors or fantasies that involve nonhuman objects, real or simulated suffering or humiliation, or nonconsenting partners.

parasomnia. Unusual or undesirable behaviors that occur during sleep (e.g., nightmares, sleep terrors, and sleepwalking).

passive-aggressive behavior. Behavior that defends an individual's own basic rights by expressing resistance to social and occupational demands. Sometimes called *indirect aggression*, this behavior takes the form of sly, devious, and undermining actions that express the opposite of what the person is really feeling.

pathological gambling. A failure to resist impulses to gamble, and gambling behavior that compromises, disrupts, or damages personal, family, or vocational pursuits.

pedophilic disorder. Recurrent urges and sexually arousing fantasies involving sexual activity with a prepubescent child.

peer assistance programs. A program established by the American Nurses Association to assist impaired nurses. The individuals who administer these efforts are nurse members of the state associations, as well as nurses who are in recovery themselves.

perseveration. Persistent repetition of the same word or idea in response to different questions.

personal distance. The distance between individuals who are having interactions of a personal nature, such as a close conversation. In the U.S. culture, personal distance is approximately 18 to 40 inches.

personal identity. An individual's self-perception that defines his or her functions as observer, standard setter, and self-evaluator. It strives to maintain a stable self-image and relates to what the individual strives to become.

personal self. See **personal identity.**

personality. Deeply ingrained patterns of behavior, which include the way one relates to, perceives, and thinks about the environment and oneself.

personalization. Taking complete responsibility for situations without considering that other circumstances may have contributed to the outcome.

pharmacoconvulsive therapy. The chemical induction of a convulsion, used in the past for the reduction of psychotic symptoms; a type of therapy no longer used in psychiatry.

phencyclidine. An anesthetic used in veterinary medicine; used illegally as a hallucinogen, referred to as PCP or angel dust.

phenotype. Characteristics of physical manifestations that identify a particular genotype. Examples of phenotypes include eye color, height, blood type, language, and hairstyle. Phenotypes may be genetic or acquired.

phobia. An irrational fear.

physical neglect of a child. The failure on the part of the parent or caregiver to provide for a child's basic needs, such as food, clothing, shelter, medical-dental care, and supervision.

PIE charting. More specifically called "APIE," this method of documentation has an assessment, problem, intervention, and evaluation (APIE) format and is a problem-oriented system used to document the nursing process.

positive reinforcement. A reinforcement stimulus that increases the probability that the behavior will recur.

postpartum depression. Depression that occurs during the postpartum period. It may be related to hormonal changes, tryptophan metabolism, or alterations in membrane transport during the early postpartum period. Other predisposing factors may also be influential.

posttraumatic stress disorder (PTSD). A syndrome of symptoms that develop following a psychologically distressing event that is outside the range of usual human experience (e.g., rape, war). The individual is unable to put the experience out of his or her mind, and has nightmares, flashbacks, and panic attacks.

posturing. The voluntary assumption of inappropriate or bizarre postures.

preassaultive tension state. Behaviors predictive of potential violence. They include excessive motor activity, tense posture, defiant affect, clenched teeth and fists, and other arguing, demanding, and threatening behaviors.

precipitating event. A stimulus arising from the internal or external environment that is perceived by an individual as taxing or exceeding his or her resources and endangering his or her well-being.

predisposing factors. A variety of elements that influence how an individual perceives and responds to a stressful event. Types of predisposing factors include genetic influences, past experiences, and existing conditions.

Premack principle. This principle states that a frequently occurring response (R1) can serve as a positive reinforcement for a response (R2) that occurs less frequently. For example, a girl may talk to friends on the phone (R2) only if she does her homework (R1).

premature ejaculation. Ejaculation that occurs with minimal sexual stimulation or before, upon, or shortly after penetration and before the person wishes it.

premenstrual dysphoric disorder. A disorder that is characterized by depressed mood, anxiety, mood swings, and decreased interest in activities during the week prior to menses and subsiding shortly after the onset of menstruation.

priapism. Prolonged painful penile erection; may occur as an adverse effect of some antidepressant medications, particularly trazodone.

primary neurocognitive disorder (NCD). NCD, such as Alzheimer's disease, in which the NCD itself is the major sign of some organic brain disease not directly related to any other organic illness.

primary gain. The receipt of positive reinforcement for somaticizing by being able to avoid difficult situations because of physical complaint.

primary prevention. Reduction of the incidence of mental disorders within the population by helping individuals to cope more effectively with stress and by trying to diminish stressors within the environment.

privileged communication. A doctrine common to most states that grants certain privileges under which health-care professionals may refuse to reveal information about and communications with clients.

problem-oriented recording (POR). A system of documentation that follows a subjective data, objective data, assessment, plan, implementation, and evaluation (SOAPIE) format. It is based on a list of identified patient problems to which each entry is directed.

prodromal syndrome. A syndrome of symptoms that often precede the onset of aggressive or violent behavior. These symptoms include anxiety and tension, verbal abuse and profanity, and increasing hyperactivity.

progressive relaxation. A method of deep muscle relaxation in which each muscle group is alternately tensed and relaxed in a systematic order with the person concentrating on the contrast of sensations experienced from tensing and relaxing.

projection. Attributing to another person feelings or impulses unacceptable to oneself.

prospective payment. The program of cost containment within the health-care profession directed at setting forth preestablished amounts that would be reimbursed for specific diagnoses.

pseudocyesis. A condition in which an individual has nearly all the signs and symptoms of pregnancy but is not pregnant; a conversion reaction.

pseudodementia. Symptoms of depression that mimic those of neurocognitive disorder (NCD).

pseudohostility. A family interaction pattern characterized by a state of chronic conflict and alienation among family members. This relationship pattern allows family members to deny underlying fears of tenderness and intimacy.

pseudomutuality. A family interaction pattern characterized by a facade of mutual regard with the purpose of denying underlying fears of separation and hostility.

pseudoparkinsonism. A side effect of some antipsychotic medications. Symptoms mimic those of Parkinson's disease, such as tremor, shuffling gait, drooling, and rigidity.

psychiatric home care. Care provided by psychiatric nurses in the client's home. Psychiatric home care nurses must have physical and psychosocial nursing skills to meet the demands of the client population they serve.

psychobiology. The study of the biological foundations of cognitive, emotional, and behavioral processes.

psychodrama. A specialized type of group therapy that employs a dramatic approach in which patients become "actors" in life situation scenarios. The goal is to resolve interpersonal conflicts in a less-threatening atmosphere than the real-life situation would present.

psychodynamic nursing. Being able to understand one's own behavior, to help others identify felt difficulties, and to apply principles of human relations to the problems that arise at all levels of experience.

psychoimmunology. The study of the implications of the immune system in psychiatry.

Psychological Recovery model. A recovery model which identifies five stages of recovery: moratorium (despair and confusion), awareness (that recovery is possible), preparation (begins the work of recovery), rebuilding (taking steps toward one's goals for recovery), and growth (some outcomes have been met and there is recognition that growth is a dynamic, lifelong process).

psychomotor domain. A category of learning in which the behaviors are processed and demonstrated. The information has been intellectually processed, and the individual is displaying motor behaviors.

psychomotor retardation. Extreme slowdown of physical movements. Posture slumps; speech is slowed; digestion becomes sluggish. Common in severe depression.

psychophysiological. Referring to psychological factors contributing to the initiation or exacerbation of a physical condition. Either a demonstrable organic pathology or a known pathophysiological process is involved.

psychosis. A mental state in which there is a severe loss of contact with reality. Symptoms may include delusions, hallucinations, disorganized speech patterns, and bizarre or catatonic behaviors.

psychosomatic. See **psychophysiological.**

psychotic disorder. A serious psychiatric disorder in which there is a gross disorganization of the

personality, a marked disturbance in reality testing, and the impairment of interpersonal functioning and relationship to the external world.

psychotropic medication. Medication that affects psychic function, behavior, or experience.

public distance. Appropriate interactional distance for speaking in public or yelling to someone some distance away. U.S. culture defines this distance as 12 feet or more.

purging. The act of attempting to rid the body of calories by self-induced vomiting or excessive use of laxatives or diuretics.

purpose. A foundational principle in the recovery model which stresses that recovery is facilitated when an individual is able to find purpose and meaning in life.

pyromania. An inability to resist the impulse to set fires.

Q

qi. In Chinese medicine, the healing energy that flows through pathways in the body called *meridians.* (Also called "chi.")

R

rape. The expression of power and dominance by means of sexual violence, most commonly by men over women, although men may also be rape victims. Rape is considered an act of aggression, not of passion.

rapport. The development between two people in a relationship of special feelings based on mutual acceptance, warmth, friendliness, common interest, a sense of trust, and a nonjudgmental attitude.

rationalization. Attempting to make excuses or formulate logical reasons to justify unacceptable feelings or behaviors.

reaction formation. Preventing unacceptable or undesirable thoughts or behaviors from being expressed by exaggerating opposite thoughts or types of behaviors.

receptor sites. Molecules that are situated on the cell membrane of the postsynaptic neuron that will accept only molecules with a complementary shape. These complementary molecules are specific to certain neurotransmitters that determine whether an electrical impulse will be excited or inhibited.

reciprocal inhibition. Also called counterconditioning, this technique serves to decrease or eliminate a behavior by introducing a more adaptive behavior, but one that is incompatible with the unacceptable behavior (e.g., introducing relaxation techniques to an anxious person; relaxation and anxiety are incompatible behaviors).

reframing. Changing the conceptual or emotional setting or viewpoint in relation to which a situation is experienced and placing it in another frame that fits the "facts" of the same concrete situation equally well or even better, and thereby changing its entire meaning. The behavior may not actually change, but the consequences of the behavior may change because of a change in the meaning attached to the behavior.

regression. A retreat to an earlier level of development and the comfort measures associated with that level of functioning.

relaxation. A decrease in tension or intensity, resulting in refreshment of body and mind. A state of refreshing tranquility.

religion. A set of beliefs, values, rites, and rituals adopted by a group of people. The practices are usually grounded in the teachings of a spiritual leader.

religiosity. Excessive demonstration of or obsession with religious ideas and behavior; common in schizophrenia.

reminiscence therapy. A process of life review by elderly individuals that promotes self-esteem and provides assistance in working through unresolved conflicts from the past.

repression. The involuntary blocking of unpleasant feelings and experiences from one's awareness.

residual stimuli. Certain beliefs, attitudes, experiences, or traits that may contribute to an individual's low self-esteem.

retrograde ejaculation. Ejaculation of the seminal fluid backwards into the bladder; may occur as a side effect of antipsychotic medications.

right. That which an individual is entitled (by ethical, legal, or moral standards) to have, or to do, or to receive from others within the limits of the law.

rigid boundaries. A person with rigid boundaries is "closed" and difficult to bond with. Such a person has a narrow perspective on life, sees things one way, and cannot discuss matters that lie outside his or her perspective.

ritualistic behavior. Purposeless activities that an individual performs repeatedly in an effort to decrease anxiety (e.g., hand washing); common in obsessive-compulsive disorder.

S

safe house or shelter. An establishment set up by many cities to provide protection for battered women and their children.

scapegoating. Occurs when hostility exists in a marriage dyad and an innocent third person (usually a child) becomes the target of blame for the problem.

schemas (also called *core beliefs*). Cognitive structures that consist of the individual's fundamental beliefs and assumptions, which develop early in life from personal experiences and identification

with significant others. These concepts are reinforced by further learning experiences and in turn, influence the formation of other beliefs, values, and attitudes.

schizotypal personality disorder. A disorder characterized by odd and eccentric behavior, not decompensating to the level of schizophrenia.

secondary gain. The receipt of positive reinforcement for somaticizing through added attention, sympathy, and nurturing.

secondary NCD. Neurocognitive disorder (NCD) that is caused by or related to another disease or condition, such as HIV disease or a cerebral trauma.

secondary prevention. Health care that is directed at reduction of the prevalence of psychiatric illness by shortening the course (duration) of the illness. This is accomplished through early identification of problems and prompt initiation of treatment.

selective abstraction (sometimes referred to as "mental filter"). A type of thinking in which a conclusion is drawn based on only a selected portion of the evidence.

self-concept. The composite of beliefs and feelings that one holds about oneself at a given time, formed from perceptions of others' reactions. The self-concept consists of the physical self, or body image; the personal self or identity; and the self-esteem.

self-consistency. The component of the personal identity that strives to maintain a stable self-image.

self-esteem. The degree of regard or respect that individuals have for themselves. It is a measure of worth that they place on their abilities and judgments.

self-ideal. The component of the personal identity that is the individual's perception of what he or she wants to be, to do, or to become.

sensate focus. A therapeutic technique used to treat individuals and couples with sexual dysfunction. The technique involves touching and being touched by another and focusing attention on the physical sensations encountered thereby. Clients gradually move through various levels of sensate focus that progress from nongenital touching to touching that includes the breasts and genitals; touching done in a simultaneous, mutual format rather than by one person at a time; and touching that extends to and allows eventually for the possibility of intercourse.

serotonin syndrome. A syndrome of symptoms related to excessive levels of serotonin in the body as a result of certain drugs or drug interactions. Symptoms may include diarrhea, nausea, vomiting, tremors, headache, agitation, restlessness, diaphoresis, and in severe cases, muscle rigidity, high fever, irregular heartbeat, seizures, unconsciousness and death, if left untreated.

sexual assault nurse examiner (SANE). A clinical forensic registered nurse who has received specialized training to provide care to the sexual assault victim.

sexual exploitation of a child. The inducement or coercion of a child into engaging in sexually explicit conduct for the purpose of promoting any performance (e.g., child pornography).

sexual masochism disorder. Sexual stimulation derived from being humiliated, beaten, bound, or otherwise made to suffer.

sexual sadism disorder. Recurrent urges and sexually arousing fantasies involving acts (real, not simulated) in which the psychological or physical suffering (including humiliation) of the victim is sexually exciting.

sexuality. Sexuality is the constitution and life of an individual relative to characteristics regarding intimacy. It reflects the totality of the person and does not relate exclusively to the sex organs or sexual behavior.

shaman. A medicine man (or woman) who uses a variety of practices which may include healing ceremonies, herbs, crystals, and other remedies with healing properties.

shaping. In learning, one shapes the behavior of another by giving reinforcements for increasingly closer approximations to the desired behavior.

shelters. A variety of places designed to help the homeless, ranging from converted warehouses that provide cots or floor space on which to sleep overnight to significant operations that provide a multitude of social and health-care services.

shiva. In the Jewish-American culture, following the death of a loved one, *shiva* is the 7-day period following the burial. During this time, mourners do not work, and no activity is permitted that diverts attention from thinking about the deceased.

short-term memory. The ability to remember events that occurred very recently. This ability deteriorates with age.

silent rape reaction. The response of a rape victim in which he or she tells no one about the assault.

slander. An action with which an individual may be charged for orally sharing information that is detrimental to a person's reputation.

social distance. The distance considered acceptable in interactions with strangers or acquaintances, such as at a cocktail party or in a public building. U.S. culture defines this distance as 4 to 12 feet.

social phobia. The fear of being humiliated in social situations.

social skills training. Educational opportunities through role play for the person with schizophrenia to learn appropriate social interaction skills and functional skills that are relevant to daily living.

Socratic questioning (also called *guided discovery*)**.** When the therapist questions the client with Socratic questioning, the client is asked to describe feelings associated with specific situations. Questions are stated in a way that may stimulate in the client a recognition of possible dysfunctional thinking and produce a dissonance about the validity of the thoughts.

somatization. A method of coping with psychosocial stress by developing physical symptoms.

specific phobia. A persistent fear of a specific object or situation, other than the fear of being unable to escape from a situation (agoraphobia) or the fear of being humiliated in social situations (social phobia).

spirituality. The human quality that gives meaning and sense of purpose to an individual's existence. Spirituality exists within each individual regardless of belief system and serves as a force for interconnectedness between the self and others, the environment, and a higher power.

splitting. A primitive ego defense mechanism in which the person is unable to integrate and accept both positive and negative feelings. In the view of these individuals, people—including themselves—and life situations are either all good or all bad. This trait is common in borderline personality disorder.

statutory law. A law that has been enacted by legislative bodies, such as a county or city council, state legislature, or the U.S. Congress.

statutory rape. Unlawful intercourse between a person who is over the age of consent and a person who is under the age of consent. Legal age of consent varies from state to state. An individual can be arrested for statutory rape even when the interaction has occurred between consenting individuals.

stereotyping. The process of classifying all individuals from the same culture or ethnic group as identical.

stimulus. In classical conditioning, that which elicits a response.

stimulus generalization. The process by which a conditioned response is elicited from all stimuli *similar* to the one from which the response was learned.

store-front clinics. Establishments that have been converted into clinics that serve the homeless population.

stress. A state of disequilibrium that occurs when there is a disharmony between demands occurring within an individual's internal or external environment and his or her ability to cope with those demands.

stress management. Various methods used by individuals to reduce tension and other maladaptive responses to stress in their lives; includes relaxation exercises, physical exercise, music, mental imagery, or any other technique that is successful for a person.

stressor. A demand from within an individual's internal or external environment that elicits a physiological and/or psychological response.

sublimation. The rechanneling of personally and/or socially unacceptable drives or impulses into activities that are more tolerable and constructive.

subluxation. The term used in chiropractic medicine to describe vertebrae in the spinal column that have become displaced, possibly pressing on nerves and interfering with normal nerve transmission.

substance abuse. Use of psychoactive drugs that poses significant hazards to health and interferes with social, occupational, psychological, or physical functioning.

substance addiction. Physical addiction is identified by the inability to stop using a substance despite attempts to do so; a continual use of the substance despite adverse consequences; a developing tolerance; and the development of withdrawal symptoms upon cessation or decreased intake. Psychological addiction is said to exist when a substance is perceived by the user to be necessary to maintain an optimal state of personal well-being, interpersonal relations, or skill performance.

substitution therapy. The use of various medications to decrease the intensity of symptoms in an individual who is withdrawing from, or experiencing the effects of excessive use of, substances.

subsystems. The smaller units of which a system is composed. In family systems theory, the subsystems are composed of husband-wife, parent-child(ren), or sibling-sibling.

sundowning. A phenomenon in neurocognitive disorder (NCD) in which the symptoms seem to worsen in the late afternoon and evening.

superego. One of the three elements of the personality identified by Freud that represents the conscience and the culturally determined restrictions that are placed on an individual.

suppression. The voluntary blocking from one's awareness of unpleasant feelings and experiences.

surrogate. One who serves as a substitute figure for another.

symbiotic relationship. A type of "psychic fusion" that occurs between two people; it is unhealthy in that severe anxiety is generated in either or both if

separation is indicated. A symbiotic relationship is normal between infant and mother.

sympathy. The actual sharing of another's thoughts and behaviors. Differs from **empathy** in that with empathy one experiences an objective understanding of what another is feeling, rather than actually sharing those feelings.

synapse. The junction between two neurons. The small space between the axon terminals of one neuron and the cell body or dendrites of another is called the synaptic cleft.

systematic desensitization. A treatment for phobias in which the individual is taught to relax and then asked to imagine various components of the phobic stimulus on a graded hierarchy, moving from that which produces the least fear to that which produces the most.

T

tangentiality. The inability to get to the point of a story. The speaker introduces many unrelated topics, until the original topic of discussion is lost.

tardive dyskinesia. Syndrome of symptoms characterized by bizarre facial and tongue movements, a stiff neck, and difficulty swallowing. It may occur as an adverse effect of long-term therapy with some antipsychotic medications.

technical expert. Peplau's term for one who understands various professional devices and possesses the clinical skills necessary to perform the interventions that are in the best interest of the client.

temperament. A set of inborn personality characteristics that influence an individual's manner of reacting to the environment, and ultimately influences his or her developmental progression.

territoriality. The innate tendency of individuals to own space. Individuals lay claim to areas around them as their own. This phenomenon can have an influence on interpersonal communication.

tertiary gain. The receipt of positive reinforcement for somaticizing by causing the focus of the family to switch to the individual and away from conflict that may be occurring within the family.

tertiary prevention. Health care that is directed toward reduction of the residual effects associated with severe or chronic physical or mental illness.

therapeutic communication. Caregiver verbal and nonverbal techniques that focus on the care receiver's needs and advance the promotion of healing and change. Therapeutic communication encourages exploration of feelings and fosters understanding of behavioral motivation. It is nonjudgmental, discourages defensiveness, and promotes trust.

therapeutic community. Also called *milieu therapy*, this approach strives to manipulate the environment so that all aspects of the client's hospital experience are considered therapeutic.

therapeutic group. Differs from group therapy in that there is a lesser degree of theoretical foundation. Focus is on group relations, interactions between group members, and the consideration of a selected issue. Leaders of therapeutic groups do not require the degree of educational preparation required of group therapy leaders.

therapeutic relationship. An interaction between two people (usually a caregiver and a care receiver) in which input from both participants contributes to a climate of healing, growth promotion, and/or illness prevention.

thought-stopping. A self-taught technique that an individual uses each time he or she wishes to eliminate intrusive or negative, unwanted thoughts from awareness.

Tidal model. A recovery focused treatment approach in which the individual is encouraged to tell their story and take an active role in deciding what changes need to occur to promote recovery.

time out. An aversive stimulus or punishment during which the individual is removed from the environment where the unacceptable behavior is being exhibited.

token economy. In behavior modification, a type of contracting in which the reinforcers for desired behaviors are presented in the form of tokens, which may then be exchanged for designated privileges.

tolerance. The need for increasingly larger or more frequent doses of a substance in order to obtain the desired effects originally produced by a lower dose.

tort. The violation of a civil law in which an individual has been wronged. In a tort action, one party asserts that wrongful conduct on the part of the other has caused harm, and compensation for harm suffered is sought.

transcendence. Erikson's last developmental stage (added in the 1990's), following the stage of integrity versus despair, in which the individual develops a broader world view that transcends oneself and enhances one's sense of meaning and purpose in life.

transference. Transference occurs when a client unconsciously displaces (or "transfers") to the nurse or therapist feelings formed toward a person from his or her past.

transgender. The individual, despite having the anatomical characteristics of a given gender, has the self-perception of being of the opposite gender, and may seek to have gender changed through surgical intervention.

transvestic disorder. Recurrent urges and sexually arousing fantasies involving dressing in the clothes of the opposite gender.

triangles. A three-person emotional configuration that is considered the basic building block of the family system. When anxiety becomes too great between two family members, a third person is brought in to form a triangle. Triangles are dysfunctional in that they offer relief from anxiety through diversion rather than through resolution of the issue.

trichotillomania (hair-pulling disorder). The recurrent failure to resist impulses to pull out one's own hair.

type A personality. The personality characteristics attributed to individuals prone to coronary heart disease, including excessive competitive drive, chronic sense of time urgency, easy anger, aggressiveness, excessive ambition, and inability to enjoy leisure time.

type B personality. The personality characteristics attributed to individuals who are not prone to coronary heart disease; includes characteristics such as ability to perform even under pressure but without the competitive drive and constant sense of time urgency experienced by the type A personality. Type Bs can enjoy their leisure time without feeling guilty, and they are much less impulsive than type A individuals; that is, they think things through before making decisions.

type C personality. The personality characteristics attributed to the cancer-prone individual. Includes characteristics such as suppression of anger, calm, passive, puts the needs of others before his or her own, but holds resentment toward others for perceived "wrongs."

type D personality. Personality characteristics attributed to individuals who are at increased risk of cardiovascular morbidity and mortality. The characteristics include a combination of negative emotions and social inhibition.

tyramine. An amino acid found in aged cheeses or other aged, overripe, and fermented foods; broad beans; pickled herring; beef or chicken liver; preserved meats; beer and wine; yeast products; chocolate; caffeinated drinks; canned figs; sour cream; yogurt; soy sauce; and some over-the-counter cold medications and diet pills. If foods high in tyramine content are consumed while an individual is taking MAO inhibitors, a potentially life-threatening syndrome called hypertensive crisis can result.

U

unconditional positive regard. Carl Rogers's term for the respect and dignity of an individual regardless of his or her unacceptable behavior.

unconditioned response. In classical conditioning, an unconditioned response refers to a reflexive response to a specific target stimulus.

unconditioned stimulus. In classical conditioning, a specific stimulus that elicits an unconditioned, reflexive response.

undoing. A mechanism used to symbolically negate or cancel out a previous action or experience that one finds intolerable.

universality. One therapeutic factor of groups (identified by Yalom) in which individuals realize that they are not alone in a problem and in the thoughts and feelings they are experiencing. Anxiety is relieved by the support and understanding of others in the group who share similar experiences.

utilitarianism. The ethical theory that espouses "the greatest happiness for the greatest number." Under this theory, action would be taken based on the end results that will produce the most good (happiness) for the most people.

V

values. Personal beliefs about the truth, beauty, or worth of a thought, object, or behavior, that influence an individual's actions.

values clarification. A process of self-discovery by which people identify their personal values and their value rankings. This process increases awareness about why individuals behave in certain ways.

velorio. In Mexican culture, following the death of a loved one, the *velorio* is a festive watch by family and friends over the body of the deceased person before burial.

veracity. An ethical principle that refers to one's duty to always be truthful.

voyeuristic disorder. Recurrent urges and sexually arousing fantasies involving the act of observing unsuspecting people, usually strangers, who are either naked, in the process of disrobing, or engaging in sexual activity.

W

waxy flexibility. A condition by which the individual with schizophrenia passively yields all movable parts of the body to any efforts made at placing them in certain positions.

Wernicke's encephalopathy. A brain disorder caused by thiamine deficiency and characterized by visual disturbances, ataxia, somnolence, stupor, and, without thiamine replacement, death.

withdrawal. The physiological and mental readjustment that accompanies the discontinuation of an addictive substance.

word salad. A group of words that are put together in a random fashion without any logical connection.

WRAP model (Wellness Recovery Action Plan). A recovery model that focuses on developing a system for monitoring distressing symptoms and planned responses to minimize or eliminate distress.

<div align="center">

Y

</div>

yin and yang. The fundamental concept of Asian health practices. Yin and yang are opposite forces of energy such as negative/positive, dark/light, cold/hot, hard/soft, and feminine/masculine. Food, medicines, and herbs are classified according to their yin and yang properties and are used to restore a balance, thereby restoring health.

yoga. A system of beliefs and practices, the ultimate goal of which is to unite the human soul with the universal spirit. In Western countries, yoga uses body postures, along with meditation and breathing exercises, to achieve a balanced, disciplined workout that releases muscle tension, tones the internal organs, and energizes the mind, body, and spirit, so that natural healing can occur.

Examples of Answers to Communication Exercises

Chapter 13. Crisis Intervention

1. "I'll try to help you to the best of my ability. Please tell me what is upsetting you." Establish rapport, convey respect, and assess precipitating events.
2. "Hi Shelley, my name is Mrs. Smith, and I am a registered nurse here to help you. I'm so glad you came in to seek help. I'd like to ask you some questions about the events you've experienced. All right?" (Convey respect, provide reassurance of help, and empower the client to be involved in decision-making.)
3. "Thomas, last evening you became very upset, stating you thought the FBI was trying to kill you, and you struck another patient." (Giving information.) "Do you remember any of those events?" (Assessing the patient's perception and memory.) "Restraint is an intervention that we only use when other efforts have failed to protect your safety and the safety of others." (Giving information.) "Let's talk about what you think would be helpful in preventing that from happening again." (Formulating a plan, empowering the client to be involved in problem-solving.)

Chapter 17. Suicide Prevention

1. "Mr. J., it sounds like you have been feeling hopeless; this is a common symptom of depression." (Giving information.) "Have you been having any thoughts of taking your own life?" (Closed-ended, directive questioning to assess for the presence of suicide ideation.)
2. Communication at this point should be focused on thorough assessment of Mr. J.'s expressed suicide ideas. Assessment questions include (but are not comprehensive): "When you have these ideas, do you have a plan in mind?" "How strong is your intention to die?" "Do you have access to the means for implementing this plan?"
3. "It sounds like you are grieving. That must be very painful. Tell me more about your experience and feelings related to losing your wife." (Empathy, exploring and encouraging description.)

Chapter 21. The Recovery Model

1. Because inability to sit still may be a side effect of many antipsychotic medications, one response is to assess the client's medications, assess the client's symptoms, and educate him about akathisia as appropriate. This response supports the principle that recovery should empower the client to make informed decisions through providing information and resources. Asking the client how he wishes to proceed supports the principle that recovery is person-driven.
   For example:
   "Joshua, I see that you are taking Thorazine, and the inability to sit still may be a side effect of this medication. There are other medications that will treat your symptoms and that don't have the same risk for this side effect. Would you like to explore these options further?"
2. Using the recovery model principles of respect and the importance of support through peers and allies, one possible response may be, "Kelly, I haven't been in an active combat situation, but I hope to earn your trust as a mental health professional and try to understand, to the best of my ability, the issues you've been struggling with. Many veterans identify, as you have, that fellow veterans are better able to provide ongoing support with an appreciation for the shared experiences you've endured. Are you interested in exploring some of those options, too?"

Chapter 22. Neurocognitive Disorders

1. "Mrs. B., you are not in a restaurant. This is the General Hospital. I am your nurse, Mary. How may I help you?" (Reality orientation.)
2. "Mrs. B., you have already eaten your breakfast. Would you like a snack?"
   "Please tell me what it was like when you lived on the farm." (Reminiscing.)

Chapter 23. Substance-Related and Addictive Disorders

1. "Tom, you are here because it has been determined that drinking alcohol is causing problems for you at home and at your work." (Confronting reality.)

2. "Tom, you are experiencing symptoms related to your body's withdrawal from alcohol. When did you have your last drink?" (Confrontation with caring.)

3. "You are feeling angry toward your boss and your wife, but your drinking is apparently interfering with your job and your marriage. Unless you abstain from alcohol, you are at risk of losing both." (Confronting reality.)

Chapter 24. Schizophrenia Spectrum and Other Psychotic Disorders

1. "I know that you believe what you are saying is true, but I find it very hard to accept." (Voicing doubt.)
"Please understand that you are safe here." (Reassurance of safety.)

2. The nurse should slowly and carefully approach Hal so that he is not startled by his or her presence. "Hal, are you hearing the voices again? What do you hear the voices saying to you?" (Encouraging description of perceptions. This type of information may help to protect the client and others from potential violence associated with command hallucinations.)
"I know the voices seem real to you, but I do not hear any voices speaking." (Presenting reality.)

3. "I don't understand what you are saying, Hal. What message do you want to give me? Might you be telling me that you are lonely?" (Seeking clarification; attempting to translate words into feelings.)

Chapter 25. Depressive Disorders

1. "You have had a lot of losses. You are feeling very much alone right now." (Verbalizing the implied.)

2. "You feel sad because you can no longer do the things that you used to do . . . the things that made you feel good about yourself." (Statement that focuses on feelings.)

3. Direct questions assessing suicide potential: "Are you or have you been thinking about harming yourself? Do you have a plan for doing so? Have you ever acted on that plan?"
Demonstrations of genuine concern and caring: "I care about you, Carrie. I will stay here with you."
Expressions of empathy: "It must be frightening to feel so all alone. But you are not alone. There are many people who care about you, and I am one of those people."

Chapter 26. Bipolar and Related Disorders

1. "Bob, I'm not sure I understand what you are saying. Are your thoughts racing?" (Clarifying, assessing.)

2. "John, I have an activity in the next room that I could use your help with. Would you please come with me?" (Offering an alternative activity, redirecting, reducing stimulation.)

Chapter 27. Anxiety, Obsessive-Compulsive, and Related Disorders

1. "John, I'd like to check your vital signs and then discuss how I can best help you feel more comfortable." (Giving information, physical assessment is a priority. Informing the client about nursing intervention with a matter-of-fact approach may facilitate anxiety reduction; offering self.)

2. "Often, when people become very anxious, they develop irrational thinking patterns that contribute to worsening their mood and impacting their behavior in negative ways. By becoming aware of thought patterns that increase your anxiety you can learn how to replace those automatic thoughts with more rational patterns in a way that improves your mood symptoms and behavior." (Giving information. The nurse in this example provides information and identifies how that is relevant to the client's recovery.)

Chapter 30. Issues Related to Human Sexuality and Gender Dysphoria

1. "Are you having thoughts of taking your own life?" (Assessment for suicide ideation and intentions are the priority because Jamie has expressed feeling that he wants to die.)

2. "I'd be glad to discuss with you the benefits and disadvantages of this option. What do you already know about hormone treatments?" (Conveys respect, collaboration, assessment.)

Chapter 31. Eating Disorders

1. "Helena, we've established a treatment plan that limits going to the restroom immediately after a meal because we are trying to help you avoid the urge to purge the food you just ate. Let's talk about how you are feeling right now and see if we can identify some other options for your behaviors before and after meals." (Setting limits, formulating a plan.)

2. "John, many people with this kind of eating disorder report feeling a loss of control, and I understand how that can alter your self-esteem. These are symptoms of an illness with many contributing factors. I want to support you in your efforts to manage this illness, and there is good evidence that recovery is achievable." (Validation of client's feelings, empathy, giving information, offering self.)

Chapter 32. Personality Disorders

1. "My name is Nancy. I am your nurse on this shift, and you will be in my care until 11 p.m. You may ask for me by my name if you have any requests." (Giving information.)

2. "You were arrested because you broke the law." (Confronting reality.)

3. "I do not give out personal information to patients, and I do not go out with patients. I hope that you will be able to get your life straightened out in a positive way." (Confrontation with caring.)

Chapter 35. Survivors of Abuse or Neglect

1. "You are not to blame, Sarah. You do not deserve to be abused in this way. He is responsible for his behavior." (Presenting reality, empathy.)

2. "There are places you can go where you and your children will be safe. I will give you that information." (Giving information.)

"You will need to consider whether you want to press charges against him." (Encouraging formulation of a plan.)

3. "You must consider the safety of yourself and your children. You have the phone number of the Safe House. It is your decision what to do now." (Patient-centered care involves communicating important information and empowering the client to make their own decisions.)

Chapter 37. The Bereaved Individual

1. "I believe we did everything we could to provide care for your husband, and it's so hard to lose someone you love to a terminal illness. I'll stay with you and try to answer any questions you have." (The nurse uses "I" communication to respond assertively with empathy; offering self.)

2. "Yes, John, it's probable that you are in the end stage of life. Let's talk about how to prepare for this." (Giving information; offering self; encouraging formulation of a plan.)

3. "Nancy, those are difficult spiritual questions. Would you like to talk more with the chaplain?" (Verbalizing the implied; formulating a plan.)

Appendix C

Mental Status Assessment

Gathering the correct information about the client's mental status is essential to the development of an appropriate plan of care. The mental status examination is a description of all the areas of the client's mental functioning. The following are the components that are considered critical in the assessment of a client's mental status. Examples of interview questions and criteria for assessment are included.

Identifying Data

1. Name
2. Gender
3. Age
   a. How old are you?
   b. When were you born?
4. Race/culture
   a. What country did you (your ancestors) come from?
5. Occupational/financial status
   a. How do you make your living?
   b. How do you obtain money for your needs?
6. Educational level
   a. What was the highest grade level you completed in school?
7. Significant other
   a. Are you married?
   b. Do you have a significant relationship with another person?
8. Living arrangements
   a. Do you live alone?
   b. With whom do you share your home?
9. Religious preference
   a. Do you have a religious preference?
10. Allergies
    a. Are you allergic to anything?
    b. Foods? Medications?
11. Special diet considerations
    a. Do you have any special diet requirements?
    b. Diabetic? Low sodium?
12. Chief complaint
    a. For what reason did you come for help today?
    b. What seems to be the problem?
13. Medical diagnosis

General Description

Appearance

1. Grooming and dress
   a. Note unusual modes of dress.
   b. Evidence of soiled clothing?
   c. Use of makeup?
   d. Neat; unkempt?
2. Hygiene
   a. Note evidence of body or breath odor.
   b. Note condition of skin, fingernails.
3. Posture
   a. Note if standing upright, rigid, slumped over.
4. Height and weight
   a. Perform accurate measurements.
5. Level of eye contact
   a. Intermittent?
   b. Occasional and fleeting?
   c. Sustained and intense?
   d. No eye contact?
6. Hair color and texture
   a. Is hair clean and healthy-looking?
   b. Greasy, matted, tangled?
7. Evidence of scars, tattoos, or other distinguishing skin marks
   a. Note any evidence of swelling or bruises.
   b. Birth marks?
   c. Rashes?
8. Evaluation of client's appearance compared with chronological age

Motor Activity

1. Tremors
   a. Do hands or legs tremble?
      • Continuously?
      • At specific times?
2. Tics or other stereotypical movements
   a. Any evidence of facial tics?
   b. Jerking or spastic movements?
3. Mannerisms and gestures
   a. Specific facial or body movements during conversation?
   b. Nail biting?
   c. Covering face with hands?
   d. Grimacing?

4. Hyperactivity
   a. Gets up and down out of chair.
   b. Paces.
   c. Unable to sit still.
5. Restlessness or agitation
   a. Lots of fidgeting.
   b. Clenching hands.
6. Aggressiveness
   a. Overtly angry and hostile.
   b. Threatening.
   c. Uses sarcasm.
7. Rigidity
   a. Sits or stands in a rigid position.
   b. Arms and legs appear stiff and unyielding.
8. Gait patterns
   a. Any evidence of limping?
   b. Limitation of range of motion?
   c. Ataxia?
   d. Shuffling?
9. Echopraxia
   a. Evidence of mimicking the actions of others?
10. Psychomotor retardation
    a. Movements are very slow.
    b. Thinking and speech are very slow.
    c. Posture is slumped.
11. Freedom of movement (range of motion)
    a. Note any limitation in ability to move.

Speech Patterns

1. Slowness or rapidity of speech
   a. Note whether speech seems very rapid or slower than normal.
2. Pressure of speech
   a. Note whether speech seems frenzied.
   b. Unable to be interrupted?
3. Intonation
   a. Are words spoken with appropriate emphasis?
   b. Are words spoken in monotone, without emphasis?
4. Volume
   a. Is speech very loud? Soft?
   b. Is speech low-pitched? High-pitched?
5. Stuttering or other speech impairments
   a. Hoarseness?
   b. Slurred speech?
6. Aphasia
   a. Difficulty forming words.
   b. Use of incorrect words.
   c. Difficulty thinking of specific words.
   d. Making up words (neologisms).

General Attitude

1. Cooperative/uncooperative
   a. Answers questions willingly.
   b. Refuses to answer questions.
2. Friendly/hostile/defensive
   a. Is sociable and responsive.
   b. Is sarcastic and irritable.
3. Uninterested/apathetic
   a. Refuses to participate in interview process.
4. Attentive/interested
   a. Actively participates in interview process.
5. Guarded/suspicious
   a. Continuously scans the environment.
   b. Questions motives of interviewer.
   c. Refuses to answer questions.

Emotions

Mood

1. Depressed; despairing
   a. An overwhelming feeling of sadness.
   b. Loss of interest in regular activities.
2. Irritable
   a. Easily annoyed and provoked to anger.
3. Anxious
   a. Demonstrates or verbalizes feeling of apprehension.
4. Elated
   a. Expresses feelings of joy and intense pleasure.
   b. Is intensely optimistic.
5. Euphoric
   a. Demonstrates a heightened sense of elation.
   b. Expresses feelings of grandeur ("Everything is wonderful!").
6. Fearful
   a. Demonstrates or verbalizes feeling of apprehension associated with real or perceived danger.
7. Guilty
   a. Expresses a feeling of discomfort associated with real or perceived wrongdoing.
   b. May be associated with feelings of sadness and despair.
8. Labile
   a. Exhibits mood swings that range from euphoria to depression or anxiety.

Affect

1. Congruence with mood
   a. Outward emotional expression is consistent with mood (e.g., if depressed, emotional expression is sadness, eyes downcast, may be crying).
2. Constricted or blunted
   a. Minimal outward emotional expression is observed.
3. Flat
   a. There is an absence of outward emotional expression.

4. Appropriate
   a. The outward emotional expression is what would be expected in a certain situation (e.g., crying upon hearing of a death).
5. Inappropriate
   a. The outward emotional expression is incompatible with the situation (e.g., laughing upon hearing of a death).

Thought Processes

Form of Thought

1. Flight of ideas
   a. Verbalizations are continuous and rapid, and flow from one to another.
2. Associative looseness
   a. Verbalizations shift from one unrelated topic to another.
3. Circumstantiality
   a. Verbalizations are lengthy and tedious, and because of numerous details, are delayed reaching the intended point.
4. Tangentiality
   a. Verbalizations that are lengthy and tedious, and never reach an intended point.
5. Neologisms
   a. The individual is making up nonsensical-sounding words, which only have meaning to him or her.
6. Concrete thinking
   a. Thinking is literal; elemental.
   b. Absence of ability to think abstractly.
   c. Unable to translate simple proverbs.
7. Clang associations
   a. Speaking in puns or rhymes; using words that sound alike but have different meanings.
8. Word salad
   a. Using a mixture of words that have no meaning together; sounding incoherent.
9. Perseveration
   a. Persistently repeating the last word of a sentence spoken to the client (e.g., Nurse: "George, it's time to go to lunch." George: "lunch, lunch, lunch, lunch").
10. Echolalia
    a. Persistently repeating what another person says.
11. Mutism
    a. Does not speak (either cannot or will not).
12. Poverty of speech
    a. Speaks very little; may respond in monosyllables.
13. Ability to concentrate and disturbance of attention
    a. Does the person hold attention to the topic at hand?
    b. Is the person easily distractible?
    c. Is there selective attention (e.g., blocks out topics that create anxiety)?

Content of Thought

1. Delusions (Does the person have unrealistic ideas or beliefs?)
   a. Persecutory: A belief that someone is out to get him or her in some way (e.g., "The FBI will be here at any time to take me away").
   b. Grandiose: An idea that he or she is all-powerful or of great importance (e.g., "I am the king—and this is my kingdom! I can do anything!").
   c. Reference: An idea that whatever is happening in the environment is about him or her (e.g., "Just watch the movie on TV tonight. It is about my life").
   d. Control or influence: A belief that his or her behavior and thoughts are being controlled by external forces (e.g., "I get my orders from Channel 27. I do only what the forces dictate").
   e. Somatic: A belief that he or she has a dysfunctional body part (e.g., "My heart is at a standstill. It is no longer beating").
   f. Nihilistic: A belief that he or she, or a part of the body, or even the world does not exist or has been destroyed (e.g., "I am no longer alive").
2. Suicidal or homicidal ideas
   a. Is the individual expressing ideas of harming self or others?
   b. Does the individual express plans and intentions to die? Or plans and intentions to harm another?
3. Obsessions
   a. Is the person verbalizing about a persistent thought or feeling that he or she is unable to eliminate from their consciousness?
4. Paranoia/suspiciousness
   a. Continuously scans the environment.
   b. Questions motives of interviewer.
   c. Refuses to answer questions.
5. Magical thinking
   a. Is the person speaking in a way that indicates his or her words or actions have power? (e.g., "If you step on a crack, you break your mother's back!")
6. Religiosity
   a. Is the individual demonstrating obsession with religious ideas and behavior?
7. Phobias
   a. Is there evidence of irrational fears (of a specific object, or a social situation)?
8. Poverty of content
   a. Is little information conveyed by the client because of vagueness or stereotypical statements or clichés?

Perceptual Disturbances

1. Hallucinations (Is the person experiencing unrealistic sensory perceptions?)
   a. Auditory (Is the individual hearing voices or other sounds that do not exist?)
   b. Visual (Is the individual seeing images that do not exist?)
   c. Tactile (Does the individual feel unrealistic sensations on the skin?)
   d. Olfactory (Does the individual smell odors that do not exist?)
   e. Gustatory (Does the individual have a false perception of an unpleasant taste?)
2. Illusions
   a. Does the individual misperceive or misinterpret real stimuli within the environment? (Sees something and thinks it is something else?)
3. Depersonalization (altered perception of the self)
   a. The individual verbalizes feeling "outside the body;" visualizing him- or herself from afar.
4. Derealization (altered perception of the environment)
   a. The individual verbalizes that the environment feels "strange or unreal." A feeling that the surroundings have changed.

Sensorium and Cognitive Ability

1. Level of alertness/consciousness
   a. Is the individual clear-minded and attentive to the environment?
   b. Or is there disturbance in perception and awareness of the surroundings?
2. Orientation. Is the person oriented to the following?
   a. Time.
   b. Place.
   c. Person.
   d. Circumstances.

3. Memory
   a. Recent (Is the individual able to remember occurrences of the past few days?)
   b. Remote (Is the individual able to remember occurrences of the distant past?)
   c. Confabulation (Does the individual fill in memory gaps with experiences that have no basis in fact?)
4. Capacity for abstract thought
   a. Can the individual interpret proverbs correctly?
      • "What does 'no use crying over spilled milk' mean?"

Impulse Control

1. Ability to control impulses. (Does psychosocial history reveal problems with any of the following?)
   a. Aggression.
   b. Hostility.
   c. Fear.
   d. Guilt.
   e. Affection.
   f. Sexual feelings.

Judgment and Insight

1. Ability to solve problems and make decisions
   a. What are your plans for the future?
   b. What do you plan to do to reach your goals?
2. Knowledge about self
   a. Awareness of limitations.
   b. Awareness of consequences of actions.
   c. Awareness of illness.
      • "Do you think you have a problem?"
      • "Do you think you need treatment?"
3. Adaptive/maladaptive use of coping strategies and ego defense mechanisms (e.g., rationalizing maladaptive behaviors, projection of blame, displacement of anger)

Appendix D

DSM-5 Classification: Categories and Codes*

International Classification of Diseases, 10th revision, Clinical Modification (ICD-10-CM) codes are provided.

Neurodevelopmental Disorders

Intellectual Disabilities

	Intellectual Disability (Intellectual Developmental Disorder)
	Specify current severity:
70	Mild
71	Moderate
72	Severe
73	Profound
F88	Global Developmental Delay
F79	Unspecified Intellectual Disability (Intellectual Developmental Disorder)

Communication Disorders

F80.9	Language Disorder
F80.0	Speech Sound Disorder
F80.81	Childhood-Onset Fluency Disorder (Stuttering) Note: Later-onset cases are diagnosed as F98.5 adult-onset fluency disorder.
F80.89	Social (Pragmatic) Communication Disorder
F80.9	Unspecified Communication Disorder

Autism Spectrum Disorder

F84.0	Autism Spectrum Disorder *Specify* if: Associated with a known medical or genetic condition or environmental factor; Associated with another neurodevelopmental, mental, or behavioral disorder *Specify* current severity for Criterion A and Criterion B: Requiring very substantial support, Requiring substantial support, Requiring support *Specify* if: With or without accompanying intellectual impairment, With or without accompanying language impairment, With catatonia (use additional code F06.1)

Attention-Deficit/Hyperactivity Disorder

	Attention-Deficit/Hyperactivity Disorder
	Specify whether:
F90.2	Combined presentation
F90.0	Predominantly inattentive presentation
F90.1	Predominantly hyperactive/impulsive presentation
	Specify if: In partial remission
	Specify current severity: Mild, Moderate, Severe
F90.8	Other Specified Attention-Deficit/Hyperactivity Disorder
F90.9	Unspecified Attention-Deficit/Hyperactivity Disorder

Specific Learning Disorder

	Specific Learning Disorder
	Specify if:
F81.0	With impairment in reading (*specify* if with word reading accuracy, reading rate or fluency, reading comprehension)
F81.81	With impairment in written expression (*specify* if with spelling accuracy, grammar and punctuation accuracy, clarity or organization of written expression)
F81.2	With impairment in mathematics (*specify* if with number sense, memorization of arithmetic facts, accurate or fluent calculation, accurate math reasoning)
	Specify current severity: Mild, Moderate, Severe

---

*Reprinted with permission from the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.* (Copyright 2013). American Psychiatric Association.

Motor Disorders

F82	Developmental Coordination Disorder
F98.4	Stereotypic Movement Disorder

Specify if: With self-injurious behavior, Without self-injurious behavior

Specify if: Associated with a known medical or genetic condition, neurodevelopmental disorder, or environmental factor

Specify current severity: Mild, Moderate, Severe

Tic Disorders

F95.2	Tourette's Disorder
F95.1	Persistent (Chronic) Motor or Vocal Tic Disorder

Specify if: With motor tics only, With vocal tics only

F95.0	Provisional Tic Disorder
F95.8	Other Specified Tic Disorder
F95.9	Unspecified Tic Disorder

Other Neurodevelopmental Disorders

F88	Other Specified Neurodevelopmental Disorder
F89	Unspecified Neurodevelopmental Disorder

Schizophrenia Spectrum and Other Psychotic Disorders

The following specifiers apply to Schizophrenia Spectrum and Other Psychotic Disorders where indicated:

[a]*Specify* if: The following course specifiers are only to be used after a 1-year duration of the disorder: First episode, currently in acute episode; First episode, currently in partial remission; First episode, currently in full remission; Multiple episodes, currently in acute episode; Multiple episodes, currently in partial remission; Multiple episodes, currently in full remission; Continuous; Unspecified

[b]*Specify* if: With catatonia (use additional code F06.1)

[c]*Specify* current severity of delusions, hallucinations, disorganized speech, abnormal psychomotor behavior, negative symptoms, impaired cognition, depression, and mania symptoms

F21	Schizotypal (Personality) Disorder
F22	Delusional Disorder[a, c]

Specify whether: Erotomanic type, Grandiose type, Jealous type, Persecutory type, Somatic type, Mixed type, Unspecified type

Specify if: With bizarre content

F23	Brief Psychotic Disorder[b, c]

Specify if: With marked stressor(s), Without marked stressor(s), With postpartum onset

F20.81	Schizophreniform Disorder[b, c]

Specify if: With good prognostic features, Without good prognostic features

F20.9	Schizophrenia[a, b, c]
	Schizoaffective Disorder[a, b, c]

Specify whether:

F25.0	Bipolar type
F25.1	Depressive type
	Substance/Medication-Induced Psychotic Disorder[c]

Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.

Specify if: With onset during intoxication, With onset during withdrawal

Psychotic Disorder Due to Another Medical Condition[c]

Specify whether:

F06.2	With delusions
F06.0	With hallucinations
F06.1	Catatonia Associated With Another Mental Disorder (Catatonia Specifier)
F06.1	Catatonic Disorder Due to Another Medical Condition
F06.1	Unspecified Catatonia

Note: Code first 781.99 (R29.818) other symptoms involving nervous and musculoskeletal systems.

F28	Other Specified Schizophrenia Spectrum and Other Psychotic Disorder
F29	Unspecified Schizophrenia Spectrum and Other Psychotic Disorder

Bipolar and Related Disorders

The following specifiers apply to Bipolar and Related Disorders where indicated:

[a]*Specify*: With anxious distress (*specify* current severity: mild, moderate, moderate-severe, severe); With mixed

features; With rapid cycling; With melancholic features; With atypical features; With mood-congruent psychotic features; With mood incongruent psychotic features; With catatonia (use additional code F06.1); With peripartum onset; With seasonal pattern

	Bipolar I Disorder[a]	
	Current or most recent episode manic	
F31.11	Mild	
F31.12	Moderate	
F31.13	Severe	
F31.2	With psychotic features	
F31.73	In partial remission	
F31.74	In full remission	
F31.9	Unspecified	
F31.0	Current or most recent episode hypomanic	
F31.73	In partial remission	
F31.74	In full remission	
F31.9	Unspecified	
	Current or most recent episode depressed	
F31.31	Mild	
F31.32	Moderate	
F31.4	Severe	
F31.5	With psychotic features	
F31.75	In partial remission	
F31.76	In full remission	
F31.9	Unspecified	
F31.9	Current or most recent episode unspecified	
F31.81	Bipolar II Disorder[a]	

Specify current or most recent episode: Hypomanic, Depressed

Specify course if full criteria for a mood episode are not currently met: In partial remission, In full remission

Specify severity if full criteria for a mood episode are not currently met: Mild, Moderate, Severe

F34.0 Cyclothymic Disorder

Specify if: With anxious distress Substance/Medication-Induced Bipolar and Related Disorder

Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.

Specify if: With onset during intoxication, With onset during withdrawal

Bipolar and Related Disorder Due to Another Medical Condition

Specify if:

F06.33	With manic features
F06.33	With manic- or hypomanic-like episode
F06.34	With mixed features
F31.89	Other Specified Bipolar and Related Disorder
F31.9	Unspecified Bipolar and Related Disorder

Depressive Disorders

The following specifiers apply to Depressive Disorders where indicated:

[a]*Specify*: With anxious distress (*specify* current severity: mild, moderate, moderate-severe, severe); With mixed features; With melancholic features; With atypical features; With mood-congruent psychotic features; With mood-incongruent psychotic features; With catatonia (use additional code F06.1); With peripartum onset; With seasonal pattern

F34.8	Disruptive Mood Dysregulation Disorder
	Major Depressive Disorder[a]
	Single episode
F32.0	Mild
F32.1	Moderate
F32.2	Severe
F32.3	With psychotic features
F32.4	In partial remission
F32.5	In full remission
F32.9	Unspecified
	Recurrent episode
F33.0	Mild
F33.1	Moderate
F33.2	Severe
F33.3	With psychotic features
F33.41	In partial remission
F33.42	In full remission
F33.9	Unspecified
F34.1	Persistent Depressive Disorder (Dysthymia)[a]

Specify if: In partial remission, In full remission

Specify if: Early onset, Late onset

Specify if: With pure dysthymic syndrome; With persistent major depressive episode; With intermittent major depressive episodes, with current episode; With intermittent major

depressive episodes, Without current episode
Specify current severity: Mild, Moderate, Severe

N94.3	Premenstrual Dysphoric Disorder
	Substance/Medication-Induced Depressive Disorder

Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.
Specify if: With onset during intoxication, With onset during withdrawal

Depressive Disorder Due to Another Medical Condition
Specify if:

F06.31	With depressive features
F06.32	With major depressive-like episode
F06.34	With mixed features
F32.8	Other Specified Depressive Disorder
F32.9	Unspecified Depressive Disorder

Anxiety Disorders

F93.0	Separation Anxiety Disorder
F94.0	Selective Mutism
	Specific Phobia
	Specify if:
F40.218	Animal
F40.228	Natural environment
	Blood-injection-injury
F40.230	Fear of blood
F40.231	Fear of injections and transfusions
F40.232	Fear of other medical care
F40.233	Fear of injury
F40.248	Situational
F40.298	Other
F40.10	Social Anxiety Disorder (Social Phobia)
	Specify if: Performance only
F41.0	Panic Disorder
	Panic Attack Specifier
F40.00	Agoraphobia
F41.1	Generalized Anxiety Disorder
	Substance/Medication-Induced Anxiety Disorder

Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.

Specify if: With onset during intoxication, With onset during withdrawal, With onset after medication use

F06.4	Anxiety Disorder Due to Another Medical Condition
F41.9	Unspecified Anxiety Disorder

Obsessive-Compulsive and Related Disorders

The following specifier applies to Obsessive-Compulsive and Related Disorders where indicated:

[a]*Specify* if: With good or fair insight, With poor insight, With absent insight/delusional beliefs

F42	Obsessive-Compulsive Disorder[a]
	Specify if: Tic-related
F45.22	Body Dysmorphic Disorder[a]
	Specify if: With muscle dysmorphia
F42	Hoarding Disorder[a]
	Specify if: With excessive acquisition
F63.3	Trichotillomania (Hair-Pulling Disorder)
L98.1	Excoriation (Skin-Picking) Disorder
	Substance/Medication-Induced Obsessive-Compulsive and Related Disorder

Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-9-CM and ICD-10-CM coding.
Specify if: With onset during intoxication, With onset during withdrawal, With onset after medication use

F06.8	Obsessive-Compulsive and Related Disorder Due to Another Medical Condition

Specify if: With obsessive-compulsive disorder-like symptoms, With appearance preoccupations, With hoarding symptoms, With hair-pulling symptoms, With skin-picking symptoms

F42	Other Specified Obsessive-Compulsive and Related Disorder
F42	Unspecified Obsessive-Compulsive and Related Disorder

Trauma- and Stressor-Related Disorders

F94.1	Reactive Attachment Disorder
	Specify if: Persistent
	Specify current severity: Severe
F94.2	Disinhibited Social Engagement Disorder
	Specify if: Persistent
	Specify current severity: Severe
F43.10	Posttraumatic Stress Disorder (includes Posttraumatic Stress Disorder for Children 6 Years and Younger)
	Specify whether: With dissociative symptoms
	Specify if: With delayed expression
F43.0	Acute Stress Disorder
	Adjustment Disorders
	Specify whether:
F43.21	With depressed mood
F43.22	With anxiety
F43.23	With mixed anxiety and depressed mood
F43.24	With disturbance of conduct
F43.25	With mixed disturbance of emotions and conduct
F43.20	Unspecified
F43.8	Other Specified Trauma- and Stressor-Related Disorder
F43.9	Unspecified Trauma- and Stressor-Related Disorder

Dissociative Disorders

F44.81	Dissociative Identity Disorder
F44.0	Dissociative Amnesia
	Specify if:
F44.1	With dissociative fugue
F48.1	Depersonalization/Derealization Disorder
F44.89	Other Specified Dissociative Disorder
F44.9	Unspecified Dissociative Disorder

Somatic Symptom and Related Disorders

F45.1	Somatic Symptom Disorder
	Specify if: With predominant pain
	Specify if: Persistent
	Specify current severity: Mild, Moderate, Severe
F45.21	Illness Anxiety Disorder
	Specify whether: Care seeking type, Care avoidant type
	Conversion Disorder (Functional Neurological Symptom Disorder)

	Specify symptom type:
F44.4	With weakness or paralysis
F44.4	With abnormal movement
F44.4	With swallowing symptoms
F44.4	With speech symptom
F44.5	With attacks or seizures
F44.6	With anesthesia or sensory loss
F44.6	With special sensory symptom
F44.7	With mixed symptoms
	Specify if: Acute episode, Persistent
	Specify if: With psychological stressor (*specify* stressor), Without psychological stressor
F54	Psychological Factors Affecting Other Medical Conditions
	Specify current severity: Mild, Moderate, Severe, Extreme
F68.10	Factitious Disorder (includes Factitious Disorder Imposed on Self, Factitious Disorder Imposed on Another)
	Specify Single episode, Recurrent episodes
F45.8	Other Specified Somatic Symptom and Related Disorder
F45.9	Unspecified Somatic Symptom and Related Disorder

Feeding and Eating Disorders

The following specifiers apply to Feeding and Eating Disorders where indicated:

[a]*Specify* if: In remission
[b]*Specify* if: In partial remission, In full remission
[c]*Specify* current severity: Mild, Moderate, Severe, Extreme

	Pica[a]
F98.3	In children
F50.8	In adults
F98.21	Rumination Disorder[a]
F50.8	Avoidant/Restrictive Food Intake Disorder[a]
	Anorexia Nervosa[b, c]
	Specify whether:
F50.01	Restricting type
F50.02	Binge-eating/purging type
F50.2	Bulimia Nervosa[b, c]
F50.8	Binge-Eating Disorder[b, c]
F50.8	Other Specified Feeding or Eating Disorder
F50.9	Unspecified Feeding or Eating Disorder

Elimination Disorders

F98.0	Enuresis
	Specify whether: Nocturnal only, Diurnal only, Nocturnal and diurnal
F98.1	Encopresis
	Specify whether: With constipation and overflow incontinence, Without constipation and overflow incontinence
	Other Specified Elimination Disorder
N39.498	With urinary symptoms
R15.9	With fecal symptoms
	Unspecified Elimination Disorder
R32	With urinary symptoms
R15.9	With fecal symptoms

Sleep-Wake Disorders

The following specifiers apply to Sleep-Wake Disorders where indicated:

[a]*Specify* if: Episodic, Persistent, Recurrent
[b]*Specify* if: Acute, Subacute, Persistent
[c]*Specify* current severity: Mild, Moderate, Severe

G47.00	Insomnia Disorder[a]
	Specify if: With non-sleep disorder mental comorbidity, With other medical comorbidity, With other sleep disorder
G47.10	Hypersomnolence Disorder[b, c]
	Specify if: With mental disorder, With medical condition, With another sleep disorder
	Narcolepsy[c]
	Specify whether:
G47.419	Narcolepsy without cataplexy but with hypocretin deficiency
G47.411	Narcolepsy with cataplexy but without hypocretin deficiency
G47.419	Autosomal dominant cerebellar ataxia, deafness, and narcolepsy
G47.419	Autosomal dominant narcolepsy, obesity, and type 2 diabetes
G47.429	Narcolepsy secondary to another medical condition

Breathing-Related Sleep Disorders

G47.33	Obstructive Sleep Apnea Hypopnea[c]
	Central Sleep Apnea
	Specify whether:
G47.31	Idiopathic central sleep apnea

R06.3	Cheyne-Stokes breathing
G47.37	Central sleep apnea comorbid with opioid use
	Note: First code opioid use disorder, if present.
	Specify current severity
	Sleep-Related Hypoventilation
	Specify whether
G47.34	Idiopathic hypoventilation
G47.35	Congenital central alveolar hypoventilation
G47.36	Comorbid sleep-related hypoventilation
	Specify current severity
	Circadian Rhythm Sleep-Wake Disorders[a]
	Specify whether:
G47.21	Delayed sleep phase type
	Specify if: Familial, Overlapping with non-24-hour sleep-wake type
G47.22	Advanced sleep phase type
	Specify if: Familial
G47.23	Irregular sleep-wake type
G47.24	Non-24-hour sleep-wake type
G47.26	Shift work type
G47.20	Unspecified type

Parasomnias

	Non-Rapid Eye Movement Sleep Arousal Disorders
	Specify whether:
F51.3	Sleepwalking type
	Specify if: With sleep-related eating, With sleep-related sexual behavior (sexsomnia)
F51.4	Sleep terror type
F51.5	Nightmare Disorder[b, c]
	Specify if: During sleep onset
	Specify if: With associated non-sleep disorder, With associated other medical condition, With associated other sleep disorder
G47.52	Rapid Eye Movement Sleep Behavior Disorder
G25.81	Restless Legs Syndrome
	Substance/Medication-Induced Sleep Disorder
	Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.

Specify whether: Insomnia type, Daytime sleepiness type, Parasomnia type, Mixed type
Specify if: With onset during intoxication, With onset during discontinuation/withdrawal

G47.09	Other Specified Insomnia Disorder
G47.00	Unspecified Insomnia Disorder
G47.19	Other Specified Hypersomno-lence Disorder
G47.10	Unspecified Hypersomnolence Disorder
G47.8	Other Specified Sleep-Wake Disorder
G47.9	Unspecified Sleep-Wake Disorder

Sexual Dysfunctions

The following specifiers apply to Sexual Dysfunctions where indicated:
    [a]*Specify* whether: Lifelong, Acquired
    [b]*Specify* whether: Generalized, Situational
    [c]*Specify* current severity: Mild, Moderate, Severe

F52.32	Delayed Ejaculation[a, b, c]
F52.21	Erectile Disorder[a, b, c]
F52.31	Female Orgasmic Disorder[a, b, c]
	Specify if: Never experienced an orgasm under any situation
F52.22	Female Sexual Interest/Arousal Disorder[a, b, c]
F52.6	Genito-Pelvic Pain/Penetration Disorder[a, c]
F52.0	Male Hypoactive Sexual Desire Disorder[a, b, c]
F52.4	Premature (Early) Ejaculation[a, b, c]
	Substance/Medication-Induced Sexual Dysfunction[c]
	Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.
	Specify if: With onset during intoxication, With onset during withdrawal, With onset after medication use
F52.8	Other Specified Sexual Dysfunction
F52.9	Unspecified Sexual Dysfunction

Gender Dysphoria

	Gender Dysphoria
F64.2	Gender Dysphoria in Children

Specify if: With a disorder of sex development

F64.1	Gender Dysphoria in Adolescents and Adults

Specify if: With a disorder of sex development
Specify if: Posttransition
Note: Code the disorder of sex development if present, in addition to gender dysphoria.

F64.8	Other Specified Gender Dysphoria
64.9	Unspecified Gender Dysphoria

Disruptive, Impulse-Control, and Conduct Disorders

F91.3	Oppositional Defiant Disorder
	Specify current severity: Mild, Moderate, Severe
F63.81	Intermittent Explosive Disorder
	Conduct Disorder
	Specify whether:
F91.1	Childhood-onset type
F91.2	Adolescent-onset type
F91.9	Unspecified onset
	Specify if: With limited prosocial emotions
	Specify current severity: Mild, Moderate, Severe
F60.2	Antisocial Personality Disorder
F63.1	Pyromania
F63.2	Kleptomania
F91.8	Other Specified Disruptive, Impulse-Control, and Conduct Disorder
F91.9	Unspecified Disruptive, Impulse-Control, and Conduct Disorder

Substance-Related and Addictive Disorders

The following specifiers and note apply to Substance-Related and Addictive Disorders where indicated:
    [a]*Specify* if: In early remission, In sustained remission
    [b]*Specify* if: In a controlled environment
    [c]*Specify* if: With perceptual disturbances
    [d]The ICD-10-CM code indicates the comorbid presence of a moderate or severe substance use disorder, which must be present in order to apply the code for substance withdrawal.

Substance-Related Disorders

Alcohol-Related Disorders

	Alcohol Use Disorder[a, b]
	Specify current severity:
F10.10	Mild
F10.20	Moderate
F10.20	Severe

	Alcohol Intoxication
F10.129	With use disorder, mild
F10.229	With use disorder, moderate or severe
F10.929	Without use disorder
	Alcohol Withdrawal[c, d]
F10.239	Without perceptual disturbances
F10.232	With perceptual disturbances
	Other Alcohol-Induced Disorders
F10.99	Unspecified Alcohol-Related Disorder

Caffeine-Related Disorders

F15.929	Caffeine Intoxication
F15.93	Caffeine Withdrawal
	Other Caffeine-Induced Disorders
F15.99	Unspecified Caffeine-Related Disorder

Cannabis-Related Disorders

	Cannabis Use Disorder[a, b]
	Specify current severity
F12.10	Mild
F12.20	Moderate
F12.20	Severe
	Cannabis Intoxication[c]
	Without perceptual disturbances
F12.129	With use disorder, mild
F12.229	With use disorder, moderate or severe
F12.929	Without use disorder
	With perceptual disturbances
F12.122	With use disorder, mild
F12.222	With use disorder, moderate or severe
F12.922	Without use disorder
F12.288	Cannabis Withdrawal[d]
	Other Cannabis-Induced Disorders
F12.99	Unspecified Cannabis-Related Disorder

Hallucinogen-Related Disorders

	Phencyclidine Use Disorder[a, b]
	Specify current severity:
F16.10	Mild
F16.20	Moderate
F16.20	Severe
	Other Hallucinogen Use Disorder[a, b]
	Specify the particular hallucinogen

	Specify current severity:
F16.10	Mild
F16.20	Moderate
F16.20	Severe
	Phencyclidine Intoxication
F16.129	With use disorder, mild
F16.229	With use disorder, moderate or severe
F16.929	Without use disorder
	Other Hallucinogen Intoxication
F16.129	With use disorder, mild
F16.229	With use disorder, moderate or severe
F16.929	Without use disorder
F16.983	Hallucinogen Persisting Perception Disorder
	Other Phencyclidine-Induced Disorders
	Other Hallucinogen-Induced Disorders
F16.99	Unspecified Phencyclidine-Related Disorder
F16.99	Unspecified Hallucinogen-Related Disorder

Inhalant-Related Disorders

	Inhalant Use Disorder[a, b]
	Specify the particular inhalant
	Specify current severity:
F18.10	Mild
F18.20	Moderate
F18.20	Severe
	Inhalant Intoxication
F18.129	With use disorder, mild
F18.229	With use disorder, moderate or severe
F18.929	Without use disorder
	Other Inhalant-Induced Disorders
F18.99	Unspecified Inhalant-Related Disorder

Opioid-Related Disorders

	Opioid Use Disorder[a]
	Specify if: On maintenance therapy, In a controlled environment
	Specify current severity:
F11.10	Mild
F11.20	Moderate
F11.20	Severe
	Opioid Intoxication[c]
	Without perceptual disturbances
F11.129	With use disorder, mild

F11.229	With use disorder, moderate or severe	
F11.922	Without use disorder	
F11.23	Opioid Withdrawal[d]	
	Other Opioid-Induced Disorders	
F11.99	Unspecified Opioid-Related Disorder	

Sedative-, Hypnotic-, or Anxiolytic-Related Disorders

	Sedative, Hypnotic, or Anxiolytic Use Disorder[a, b]
	Specify current severity:
F13.10	Mild
F13.20	Moderate
F13.20	Severe
	Sedative, Hypnotic, or Anxiolytic Intoxication
F13.129	With use disorder, mild
F13.229	With use disorder, moderate or severe
F13.929	Without use disorder
	Sedative, Hypnotic, or Anxiolytic Withdrawal[c, d]
F13.239	Without perceptual disturbances
F13.232	With perceptual disturbances
	Other Sedative-, Hypnotic-, or Anxiolytic-Induced Disorders
F13.99	Unspecified Sedative-, Hypnotic-, or Anxiolytic-Related Disorder

Stimulant-Related Disorders

	Stimulant Use Disorder[a, b]
	Specify current severity:
	Mild
F15.10	Amphetamine-type substance
F14.10	Cocaine
F15.10	Other or unspecified stimulant
	Moderate
F15.20	Amphetamine-type substance
F14.20	Cocaine
F15.20	Other or unspecified stimulant
	Severe
F15.20	Amphetamine-type substance
F14.20	Cocaine
F15.20	Other or unspecified stimulant
	Stimulant Intoxication[c]

	Specify the specific intoxicant
	Amphetamine or other stimulant, Without perceptual disturbances
F15.129	With use disorder, mild
F15.229	With use disorder, moderate or severe
F15.929	Without use disorder
	Cocaine, Without perceptual disturbances
F14.129	With use disorder, mild
F14.229	With use disorder, moderate or severe
F14.929	Without use disorder
	Amphetamine or other stimulant, With perceptual disturbances
F15.122	With use disorder, mild
F15.222	With use disorder, moderate or severe
F15.922	Without use disorder
	Cocaine, With perceptual disturbances
F14.122	With use disorder, mild
F14.222	With use disorder, moderate or severe
F14.922	Without use disorder
	Stimulant Withdrawal[d]
	Specify the specific substance causing the withdrawal syndrome
F15.23	Amphetamine or other stimulant
F14.23	Cocaine
	Other Stimulant-Induced Disorders
	Unspecified Stimulant-Related Disorder
F15.99	Amphetamine or other stimulant
F14.99	Cocaine

Tobacco-Related Disorders

	Tobacco Use Disorder[a]
	Specify if: On maintenance therapy, In a controlled environment
	Specify current severity:
Z72.0	Mild
F17.200	Moderate
F17.200	Severe
F17.203	Tobacco Withdrawal[d]
	Other Tobacco-Induced Disorders
F17.209	Unspecified Tobacco-Related Disorder

Other (or Unknown) Substance-Related Disorders

	Other (or Unknown) Substance Use Disorder[a, b]
	Specify current severity:
F19.10	Mild
F19.20	Moderate
F19.20	Severe
	Other (or Unknown) Substance Intoxication
F19.129	With use disorder, mild
F19.229	With use disorder, moderate or severe
F19.929	Without use disorder
F19.239	Other (or Unknown) Substance Withdrawal[d]
	Other (or Unknown) Substance-Induced Disorders
F19.99	Unspecified Other (or Unknown) Substance-Related Disorder

Non-Substance-Related Disorders

F63.0	Gambling Disorder[a]
	Specify if: Episodic, Persistent
	Specify current severity: Mild, Moderate, Severe

Neurocognitive Disorders

	Delirium[a]
	Note: See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.
	Specify whether:
	Substance intoxication delirium[a]
	Substance withdrawal delirium[a]
	Medication-induced delirium[a]
F05	Delirium due to another medical condition
F05	Delirium due to multiple etiologies
	Specify if: Acute, Persistent
	Specify if: Hyperactive, Hypoactive, Mixed level of activity
R41.0	Other Specified Delirium
R41.0	Unspecified Delirium

Major and Mild Neurocognitive Disorders

Specify whether due to: Alzheimer's disease, Frontotemporal lobar degeneration, Lewy body disease, Vascular disease, Traumatic brain injury, Substance/medication use, HIV infection, Prion disease, Parkinson's disease, Huntington's disease, Another medical condition, Multiple etiologies, Unspecified

[a]*Specify* Without behavioral disturbance, With behavioral disturbance. For possible major neurocognitive disorder and for mild neurocognitive disorder, behavioral disturbance cannot be coded but should still be indicated in writing.

[b]*Specify* current severity: Mild, Moderate, Severe. This specifier applies only to major neurocognitive disorders (including probable and possible).

Note: As indicated for each subtype, an additional medical code is needed for probable major neurocognitive disorder or major neurocognitive disorder. An additional medical code should *not* be used for possible major neurocognitive disorder or mild neurocognitive disorder.

Major or Mild Neurocognitive Disorder Due to Alzheimer's Disease

	Probable Major Neurocognitive Disorder Due to Alzheimer's Disease[b]
	Note: Code first G30.9 Alzheimer's disease.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.9	Possible Major Neurocognitive Disorder Due to Alzheimer's Disease[a, b]
G31.84	Mild Neurocognitive Disorder Due to Alzheimer's Disease[a]

Major or Mild Frontotemporal Neurocognitive Disorder

	Probable Major Neurocognitive Disorder Due to Frontotemporal Lobar Degeneration[b]
	Note: Code first G31.09 frontotemporal disease.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.9	Possible Major Neurocognitive Disorder Due to Frontotemporal Lobar Degeneration[a, b]
G31.84	Mild Neurocognitive Disorder Due to Frontotemporal Lobar Degeneration[a]

Major or Mild Neurocognitive Disorder With Lewy Bodies

	Probable Major Neurocognitive Disorder With Lewy Bodies[b]
	Note: Code first G31.83 Lewy body disease.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance

G31.9	Possible Major Neurocognitive Disorder With Lewy Bodies[a, b]
G31.84	Mild Neurocognitive Disorder With Lewy Bodies[a]

Major or Mild Vascular Neurocognitive Disorder

	Probable Major Vascular Neurocognitive Disorder[b] Note: No additional medical code for vascular disease.
F01.51	With behavioral disturbance
F01.50	Without behavioral disturbance
G31.9	Possible Major Vascular Neurocognitive Disorder[a, b]
G31.84	Mild Vascular Neurocognitive Disorder[a]

Major or Mild Neurocognitive Disorder Due to Traumatic Brain Injury

	Major Neurocognitive Disorder Due to Traumatic Brain Injury[b] Note: For ICD-9-CM, code first 907.0 late effect of intracranial injury without skull fracture. For ICD-10-CM, code first S06.2X9S diffuse traumatic brain injury with loss of consciousness of unspecified duration, sequela.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.84	Mild Neurocognitive Disorder Due to Traumatic Brain Injury[a]

Substance/Medication-Induced Major or Mild Neurocognitive Disorder[a]

Note: No additional medical code. See the criteria set and corresponding recording procedures for substance-specific codes and ICD-10-CM coding.
   Specify if: Persistent

Major or Mild Neurocognitive Disorder Due to HIV Infection

	Major Neurocognitive Disorder Due to HIV Infection[b] Note: Code first B20 HIV infection.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.84	Mild Neurocognitive Disorder Due to HIV Infection[a]

Major or Mild Neurocognitive Disorder Due to Prion Disease

	Major Neurocognitive Disorder Due to Prion Disease[b] Note: Code first A81.9 prion disease.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.84	Mild Neurocognitive Disorder Due to Prion Disease[a]

Major or Mild Neurocognitive Disorder Due to Parkinson's Disease

	Major Neurocognitive Disorder Probably Due to Parkinson's Disease[b] Note: Code first 332.0 (G20) Parkinson's disease.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.9	Major Neurocognitive Disorder Possibly Due to Parkinson's Disease[a, b]
G31.84	Mild Neurocognitive Disorder Due to Parkinson's Disease[a]

Major or Mild Neurocognitive Disorder Due to Huntington's Disease

	Major Neurocognitive Disorder Due to Huntington's Disease[b] Note: Code first G10 Huntington's disease.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.84	Mild Neurocognitive Disorder Due to Huntington's Disease[a]

Major or Mild Neurocognitive Disorder Due to Another Medical Condition

	Major Neurocognitive Disorder Due to Another Medical Condition[b] Note: Code first the other medical condition.
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.84	Mild Neurocognitive Disorder Due to Another Medical Condition[a]

Major or Mild Neurocognitive Disorder Due to Multiple Etiologies

	Major Neurocognitive Disorder Due to Multiple Etiologies[b] Note: Code first all the etiological medical conditions (with the exception of vascular disease).
F02.81	With behavioral disturbance
F02.80	Without behavioral disturbance
G31.84	Mild Neurocognitive Disorder Due to Multiple Etiologies[a]

Unspecified Neurocognitive Disorder

R41.9	Unspecified Neurocognitive Disorder[a]

Personality Disorders

Cluster A Personality Disorders

F60.0	Paranoid Personality Disorder
F60.1	Schizoid Personality Disorder
F21	Schizotypal Personality Disorder

Cluster B Personality Disorders

F60.2	Antisocial Personality Disorder
F60.3	Borderline Personality Disorder
F60.4	Histrionic Personality Disorder
F60.81	Narcissistic Personality Disorder

Cluster C Personality Disorders

F60.6	Avoidant Personality Disorder
F60.7	Dependent Personality Disorder
F60.5	Obsessive-Compulsive Personality Disorder

Other Personality Disorders

F07.0	Personality Change Due to Another Medical Condition *Specify* whether: Labile type, Disinhibited type, Aggressive type, Apathetic type, Paranoid type, Other type, Combined type, Unspecified type
F60.89	Other Specified Personality Disorder
F60.9	Unspecified Personality Disorder

Paraphilic Disorders

The following specifier applies to Paraphilic Disorders where indicated:

[a]*Specify* if: In a controlled environment, In full remission

F65.3	Voyeuristic Disorder[a]
F65.2	Exhibitionistic Disorder[a]

	Specify whether: Sexually aroused by exposing genitals to prepubertal children, Sexually aroused by exposing genitals to physically mature individuals, Sexually aroused by exposing genitals to prepubertal children and to physically mature individuals.
F65.81	Frotteuristic Disorder[a]
F65.51	Sexual Masochism Disorder[a] *Specify* if: With asphyxiophilia
F65.52	Sexual Sadism Disorder[a]
F65.4	Pedophilic Disorder *Specify* whether: Exclusive type, Nonexclusive type *Specify* if: Sexually attracted to males, Sexually attracted to females, Sexually attracted to both *Specify* if: Limited to incest
F65.0	Fetishistic Disorder[a] *Specify*: Body part(s), Nonliving object(s), Other

Other Mental Disorders

F06.8	Other Specified Mental Disorder Due to Another Medical Condition
F09	Unspecified Mental Disorder Due to Another Medical Condition
F99	Other Specified Mental Disorder
F99	Unspecified Mental Disorder

Medication-Induced Movement Disorders and Other Adverse Effects of Medication

G21.11	Neuroleptic-Induced Parkinsonism
G21.19	Other Medication-Induced Parkinsonism
G21.0	Neuroleptic Malignant Syndrome
G24.02	Medication-Induced Acute Dystonia
G25.71	Medication-Induced Acute Akathisia
G24.01	Tardive Dyskinesia
G24.09	Tardive Dystonia
G25.71	Tardive Akathisia
G25.1	Medication-Induced Postural Tremor

G25.79	Other Medication-Induced Movement Disorder
	Antidepressant Discontinuation Syndrome
T43.205A	Initial encounter
T43.205D	Subsequent encounter
T43.205S	Sequelae
	Other Adverse Effect of Medication
T50.905A	Initial encounter
T50.905D	Subsequent encounter
T50.905S	Sequelae

Other Conditions That May Be a Focus of Clinical Attention

Relational Problems

Problems Related to Family Upbringing

Z62.820	Parent-Child Relational Problem
Z62.891	Sibling Relational Problem
Z62.29	Upbringing Away From Parents
Z62.898	Child Affected by Parental Relationship Distress

Other Problems Related to Primary Support Group

Z63.0	Relationship Distress With Spouse or Intimate Partner
Z63.5	Disruption of Family by Separation or Divorce
Z63.8	High Expressed Emotion Level Within Family
Z63.4	Uncomplicated Bereavement

Abuse and Neglect

Child Maltreatment and Neglect Problems

Child Physical Abuse, Confirmed

T74.12XA	Initial encounter
T74.12XD	Subsequent encounter

Child Physical Abuse, Suspected

T76.12XA	Initial encounter
T76.12XD	Subsequent encounter

Other Circumstances Related to Child Physical Abuse

Z69.010	Encounter for mental health services for victim of child abuse by parent
Z69.020	Encounter for mental health services for victim of non-parental child abuse
Z62.810	Personal history (past history) of physical abuse in childhood
Z69.011	Encounter for mental health services for perpetrator of parental child abuse

Z69.021	Encounter for mental health services for perpetrator of nonparental child abuse
F65.1	Transvestic Disorder[a]
	Specify if: With fetishism, With autogynephilia
F65.89	Other Specified Paraphilic Disorder
F65.9	Unspecified Paraphilic Disorder

Child Sexual Abuse, Confirmed

T74.22XA	Initial encounter
T74.22XD	Subsequent encounter

Child Sexual Abuse, Suspected

T76.22XA	Initial encounter
T76.22XD	Subsequent encounter

Other Circumstances Related to Child Sexual Abuse

Z69.010	Encounter for mental health services for victim of child sexual abuse by parent
Z69.020	Encounter for mental health services for victim of non-parental child sexual abuse
Z62.810	Personal history (past history) of sexual abuse in childhood
Z69.011	Encounter for mental health services for perpetrator of parental child sexual abuse
Z69.021	Encounter for mental health services for perpetrator of non-parental child sexual abuse

Child Neglect, Confirmed

T74.02XA	Initial encounter
T74.02XD	Subsequent encounter

Child Neglect, Suspected

T76.02XA	Initial encounter
T76.02XD	Subsequent encounter

Other Circumstances Related to Child Neglect

Z69.010	Encounter for mental health services for victim of child neglect by parent
Z69.020	Encounter for mental health services for victim of non-parental child neglect
Z62.812	Personal history (past history) of neglect in childhood
Z69.011	Encounter for mental health services for perpetrator of parental child neglect

Z69.021   Encounter for mental health services for perpetrator of non-parental child neglect

Child Psychological Abuse, Confirmed
T74.32XA   Initial encounter
T74.32XD   Subsequent encounter

Child Psychological Abuse, Suspected
T76.32XA   Initial encounter
T76.32XD   Subsequent encounter

Other Circumstances Related to Child Psychological Abuse
Z69.010   Encounter for mental health services for victim of child psychological abuse by parent
Z69.020   Encounter for mental health services for victim of non-parental child psychological abuse
Z62.811   Personal history (past history) of psychological abuse in childhood
Z69.011   Encounter for mental health services for perpetrator of parental child psychological abuse
Z69.021   Encounter for mental health services for perpetrator of nonparental child psychological abuse

Adult Maltreatment and Neglect Problems

Spouse or Partner Violence, Physical, Confirmed
T74.11XA   Initial encounter
T74.11XD   Subsequent encounter

Spouse or Partner Violence, Physical, Suspected
T76.11XA   Initial encounter
T76.11XD   Subsequent encounter

Other Circumstances Related to Spouse or Partner Violence, Physical
Z69.11   Encounter for mental health services for victim of spouse or partner violence, physical
Z91.410   Personal history (past history) of spouse or partner violence, physical
Z69.12   Encounter for mental health services for perpetrator of spouse or partner violence, physical

Spouse or Partner Violence, Sexual, Confirmed
T74.21XA   Initial encounter
T74.21XD   Subsequent encounter

Spouse or Partner Violence, Sexual, Suspected
T76.21XA   Initial encounter
T76.21XD   Subsequent encounter

Other Circumstances Related to Spouse or Partner Violence, Sexual
Z69.81   Encounter for mental health services for victim of spouse or partner violence, sexual
Z91.410   Personal history (past history) of spouse or partner violence, sexual
Z69.12   Encounter for mental health services for perpetrator of spouse or partner violence, sexual

Spouse or Partner Neglect, Confirmed
T74.01XA   Initial encounter
T74.01XD   Subsequent encounter

Spouse or Partner Neglect, Suspected
T76.01XA   Initial encounter
T76.01XD   Subsequent encounter

Other Circumstances Related to Spouse or Partner Neglect
Z69.11   Encounter for mental health services for victim of spouse or partner neglect
Z91.412   Personal history (past history) of spouse or partner neglect
Z69.12   Encounter for mental health services for perpetrator of spouse or partner neglect

Spouse or Partner Abuse, Psychological, Confirmed
T74.31XA   Initial encounter
T74.31XD   Subsequent encounter

Spouse or Partner Abuse, Psychological, Suspected
T76.31XA   Initial encounter
T76.31XD   Subsequent encounter

Other Circumstances Related to Spouse or Partner Abuse, Psychological
Z69.11   Encounter for mental health services for victim of spouse or partner psychological abuse
Z91.411   Personal history (past history) of spouse or partner psychological abuse

Z69.12   Encounter for mental health services for perpetrator of spouse or partner psychological abuse

Adult Physical Abuse by Nonspouse or Nonpartner, Confirmed
T74.11XA   Initial encounter
T74.11XD   Subsequent encounter

Adult Physical Abuse by Nonspouse or Nonpartner, Suspected
T76.11XA   Initial encounter
T76.11XD   Subsequent encounter

Adult Sexual Abuse by Nonspouse or Nonpartner, Confirmed
T74.21XA   Initial encounter
T74.21XD   Subsequent encounter

Adult Sexual Abuse by Nonspouse or Nonpartner, Suspected
T76.21XA   Initial encounter
T76.21XD   Subsequent encounter

Adult Psychological Abuse by Nonspouse or Nonpartner, Confirmed
T74.31XA   Initial encounter
T74.31XD   Subsequent encounter

Adult Psychological Abuse by Nonspouse or Nonpartner, Suspected
T76.31XA   Initial encounter
T76.31XD   Subsequent encounter

Other Circumstances Related to Adult Abuse by Nonspouse or Nonpartner
Z69.81   Encounter for mental health services for victim of nonspousal adult abuse
Z69.82   Encounter for mental health services for perpetrator of nonspousal adult abuse

Educational and Occupational Problems
Educational Problems
Z55.9   Academic or Educational Problem

Occupational Problems
Z56.82   Problem Related to Current Military Deployment Status
Z56.9   Other Problem Related to Employment

Housing and Economic Problems
Housing Problems
Z59.0   Homelessness
Z59.1   Inadequate Housing
Z59.2   Discord With Neighbor, Lodger, or Landlord
Z59.3   Problem Related to Living in a Residential Institution

Economic Problems
Z59.4   Lack of Adequate Food or Safe Drinking Water
Z59.5   Extreme Poverty
Z59.6   Low Income
Z59.7   Insufficient Social Insurance or Welfare Support
Z59.9   Unspecified Housing or Economic Problem

Other Problems Related to the Social Environment
Z60.0   Phase of Life Problem
Z60.2   Problem Related to Living Alone
Z60.3   Acculturation Difficulty
Z60.4   Social Exclusion or Rejection
Z60.5   Target of (Perceived) Adverse Discrimination or Persecution
Z60.9   Unspecified Problem Related to Social Environment

Problems Related to Crime or Interaction With the Legal System
Z65.4   Victim of Crime
Z65.0   Conviction in Civil or Criminal Proceedings Without Imprisonment
Z65.1   Imprisonment or Other Incarceration
Z65.2   Problems Related to Release From Prison
Z65.3   Problems Related to Other Legal Circumstances

Other Health Service Encounters for Counseling and Medical Advice
Z70.9   Sex Counseling
Z71.9   Other Counseling or Consultation

Problems Related to Other Psychosocial, Personal, and Environmental Circumstances
Z65.8   Religious or Spiritual Problem
Z64.0   Problems Related to Unwanted Pregnancy

Z64.1	Problems Related to Multiparity
Z64.4	Discord With Social Service Provider, Including Probation Officer, Case Manager, or Social Services Worker
Z65.4	Victim of Terrorism or Torture
Z65.5	Exposure to Disaster, War, or Other Hostilities
Z65.8	Other Problem Related to Psychosocial Circumstances
Z65.9	Unspecified Problem Related to Unspecified Psychosocial Circumstances

Other Circumstances of Personal History

Z91.49	Other Personal History of Psychological Trauma
Z91.5	Personal History of Self-Harm
Z91.82	Personal History of Military Deployment
Z91.89	Other Personal Risk Factors

Z72.9	Problem Related to Lifestyle
Z72.811	Adult Antisocial Behavior
Z72.810	Child or Adolescent Antisocial Behavior

Problems Related to Access to Medical and Other Health Care

Z75.3	Unavailability or Inaccessibility of Health Care Facilities
Z75.4	Unavailability or Inaccessibility of Other Helping Agencies

Nonadherence to Medical Treatment

Z91.19	Nonadherence to Medical Treatment
E66.9	Overweight or Obesity
Z76.5	Malingering
Z91.83	Wandering Associated With a Mental Disorder
R41.83	Borderline Intellectual Functioning

Appendix E

Assigning NANDA International Nursing Diagnoses to Client Behaviors

Following is a list of client behaviors and the NANDA-I nursing diagnoses that correspond to the behaviors and that may be used in planning care for the client exhibiting the specific behavioral symptoms.

BEHAVIORS	NANDA-I NURSING DIAGNOSES
Aggression; hostility	Risk for injury; Risk for other-directed violence
Anorexia or refusal to eat	Imbalanced nutrition: Less than body requirements
Anxious behavior	Anxiety (Specify level)
Confusion; memory loss	Confusion (acute/chronic); Impaired memory; Disturbed thought processes*
Delusions	Disturbed thought processes*
Denial of problems	Ineffective denial
Depressed mood or anger turned inward	Complicated grieving; Risk for self-directed violence
Detoxification; withdrawal from substances	Risk for injury
Difficulty accepting new diagnosis or recent change in health status	Risk-prone health behavior
Difficulty making important life decision	Decisional conflict
Difficulty sleeping	Insomnia; Disturbed sleep pattern
Difficulty with interpersonal relationships	Impaired social interaction; Ineffective relationship
Disruption in capability to perform usual responsibilities	Ineffective role performance
Dissociative behaviors (depersonalization; derealization)	Disturbed sensory perception (kinesthetic)*
Expresses feelings of disgust about body or body part	Disturbed body image
Expresses anger at God	Spiritual distress
Expresses lack of control over personal situation	Powerlessness
Fails to follow prescribed therapy	Ineffective health management; Noncompliance
Flashbacks, nightmares, obsession with traumatic experience	Post-trauma syndrome
Hallucinations	Disturbed sensory perception (auditory; visual)*
Highly critical of self or others	Low self-esteem (chronic; situational)
HIV positive; altered immunity	Ineffective protection; Risk for infection
Inability to meet basic needs	Self-care deficit (feeding; bathing; dressing; toileting); Impaired home maintenance; Self-neglect
Loose associations or flight of ideas	Impaired verbal communication

BEHAVIORS	NANDA-I NURSING DIAGNOSES
Loss of a valued entity, recently experienced	Risk for complicated grieving
Manic hyperactivity	Risk for injury; Insomnia; Sleep deprivation
Manipulative behavior	Ineffective coping
Multiple personalities	Disturbed personal identity
Orgasm, problems with; lack of sexual desire; erectile dysfunction	Sexual dysfunction
Overeating, compulsive	Risk for overweight; Overweight; or Obesity
Phobias	Fear; Ineffective coping
Physical symptoms as coping behavior	Ineffective coping
Potential or anticipated loss of significant entity	Risk for complicated grieving
Projection of blame; rationalization of failures; denial of personal responsibility	Defensive coping
Ritualistic behaviors	Anxiety (severe); Ineffective coping
Seductive remarks; inappropriate sexual behaviors	Impaired social interaction
Self-inflicted injuries (non-life-threatening)	Self-mutilation; Risk for self-mutilation
Sexual behaviors (difficulty, limitations, or changes in; reported dissatisfaction)	Ineffective sexuality pattern
Stress from caring for chronically ill person	Caregiver role strain
Stress from locating to new environment	Relocation stress syndrome
Substance use as a coping behavior	Ineffective coping
Substance use (denies use is a problem)	Ineffective denial
Suicidal gestures/threats; suicidal ideation	Risk for suicide; Risk for self-directed violence
Suspiciousness	Ineffective coping; Disturbed thought processes*
Vomiting, excessive, self-induced	Risk for deficient fluid volume; Risk for electrolyte imbalance
Withdrawn behavior	Social isolation

*These diagnoses have been resigned from the NANDA-I list of approved nursing diagnoses.
